

Dual Input Multiservice Line Card Adaptive Clock Translator

Data Sheet

AD9557

FEATURES

Supports GR-1244 Stratum 3 stability in holdover mode Supports smooth reference switchover with virtually no disturbance on output phase

Supports Telcordia GR-253 jitter generation, transfer, and tolerance for SONET/SDH up to OC-192 systems

Supports ITU-T G.8262 synchronous Ethernet slave clocks Supports ITU-T G.823, G.824, G.825, and G.8261 Auto/manual holdover and reference switchover 2 reference inputs (single-ended or differential) Input reference frequencies: 2 kHz to 1250 MHz Reference validation and frequency monitoring (1 ppm) Programmable input reference switchover priority 20-bit programmable input reference divider

2 pairs of clock output pins, with each pair configurable as a single differential LVDS/HSTL output or as 2 single-ended CMOS outputs

Output frequencies: 360 kHz to 1250 MHz

- Programmable 17-bit integer and 23-bit fractional feedback divider in digital PLL
- Programmable digital loop filter covering loop bandwidths from 0.1 Hz to 5 kHz (2 kHz maximum for <0.1 dB of peaking)
- Low noise system clock multiplier
- Frame sync support

Adaptive clocking

- Optional crystal resonator for system clock input
- On-chip EEPROM to store multiple power-up profiles
- Pin program function for easy frequency translation

configuration

- Software controlled power-down
- 40-lead, 6 mm × 6 mm, LFCSP package

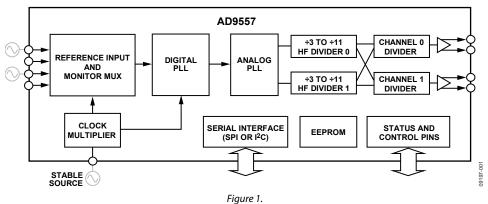

APPLICATIONS

Network synchronization, including synchronous Ethernet and SDH to OTN mapping/demapping Cleanup of reference clock jitter SONET/SDH/OTN clocks up to 100 Gbps, including FEC Stratum 3 holdover, jitter cleanup, and phase transient control Wireless base station controllers Cable infrastructure Data communications

GENERAL DESCRIPTION

The AD9557 is a low loop bandwidth clock multiplier that provides jitter cleanup and synchronization for many systems, including synchronous optical networks (OTN/SONET/SDH). The AD9557 generates an output clock synchronized to up to four external input references. The digital PLL allows for reduction of input time jitter or phase noise associated with the external references. The digitally controlled loop and holdover circuitry of the AD9557 continuously generates a low jitter output clock even when all reference inputs have failed.

The AD9557 operates over an industrial temperature range of -40° C to $+85^{\circ}$ C. If more inputs/outputs are needed, refer to the AD9558 for the four-input/six-output version of the same device.

10/2011—Revision 0: Initial Version

SPECIFICATIONS

Minimum (min) and maximum (max) values apply for the full range of supply voltage and operating temperature variations. Typical (typ) values apply for AVDD3 = $DVDD_I/O = 3.3 \text{ V}$; AVDD = DVDD = 1.8 V; $T_A = 25^{\circ}C$, unless otherwise noted.

SUPPLY VOLTAGE

| Table 1. | | | | | | |
|----------------|-------|------|-------|------|--------------------------|--|
| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments | |
| SUPPLY VOLTAGE | | | | | | |
| DVDD3 | 3.135 | 3.30 | 3.465 | V | | |
| DVDD | 1.71 | 1.80 | 1.89 | V | | |
| AVDD3 | 3.135 | 3.30 | 3.465 | V | | |
| AVDD | 1.71 | 1.80 | 1.89 | V | | |

SUPPLY CURRENT

The test conditions for the maximum (max) supply current are the same as the test conditions for the All Blocks Running parameter of Table 3. The test conditions for the typical (typ) supply current are the same as the test conditions for the Typical Configuration parameter of Table 3.

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|--|-----|-----|-----|------|---|
| SUPPLY CURRENT FOR TYPICAL CONFIGURATION | | | | | Typical numbers are for the typical configuration listed in Table 3 |
| DVDD3 | 12 | 18 | 26 | mA | Pin 30, Pin 31, Pin 40 |
| lovdd | 13 | 20 | 28 | mA | Pin 6, Pin 34, Pin 35 |
| I _{AVDD3} | 35 | 49 | 63 | mA | Pin 14, Pin 19 |
| lavdd | 112 | 162 | 215 | mA | Pin 7, Pin 10, Pin 11, Pin 17, Pin 18, Pin 22, Pin 23, Pin 24 |
| SUPPLY CURRENT FOR THE ALL BLOCKS RUNNING CONFIGURATION | | | | | Maximum numbers are for all blocks running configuration in Table 3 |
| I _{DVDD3} | 12 | 18 | 33 | mA | Pin 30, Pin 31, Pin 40 |
| lovdd | 10 | 19 | 30 | mA | Pin 6, Pin 34, Pin 35 |
| I _{AVDD3} | 47 | 68 | 89 | mA | Pin 14, Pin 19 |
| AVDD | 113 | 163 | 215 | mA | Pin 7, Pin 10, Pin 11, Pin 17, Pin 18, Pin 22, Pin 23, Pin 24 |

POWER DISSIPATION

Table 3.

