

### FEATURES

- 2 channels in a small, 4 mm × 4 mm LFCSP
- LFCSP package has no metal pad
  - More routing room
  - No current leakage to pad
- Gain set with 1 external resistor
  - Gain range: 1 to 1000
- Input voltage goes below ground
- Inputs protected beyond supplies
- Very wide power supply range
  - Single supply: 2.2 V to 36 V
  - Dual supply: ±1.35 V to ±18 V
- Bandwidth (G = 1): 1 MHz
- CMRR (G = 1): 80 dB minimum
- Input noise: 24 nV/√Hz
- Typical supply current (per amplifier): 350 μA
- Specified temperature range: -40°C to +125°C

### APPLICATIONS

- Industrial process controls
- Bridge amplifiers
- Medical instrumentation
- Portable data acquisition
- Multichannel systems

### GENERAL DESCRIPTION

The [AD8426](#) is a dual-channel, low cost, wide supply range instrumentation amplifier that requires only one external resistor to set any gain from 1 to 1000.

The [AD8426](#) is designed to work with a variety of signal voltages. A wide input range and rail-to-rail output allow the signal to make full use of the supply rails. Because the input range can also go below the negative supply, small signals near ground can be amplified without requiring dual supplies. The [AD8426](#) operates on supplies ranging from ±1.35 V to ±18 V for dual supplies and 2.2 V to 36 V for a single supply.

The robust [AD8426](#) inputs are designed to connect to real-world sensors. In addition to its wide operating range, the [AD8426](#) can handle voltages beyond the rails. For example, with a ±5 V supply, the part is guaranteed to withstand ±35 V at the input with no damage. Minimum and maximum input bias currents are specified to facilitate open-wire detection.

<sup>1</sup> See [www.analog.com](http://www.analog.com) for the latest instrumentation amplifiers.

The [AD8426](#) is designed to make PCB routing easy and efficient. The two amplifiers are arranged in a logical way so that typical application circuits have short routes and few vias. Unlike most chip scale packages, the [AD8426](#) does not have an exposed metal pad on the bottom of the part, which frees additional space for routing and vias. The [AD8426](#) offers two in-amps in the equivalent board space of a typical MSOP package.

The [AD8426](#) is ideal for multichannel, space-constrained industrial applications. Unlike other low cost, low power instrumentation amplifiers, the [AD8426](#) is designed with a minimum gain of 1 and can easily handle ±10 V signals. With its space-saving LFCSP package and 125°C temperature rating, the [AD8426](#) thrives in tightly packed, zero airflow designs.

The [AD8226](#) is the single-channel version of the [AD8426](#).

## ABSOLUTE MAXIMUM RATINGS

Table 8.

Parameter	Rating
Supply Voltage	±18 V
Output Short-Circuit Current	Indefinite
Maximum Voltage at –INx or +INx	–V <sub>S</sub> + 40 V
Minimum Voltage at –INx or +INx	+V <sub>S</sub> – 40 V
REFx Voltage	±V <sub>S</sub>
Storage Temperature Range	–65°C to +150°C
Specified Temperature Range	–40°C to +125°C
Maximum Junction Temperature	130°C
<b>ESD</b>	
Human Body Model	1.5 kV
Charged Device Model	1.5 kV
Machine Model	100 V

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## THERMAL RESISTANCE

The  $\theta_{JA}$  value in Table 9 assumes a 4-layer JEDEC standard board with zero airflow.

Table 9.

Package	$\theta_{JA}$	Unit
16-Lead LFCSP (CP-16-19)	86	°C/W

## ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

Figure 61. Simplified Schematic

### ARCHITECTURE

The AD8426 is based on the classic 3-op-amp topology. This topology has two stages: a gain stage (preamplifier) to provide differential amplification, followed by a difference amplifier stage to remove the common-mode voltage. Figure 61 shows a simplified schematic of one of the instrumentation amplifiers in the AD8426.

