

## FEATURES

- Low cost and easy to use
- Pretrimmed for J or K type thermocouples
- Internal cold junction compensation
- High impedance differential input
- Standalone 5 mV/°C thermometer
- Reference pin allows offset adjustment
- Thermocouple break detection
- Laser wafer trimmed to 1°C initial accuracy and 0.025°C/°C ambient temperature rejection
- Low power: <1 mW at  $V_S = 5\text{ V}$
- Wide power supply range
  - Single supply: 2.7 V to 36 V
  - Dual supply:  $\pm 2.7\text{ V}$  to  $\pm 18\text{ V}$
- Small, 8-lead MSOP

## APPLICATIONS

- J or K type thermocouple temperature measurement
- Setpoint controller
- Celsius thermometer
- Universal cold junction compensator
- White goods (oven, stovetop) temperature measurements
- Exhaust gas temperature sensing
- Catalytic converter temperature sensing

## GENERAL DESCRIPTION

The AD8494/AD8495/AD8496/AD8497 are precision instrumentation amplifiers with thermocouple cold junction compensators on an integrated circuit. They produce a high level (5 mV/°C) output directly from a thermocouple signal by combining an ice point reference with a precalibrated amplifier. They can be used as standalone thermometers or as switched output setpoint controllers using a fixed or remote setpoint control.

The AD8494/AD8495/AD8496/AD8497 can be powered from a single-ended supply (less than 3 V) and can measure temperatures below 0°C by offsetting the reference input. To minimize self-heating, an unloaded AD849x typically operates with a total supply current of 180  $\mu\text{A}$ , but it is also capable of delivering in excess of  $\pm 5\text{ mA}$  to a load.

The AD8494 and AD8496 are precalibrated by laser wafer trimming to match the characteristics of J type (iron-constantan) thermocouples; the AD8495 and AD8497 are laser trimmed to match the characteristics of K type (chromel-alumel) thermocouples. See Table 1 for the optimized ambient temperature range of each part.

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

Table 1. Device Temperature Ranges

Part No.	Thermo-Couple Type	Optimized Temperature Range	
		Ambient Temperature (Reference Junction)	Measurement Junction
AD8494	J	0°C to 50°C	Full J type range
AD8495	K	0°C to 50°C	Full K type range
AD8496	J	25°C to 100°C	Full J type range
AD8497	K	25°C to 100°C	Full K type range

The AD8494/AD8495/AD8496/AD8497 allow a wide variety of supply voltages. With a 5 V single supply, the 5 mV/°C output allows the devices to cover nearly 1000 degrees of a thermocouple's temperature range.

The AD8494/AD8495/AD8496/AD8497 work with 3 V supplies, allowing them to interface directly to lower supply ADCs. They can also work with supplies as large as 36 V in industrial systems that require a wide common-mode input range.

## PRODUCT HIGHLIGHTS

1. Complete, precision laser wafer trimmed thermocouple signal conditioning system in a single IC package.
2. Flexible pinout provides for operation as a setpoint controller or as a standalone Celsius thermometer.
3. Rugged inputs withstand 4 kV ESD and provide over-voltage protection (OVP) up to  $V_S \pm 25\text{ V}$ .
4. Differential inputs reject common-mode noise on the thermocouple leads.
5. Reference pin voltage can be offset to measure 0°C on single supplies.
6. Available in a small, 8-lead MSOP that is fully RoHS compliant.

		Min	Typ	Max	Min	Typ	Max	
TEMPERATURE RANGE (T <sub>A</sub> )								
Specified Performance								
AD8494/AD8495		0		50	0		50	°C
AD8496/AD8497		25		100	25		100	°C
Operational		-40		+125	-40		+125	°C

<sup>1</sup> Ambient temperature rejection specifies the change in the output measurement (in °C) for a given change in temperature of the cold junction. For the AD8494 and AD8495, ambient temperature rejection is defined as the slope of the line connecting errors calculated at 0°C and 50°C ambient temperature. For the AD8496 and AD8497, ambient temperature rejection is defined as the slope of the line connecting errors calculated at 25°C and 100°C ambient temperature.

<sup>2</sup> Error does not include thermocouple gain error or thermocouple nonlinearity.