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|-----------------------------------|------|------|------|------|--|
| POWER DISSIPATION | | | | | |
| Typical Configuration | 0.36 | 0.55 | 0.76 | W | System clock: 49.152 MHz crystal; DPLL active; both 19.44 MHz input references in differential mode; one HSTL driver at 644.53125 MHz; one 3.3 V CMOS driver at 161.1328125 MHz and 80 pF capacitive load on CMOS output |
| All Blocks Running | 0.39 | 0.61 | 0.85 | W | System clock: 49.152 MHz crystal; DPLL active; both input references in differential mode; one HSTL driver at 750 MHz; two 3.3 V CMOS drivers at 250 MHz and 80 pF capacitive load on CMOS outputs |
| Full Power-Down | | 44 | 125 | mW | Typical configuration with no external pull-up or pull- down resistors; approximately 2/3 of this power is on AVDD3 |
| Incremental Power Dissipation | | | | | Conditions = typical configuration; table values show th change in power due to the indicated operation |
| Input Reference On/Off | | | | | |
| Differential Without Divide-by-2 | 20 | 25 | 32 | mW | Additional current draw is in the DVDD3 domain only |
| Differential With Divide-by-2 | 26 | 32 | 40 | mW | Additional current draw is in the DVDD3 domain only |
| Single-Ended Without Divide-by-2 | 5 | 7 | 9 | mW | Additional current draw is in the DVDD3 domain only |
| Output Distribution Driver On/Off | | | | | |
| LVDS (at 750 MHz) | 12 | 17 | 22 | mW | Additional current draw is in the AVDD domain only |
| HSTL (at 750 MHz) | 14 | 21 | 28 | mW | Additional current draw is in the AVDD domain only |
| 1.8 V CMOS (at 250 MHz) | 14 | 21 | 28 | mW | A single 1.8 V CMOS output with an 80 pF load |
| 3.3 V CMOS (at 250 MHz) | 18 | 27 | 36 | mW | A single 3.3 V CMOS output with an 80 pF load |
| Other Blocks On/Off | | | | | |
| Second RF Divider | 36 | 51 | 64 | mW | Additional current draw is in the AVDD domain only |
| Channel Divider Bypassed | 10 | 17 | 23 | mW | Additional current draw is in the AVDD domain only |

LOGIC INPUTS (RESET, SYNC, PINCONTROL, M3 TO M0)

Table 4.

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|--|-----|-----|------|------|--------------------------|
| LOGIC INPUTS (RESET, SYNC, PINCONTROL) | | | | | |
| Input High Voltage (V _⊮) | 2.1 | | | V | |
| Input Low Voltage (V _{IL}) | | | 0.8 | V | |
| Input Current (I _{INH} , I _{INL}) | | ±50 | ±100 | μΑ | |
| Input Capacitance (C _{IN}) | | 3 | | pF | |
| LOGIC INPUTS (M3 to M0) | | | | | |
| Input High Voltage (V⊩) | 2.5 | | | V | |
| Input ½ Level Voltage (V _{IM}) | 1.0 | | 2.2 | V | |
| Input Low Voltage (V _{IL}) | | | 0.6 | V | |
| Input Current (I _{INH} , I _{INL}) | | ±60 | ±100 | μΑ | |
| Input Capacitance (C _{IN}) | | 3 | | pF | |

LOGIC OUTPUTS (M3 TO M0, IRQ)

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|--|-------------|-----|------|------|--------------------------|
| LOGIC OUTPUTS (M3 to M0, IRQ) | | | | | |
| Output High Voltage (V _{он}) | DVDD3 - 0.4 | | | V | $I_{OH} = 1 \text{ mA}$ |
| Output Low Voltage (Vol) | | | 0.4 | V | $I_{OL} = 1 \text{ mA}$ |
| IRQ Leakage Current | | | | | Open-drain mode |
| Active Low Output Mode | | | -200 | μA | V _{OH} = 3.3 V |
| Active High Output Mode | | | 100 | μA | $V_{OL} = 0 V$ |

SYSTEM CLOCK INPUTS (XOA, XOB)

