1. Confirmed by design and characterization, not 100% tested in production.
2. Slew rate measured through Vswing centered around differential zero.
3. Vxabs is defined as the voltage where CLK = CLK#.
4. Only applies to the differential rising edge (CLK rising and CLK# falling).
5. Defined as the total variation of all crossing voltages of CLK rising and CLK# falling. Matching applies to rising edge rate of CLK and falling edge of CLK#. It is measured using a ±75mV window centered on the average cross point where CLK meets CLK#.
6. This figure refers to the maximum distortion of the input wave form.
7. The 9DBL411B has no PLL, so the part itself contributes very little jitter to the input clock. But this also means that the 9DBL411 cannot “de-jitter” a noisy input clock. Values calculated per PCI SIG and per Intel Clock Jitter tool version 1.5.

### 3. Terminations

$Z_0 - 17 = R_s$  (ohms), where  $Z_0$  is the single-ended intrinsic impedance of the board transmission line. Single-ended intrinsic impedance is  $\frac{1}{2}$  that of the differential impedance.

Single-ended Impedance ( $Z_0$ )	$R_s$ 5% Tolerance	$R_s$ 2% Tolerance	Notes
50	33	33.2	In general, 5% resistors may be used. All values are in ohms.
45	27	27.4	
42.5	24 or 27	24.9