<sup>3</sup> With a 100 kΩ load, measurement junction temperatures beyond approximately 880°C for the AD8494 and AD8496 and beyond approximately 960°C for the AD8495 and AD8497 require supply voltages larger than 5 V or a negative voltage applied to the reference pin. Measurement junction temperatures below 5°C require either a positive offset voltage applied to the reference pin or a negative supply.

<sup>4</sup> Input stage uses PNP transistors, so bias current always flows out of the part.

<sup>5</sup> Large output currents can increase the internal temperature rise of the part and contribute to cold junction compensation (CJC) error.

<sup>6</sup> Unbalanced supplies can also be used. Care should be taken that the common-mode voltage of the thermocouple stays within the input voltage range of the part.

## ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
Supply Voltage	$\pm 18$ V
Maximum Voltage at $-IN$ or $+IN$	$-V_S + 25$ V
Minimum Voltage at $-IN$ or $+IN$	$+V_S - 25$ V
REF Voltage	$\pm V_S$
Output Short-Circuit Current Duration	Indefinite
Storage Temperature Range	$-65^\circ\text{C}$ to $+150^\circ\text{C}$
Operating Temperature Range	$-40^\circ\text{C}$ to $+125^\circ\text{C}$
Maximum IC Junction Temperature	$140^\circ\text{C}$
ESD	
Human Body Model	4.5 kV
Field-Induced Charged Device Model	1.5 kV

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

$\theta_{JA}$  is specified for a device on a 4-layer JEDEC PCB in free air.

Table 4.

Package	$\theta_{JA}$	Unit
8-Lead MSOP (RM-8)	135	$^\circ\text{C}/\text{W}$

## ESD CAUTION

### ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	-IN	Negative Input.
2	REF	Reference. This pin must be driven by low impedance.
3	-Vs	Negative Supply.
4	NC	No Connect.
5	SENSE	Sense Pin. In measurement mode, connect to output; in setpoint mode, connect to setpoint voltage.
6	OUT	Output.
7	+Vs	Positive Supply.
8	+IN	Positive Input.

## THEORY OF OPERATION

### THERMOCOUPLES

A thermocouple is a rugged, low cost temperature transducer whose output is proportional to the temperature difference between a measurement junction and a reference junction. It has a very wide temperature range. Its low level output (typically tens of microvolts per °C) requires amplification. Variation in the reference junction temperature results in measurement error unless the thermocouple signal is properly compensated.

A thermocouple consists of two dissimilar metals. These metals are connected at one end to form the measurement junction, also called the hot junction. The other end of the thermocouple is connected to the metal lines that lead to the measurement electronics. This connection forms a second junction: the reference junction, also called the cold junction.

Figure 26. Thermocouple Junctions

To derive the temperature at the measurement junction ( $T_{MJ}$ ), the user must know the differential voltage created by the thermocouple. The user must also know the error voltage generated by the temperature at the reference junction ( $T_{RJ}$ ). Compensating for the reference junction error voltage is typically called cold junction compensation. The electronics must compensate for any changes in temperature at the reference (cold) junction so that the output voltage is an accurate representation of the hot junction measurement.

### THERMOCOUPLE SIGNAL CONDITIONER

The AD8494/AD8495/AD8496/AD8497 thermocouple amplifiers provide a simple, low cost solution for measuring thermocouple temperatures. These amplifiers simplify many of the difficulties of measuring thermocouples. An integrated temperature sensor performs cold junction compensation. A fixed-gain instrumentation amplifier amplifies the small thermocouple voltage to provide a 5 mV/°C output. The high common-mode rejection of the amplifier blocks common-mode noise that the long thermocouple leads can pick up. For additional protection, the high impedance inputs of the amplifier make it easy to add extra filtering.

Table 6 shows an example of a J type thermocouple voltage for various combinations of 0°C and 50°C on the reference and measurement junctions. Table 6 also shows the performance of the AD8494 amplifying the thermocouple voltage and compensating for the reference junction temperature changes, thus eliminating the error.

Table 6. J Type Thermocouple Voltages and AD8494 Readings

Measurement Junction Temperature ( $T_{MJ}$ )	Reference Junction Temperature ( $T_{RJ}$ )	Thermocouple Voltage	AD8494 Reading
50°C	0°C	+2.585 mV	250 mV
50°C	50°C	0 mV	250 mV
0°C	0°C	0 mV	0 mV
0°C	50°C	-2.585 mV	0 mV

### AD8494/AD8495/AD8496/AD8497 ARCHITECTURE

Figure 27 shows a block diagram of the AD849x circuitry. The AD849x consists of a low offset, fixed-gain instrumentation amplifier and a temperature sensor.