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|--|------|------|------|--------|---|
| SYSTEM CLOCK MULTIPLIER | | | | | |
| Output Frequency Range | 750 | | 805 | MHz | The VCO range may place limitations on nonstandard system clock input frequencies |
| Phase Frequency Detector (PFD) Rate | | | 150 | MHz | |
| Frequency Multiplication Range | 2 | | 255 | | Assumes valid system clock and PFD rates |
| SYSTEM CLOCK REFERENCE INPUT PATH | | | | | |
| Input Frequency Range | 10 | | 600 | MHz | |
| Minimum Input Slew Rate | 20 | | | V/µs | Minimum limit imposed for jitter performance |
| Common-Mode Voltage | 1.05 | 1.16 | 1.25 | V | Internally generated |
| Differential Input Voltage Sensitivity | 250 | | | mV p-p | Minimum voltage across pins required to ensure switching between logic states; the instantaneous voltage on either pin must not exceed the supply rails; can accommodate single-ended input by ac grounding of complementary input; 1 V p-p recommended for optimal jitter performance |
| System Clock Input Doubler Duty Cycle | | | | | This is the amount of duty cycle variation that can be tolerated on the system clock input to use the doubler |
| System Clock Input = 50 MHz | 45 | 50 | 55 | % | |
| System Clock Input = 20 MHz | 46 | 50 | 54 | % | |
| System Clock Input = 16 MHz to 20 MHz | 47 | 50 | 53 | % | |
| Input Capacitance | | 3 | | pF | Single-ended, each pin |
| Input Resistance | | 4.2 | | kΩ | |
| CRYSTAL RESONATOR PATH | | | | | |
| Crystal Resonator Frequency Range | 10 | | 50 | MHz | Fundamental mode, AT cut crystal |
| Maximum Crystal Motional Resistance | | | 100 | Ω | |

REFERENCE INPUTS

Table 7.

| Input Capacitance | | 3 | | pF | |
| Minimum Pulse Width High | 1.5 | | | ns | |
| Minimum Pulse Width Low | 1.5 | | | ns | |

REFERENCE MONITORS

Table 8.

| Parameter | Min | Тур | Мах | Unit | Test Conditions/Comments |
|----------------------------------|-------|-----|--------|------------------------------|--|
| REFERENCE MONITORS | | | | | |
| Reference Monitor | | | | | |
| Loss of Reference Detection Time | | | 1.1 | DPLL PFD period | Nominal phase detector period = R/f_{REF}^{1} |
| Frequency Out-of Range Limits | <2 | | 10⁵ | ∆f/f _{REF} (ppm) | Programmable (lower bound is subject to quality of the system clock (SYSCLK)); SYSCLK accuracy must be better than the lower bound |
| Validation Timer | 0.001 | | 65.535 | sec | Programmable in 1 ms increments |

 $^1\,f_{\text{REF}}$ is the frequency of the active reference; R is the frequency division factor determined by the R divider.

REFERENCE SWITCHOVER SPECIFICATIONS

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|--|-----|-----|------|--------------------|--|
| REFERENCE SWITCHOVER SPECIFICATIONS | | | | | Assumes a jitter-free reference; satisfies |
| Maximum Output Phase Perturbation | | | | | Telcordia GR-1244-CORE requirements; select |
| (Phase Build-Out Switchover) | | | | | high PM base loop filter bit (Register 0x070E, Bit 0 is set to 1 for all active references |
| 50 Hz DPLL Loop Bandwidth | | | | | Valid for automatic and manual reference switching |
| Peak | | 0 | ±100 | ps | |
| Steady State | | 0 | ±100 | ps | |
| 2 kHz DPLL Loop Bandwidth | | | | | Valid for automatic and manual reference switching |
| Peak | | 0 | ±250 | ps | |
| Steady State | | 0 | ±100 | ps | |
| Time Required to Switch to a New Reference | | | | | |
| Phase Build-Out Switchover | | | 1.1 | DPLL PFD period | Calculated using the nominal phase detector period (NPDP = R/f_{REF}); the total time required is equal to the time plus the reference validation time and the time required to lock to the new reference |

DISTRIBUTION CLOCK OUTPUTS

Table 10.

| Parameter | Min | Тур | Max | Unit | Test Conditions/Comments |
|---|----------------------------|------|-------|------|--|
| HSTL MODE | | | | | |
| Output Frequency | 0.36 | | 1250 | MHz | |

ABSOLUTE MAXIMUM RATINGS

Table 19.

| Parameter | Rating |
|-------------------------------------|-------------------------|
| Analog Supply Voltage (AVDD) | 2 V |
| Digital Supply Voltage (DVDD) | 2 V |
| Digital I/O Supply Voltage (DVDD3) | 3.6 V |
| Analog Supply Voltage (AVDD3) | 3.6 V |
| Maximum Digital Input Voltage | –0.5 V to DVDD3 + 0.5 V |
| Storage Temperature Range | –65°C to +150°C |
| Operating Temperature Range | -40°C to +85°C |
| Lead Temperature (Soldering 10 sec) | 300°C |
| Maximum Junction Temperature | 150°C |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

