

1 MHz Bandwidth, Galvanically Isolated Current Sensor IC in SOIC-16 Package

FEATURES AND BENEFITS

- AEC-Q100 automotive qualified
- High bandwidth, 1 MHz analog output
- · Differential Hall sensing rejects common-mode fields
- High-isolation SOIC16 wide body package provides galvanic isolation for high-voltage applications
- Industry-leading noise performance with greatly improved bandwidth through proprietary amplifier and filter design
- UL 60950-1 (ed. 2) and UL 62368 (ed. 1) certified □ Dielectric Strength Voltage = 4.8 kV_{RMS}
 - \Box Basic Isolation Working Voltage = 1097 V_{RMS}
- \Box Reinforced Isolation Working Voltage = 550 V_{RMS}
- Fast and externally configurable overcurrent fault detection
- $0.85 \text{ m}\Omega$ primary conductor resistance for low power loss and high inrush current withstand capability
- Options for 3.3 V and 5 V single supply operation
- Output voltage proportional to AC and DC current
- Factory-trimmed sensitivity and quiescent output voltage for improved accuracy
- Ratiometric output from supply voltage

PACKAGE: 16-Pin SOICW (suffix MA)

Not to scale

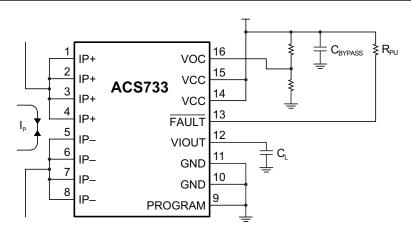

The ACS732KMA and ACS733KMA are a new generation of high bandwidth current sensor ICs from Allegro[™]. These devices provide a compact, fast, and accurate solution for measuring high-frequency currents in DC/DC converters and other switching power applications. The ACS732 and ACS733 offer high isolation, high bandwidth Hall-effect-based current sensing with user-configurable overcurrent fault detection. These features make them ideally suited for high-frequency transformer and current transformer replacement in applications running at high voltages.

The ACS732 and ACS733 are suitable for all markets, including automotive, industrial, commercial, and communications systems. They may be used in motor control, load detection and management, switch-mode power supplies, and overcurrent fault protection applications.

The wide body SOIC-16 package allows for easy implementation. Applied current flowing through the copper conduction path generates a magnetic field that is sensed by the IC and converted to a proportional voltage. Current is sensed differentially in order to reject external common-mode fields. Device accuracy is optimized through the close proximity of the magnetic field to the Hall transducers. A precise, proportional voltage is provided by the HallIC, which is factory-programmed after packaging for high accuracy. The fully integrated package has an internal copper conductive path with a typical resistance of 0.85 m Ω , providing low power loss.

The current-carrying pins (pins 1 through 8) are electrically isolated from the sensor leads (pins 9 through 16). This allows the devices to be used in high-side current sensing applications without the use of high-side differential amplifiers or other costly isolation techniques.

CB Certificate Number:

US-32210-M3-UL

US-36315-UL

Figure 1: Typical Application Circuit

ACS732/ACS733 outputs an analog signal, V_{IOUT} , that changes proportionally with the bidirectional AC or DC primary sensed current, I_{P} , within the specified measurement range.

The overcurrent threshold may be set with a resistor divider tied to the V_{OC} pin.

DESCRIPTION (continued)

The ACS732 and ACS733 are provided in a small, low profile, surface-mount SOIC-16 wide-body package. The leadframe is plated with 100% matte tin, which is compatible with standard lead (Pb)

free printed circuit board assembly processes. Internally, the device is lead-free. These devices are fully calibrated prior to shipment from the Allegro factory.

V _{OC} Input Current	I _{VOC}		_	10	100	nA

^[1] Typical values with ± are ±3 sigma values.

^[2] Use of a bypass capacitor is required to increase output stability.

^[3] See definitions of Dynamic Response Characteristics section of this datasheet.

[4] The sensor will continue to respond to current beyond the range of IPR until the high or low output saturation voltage. However, the nonlinearity in this region may be worse than the nominal operating range.

^[5] Guaranteed by design.

[7] Fault error is defined as the value at which a fault is reported relative to the desired threshold for I_{FAULT} .

For information regarding bandwidth characterization methods used for the ACS732 and ACS733, see the "Characterizing System Bandwidth" application note on the Allegro <u>website</u>.