Figure 27. Block Diagram

The AD849x output is a voltage that is proportional to the temperature at the measurement junction of the thermocouple ( $T_{MJ}$ ). To derive the measured temperature from the AD849x output voltage, use the following transfer function:

$$T_{MJ} = (V_{OUT} - V_{REF}) / (5 \text{ mV}/^\circ\text{C})$$

An ideal AD849x achieves this output with an error of less than  $\pm 2^\circ\text{C}$ , within the specified operating ranges listed in Table 7.

### Instrumentation Amplifier

A thermocouple signal is so small that considerable gain is required before it can be sampled properly by most ADCs. The AD849x has an instrumentation amplifier with a fixed gain that generates an output voltage of 5 mV/°C for J type and K type thermocouples.

$$V_{OUT} = (T_{MJ} \times 5 \text{ mV}/^\circ\text{C}) + V_{REF}$$

To accommodate the nonlinear behavior of the thermocouple, each amplifier has a different gain so that the 5 mV/°C is accurately maintained for a given temperature measurement range.

- The AD8494 and AD8496 (J type) have an instrumentation amplifier with a gain of 96.7 and 90.35, respectively.
- The AD8495 and AD8497 (K type) have an instrumentation amplifier with a gain of 122.4.

The small thermocouple voltages mean that signals are quite vulnerable to interference, especially when measured with single-ended amplifiers. The AD849x addresses this issue in several ways. Low input bias currents and high input impedance allow for easy filtering at the inputs. The excellent common-mode rejection of the AD849x prevents variations in ground potential and other common-mode noise from affecting the measurement.

### Temperature Sensor (Cold Junction Compensation)

The AD849x also includes a temperature sensor for cold junction compensation. This temperature sensor is used to measure the reference junction temperature of the thermocouple and to cancel its effect.

- The AD8494/AD8495 cold junction compensation is optimized for operation in a lab environment, where the ambient temperature is around 25°C. The AD8494/AD8495 are specified for an ambient range of 0°C to 50°C.
- The AD8496/AD8497 cold junction compensation is optimized for operation in a less controlled environment, where the temperature is around 60°C. The AD8496/AD8497 are specified for an ambient range of 25°C to 100°C. Application examples for the AD8496/AD8497 include automotive applications, autoclave, and ovens.

### Thermocouple Break Detection

The AD849x offers open thermocouple detection. The inputs of the AD849x are PNP type transistors, which means that the bias current always flows out of the inputs. Therefore, the input bias current drives any unconnected input high, which rails the output. Connecting the negative input to ground through a 1 MΩ resistor causes the AD849x output to rail high in an open thermocouple condition (see Figure 6, Figure 28, and the Ground Connection section).

Figure 28. Ground the Negative Input Through a 1 MΩ Resistor for Open Thermocouple Detection

### Input Voltage Protection

The AD849x has very robust inputs. Input voltages can be up to 25 V from the opposite supply rail. For example, with a +5 V positive supply and a –3 V negative supply, the part can safely withstand voltages at the inputs from –20 V to +22 V. Voltages at the reference and sense pins should not go beyond 0.3 V of the supply rails.

## MAXIMUM ERROR CALCULATION

As is normally the case, the AD849x outputs are subject to calibration, gain, and temperature sensitivity errors. The user can calculate the maximum error from the AD849x using the following information.

The five primary sources of AD849x error are described in this section.

### AD849x Initial Calibration Accuracy

Error at the initial calibration point can be easily calibrated out with a one-point temperature calibration. See Table 2 for the specifications.

### AD849x Ambient Temperature Rejection

The specified ambient temperature rejection represents the ability of the AD849x to reject errors caused by changes in the ambient temperature/reference junction. For example, with 0.025°C/°C ambient temperature rejection, a 20°C change in the reference junction temperature adds less than 0.5°C error to the measurement. See Table 2 for the specifications.

