

## Description

The 9ZXL revision E family of Zero-Delay/Fanout Buffers (ZDB, FOB) with SMBus Write Protect are 2nd-generation enhanced performance buffers for PCIe and CPU applications. The devices have hardware SMBUS write protection to prevent accidental writes. The family meets all published QPI/UPI, DB2000Q and PCIe Gen1–5 jitter specifications. Devices range from 6 to 12 outputs, with each output having an OE# pin to support the PCIe CLKREQ# function for low power states. All devices meet DB2000Q, DB1200ZL and DB800ZL jitter and skew requirements.

## PCIe Clocking Architectures

- Common Clocked (CC)
- Independent Reference (IR) with and without spread spectrum (SRIS, SRNS)

## Key Specifications

- Fanout Buffer Mode additive phase jitter:
  - PCIe Gen5 CC, UPI  $\geq 20\text{Gb/s}$  < 24fs RMS
  - DB2000Q additive jitter < 39fs RMS
  - QPI/UPI 11.4GB/s < 40fs RMS
  - IF-UPI additive jitter < 70fs RMS
- ZDB Mode phase jitter:
  - PCIe Gen5 CC, UPI  $\geq 20\text{Gb/s}$  < 22fs RMS
  - QPI/UPI 11.4GB/s < 120fs RMS
  - IF-UPI additive jitter < 130fs RMS
- Cycle-to-cycle jitter < 50ps
- Output-to-output skew < 50ps

## Block Diagram

## Features

- SMBus Write Protect pin prevents SMBus against accidental writes
- 6–12 Low-power HCSL (LP-HCSL) outputs
- Integrated terminations eliminate up to 4 resistors per output pair
- Dedicated OE# pins support PCIe CLKREQ# function
- Up to 9 selectable SMBus addresses (9ZXL12xx, 9ZXL0853)
- Selectable PLL bandwidths minimizes jitter peaking in cascaded PLL topologies
- Hardware/SMBus control of ZDB and FOB modes allow change without power cycle
- Spread spectrum compatible
- 1–400MHz FOB operation (all devices)
- 100MHz and 133.33MHz ZDB mode (9ZXL12xx, 9ZXL08xx)
- 100MHz ZDB mode (9ZXL06xx)
- 40°C to +85°C operating temperature range
- Packages: See [Ordering Information](#) for more details

## Typical Applications

- Servers/High-performance Computing
- nVME Storage
- Networking
- Accelerators
- Industrial Control

vSADR0_tri	Input	SMBus address bit. This is a tri-level input that works in conjunction with other SADR pins, if present, to decode SMBus Addresses. It has an internal pull-down resistor. See the <a href="#">SMBus Addressing</a> table.	11	—	5	—
vSADR1_tri	Input	SMBus address bit. This is a tri-level input that works in conjunction with other SADR pins, if present, to decode SMBus Addresses. It has an internal pull-down resistor. See the <a href="#">SMBus Addressing</a> table.	14	—	8	—
vSMB_WRTLOCK	Input	This pin prevents SMBus writes when asserted. SMBus reads are not affected. This pin has an internal pull-down. 0 = SMBus writes allows, 1 = SMBus writes blocked.	3	46	46	1

## Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the 9ZXL06x2E/9ZXL08xxE/9ZXL12x2E. These ratings, which are standard values for Renesas commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

**Table 2. Absolute Maximum Ratings**

Parameter	Symbol	Conditions	Minimum	Typical	Maximum	Units	Notes
Supply Voltage	VDDx				3.9	V	1,2
Input Low Voltage	V <sub>IL</sub>		GND - 0.5			V	1
Input High Voltage	V <sub>IH</sub>	Except for SMBus interface.			V <sub>DD</sub> + 0.5	V	1,3
Input High Voltage	V <sub>IHSMB</sub>	SMBus clock and data pins.			3.9	V	1
Storage Temperature	T <sub>s</sub>		-65		150	°C	1
Junction Temperature	T <sub>j</sub>				125	°C	1
Input ESD Protection	ESD prot	Human Body Model.	2500			V	1

<sup>1</sup> Guaranteed by design and characterization, not 100% tested in production.

<sup>2</sup> Operation under these conditions is neither implied nor guaranteed.

<sup>3</sup> Not to exceed 3.9V.