The first stage works as follows. To maintain a constant voltage across the bias resistor,  $R_B$ , A1 must keep Node 3 at a constant diode drop above the positive input voltage. Similarly, A2 keeps Node 4 at a constant diode drop above the negative input voltage. Therefore, a replica of the differential input voltage is placed across the gain setting resistor,  $R_G$ . The current that flows across this resistance must also flow through the  $R_1$  and  $R_2$  resistors, creating a gained differential signal between the A2 and A1 outputs. Note that, in addition to a gained differential signal, the original common-mode signal, shifted up by a diode drop, is also still present.

The second stage is a difference amplifier, composed of A3 and four 50 kΩ resistors. The purpose of this stage is to remove the common-mode signal from the amplified differential signal.

The transfer function of the AD8426 is

$$V_{OUT} = G \times (V_{IN+} - V_{IN-}) + V_{REF}$$

where:

$$G = 1 + \frac{49.4 \text{ k}\Omega}{R_G}$$

### GAIN SELECTION

Placing a resistor across the  $R_G$  terminals sets the gain of the AD8426. The gain can be calculated by referring to Table 11 or by using the following gain equation:

$$R_G = \frac{49.4 \text{ k}\Omega}{G - 1}$$

Table 11. Gains Achieved Using 1% Resistors

1% Standard Table Value of $R_G$	Calculated Gain
49.9 kΩ	1.990
12.4 kΩ	4.984
5.49 kΩ	9.998
2.61 kΩ	19.93
1.00 kΩ	50.40
499 Ω	100.0
249 Ω	199.4
100 Ω	495.0
49.9 Ω	991.0

The AD8426 defaults to  $G = 1$  when no gain resistor is used. The tolerance and gain drift of the  $R_G$  resistor should be added to the AD8426 specifications to determine the total gain accuracy of the system. When the gain resistor is not used, gain error and gain drift are minimal.

## REFERENCE TERMINAL

The output voltage of the AD8426 is developed with respect to the potential on the reference terminal. This is useful when the output signal needs to be offset to a precise midsupply level. For example, a voltage source can be tied to the REF pin to level-shift the output so that the AD8426 can drive a single-supply ADC. The REF pin is protected with ESD diodes and should not exceed either +V<sub>S</sub> or -V<sub>S</sub> by more than 0.3 V.

For the best performance, source impedance to the REF terminal should be kept below 2 Ω. As shown in Figure 62, the reference terminal, REF, is at one end of a 50 kΩ resistor. Additional impedance at the REF terminal adds to this 50 kΩ resistor and results in amplification of the signal connected to the positive input. The amplification from the additional R<sub>REF</sub> can be computed by  $2 \times (50 \text{ k}\Omega + R_{REF})/100 \text{ k}\Omega + R_{REF}$ .

Only the positive signal path is amplified; the negative path is unaffected. This uneven amplification degrades the CMRR of the amplifier.

Figure 62. Driving the Reference Pin

## INPUT VOLTAGE RANGE

The 3-op-amp architecture of the AD8426 applies gain in the first stage before removing common-mode voltage in the difference amplifier stage. In addition, the input transistors in the first stage shift the common-mode voltage up one diode drop. Therefore, internal nodes between the first and second stages (Node 1 and Node 2 in Figure 61) experience a combination of gained signal, common-mode signal, and a diode drop. This combined signal can be limited by the voltage supplies even when the individual input and output signals are not limited. Figure 9 to Figure 15 and Figure 18 show the allowable common-mode input voltage ranges for various output voltages and supply voltages.

Equation 1 to Equation 3 can be used to understand the interaction of the gain (G), common-mode input voltage (V<sub>CM</sub>), differential input voltage (V<sub>DIFF</sub>), and reference voltage (V<sub>REF</sub>). The values for the constants (V<sub>-LIMIT</sub>, V<sub>+LIMIT</sub>, and V<sub>REF\_LIMIT</sub>) at different temperatures are shown in Table 12. These three equations, along with the input and output voltage range specifications in Table 2 and Table 5, set the operating boundaries of the part.