### AD849x Gain Error

Gain error is the amount of additional error when measuring away from the measurement junction calibration point. For example, if the part is calibrated at 25°C and the measurement junction is 100°C with a gain error of 0.1%, the gain error contribution is  $(100°C - 25°C) \times (0.1\%) = 0.075°C$ . This error can be calibrated out with a two-point calibration if needed, but it is usually small enough to ignore. See Table 2 for the specifications.

### Manufacturing Tolerances of the Thermocouple

Consult the data sheet for your thermocouple to find the specified tolerance of the thermocouple.

### Linearity Error of the Thermocouple

Each part in the AD849x family is precision trimmed to optimize a linear operating range for a specific thermocouple type and for the widest possible measurement and ambient temperature ranges. The AD849x achieves a linearity error of less than  $\pm 2^\circ\text{C}$ , within the specified operating ranges listed in Table 7. This error is due only to the nonlinearity of the thermocouple.

Table 7. AD849x  $\pm 2^\circ\text{C}$  Accuracy Temperature Ranges

Part	Thermocouple Type	Max Error	Ambient Temperature Range	Measurement Temperature Range
AD8494	J	$\pm 2^\circ\text{C}$	0°C to 50°C	–35°C to +95°C
AD8495	K	$\pm 2^\circ\text{C}$	0°C to 50°C	–25°C to +400°C
AD8496	J	$\pm 2^\circ\text{C}$	25°C to 100°C	+55°C to +565°C
AD8497	K	$\pm 2^\circ\text{C}$	25°C to 100°C	–25°C to +295°C

For temperature ranges outside those listed in Table 7 or for instructions on how to correct for thermocouple nonlinearity error with software, see the [AN-1087](#) Application Note for additional details.

**RECOMMENDATIONS FOR BEST CIRCUIT PERFORMANCE**

**Input Filter**

A low-pass filter before the input of the AD849x is strongly recommended (see Figure 29), especially when operating in an electrically noisy environment. Long thermocouple leads can function as an excellent antenna and pick up many unwanted signals.

The filter should be set to a low corner frequency that still allows the input signal to pass through undiminished. The primary purpose of the filter is to remove RF signals, which, if allowed to reach the AD849x, can be rectified and appear as temperature fluctuations.

Figure 29. Filter for Any Thermocouple Style

To prevent input offset currents from affecting the measurement accuracy, the filter resistor values should be less than 50 kΩ.

**Ground Connection**

It is always recommended that the thermocouple be connected to ground through a 100 kΩ to 1 MΩ resistor placed at the negative (inverting) input of the amplifier on the PCB (see Figure 30). This solution works well regardless of the thermocouple tip style.

Figure 30. Ground the Thermocouple with a 1 MΩ Resistor

If there is no electrical connection at the measurement junction (insulated tip), the resistor value is small enough that no meaningful common-mode voltage is generated. If there is an electrical connection through a grounded or exposed tip, the resistor value is large enough that any current from the measurement tip to ground is very small, preventing measurement errors.

The AD849x inputs require only one ground connection or source of common-mode voltage. Any additional ground connection is detrimental to performance because ground loops can form through the thermocouple, easily swamping the small thermocouple signal. Grounding the thermocouple through a resistor as recommended prevents such problems.

**Keeping the AD849x at the Same Temperature as the Reference Junction**

The AD849x compensates for thermocouple reference junction temperature by using an internal temperature sensor. It is critical to keep the reference junction (thermocouple-to-PCB connection) as close to the AD849x as possible. Any difference in temperature between the AD849x and the reference junction appears directly as temperature error. Temperature difference between the device and the reference junction may occur if the AD849x is not physically close to the reference junction or if the AD849x is required to supply large amounts of output power.

Figure 31. Compensating for Thermocouple Reference Junction Temperature

**Driving the Reference Pin**

The AD849x comes with a reference pin, which can be used to offset the output voltage. This is particularly useful when reading a negative temperature in a single-supply system.

Figure 32. Driving the Reference Pin

For best performance, the reference pin should be driven with a low output impedance source, not a resistor divider. The AD8613 and the OP777 are good choices for the buffer amplifier.

**Debugging Tip**

If the AD849x is not providing the expected performance, a useful debugging step is to implement the ambient temperature configuration in Figure 34. If the ambient temperature sensor does not work as expected, the problem is likely with the AD849x or with the downstream circuitry. If the ambient temperature sensor configuration is working correctly, the problem typically lies with how the thermocouple is connected to the AD849x. Common errors include an incorrect grounding configuration or lack of filtering.