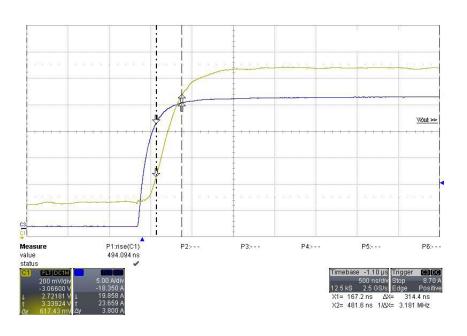

CHARACTERISTIC PERFORMANCE: ACS732 (5 V), Rise Time

Test Conditions: $T_A = 25^{\circ}C$, $C_{BYPASS} = 0.1 \mu$ F, $C_{LOAD} = 220 \text{ pF}$. Input Step = 25 A with 0.3 μ s rise time.

 $\label{eq:response time} \ensuremath{\text{Response Time}} \ensuremath{\text{Test Conditions: }} T_A = 25^\circ\text{C}, \ensuremath{\text{C}_{\text{BYPASS}}} = 0.1 \ \mu\text{F}, \ensuremath{\text{C}_{\text{LOAD}}} = 220 \ \text{pF. Input Step} = 25 \ \text{A with } 0.3 \ \mu\text{s rise time.} \ensuremath{}$

1 MHz Bandwidth, Galvanically Isolated Current Sensor IC in SOIC-16 Package

Propagation Delay Time

OVERCURRENT FAULT

Overcurrent Fault

The ACS732 and ACS733 have fast and accurate overcurrent fault detection circuitry. The overcurrent fault threshold (I_{FAULT}) is user-configurable via an external resistor divider and supports a range of 50% to 200% of the full-scale primary input ($I_{PR(MAX)}$). Fault response and the overcurrent fault thresholds are described in the following sections.

Fault Response

The high bandwidth of the ACS732 and ACS733 devices allow for extremely fast and accurate overcurrent fault detection. An overcurrent event occurs when the magnitude of the input current (I_p) exceeds the user-set threshold (I_{FAULT}). Fault response time (t_{RESPONSE(F)}) is defined from the time I_p goes above I_{FAULT} to the time the FAULT pin goes below V_{FAULT}. Overcurrent fault response is illustrated in Figure 3. When I_p goes below I_{FAULT} – I_{HYST}, the FAULT pin will be released. The rise time of V_{FAULT} will depend on the value of the resistor R_{F(PULLUP)} and the capacitance on the pin.

Setting the Overcurrent Fault Threshold

The overcurrent fault threshold (I_{FAULT}) is set via a resistor divider from V_{CC} to ground on the VOC pin. The voltage on the VOC pin, V_{VOC}, may range from $0.1 \times V_{CC}$ to $0.4 \times V_{CC}$. I_{FAULT} may be set anywhere from 50% to 200% I_{PR(MAX)}.

Overcurrent fault threshold versus V_{VOC} is shown in Figure 4.

The equation for calculating the trip current is shown below. For bidirectional devices, the fault will trip for both positive and negative currents.

$$I_{FAULT} = I_{PR(MAX)} \left\{ 5 \times \frac{V_{VOC}}{V_{CC}} \right\}$$

This may be rearranged to solve for the appropriate $V_{\rm VOC}$ value based on a desired over current fault threshold, shown by the equation:

$$V_{VOC} = \frac{V_{CC}}{5} \times \frac{I_{FAULT}}{I_{PR(MAX)}}$$

By setting V_{VOC} with a resistor divider from V_{CC} , the ratio of V_{VOC} / V_{CC} will remain constant with changes to V_{CC} . In this regard, the fault trip point will remain constant even as the supply voltage varies.

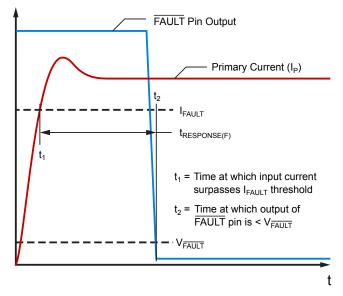

Figure 3: Overcurrent Fault Response

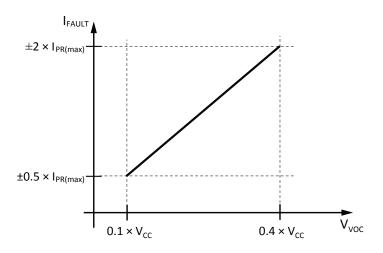

Figure 4: Fault Threshold vs. V_{VOC}

It is best practice to use resistor values < 10 k Ω for setting V_{VOC}. With larger resistor values, the leakage current on VOC may result in errors in the trip point.

