# **ACPL-P343 and ACPL-W343**

4.0 Amp Output Current IGBT Gate Drive Optocoupler with Rail-to-Rail Output Voltage in Stretched SO6

# **Data Sheet**

# **Description**

The ACPL-P343/W343 contains an AlGaAs LED, which is optically coupled to an integrated circuit with a power output stage. This optocoupler is ideally suited for driving power IGBTs and MOSFETs used in motor control inverter applications. The high operating voltage range of the output stage provides the drive voltages required by gate controlled devices. The voltage and high peak output current supplied by this optocoupler make it ideally suited for direct driving IGBT with ratings up to 1200V/200A. For IGBTs with higher ratings, this optocoupler can be used to drive a discrete power stage which drives the IGBT gate. The ACPL-P343 and ACPL-W343 have the highest insulation voltage of V<sub>IORM</sub> = 891 V<sub>peak</sub> and V<sub>IORM</sub> = 1140 V<sub>peak</sub>, respectively, in the IEC/EN/DIN EN 60747-5-5.

## **Features**

- 4.0-A maximum peak output current
- 3.0-A minimum peak output current
- Rail-to-rail output voltage
- 200-ns maximum propagation delay
- 100-ns maximum propagation delay difference
- **LED current input with hysteresis**
- 35 kV/μs minimum Common Mode Rejection (CMR) at  $V_{CM} = 1500V$
- $I_{CC}$  = 3.0 mA maximum supply current
- Under voltage lock-out protection (UVLO) with hysteresis
- Wide operating  $V_{CC}$  range: 15V to 30V
- Industrial temperature range: -40°C to 105°C
- **Safety approval:** 
	- UL Recognized 3750/5000 V<sub>RMS</sub> for 1 min.
	- **—** CSA
	- IEC/EN/DIN EN 60747-5-5 V<sub>IORM</sub> = 891/1140 V<sub>peak</sub>

## **Applications**

- IGBT/MOSFET gate drive
- AC and brushless DC motor drives
- Renewable energy inverters
- **Industrial inverters**
- Switching power supplies

**CAUTION:** It is advised that normal static precautions be taken in handling and assembly of this component to prevent damage and/or degradation that may be induced by ESD. The components featured in this data sheet are not to be used in military or aerospace applications or environments.

## **Functional DIagram**

## **Truth Table**

## **Ordering Information**

ACPL-P343 is UL Recognized with 3750  $V<sub>RMS</sub>$  for 1 minute per UL1577.

ACPL-W343 is UL Recognized with 5000 V<sub>RMS</sub> for 1 minute per UL1577.

To order, choose a part number from the part number column and combine with the desired option from the option column to form an order entry.

Example 1:

ACPL-P343-560E to order product of Stretched SO-6 Surface Mount package in Tape and Reel packaging with IEC/EN/DIN EN 60747-5-5 Safety Approval in RoHS compliant.

Example 2:

ACPL-W343-000E to order product of Stretched SO-6 Surface Mount package in Tube packaging and RoHS compliant.

Option data sheets are available. Contact your Broadcom sales representative or authorized distributor for information.

 $\blacksquare$  IEC/EN/DIN EN 60747-5-5 (Option 060 Only) Maximum Working Insulation Voltage V<sub>IORM</sub> = 891 V<sub>peak</sub> (ACPL-P343) and V<sub>IORM</sub> = 1140 V<sub>peak</sub> (ACPL-W343)

# **IEC/EN/DIN EN 60747-5-5 Insulation Characteristics (Option 060 – Under Evaluation)**

a. Refer to IEC/EN/DIN EN 60747-5-5 Optoisolator Safety Standard section of the Broadcom Regulatory Guide to Isolation Circuits, AV02-2041EN, for a detailed description of Method a and Method b partial discharge test profiles.

**NOTE** These optocouplers are suitable for "safe electrical isolation" only within the safety limit data. Maintenance of the safety data shall be ensured by means of protective circuits. Surface-mount classification is Class A in accordance with CECC 00802.

## **Insulation and Safety Related Specifications**

**NOTE** All Broadcom data sheets report the creepage and clearance inherent to the optocoupler component itself. These dimensions are needed as a starting point for the equipment designer when determining the circuit insulation requirements. However, once mounted on a printed circuit board, minimum creepage and clearance requirements must be met as specified for individual equipment standards. For creepage, the shortest distance path along the surface of a printed circuit board between the solder fillets of the input and output leads must be considered (the recommended land pattern does not necessarily meet the minimum creepage of the device). There are recommended techniques such as grooves and ribs which may be used on a printed circuit board to achieve desired creepage and clearances. Creepage and clearance distances will also change depending on factors, such as pollution degree and insulation level.