Jitter, Cycle to Cycle	$t_{jyc-cyc}$	PLL Mode.		14	50	ps	1,10
		Additive jitter in Bypass Mode.		0.1	5	ps	1,10

<sup>1</sup> Measured into fixed 2pF load cap. Input-to-output skew is measured at the first output edge following the corresponding input.

<sup>2</sup> Measured from differential cross-point to differential cross-point. This parameter can be tuned with external feedback path, if present.

<sup>3</sup> All Bypass Mode input-to-output specs refer to the timing between an input edge and the specific output edge created by it.

<sup>4</sup> This parameter is deterministic for a given device.

<sup>5</sup> Measured with scope averaging on to find mean value.

<sup>6</sup> Measured as maximum pass band gain. At frequencies within the loop BW, highest point of magnification is called PLL jitter peaking.

<sup>7</sup> Guaranteed by design and characterization, not 100% tested in production.

<sup>8</sup> Measured at 3db down or half power point.

<sup>9</sup> Duty cycle distortion is the difference in duty cycle between the output and the input clock when the device is operated in Bypass Mode.

<sup>10</sup> Measured from differential waveform.

Minimum Voltage	V <sub>min</sub>		-150	-35	150	-300		7,8
Crossing Voltage (abs)	V <sub>cross_abs</sub>	Scope averaging off.	300	372	462	250–550	mV	1,5,7
Crossing Voltage (var)	Δ-V <sub>cross</sub>	Scope averaging off.		15	50	140	mV	1,6,7

<sup>1</sup> Guaranteed by design and characterization, not 100% tested in production.

<sup>2</sup> Measured from differential waveform.

<sup>3</sup> Slew rate is measured through the V<sub>swing</sub> voltage range centered around differential 0 V. This results in a ±150mV window around differential 0V.

<sup>4</sup> Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a ±75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

<sup>5</sup> V<sub>cross</sub> is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

<sup>6</sup> The total variation of all V<sub>cross</sub> measurements in any particular system. Note that this is a subset of V<sub>cross\_min/max</sub> (V<sub>cross</sub> absolute) allowed. The intent is to limit V<sub>cross</sub> induced modulation by setting Δ-V<sub>cross</sub> to be smaller than V<sub>cross</sub> absolute.

<sup>7</sup> At default SMBus settings.

<sup>8</sup> Includes previously separate values of +300mV overshoot and -300mV of undershoot.

<sup>1</sup> The Refclk jitter is measured after applying the filter functions found in PCI Express Base Specification 5.0, Revision 1.0. See the [Test Loads](#) section of the data sheet for the exact measurement setup. The worst case results for each data rate are summarized in this table. Equipment noise is removed from all results.

<sup>2</sup> Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately, jitter measurements may be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200MHz (at 300MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5 GT/s data rate, the RMS jitter is converted to peak-to-peak jitter using a multiplication factor of 8.83. In the case where real-time oscilloscope and PNA measurements have both been done and produce different results, the RTO result must be used.

<sup>3</sup> SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.

<sup>4</sup> Note that 0.7ps RMS is to be used in channel simulations to account for additional noise in a real system.

<sup>5</sup> Note that 0.25ps RMS is to be used in channel simulations to account for additional noise in a real system.

<sup>6</sup> The PCI Express Base Specification 5.0, Revision 1.0 provides the filters necessary to calculate SRIS jitter values, however, it does not provide specification limits, hence the n/a in the Limit column. SRIS values are informative only. In general, a clock operating in an SRIS system must be twice as good as a clock operating in a Common Clock system. For RMS values, twice as good is equivalent to dividing the CC value by  $\sqrt{2}$ . An additional consideration is the value for which to divide by  $\sqrt{2}$ . The conservative approach is to divide the ref clock jitter limit, and the case can be made for dividing the channel simulation values by  $\sqrt{2}$ , if the ref clock is close to the Tx clock input. An example for Gen4 is as follows. A "rule-of-thumb" SRIS limit would be either  $0.5\text{ps RMS}/\sqrt{2} = 0.35\text{ps RMS}$  if the clock chip is far from the clock input, or  $0.7\text{ps RMS}/\sqrt{2} = 0.5\text{ps RMS}$  if the clock chip is near the clock input.

<sup>7</sup> This specification also applied to UPI data rates  $\geq 20\text{Gb/s}$ .