DEFINITIONS OF DYNAMIC RESPONSE CHARACTERISTICS

Power-On Delay Time (t_{POD})

When the supply is ramped to its operating voltage, the device requires a finite amount of time to power its internal components before responding to an input magnetic field. Power-On Delay Time (t_{POD}) is defined as the time interval between a) the power supply has reached its minimum specified operating voltage ($V_{CC(MIN)}$), and b) when the sensor output has settled within $\pm 10\%$ of its steady-state value under an applied magnetic field. Power-On Delay Time is illustrated in Figure 5.

Figure 5: Power-On Delay Time (t_{POD})

Rise Time (t_r)

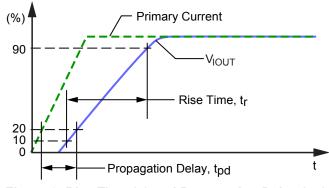

The time interval between a) when the sensor reaches 10% of its full-scale value, and b) when it reaches 90% of its full-scale value.

Propagation Delay (t_{pd})

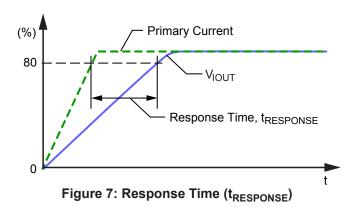

The time interval between a) when the sensed input current reaches 20% of its full-scale value, and b) when the sensor output reaches 20% of its full-scale value.

Response Time (t_{RESPONSE})

The time interval between a) when the sensed input current reaches 80% of its final value, and b) when the sensor output reaches 80% of its full-scale value.

1 MHz Bandwidth, Galvanically Isolated Current Sensor IC in SOIC-16 Package

DEFINITIONS OF ACCURACY CHARACTERISTICS

Sensitivity (Sens). The change in sensor IC output in response to a 1 A change through the primary conductor. The sensitivity is the product of the magnetic circuit sensitivity (G/A) (1 G = 0.1 mT) and the linear IC amplifier gain (mV/G). The linear IC amplifier gain is programmed at the factory to optimize the sensitivity (mV/A) for the full-scale current of the device.

Nonlinearity (E_{LIN}). The nonlinearity is a measure of how linear the output of the sensor IC is over the full current measurement range. The nonlinearity is calculated as:

$$E_{LIN} = \left\{ 1 - \left[\frac{V_{IOUT}(I_{PR(max)}) - V_{IOUT(Q)}}{2 \times V_{IOUT}(I_{PR(max)}/2) - V_{IOUT(Q)}} \right] \right\}$$

where $V_{IOUT}(I_{PR(max)})$ is the output of the sensor IC with the maximum measurement current flowing through it and $V_{IOUT}(I_{PR(max)}/2)$ is the output of the sensor IC with half of the maximum measurement current flowing through it.

Zero Current Output Voltage (V_{IOUT(Q)}). The output of the sensor when the primary current is zero. For a unipolar supply voltage, it nominally remains at $0.5 \times V_{CC}$ for a bidirectional device and $0.1 \times V_{CC}$ for a unidirectional device. For example, in the case of a bidirectional output device, $V_{CC} = 3.3$ V translates into $V_{IOUT(Q)} = 1.65$ V. Variation in $V_{IOUT(Q)}$ can be attributed to the resolution of the Allegro linear IC quiescent voltage trim and thermal drift.

Offset Voltage (V_{OE}). The deviation of the device output from its ideal quiescent value of $0.5 \times V_{CC}$ (bidirectional) or $0.1 \times V_{CC}$ (unidirectional) due to nonmagnetic causes. To convert this voltage to amperes, divide by the device sensitivity, Sens.