## **Absolute Maximum Ratings**

a. Derate linearly above 70°C free-air temperature at a rate of 0.3 mA/°C.

<span id="page-5-0"></span>b. Maximum pulse width = 10 µs. This value is intended to allow for component tolerances for designs with  $I_0$  peak minimum = 3.0A. See the applications section for additional details on limiting  $I<sub>OH</sub>$  peak.

c. Derate linearly above 85°C free-air temperature at a rate of 16.9 mW/°C.

d. Derate linearly above 85° C free-air temperature at a rate of 15.3 mW/°C. The maximum LED junction temperature should not exceed 125°C.

# **Recommended Operating Conditions**

## **Electrical Specifications (DC)**

Unless otherwise noted, all typical values are at  $T_A = 25^\circ C$ , V<sub>CC</sub> – V<sub>EE</sub> = 30V, V<sub>EE</sub> = Ground; all minimum and maximum specifi cations are at recommended operating conditions ( $T_A = -40^{\circ}C$  to 105°C,  $I_{F(ON)} = 7$  mA to 16 mA,  $V_{F(OFF)} = -3.6V$  to 0.8V,  $V_{EE} =$  Ground,  $V_{CC}$  = 15V to 30V).

<span id="page-6-0"></span>a. Maximum pulse width =  $50 \,\mu s$ .

b. Output is sourced at –3.0A with a maximum pulse width = 10 µs. V<sub>CC</sub> – V<sub>O</sub> is measured to ensure 15V or below.

c. Output is sourced at 3.0A with a maximum pulse width = 10 μs.  $V_O - V_{EE}$  is measured to ensure 15V or below.

<span id="page-6-1"></span>d. Output is sourced at -3.0A/3.0A with a maximum pulse width = 10  $\mu$ s.

e. In this test, V<sub>OH</sub> is measured with a DC load current. When driving capacitive loads, V<sub>OH</sub> will approach V<sub>CC</sub> as I<sub>OH</sub> approaches 0 amps.

f. Maximum pulse width  $= 1$  ms.

# **Switching Specifications (AC)**

Unless otherwise noted, all typical values are at T<sub>A</sub> = 25°C, V<sub>CC</sub> – V<sub>EE</sub> = 30V, V<sub>EE</sub> = Ground; all minimum and maximum specifications are at recommended operating conditions (T<sub>A</sub> = –40°C to 105°C, I<sub>F(ON)</sub> = 7 mA to 16 mA, V<sub>F(OFF)</sub> = –3.6V to 0.8V, V<sub>EE</sub> = Ground,  $V_{CC}$  = 15V to 30V).

a. Pulse Width Distortion (PWD) is defi ned as  $|t_{PHL} - t_{PLH}|$  for any given device.

b. The diff erence between t<sub>PHL</sub> and t<sub>PLH</sub> between any two ACPL-P343 parts under the same test condition.

<span id="page-7-0"></span>c. Pin 2 must be connected to LED common.

d. Common mode transient immunity in the high state is the maximum tolerable dV<sub>CM</sub>/dt of the common mode pulse, V<sub>CM</sub>, to assure that the output will remain in the high state (that is,  $V_{\Omega} > 15.0V$ ).

e. Common mode transient immunity in a low state is the maximum tolerable dV<sub>CM</sub>/dt of the common mode pulse, V<sub>CM</sub>, to assure that the output will remain in a low state (that is,  $V<sub>O</sub> < 1.0V$ ).

# **Package Characteristics**

Unless otherwise noted, all typical values are at  $T_A = 25^{\circ}$ C; all minimum/maximum specifi cations are at recommended operating conditions.

a. The Input-Output Momentary Withstand Voltage is a dielectric voltage rating that should not be interpreted as an input-output continuous voltage rating. For the continuous voltage rating, refer to your equipment level safety specification or Broadcom Application Note 1074, Optocoupler Input-Output Endurance Voltage.

b. In accordance with UL1577, each optocoupler is proof tested by applying an insulation test voltage  $\leq 4500$  V<sub>RMS</sub> for 1 second (leakage detection current limit, l<sub>I-O</sub> < 5 μA).