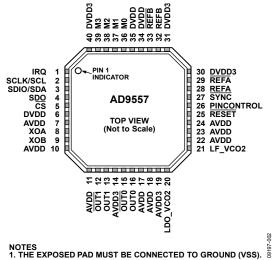

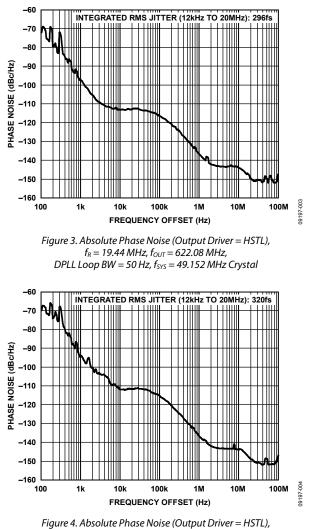

Figure 2. Pin Configuration **Table 20. Pin Function Descriptions** Input/ Pin No. Mnemonic Output **Pin Type** Description IRQ 3.3 V CMOS 1 0 Interrupt Request Line. 2 SCLK/SCL Т 3.3 V CMOS Serial Programming Clock (SCLK) in SPI Mode, Data clock for serial programming. Open-Collector Serial Clock Pin (SCL) in I²C Mode. Requires a pull-up resistor, usually 2.2 k Ω ; the resistor size depends on the number of I²C devices on the bus. Serial Data Input/Output (SDIO) in SPI Mode. When the device is in 4-wire SPI 3 SDIO/SDA I/O 3.3 V CMOS mode, data is written via this pin. In 3-wire SPI mode, both data reads and writes occur on this pin. There is no internal pull-up/pull-down resistor on this pin. Open-Collector Serial Data Pin (SDA) in I²C Mode. Requires a pull-up resistor, usually 2.2 k Ω ; the resistor size depends on the number of I²C devices on the bus. SDO 0 3.3 V CMOS Serial Data Output. Use this pin to read data in 4-wire mode. There is no internal 4 pull-up/pull-down resistor on this pin. This pin is high impedance in the default 3-wire mode. 5 CS 3.3 V CMOS Chip Select (SPI), Active Low. When programming a device, this pin must be held Т low. In systems where more than one AD9557 is present, this pin enables individual programming of each AD9557. This pin has an internal 10 k Ω pull-up resistor. DVDD 1.8 V Digital Supply. 6, 34, 35 1 Power 7 AVDD I Power 1.8 V Analog (SYSCLK) Power Supply. 8 XOA Differential System Clock Input. XOA contains internal dc biasing. It is recommended to ac I input couple XOA with a 0.01 µF capacitor, except when using a crystal. If a crystal is used, connect the crystal across XOA and XOB. Single-ended 1.8 V CMOS is also an option but can introduce a spur if the duty cycle is not 50%. When using XOA as a single-ended input, connect a 0.01 µF capacitor from XOB to ground. XOB Differential Complementary System Clock Input. Complementary signal to XOA. XOB 9 Т input contains internal dc biasing. It is recommended to ac couple XOB with a 0.01 μ F capacitor, except when using a crystal. If a crystal is used, connect the crystal across XOA and XOB. AVDD 1.8 V Analog Power Supply. 10, 22, 23, Т Power 24 1.8 V Analog (Output Divider and Drivers) Power Supply. 11, 17, 18 AVDD Т Power 12 OUT1 0 HSTL, LVDS, or Complementary Output 1. This output can be configured as HSTL, LVDS, or 1.8 V CMOS single-ended 1.8 V CMOS.

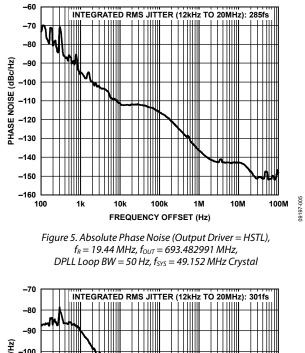

| | | Input/ | | |
|-------------------|-------------------|--------|---|--|
| Pin No. | Mnemonic | Output | Pin Type | Description |
| 13 | OUT1 | 0 | HSTL, LVDS, or 1.8 V CMOS | Output 1. This output can be configured as HSTL, LVDS, or single-ended 1.8 V CMOS. LVPECL levels can be achieved by ac coupling and using the Thevenin-equivalent termination as described in the Input/Output Termination Recommendations section. |
| 14, 19 | AVDD3 | 1 | Power | 3.3 V Analog Power Supply. |
| 15 | OUTO | 0 | HSTL, LVDS, 1.8 V CMOS, 3.3 V CMOS | Complementary Output 0. This output can be configured as HSTL, LVDS, or single-ended 1.8 V or 3.3 V CMOS. |
| 16 | OUTO | 0 | HSTL, LVDS, 1.8 V CMOS, 3.3 V CMOS | Output 0. This output can be configured as HSTL, LVDS, or single-ended 1.8 V or 3.3 V CMOS. LVPECL levels can be achieved by ac coupling and using the Thevenin-equivalent termination as described in the Input/Output Termination Recommendations section. |
| 20 | LDO_VCO2 | I | LDO bypass | Output PLL Loop Filter Voltage Regulator. Connect a 0.47 μ F capacitor from this pin to ground. This pin is also the ac ground reference for the integrated output PLL external loop filter. |
| 21 | LF_VCO2 | I/O | Loop filter | Loop Filter Node for the Output PLL. Connect an external 6.8 nF capacitor from this pin to Pin 20 (LDO_VCO2). |
| 25 | RESET | I | 3.3 V CMOS | Chip Reset. When this active low pin is asserted, the chip goes into reset. This pin has an internal 50 k Ω pull-up resistor. |
| 26 | PINCONTROL | I | 3.3 V CMOS | Pin Program Mode Enable Pin. When pulled high during startup, this pin enables pin programming of the AD9557 configuration during startup. If this pin is low during startup, the user must program the device via the serial port or use values that are stored in the EEPROM. |
| 27 | SYNC | I | 3.3 V CMOS | Clock Distribution Synchronization Pin. When this pin is activated, output drivers are held static and then synchronized on a low-to-high transition of this pin. This pin has an internal 60 k Ω pull-up resistor. |
| 28 | REFA | I | Differential input | Reference A Input. This internally biased input is typically ac-coupled and, when configured as such, can accept any differential signal with single-ended swing up to 3.3 V. If dc-coupled, this input can be LVPECL, LVDS, or single-ended CMOS. |
| 29 | REFA | I | Differential input | Complementary Reference A Input. This pin is the complementary input to Pin 28. |
| 30, 31, 40 | DVDD3 | 1 | Power | 3.3 V Digital Power Supply. |
| 32 | REFB | 1 | Differential input | Reference B Input. This internally biased input is typically ac-coupled and, when configured as such, can accept any differential signal with single-ended swing up to 3.3 V. If dc-coupled, this input can be LVPECL, LVDS, or single-ended CMOS. |
| 33 | REFB | I | Differential input | Complementary Reference B Input. This pin is the complementary input to Pin 32. |
| 36, 37, 38, 39 | M0, M1, M2, M3 | I/O | 3.3 V CMOS (3-level logic at startup) | Configurable I/O Pins. These pins are 3-level logic at startup and are used for pin strapping the input and output frequency configuration at startup. Setting Register 0x0200, Bit 0 = 1 changes these pins to 2-level logic and allows these pins to be used for status and control of the AD9557. These pins have both a 30 k Ω pull-up resistor and a 30 k Ω pull-down resistor. |
| | EP | 0 | Exposed pad | The exposed pad must be connected to ground (VSS). |