Total Output Error (\mathbf{E}_{TOT}). The difference between the current measurement from the sensor IC and the actual current (I_p), relative to the actual current. This is equivalent to the difference between the ideal output voltage and the actual output voltage, divided by the ideal sensitivity, relative to the current flowing through the primary conduction path:

$$E_{TOT}(I_P) = \frac{V_{IOUT_{ideal}}(I_P) - V_{IOUT}(I_P)}{Sens_{ideal}(I_P) \times I_P} \times 100 \ (\%)$$

The Total Output Error incorporates all sources of error and is a function of I_P. At relatively high currents, E_{TOT} will be mostly due to sensitivity error, and at relatively low currents, E_{TOT} will be mostly due to Offset Voltage (V_{OE}). In fact, as I_P approaches zero, E_{TOT} approaches infinity due to the offset voltage. This is illustrated in Figure 8 and Figure 9. Figure 8 shows a distribution of output voltages versus I_P at 25°C and across temperature. Figure 9 shows the corresponding E_{TOT} versus I_P.

APPLICATION INFORMATION

Ratiometry

The ACS732 and ACS733 are both ratiometric sensors. This means that for a given change in supply voltage, the device's zero current output voltage and sensitivity will scale proportionally.

Sensitivity Ratiometry

Ideally, a 5% increase in V_{CC} will result in a 5% increase in sensitivity. However, the ratiometric response of any sensor is not ideal. Ratiometric Sensitivity Error $E_{RAT(SENS)}$ is specified by the equation:

$$E_{RAT(SENS)} = 100\% \times (1 - \frac{Sensitivity_{VCC}}{Sensitivity_{VCC(N)}} \times \frac{V_{CC(N)}}{V_{CC}} E^2$$

where $V_{CC(N)}$ is equal to the nominal V_{CC} (3.3 V, or 5.0 V) and Sensitivity_{VCC(N)} is the measured sensitivity at nominal V_{CC} for a particular device. The symbol V_{CC} is the measured V_{CC} value in application and Sensitivity_{VCC} is the measured sensitivity at that V_{CC} level for a particular device.

Zero Current Offset Ratiometry

Ratiometric error for Zero Current Offset may be calculated using the following equation:

$$E_{RAT(Q)} = V_{IOUT(Q)VCC} - V_{IOUT(Q)VCC(N)} \times \frac{V_{CC}}{V_{CC(N)}}$$

Where $V_{CC(N)}$ is equal to the nominal V_{CC} (3.3 V, or 5.0 V) and $V_{IOUT(Q)VCC(N)}$ is the measured Zero Current Offset voltage at nominal V_{CC} for a particular device. The symbol V_{CC} is the measured V_{CC} value in application and $V_{IOUT(Q)VCC}$ is the measured zero current offset voltage for a particular device.

Estimating Total Error vs. Sensed Current

The performance characteristics tables give distribution (±3 sigma) values for Total Error at $I_{PR(MAX)}$; however, one may be interested in the expected error at a particular current. This error may be estimated using the distribution data for the components of Total Error, Sensitivity Error, and Offset Voltage. The ±3 sigma value for Total Error (E_{TOT}) as a function if the sensed current is estimated as:

$$E_{TOT}(I_p) = \sqrt{E_{SENS}^2 + \left(\frac{100 \times V_{OE}}{Sens \times I_p}\right)^2}$$

where E_{SENS} and V_{OE} are the ±3 sigma values for those error terms.

If there is an average sensitivity error or average offset voltage, then the average Total Error is estimated as:

$$E_{TOT_{AVG}}(I_p) = E_{SENS_{AVG}} + \frac{100 \times V_{OE_{AVG}}}{Sens \times I_p}$$

Layout Guidelines

There are a few considerations during PCB layout that will help to maintain high accuracy when using Allegro's integrated current sensors. Below is a list of common layout mistakes that should be avoided:

- Extending current carrying traces too far beneath the IC, or injecting current from the side of the IC
- Placing secondary current phase traces too close to or below the IC

Extending the Current Traces

The length of copper trace beneath the IC may impact the path of current flowing through the IP bus. This may cause variation in the coupling factor from the primary current loop of the package to the IC, and may reduce the overall creepage distance in application.

It is best practice for the current to approach the IC parallel to the current-carrying pins, and for the current-carrying trace to not creep towards the center of the package. Refer to Figure 10.

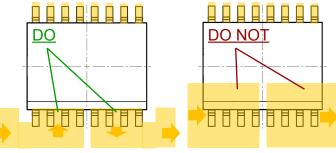

Figure 10: Best Practice Layout Techniques for Current Traces

If current must approach the package from the side, it is recommended to reduce the angle as much as possible. For more information on best current sensor layout practices refer to the application note "Techniques to Minimize Common-Mode Field Interference When Using Allegro Current Sensor ICs" on the Allegro website.