<span id="page-8-0"></span>c. Device considered a two-terminal device: pins 1, 2, and 3 shorted together and pins 4, 5, and 6 shorted together.

d. In accordance with UL1577, each optocoupler is proof tested by applying an insulation test voltage ≤ 6000 V<sub>RMS</sub> for 1 second (leakage detection current limit, l<sub>I-O</sub> < 5 μA).

e. The device was mounted on a high conductivity test board as per JEDEC 51-7.

# **Application Information**

## **Product Overview Description**

The ACPL-P343/W343 is an optically isolated power output stage capable of driving IGBTs of up to 200A and 1200V. Based on BCDMOS technology, this gate drive optocoupler delivers higher peak output current, better rail-to-rail output voltage performance and two times faster speed than the previous generation products.

The high peak output current and short propagation delay are needed for fast IGBT switching to reduce dead time and improve system overall efficiency. Rail-to-rail output voltage ensures that the IGBT's gate voltage is driven to the optimum intended level with no power loss across IGBT. This helps the designer lower the system power which is suitable for bootstrap power supply operation.

It has very high CMR(common mode rejection) rating which allows the microcontroller and the IGBT to operate at very large common mode noise found in industrial motor drives and other power switching applications. The input is driven by direct LED current and has a hysteresis that prevents output oscillation if insufficient LED driving current is applied. This will eliminates the need of additional Schmitt trigger circuit at the input LED.

The stretched SO6 package which is up to 50% smaller than conventional DIP package facilitates smaller more compact design. These stretched packages are compliant to many industrial safety standards, such as IEC/EN/DIN EN 60747-5-5, UL 1577, and CSA.

## **Recommended Application Circuit**

The recommended application circuit shown in [Figure 28](#page-15-0) illustrates a typical gate drive implementation using the ACPL-P343. The following describes about driving IGBT. However, it is also applicable to MOSFET. Designers will need to adjust the  $V_{CC}$  supply voltage, depending on the MOSFET or IGBT gate threshold requirements (recommended  $V_{CC} = 15V$ for IGBT and 12V for MOSFET).

The supply bypass capacitors  $(1 \mu F)$  provide the large transient currents necessary during a switching transition. Because of the transient nature of the charging currents, a low current (3.0 mA) power supply will be enough to power the device. The split resistors (in the ratio of 1.5:1) across the LED will provide a high CMR response by providing a balanced resistance network across the LED.

The gate resistor  $R_G$  serves to limit gate charge current and controls the IGBT collector voltage rise and fall times.

In PC board design, care should be taken to avoid routing the IGBT collector or emitter traces close to the ACPL-P343 input as this can result in unwanted coupling of transient signals into ACPL-P343 and degrade performance.

#### <span id="page-15-0"></span>**Figure 28 Recommended Application Circuit with Split Resistors LED Drive**

[Figure 29](#page-16-0) shows a typical gate driver's high current output stage with 3 bipolar transistors in darlington configuration. During the output high transition, the output voltage rises rapidly to within 3 diode drops of  $V_{CC}$ . To ensure the  $V_{OUT}$  is at  $V_{CC}$  in order to achieve IGBT rated  $V_{CE(ON)}$  voltage. The level of  $V_{CC}$  will need to be raised to beyond  $V_{CC}+3(V_{BE})$  to account for the diode drops. And to limit the output voltage to  $V_{CC}$ , a pull-down resistor,  $R_{PULL-DOWN}$  between the output and  $V_{EE}$  is recommended to sink a static current while the output is high. ACPL-P343 uses a power PMOS to deliver the large current and pull it to  $V_{CC}$  to achieve rail-to-rail output voltage as shown in [Figure 30.](#page-16-1) This ensures that the IGBT's gate voltage is driven to the optimum intended level with no power loss across IGBT even when an unstable power supply is used.

### <span id="page-16-0"></span>**Figure 29 Typical Gate Driver with Output Stage in Darlington Confi guration**

<span id="page-16-1"></span>**Figure 30 ACPL-P343/W343 with PMOS and NMOS Output Stage for Rail-to-Rail Output Voltage**

# **Selecting the Gate Resistor (Rg)**

**Step 1**: Calculate Rg minimum from the IOL peak specification. The IGBT and Rg in [Figure 28](#page-15-0) can be analyzed as a simple RC circuit with a voltage supplied by ACPL-P343/W343.

 $Rg \geq (V_{CC} - V_{EE} - V_{OL}) / I_{OLPEAK}$ 

 $= (15V + 5V - 2.9V) / 4A$ 

 $= 4.3 \Omega \approx 5 \Omega$ 

The V<sub>OL</sub> value of 2.9V in the previous equation is the V<sub>OL</sub> at the peak current of 4.0A (see [Figure 7\)](#page-10-0).