GETTING STARTED CHIP POWER MONITOR AND STARTUP

The AD9557 monitors the voltage on the power supplies at power-up. When DVDD3 is greater than $2.35 \text{ V} \pm 0.1 \text{ V}$ and DVDD and AVDD are greater than $1.4 \text{ V} \pm 0.05 \text{ V}$, the device generates a 20 ms reset pulse. The power-up reset pulse is internal and independent of the RESET pin. This internal power-up reset sequence eliminates the need for the user to provide external power supply sequencing. Within 45 ns after the leading edge of the internal reset pulse, the M3 to M0 multifunction pins behave as high impedance digital inputs and continue to do so until programmed otherwise. The delay on the M3 to M0 pin function change is 45 ns for pin reset or soft reset.

During a device reset (either via the power-up reset pulse or the RESET pin), the multifunction pins (M3 to M0) behave as high impedance inputs; however upon removal of the reset condition, level-sensitive latches capture the logic pattern present on the multifunction pins.

MULTIFUNCTION PINS AT RESET/POWER-UP

The AD9557 requires the user to supply the desired logic state to the PINCONTROL pin, as well as the M3 to M0 pins. If PINCONTROL is high, the part is in hard pin programming mode. See the Pin Program Function Description section for details on hard pin programming.

At startup, there are three choices for the M3 to M0 pins: pull-up, pull-down, and floating. If the PINCONTROL pin is low, the M3 to M0 pins determine the following configurations:

- Following a reset, the M1 and M0 pins determine whether the serial port interface behaves according to the SPI or I²C protocol. Specifically, 0x00 selects the SPI interface, and any other value selects the I²C port. The 3-level logic of M1 and M0 allows the user to select eight possible I²C addresses (see Table 24).
- The M3 and M2 pins select which of the eight possible EEPROM profiles are loaded, or if the EEPROM loading is bypassed. Leaving M3 and M2 floating at startup bypasses the EEPROM loading, and the factory defaults are used instead (see Table 22).

DEVICE REGISTER PROGRAMMING USING A REGISTER SETUP FILE

The evaluation software contains a programming wizard and a convenient graphical user interface that assists the user in determining the optimal configuration for the DPLLs, APLLs, and SYSCLK based on the desired input and output frequencies. It generates a register setup file with a .STP extension that is easily readable using a text editor.

After using the evaluation software to create the setup file, refer to Figure 34, Figure 35, and Figure 36 for the correct sequence to program the AD9557.