$$V_{CM} - \left| \frac{V_{DIFF} \times G}{2} \right| > -V_S + V_{-LIMIT} \quad (1)$$

$$V_{CM} + \left| \frac{V_{DIFF} \times G}{2} \right| < +V_S - V_{+LIMIT} \quad (2)$$

$$\left( \frac{\frac{V_{DIFF} \times G}{2} + V_{CM} + V_{REF}}{2} \right) < +V_S - V_{REF\_LIMIT} \quad (3)$$

Table 12. Input Voltage Range Constants for Various Temperatures

Temperature	V <sub>-LIMIT</sub> (V)	V <sub>+LIMIT</sub> (V)	V <sub>REF_LIMIT</sub> (V)
-40°C	-0.55	+0.8	+1.3
+25°C	-0.35	+0.7	+1.15
+85°C	-0.15	+0.65	+1.05
+125°C	-0.05	+0.6	+0.9

The common-mode input voltage range shifts upward with temperature. At cold temperatures, the part requires extra headroom from the positive supply, whereas operation near the negative supply has more margin. Conversely, at hot temperatures, the part requires less headroom from the positive supply but is subject to the worst-case conditions for input voltages near the negative supply.

A typical part functions up to the boundaries described in this section. However, for best performance, designing with a few hundred millivolts of extra margin is recommended. As signals approach the boundary, internal transistors begin to saturate, which can affect frequency and linearity performance.

## LAYOUT

To ensure optimum performance of the AD8426 at the PCB level, care must be taken in the design of the board layout. The AD8426 pins are arranged in a logical manner to aid in this task.

Figure 63. Pinout Diagram

## Package Considerations

The AD8426 is available in a 16-lead, 4 mm × 4 mm LFCSP with no exposed paddle. The footprint from another 4 mm × 4 mm LFCSP part should not be copied because it may not have the correct lead pitch and lead width dimensions. Refer to the Outline Dimensions section to verify that the corresponding dimensional symbol has the correct dimensions.

## Hidden Paddle Package

The AD8426 is available in an LFCSP package with a hidden paddle. Unlike chip scale packages where the pad limits routing capability, this package allows routes and vias directly beneath the chip. In this way, the full space savings of the small LFCSP can be realized. Although the package has no metal in the center of the part, the manufacturing process leaves a very small section of exposed metal at each of the package corners, as shown in Figure 64 and in Figure 73 in the Outline Dimensions section. This metal is connected to  $-V_S$  through the part. Because of the possibility of a short, vias should not be placed beneath these exposed metal tabs.

NOTES  
1. EXPOSED METAL TABS AT THE FOUR CORNERS OF THE PACKAGE ARE INTERNALLY CONNECTED TO  $-V_S$ .

Figure 64. Hidden Paddle Package, Bottom View

## Common-Mode Rejection Ratio over Frequency

Poor layout can cause some of the common-mode signals to be converted to differential signals before reaching the in-amp. Such conversions occur when one input path has a frequency response that is different from the other. To keep CMRR over frequency high, the input source impedance and capacitance of each path should be closely matched. Additional source resistance in the input paths (for example, for input protection) should be placed close to the in-amp inputs to minimize the interaction of the inputs with parasitic capacitance from the PCB traces.

Parasitic capacitance at the gain setting pins can also affect CMRR over frequency. If the board design has a component at the gain setting pins (for example, a switch or jumper), the component should be chosen so that the parasitic capacitance is as small as possible.

## Power Supplies

A stable dc voltage should be used to power the instrumentation amplifier. Noise on the supply pins can adversely affect performance. See the PSRR performance curves in Figure 22 and Figure 25 for more information.

A 0.1  $\mu\text{F}$  capacitor should be placed as close as possible to each supply pin. As shown in Figure 65, a 10  $\mu\text{F}$  capacitor can be used farther away from the part. In most cases, it can be shared by other precision integrated circuits.

Figure 65. Supply Decoupling, REF, and Output Referred to Local Ground

## References

The output voltage of the AD8426 is developed with respect to the potential on the reference terminal. Care should be taken to tie the REFx pins to the appropriate local ground. This should also help minimize crosstalk between the two channels.

# AD8426

## INPUT BIAS CURRENT RETURN PATH

The input bias current of the AD8426 must have a return path to ground. When the source, such as a thermocouple, cannot provide a current return path, one should be created, as shown in Figure 66.