**Step 2**: Check the ACPL-P343/W343 power dissipation and increase Rg if necessary. The ACPL-P343/W343 total power dissipation  $(P_T)$  is equal to the sum of the emitter power  $(P_F)$  and the output power  $(P_O)$ .

- $PT = P_F + P_O$
- $PE = I_F \times V_F \times Duty$  Cycle
- $PO = P_{O(BIAS)} + P_{O(SWITCHING)}$  $= I_{CC} \times (V_{CC} - V_{EE}) + E_{SW}(Rg;Cg) \times f$

Using  $I_F$ (worst case) = 16 mA, Rg = 5 $\Omega$ , Max Duty Cycle = 80%, Cg = 25 nF, f = 25 kHz and T<sub>A</sub> max = 85°C:

- $PE = 16$  mA  $\times$  1.95V  $\times$  0.8 = 25 mW
- $PO = 3 mA \times 20V + 5 mJ \times 25 kHz$ 
	- $= 60$  mW  $+ 125$  mW
	- $= 185$  mW < 700 mW (P<sub>O(MAX)</sub> @ 85°C)

The value of 3 mA for  $I_{CC}$  in the previous equation is the maximum  $I_{CC}$  over the entire operating temperature range.

Since P<sub>O</sub> is less than P<sub>O(MAX)</sub>, Rg = 5 $\Omega$  is alright for the power dissipation.

### **Figure 31 Energy Dissipated in the ACPL-P343/W343 for Each IGBT Switching Cycle**

## **LED Drive Circuit Considerations for High CMR Performance**

[Figure 32](#page-18-1) shows the recommended drive circuit for the ACPL-P343/W343 that gives optimum common-mode rejection. The two current setting resistors balance the common mode impedances at the LED's anode and cathode. Common-mode transients can be capacitive coupled from the LED anode, through  $CL_A$  (or cathode through  $CL_C$ ) to the output-side ground causing current to be shunted away from the LED (which is not wanted when the LED should be on) or conversely cause current to be injected into the LED (which is not wanted when the LED should be off).

[Table 1](#page-18-0) shows the directions of  $I_{LP}$  and  $I_{IN}$  depend on the polarity of the common-mode transient. For transients occurring when the LED is on, common-mode rejection (CM<sub>H</sub>, since the output is at "high" state) depends on LED current  $(I_F)$ . For conditions where  $I_F$  is close to the switching threshold  $(I_{FIH})$ , CM<sub>H</sub> also depends on the extent to which  $I_{LP}$  and  $I_{IN}$ balance each other. In other words, any condition where a common-mode transient causes a momentary decrease in  $I_F$ (that is, when  $dV_{CM}/dt > 0$  and  $|I_{LP}| > |I_{LN}|$ , referring to [Table 1](#page-18-0)) will cause a common-mode failure for transients which are fast enough.

Likewise for a common-mode transient that occurs when the LED is off (that is,  $CM<sub>1</sub>$ , since the output is at "low" state), if an imbalance between  $I_{LP}$  and  $I_{IN}$  results in a transient  $I_F$  equal to or greater than the switching threshold of the optocoupler, the transient "signal" may cause the output to spike above 1V, which constitutes a CM<sub>I</sub> failure. The balanced  $I_{\text{IFD}}$ -setting resistors help equalize the common mode voltage change at the anode and cathode. The shunt drive input circuit will also help to achieve high  $CM<sub>1</sub>$  performance by shunting the LED in the off state.

#### <span id="page-18-1"></span>**Figure 32 Recommended High-CMR Drive Circuit for the ACPL-P343/W343**

#### <span id="page-18-0"></span>**Table 1 Common Mode Pulse Polarity and LED Current Transients**

## **Dead Time and Propagation Delay Specifications**

The ACPL-P343/W343 includes a Propagation Delay Difference (PDD) specification intended to help designers minimize "dead time" in their power inverter designs. Dead time is the time period during which both the high and low side power transistors (Q1 and Q2 in [Figure 28\)](#page-15-0) are off. Any overlap in Q1 and Q2 conduction will result in large currents flowing through the power devices between the high and low voltage motor rails.

To minimize dead time in a given design, the turn on of LED2 should be delayed (relative to the turn off of LED1) so that under worst-case conditions, transistor Q1 has just turned off when transistor Q2 turns on, as shown in [Figure 33](#page-19-0). The amount of delay necessary to achieve this condition is equal to the maximum value of the propagation delay difference specification, PDD<sub>MAX</sub>, which is specified to be 100 ns over the operating temperature range of 40°C to 105°C.