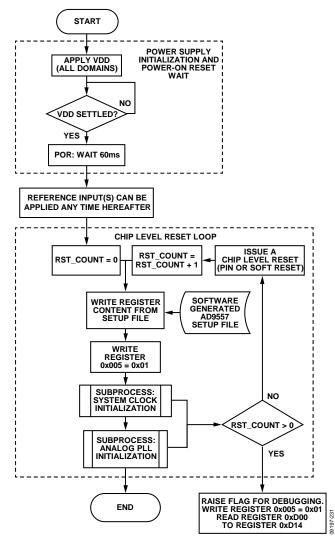

Figure 35. AD9557 Initialization Flowchart

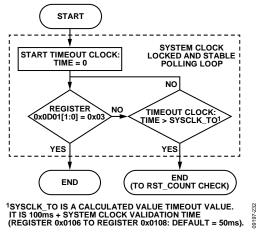

Figure 36. AD9557 System Clock Initialization Subprocess Flowchart

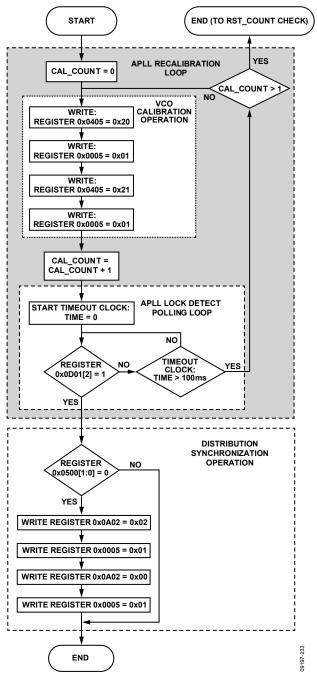

Figure 37. AD9557 APLL Initialization Subprocess Flowchart

REGISTER PROGRAMMING OVERVIEW

This section provides an overview of the register blocks in the AD9557, and describes their functions and importance.

Registers Differing from Defaults for Optimal Performance

Ensure that the following registers are programmed to the listed values for optimal performance:

- Register 0x0405, Bits [7:4] = 0x2
- Register 0x0403 = 0x07
- Register 0x0400 = 0x81

If the silicon revision (Register 0x000A) equals 0x21 or higher, the values listed here are already the default values.

Program the System Clock and Free Run Tuning Word

The system clock multiplier (SYSCLK) parameters are at Register 0x0100 to Register 0x0108, and the free run tuning word is at Register 0x0300 to Register 0x0303. Use the following steps for optimal performance:

- 1. Set the system clock PLL input type and divider values.
- Set the system clock period. It is essential to program the system clock period because many of the AD9557 subsystems rely on this value.
- 3. Set the system clock stability timer.
 - It is highly recommended that the system clock stability timer be programmed. This is especially important when using the system clock multiplier and also applies when using an external system clock source, especially if the external source is not expected to be completely stable when power is applied to the AD9557. The system clock stability timer specifies the amount of time that the system clock PLL must be locked before the device declares that the system clock is stable. The default value is 50 ms.
- 4. Program the free run tuning word. The free run frequency of the digital PLL (DPLL) determines the frequency appearing at the APLL input when free run mode is selected. The free run tuning word is at Register 0x0300 to Register 0x0303. The correct free run frequency is required for the APLL to calibrate and lock correctly.
- 5. Set user free run mode (Register 0x0A01, Bit 5 = 1b).

Initialize and Calibrate the Output PLL (APLL)

The registers controlling the APLL are at Register 0x0400 to Register 0x0408. This low noise, integer-N PLL multiplies the DPLL output (which is usually 175 MHz to 200 MHz) to a frequency in the 3.35 GHz to 4.05 GHz range. After the system clock is configured and the free run tuning word is set in Register 0x0300 to Register 0x0303, the user can set the manual APLL VCO calibration bit (Register 0x0405, Bit 0) and issue an I/O update (Register 0x0005, Bit 0). This process performs the APLL VCO calibration. VCO calibration ensures that, at the time of calibration, the dc control voltage of the APLL VCO is centered in the middle of its operating range. It is important to remember the following points when calibrating the APLL VCO:

- The system clock must be stable.
- The APLL VCO must have the correct frequency from the 30-bit digitally controlled oscillator (DCO) during calibration.
- The APLL VCO must be recalibrated any time the APLL frequency changes.
- APLL VCO calibration occurs on the low-to-high transition of the manual APLL VCO calibration bit, and this bit is not autoclearing. Therefore, this bit must be cleared (and an I/O update issued) before another APLL calibration is started.
- The best way to monitor successful APLL calibration is to monitor Bit 2 in Register 0x0D01 (APLL lock).

Program the Clock Distribution Outputs

The APLL output goes to the clock distribution block. The clock distribution parameters reside in Register 0x0500 to Register 0x0509. They include the following:

- Output power-down control
- Output enable (disabled by default)
- Output synchronization
- Output mode control
- Output divider functionality

See the Clock Distribution section for more information.

Generate the Output Clock

If Register 0x0500, Bits[1:0] is programmed for automatic clock distribution synchronization via the DPLL phase or frequency lock, the synthesized output signal appears at the clock distribution outputs. Otherwise, set and then clear the soft sync clock distribution bit (Register 0x0A02, Bit 1) or use a multifunction pin input (if programmed for use) to generate a clock distribution sync pulse, which causes the synthesized output signal to appear at the clock distribution outputs.

Program the Multifunction Pins (Optional)

This step is required only if the user intends to use any of the multifunction pins for status or control. The multifunction pin parameters are in Register 0x0200 to Register 0x0208.

Program the IRQ Functionality (Optional)

This step is required only if the user intends to use the IRQ feature. The IRQ monitor registers are in Register 0x0D02 to Register 0x0D09. If the desired bits in the IRQ mask registers at Register 0x020A to Register 0x020F are set high, the appropriate IRQ monitor bit at Register 0x0D02 to Register 0x0D07 is set high when the indicated event occurs.