Figure 66. Creating an Input Bias Current Return Path

## INPUT PROTECTION

The AD8426 has very robust inputs and typically does not need additional input protection. Input voltages can be up to 40 V from the opposite supply rail. For example, with a +5 V positive supply and a -8 V negative supply, the part can safely withstand voltages from -35 V to +32 V. Unlike some other instrumentation amplifiers, the part can handle large differential input voltages even when the part is in high gain. Figure 16, Figure 17, Figure 19, and Figure 20 show the behavior of the part under overvoltage conditions.

The other AD8426 terminals should be kept within the supplies. All terminals of the AD8426 are protected against ESD.

For applications where the AD8426 encounters voltages beyond the allowed limits, external current limiting resistors and low leakage diode clamps such as the BAV199L, the FJH1100, or the SP720 should be used.

## RADIO FREQUENCY INTERFERENCE (RFI)

RF interference is often a problem when amplifiers are used in applications where there are strong RF signals. The precision circuits in the AD8426 can rectify the RF signals so that they appear as a dc offset voltage error. To avoid this rectification, place a low-pass RC filter at the input of the instrumentation amplifier (see Figure 67). The filter limits both the differential and common-mode bandwidth, as shown in the following equations:

$$FilterFrequency_{DIFF} = \frac{1}{2\pi R(2C_D + C_C)}$$

$$FilterFrequency_{CM} = \frac{1}{2\pi RC_C}$$

where  $C_D \geq 10 C_C$ .

Figure 67. RFI Suppression

$C_D$  affects the differential signal, and  $C_C$  affects the common-mode signal. Values of  $R$  and  $C_C$  should be chosen to minimize RFI. Any mismatch between the  $R \times C_C$  at the positive input and the  $R \times C_C$  at the negative input degrades the CMRR of the AD8426. By using a value of  $C_D$  one order of magnitude larger than  $C_C$ , the effect of the mismatch is reduced, and performance is improved.

## APPLICATIONS INFORMATION

### PRECISION STRAIN GAGE

The low offset and high CMRR over frequency of the [AD8426](#) make it an excellent candidate for bridge measurements. The bridge can be connected directly to the inputs of the amplifier (see Figure 68).

Figure 68. Precision Strain Gage

### DIFFERENTIAL DRIVE

The differential output configuration of the [AD8426](#) has the same excellent dc precision specifications as the single-ended output configuration.

#### Differential Output Using Both AD8426 Amplifiers

The circuit configuration is shown in Figure 69. The differential output specifications in Table 2, Table 4, Table 5, and Table 7 refer to this configuration only. The circuit includes an RC filter that maintains the stability of the loop.

Figure 69. Differential Circuit Schematic

The differential output voltage is set by the following equation:

$$V_{DIFF\_OUT} = V_{OUT+} - V_{OUT-} = G \times (V_{IN+} - V_{IN-})$$

where:

$$G = 1 + \frac{49.4 \text{ k}\Omega}{R_G}$$

The common-mode output voltage is set by the average of +IN2 and REF2. The transfer function is

$$V_{CM\_OUT} = (V_{OUT+} + V_{OUT-})/2 = (V_{+IN2} + V_{REF2})/2$$

A common application sets the common-mode output voltage to the midscale of a differential ADC. In this case, the ADC reference voltage is sent to the +IN2 terminal, and ground is connected to the REF2 terminal. This produces a common-mode output voltage of half the ADC reference voltage.

#### 2-Channel Differential Output Using a Dual Op Amp

Another differential output topology is shown in Figure 70. Instead of a second in-amp, one-half of a dual op amp creates the inverted output. The recommended dual op amps (the [AD8642](#) and the [AD822](#)) are packaged in an MSOP. This configuration allows the creation of a dual-channel, precision differential output in-amp with little board area.

Figure 70 shows how to configure the [AD8426](#) for differential output.

RECOMMENDED OP AMPS: AD8642, AD822.  
RECOMMENDED R VALUES: 5kΩ TO 20kΩ.