## APPLICATIONS INFORMATION

### BASIC CONNECTION

Figure 33 shows an example of a basic connection for the AD849x, with a J type or K type thermocouple input.

Figure 33. Basic Connection for the AD849x

To measure negative temperatures, apply a voltage at the reference pin to offset the output voltage at 0°C. The output voltage of the AD849x is

$$V_{OUT} = (T_{MJ} \times 5 \text{ mV}/^{\circ}\text{C}) + V_{REF}$$

A filter at the input is recommended to remove high frequency noise. The 1 MΩ resistor to ground enables open thermocouple detection and proper grounding of the thermocouple. The sense pin should be connected to the output pin of the AD849x.

Decoupling capacitors should be used to ensure clean power supply voltages on +Vs and, if using dual supplies, on -Vs, also. A 0.1 μF capacitor should be placed as close as possible to each AD849x supply pin. A 10 μF tantalum capacitor can be used farther away from the part and can be shared.

### AMBIENT TEMPERATURE SENSOR

The AD849x can be configured as a standalone Celsius thermometer with a 5 mV/°C output, as shown in Figure 34. The thermocouple sensing functionality is disabled by shorting both AD849x inputs to ground; the AD849x simply outputs the value from the on-board temperature sensor.

As a temperature sensor, the AD8494 has a measurement temperature range of -40°C to +125°C with a precision output of

$$V_{OUT} = T_A \times 5 \text{ mV}/^{\circ}\text{C}$$

Figure 34. Ambient Temperature Sensor

The AD8494 is the best choice for use as an ambient temperature sensor. The AD8495, AD8496, and AD8497 can also be configured as ambient temperature sensors, but their output transfer functions are not precisely 5 mV/°C. For information about the exact transfer functions of the AD8494/AD8495/AD8496/AD8497, see the [AN-1087](#) Application Note for additional details.

The thermometer mode can be particularly useful for debugging a misbehaving circuit. If the basic connection is not working, disconnect the thermocouple and short both inputs to ground. If the system reads the ambient temperature correctly, the problem is related to the thermocouple. If the system does not read the ambient temperature correctly, the problem is with the AD849x or with the downstream circuitry.

**SETPOINT CONTROLLER**

The AD849x can be used as a temperature setpoint controller, with a thermocouple input from a remote location or with the AD849x itself being used as a temperature sensor. When the measured temperature is below the setpoint temperature, the output voltage goes to  $-V_s$ . When the measured temperature is above the setpoint temperature, the output voltage goes to  $+V_s$ . For best accuracy and CMRR performance, the setpoint voltage should be created with a low impedance source. If the setpoint voltage is generated with a voltage divider, a buffer is recommended.

Figure 35. Setpoint Controller

Hysteresis can be added to the setpoint controller by using a resistor divider from the output to the reference pin, as shown in Figure 36. The hysteresis in  $^{\circ}\text{C}$  is

$$T_{HYST} = \frac{V_s \times R1 / (R1 + R2)}{5 \text{ mV}/^{\circ}\text{C}}$$

Figure 36. Adding 10 Degrees of Hysteresis

A resistor equivalent to the output resistance of the divider should be connected to the sense pin to ensure good CMRR.

**MEASURING NEGATIVE TEMPERATURES**

The AD849x can measure negative temperatures on dual supplies and on a single supply. When operating on dual supplies with the reference pin grounded, a negative output voltage indicates a negative temperature at the thermocouple measurement junction.

$$V_{OUT} = (T_{MJ} \times 5 \text{ mV}/^{\circ}\text{C}) + V_{REF}$$

When operating the AD849x on a single supply, level-shift the output by applying a positive voltage (less than  $+V_s$ ) on the reference pin. An output voltage less than  $V_{REF}$  indicates a negative temperature at the thermocouple measurement junction.

**REFERENCE PIN ALLOWS OFFSET ADJUSTMENT**

The reference pin can be used to level-shift the AD849x output voltage. This is useful for measuring negative temperatures on a single supply and to match the AD849x output voltage range to the input voltage range of the subsequent electronics in the signal chain.

The reference pin can also be used to offset any initial calibration errors. Apply a small reference voltage proportional to the error to nullify the effect of the calibration error on the output.