Individual IRQ events are cleared by using the IRQ clearing the registers at Register 0x0A04 to Register 0x0A09 or by setting the clear all IRQs bit (Register 0x0A03, Bit 1) to 1b.

The default values of the IRQ mask registers are such that interrupts are not generated. The IRQ pin mode default is opendrain NMOS.

Program the Watchdog Timer (Optional)

This step is required only if the user intends to use the watchdog timer. The watchdog timer control is in Register 0x0210 and Register 0x0211 and is disabled by default.

The watchdog timer is useful for generating an IRQ after a fixed amount of time. The timer is reset by setting the clear watchdog timer bit (Register 0x0A03, Bit 0) to 1b.

Program the Digital Phase-Locked Loop (DPLL)

The DPLL parameters reside in Register 0x0300 to Register 0x032E. They include the following:

- Free run frequency
- DPLL pull-in range limits
- DPLL closed-loop phase offset
- Phase slew control (for hitless reference switching)
- Tuning word history control (for holdover operation)

Program the Reference Inputs

The reference input parameters reside in Register 0x0600 to Register 0x0602. See the Reference Clock Input section for details on programming these functions. They include the following:

- Reference power-down
- Reference logic family
- Reference priority

Program the Reference Profiles

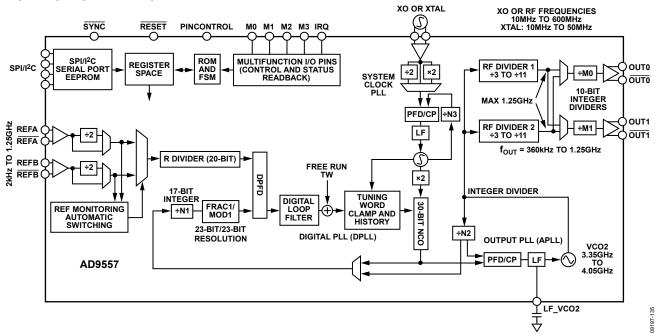

The reference profile parameters reside in Register 0x0700 to Register 0x0766. The AD9557 evaluation software contains a wizard that calculates these values based on the user input frequency. See the Reference Profiles section for details on programming these functions. They include the following:

- Reference period
- Reference period tolerance
- Reference validation timer
- Selection of high phase margin, loop filter coefficients
- DPLL loop bandwidth
- Reference prescaler (R divider)
- Feedback dividers (N1, N2, N3, FRAC1, and MOD1)
- Phase and frequency lock detector controls

Generate the Reference Acquisition

After the registers are programmed, the user can clear the user free run bit (Register 0x0A01, Bit 5) and issue an I/O update, using Register 0x0005, Bit 0 to invoke all of the register settings that are programmed up to this point.

After the registers are programmed, the DPLL locks to the first available valid reference that has the highest priority.

THEORY OF OPERATION

Figure 38. Detailed Block Diagram

OVERVIEW

The AD9557 provides clocking outputs that are directly related in phase and frequency to the selected (active) reference, but with jitter characteristics that are governed by the system clock, the DCO, and the analog integer-N PLL (APLL). The AD9557 supports up to two reference inputs and input frequencies ranging from 2 kHz to 1250 MHz. The core of this product is a digital phase-locked loop (DPLL). The DPLL has a programmable digital loop filter that greatly reduces jitter that is transferred from the active reference to the output. The AD9557 supports both manual and automatic holdover. While in holdover, the AD9557 continues to provide an output as long as the system clock is present. The holdover output frequency is a time average of the output frequency history just prior to the transition to the holdover condition. The device offers manual and automatic reference switchover capability if the active reference is degraded or fails completely. The AD9557 also has adaptive clocking capability that allows the DPLL divider ratios to be changed while the DPLL is locked.

The AD9557 has a system clock multiplier, a DPLL, and an APLL. The input signal goes first to the DPLL, which performs the jitter cleaning and most of the frequency translation. The DPLL features a 30-bit digitally controlled oscillator (DCO) output that generates a signal in the 175 MHz to 200 MHz range. The DPLL output goes to an APLL, which multiplies the signal up to the 3.35 GHz to 4.05 GHz range. That signal is then sent to the clock distribution section, which has two divide-by-3 to divide-by-11 RF dividers that are cascaded with 10-bit integer (divide-by-1 to divide-by-1024) channel dividers.

The XOA and XOB inputs provide the input for the system clock. These pins accept a reference clock in the 10 MHz to 600 MHz range, or a 10 MHz to 50 MHz crystal connected directly across the XOA and XOB inputs. The system clock provides the clocks to the frequency monitors, the DPLL, and internal switching logic.

The AD9557 has two differential output drivers. Each driver has a dedicated 10-bit programmable post divider. Each differential driver is programmable either as a single differential or dual single-ended CMOS output. The clock distribution section operates at up to 1250 MHz.