Figure 70. Differential Output Using an Op Amp

The differential output voltage is set by the following equation:

$$V_{DIFF\_OUT} = V_{OUT+} - V_{OUT-} = G \times (V_{IN+} - V_{IN-})$$

where:

$$G = 1 + \frac{49.4 \text{ k}\Omega}{R_G}$$

The common-mode output voltage is set by the following equation:

$$V_{CM\_OUT} = (V_{OUT+} - V_{OUT-})/2 = V_{BIAS}$$

The advantage of this circuit is that the dc differential accuracy depends on the [AD8426](#) and not on the op amp or the resistors. This circuit takes advantage of the precise control of the [AD8426](#) over its output voltage relative to the reference voltage. Op amp dc performance and resistor matching do affect the dc common-mode output accuracy. However, because common-mode errors are likely to be rejected by the next device in the signal chain, these errors typically have little effect on overall system accuracy.

For best ac performance, an op amp with gain bandwidth of at least 2 MHz and a slew rate of at least 1 V/μs is recommended. Good choices for op amps are the [AD8642](#) and the [AD822](#).

# AD8426

## Tips for Best Differential Output Performance

Keep trace lengths from resistors to the inverting terminal of the op amp as short as possible. Excessive capacitance at this node can cause the circuit to be unstable. If capacitance cannot be avoided, use lower value resistors.

For best linearity and ac performance, a minimum positive supply voltage ( $+V_S$ ) is required. Table 13 shows the minimum supply voltage required for optimum performance, where  $V_{CM\_MAX}$  indicates the maximum common-mode voltage expected at the input of the AD8426.

**Table 13. Minimum Positive Supply Voltage**

Temperature	Equation
Less than $-10^{\circ}\text{C}$	$+V_S > (V_{CM\_MAX} + V_{BIAS})/2 + 1.4\text{ V}$
$-10^{\circ}\text{C}$ to $+25^{\circ}\text{C}$	$+V_S > (V_{CM\_MAX} + V_{BIAS})/2 + 1.25\text{ V}$
More than $+25^{\circ}\text{C}$	$+V_S > (V_{CM\_MAX} + V_{BIAS})/2 + 1.1\text{ V}$

## DRIVING A CABLE

All cables have a certain capacitance per unit length, which varies widely with cable type. The capacitive load from the cable may cause peaking in the output response of the AD8426. To reduce the peaking, use a resistor between the AD8426 outputs and the cable (see Figure 71). Because cable capacitance and desired output response vary widely, this resistor is best determined empirically. A good starting point is  $50\ \Omega$ .

Figure 71. Driving a Cable

The AD8426 operates at such a relatively low frequency that transmission line effects are rarely an issue; therefore, the resistor need not match the characteristic impedance of the cable.

## DRIVING AN ADC

Figure 72 shows several different methods of driving an ADC. The ADC in the ADuC7026 microcontroller was chosen for this example because it has an unbuffered, charge sampling architecture that is typical of most modern ADCs. This type of architecture typically requires an RC buffer stage between the ADC and the amplifier to work correctly.

Option 1 shows the minimum configuration required to drive a charge sampling ADC. The capacitor provides charge to the ADC sampling capacitor, and the resistor shields the AD8426 from the capacitance. To keep the AD8426 stable, the RC time constant of the resistor and capacitor needs to stay above 5  $\mu$ s. This circuit is mainly useful for lower frequency signals.

Option 2 shows a circuit for driving higher frequency signals. It uses a precision op amp (AD8616) with relatively high bandwidth and output drive. This amplifier can drive a resistor and capacitor with a much higher time constant and is, therefore, suited for higher frequency applications.

Option 3 is useful for applications where the AD8426 must operate from a large voltage supply but drives a single-supply ADC. In normal operation, the AD8426 output signal stays within the ADC range, and the AD8616 simply buffers the signal. However, in a fault condition, the output of the AD8426 may go outside the supply range of both the AD8616 and the ADC. This is not a problem in this circuit, because the 10 k $\Omega$  resistor between the two amplifiers limits the current into the AD8616 to a safe level.

Figure 72. Driving an ADC