Thermal Rise vs. Primary Current

Self-heating due to the flow of current should be considered during the design of any current sensing system. The sensor, printed circuit board (PCB), and contacts to the PCB will generate heat as current moves through the system.

The thermal response is highly dependent on PCB layout, copper thickness, cooling techniques, and the profile of the injected current. The current profile includes peak current, current "on-time", and duty cycle. While the data presented in this section was collected with direct current (DC), these numbers may be used to approximate thermal response for both AC signals and current pulses.

The plot in Figure 11 shows the measured rise in steady-state die temperature of the ACS732/3 versus continuous current at an ambient temperature, T_A , of 25°C. The thermal offset curves may be directly applied to other values of T_A . Conversely, Figure 12 shows the maximum continuous current at a given T_A . Surges beyond the maximum current listed in Figure 12 are allowed given the maximum junction temperature, $T_{J(MAX)}$ (165°C), is not exceeded.

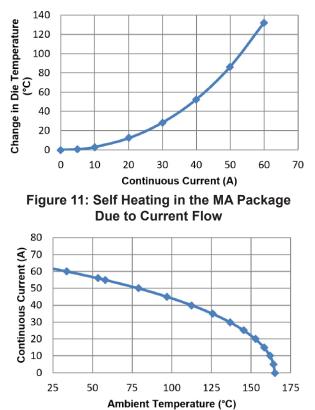

Figure 12: Maximum Continuous Current at a Given T_A

The thermal capacity of the ACS732/3 should be verified by the end user in the application's specific conditions. The maximum junction temperature, $T_{J(MAX)}$, should not be exceeded. Further information on this application testing is available in the DC and Transient Current Capability application note on the Allegro website.

ASEK73x Evaluation Board Layout

Thermal data shown in Figure 11 was collected using the ASEK73x Evaluation Board (TED-0002717). This board includes 1500 mm² of 2 oz. (0.0694 mm) copper connected to pins 1 through 4 and pins 5 through 8, with thermal vias connecting the layers. Top and bottom layers of the PCB are shown below in Figure 13.

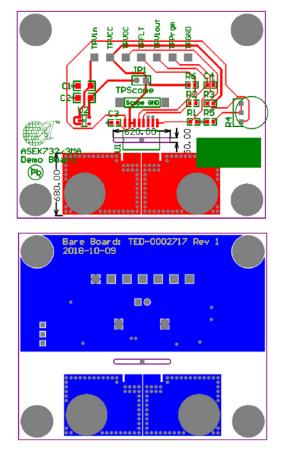

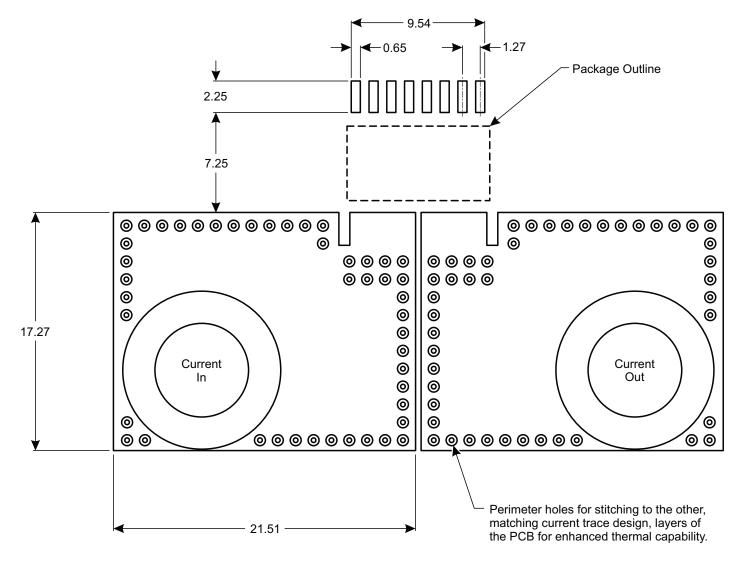

Figure 13: Top and Bottom Layers for ASEK73x Evaluation Board

Gerber files for the ASEK73x evaluation board are available for download from our website. Please see the technical documents section of the ACS733 and ACS732 device webpage.