#### <span id="page-19-0"></span>**Figure 33 Minimum LED Skew for Zero Dead Time**

\*PDD = Propagation Delay Difference Note: for PDD calculations the propagation delays Are taken at the same temperature and test conditions. Delaying the LED signal by the maximum propagation delay difference ensures that the minimum dead time is zero, but it does not tell a designer what the maximum dead time will be. The maximum dead time is equivalent to the difference between the maximum and minimum propagation delay difference specifications as shown in [Figure 34](#page-19-1). The maximum dead time for the ACPL-P343/W343 is 200 ns  $(= 100 \text{ ns} -$ (–100 ns)) over an operating temperature range of –40°C to 105°C.

Note that the propagation delays used to calculate PDD and dead time are taken at equal temperatures and test conditions since the optocouplers under consideration are typically mounted in close proximity to each other and are switching identical IGBTs.

#### <span id="page-19-1"></span>**Figure 34 Waveforms for Dead Time**

\*PDD = Propagation Delay Difference

Note: For Dead Time and PDD calculations all propagation delays are taken at the same temperature and test conditions.

## **LED Current Input with Hysteresis**

The detector has optical receiver input stage with built in Schmitt trigger to provide logic compatible waveforms, eliminating the need for additional wave shaping. The hysteresis ([Figure 12](#page-10-5)) provides differential mode noise immunity and minimizes the potential for output signal chatter.

# **Under Voltage Lockout**

The ACPL-P343/W343 Under Voltage Lockout (UVLO) feature is designed to prevent the application of insufficient gate voltage to the IGBT by forcing the ACPL-P343/W343 output low during power-up. IGBTs typically require gate voltages of 15V to achieve their rated  $V_{CE(ON)}$  voltage. At gate voltages below 13V typically, the  $V_{CE(ON)}$  voltage increases dramatically, especially at higher currents. At very low gate voltages (below 10V), the IGBT may operate in the linear region and quickly overheat. The UVLO function causes the output to be clamped whenever insufficient operating supply ( $V_{CC}$ ) is applied. Once  $V_{CC}$ exceeds  $V_{UVLO+}$  (the positive-going UVLO threshold), the UVLO clamp is released to allow the device output to turn on in response to input signals.

## **Thermal Model for ACPL-P343/W343 Stretched SO6 Package Optocoupler**

## **Definitions:**

 $R_{11}$ : Junction to ambient thermal resistance of LED due to heating of LED.

 $R_{12}$ : Junction to ambient thermal resistance of LED due to heating of detector (output IC).

 $R_{21}$ : Junction to ambient thermal resistance of detector (output IC) due to heating of LED.

 $R_{22}$ : Junction to ambient thermal resistance of detector (output IC) due to heating of detector (output IC).

 $P_1$ : Power dissipation of LED (W).

P<sub>2</sub>: Power dissipation of detector/output IC (W).

 $T_1$ : Junction temperature of LED (°C).

 $T_2$ : Junction temperature of detector (°C).

Ta: Ambient temperature.

### **Ambient Temperature:**

Junction to Ambient Thermal Resistances were measured approximately 1.25 cm above optocoupler at ~23°C in still air

This thermal model assumes that an 6-pin single-channel plastic package optocoupler is soldered into a 7.62 cm × 7.62 cm printed circuit board (PCB) per JEDEC standards. The temperature at the LED and detector junctions of the optocoupler can be calculated using the following equations.

$$
T_1 = (R_{11} \times P_1 + R_{12} \times P_2) + Ta
$$
 (1)

$$
T_2 = (R_{21} \times P_1 + R_{22} \times P_2) + Ta
$$
 (2)

Using the given thermal resistances and thermal model formula in this data sheet, we can calculate the junction temperature for both LED and the output detector. Both junction temperature should be within the absolute maximum rating.

For example, given P<sub>1</sub> = 25 mW, P<sub>2</sub> = 185 mW, Ta = 85° C:

LED junction temperature,

$$
T_1 = (R_{11} \times P_1 + R_{12} \times P_2) + Ta
$$
  
= (135 × 0.025 + 27 × 0.185) + 85

 $= 93.4$ ° C

Output IC junction temperature,

 $T_2 = (R_{21} \times P_1 + R_{22} \times P_2) + Ta$  $=(39 \times 0.025 + 47 \times 0.185) + 85$  $= 94.7$ °C

 $T_1$  and  $T_2$  should be limited to 125°C based on the board layout and part placement.