In differential mode, the output drivers run on a 1.8 V power supply to offer very high performance with minimal power consumption. There are two differential modes: LVDS and 1.8 V HSTL. In 1.8 V HSTL mode, the voltage swing is compatible with LVPECL. If LVPECL signal levels are required, the designer can ac-couple the AD9557 output and use Thevenin-equivalent termination at the destination to drive the LVPECL inputs.

In single-ended mode, each differential output driver can operate as two single-ended CMOS outputs. OUT0 supports either 1.8 V or 3.3 V CMOS operation. OUT1 supports only 1.8 V operation.

Note that the APLL is also referred to as the output PLL elsewhere in this data sheet.

REFERENCE CLOCK INPUTS

Two pairs of pins provide access to the reference clock receivers. To accommodate input signals with slow rising and falling edges, both the differential and single-ended input receivers employ hysteresis. Hysteresis also ensures that a disconnected or floating input does not cause the receiver to oscillate.

When configured for differential operation, the input receivers accommodate either ac- or dc-coupled input signals. The input receivers are capable of accepting dc-coupled LVDS and 2.5 V and 3.3 V LVPECL signals. The receiver is internally dc biased to handle ac-coupled operation, but there is no internal 50 Ω or 100 Ω termination.

When configured for single-ended operation, the input receivers exhibit a pull-down load of 45 k Ω (typical). Three user-programmable threshold voltage ranges are available for each single-ended receiver.

REFERENCE MONITORS

The accuracy of the input reference monitors depends on a known and accurate system clock period. Therefore, the functioning of the reference monitors is not operable until the system clock is stable.

Reference Period Monitor

Each reference input has a dedicated monitor that repeatedly measures the reference period. The AD9557 uses the reference period measurements to determine the validity of the reference based on a set of user-provided parameters in the profile register area of the register map.

The monitor works by comparing the measured period of a particular reference input with the parameters stored in the profile register assigned to that same reference input. The parameters include the reference period, an inner tolerance, and an outer tolerance. A 40-bit number defines the reference period in units of femtoseconds (fs). The 40-bit range allows a reference period entry of up to 1.1 ms. A 20-bit number defines the inner and outer tolerances. The value stored in the register is the reciprocal of the tolerance specification. For example, a tolerance specification of 50 ppm yields a register value of 1/(50 ppm) = 1/0.000050 = 20,000 (0x04E20).

The use of two tolerance values provides hysteresis for the monitor decision logic. The inner tolerance applies to a previously faulted reference and specifies the largest period tolerance that a previously faulted reference can exhibit before it qualifies as nonfaulted. The outer tolerance applies to an already nonfaulted reference. It specifies the largest period tolerance that a nonfaulted reference can exhibit before being faulted.

To produce decision hysteresis, the inner tolerance must be less than the outer tolerance. That is, a faulted reference must meet tighter requirements to become nonfaulted than a nonfaulted reference must meet to become faulted.

Reference Validation Timer

Each reference input has a dedicated validation timer. The validation timer establishes the amount of time that a previously faulted reference must remain unfaulted before the AD9557 declares it valid. The timeout period of the validation timer is programmable via a 16-bit register. The 16-bit number stored in the validation register represents units of milliseconds (ms), which yields a maximum timeout period of 65,535 ms.

It is possible to disable the validation timer by programming the validation timer to 0b. With the validation timer disabled, the user must validate a reference manually via the manual reference validation override controls register (Address 0x0A0B).

Reference Validation Override Control

The user also has the ability to override the reference validation logic and can either force an invalid reference to be treated as valid, or force a valid reference to be treated as an invalid reference. These controls are in Register 0x0A0B to Register 0x0A0D.

REFERENCE PROFILES

The AD9557 has an independent profile for each reference input. A profile consists of a set of device parameters such as the R divider and N divider, among others. The profiles allow the user to prescribe the specific device functionality that takes effect when one of the input references becomes the active reference.

The AD9557 evaluation software includes a frequency planning wizard that can configure the profile parameters, given the input and output frequencies.

Do not change a profile that is currently in use because unpredictable behavior may result. The user can either select free run or holdover mode or invalidate the reference input prior to changing it.

REFERENCE SWITCHOVER

An attractive feature of the AD9557 is its versatile reference switchover capability. The flexibility of the reference switchover functionality resides in a sophisticated prioritization algorithm that is coupled with register-based controls. This scheme provides the user with maximum control over the state machine that handles reference switchover.

The main reference switchover control resides in the loop mode register (Address 0x0A01). The REF switchover mode bits (Register 0x0A01, Bits[4:2]) allow the user to select one of the five operating modes of the reference switchover state machine, as follows:

- Automatic revertive mode
- Automatic nonrevertive mode
- Manual with automatic fallback mode
- Manual with holdover mode
- Full manual mode (without automatic holdover)

In the automatic modes, a fully automatic priority-based algorithm selects which reference is the active reference. When programmed for an automatic mode, the device chooses the highest priority

AD9557

valid reference. When both references have the same priority, REFA gets preference over REFB. However, the reference position is used only as a tie-breaker and does not initiate a reference switch.

The following list gives an overview of the five operating modes:

- Automatic revertive mode. The device selects the highest priority valid reference and switches to a higher priority reference if it becomes available, even if the reference in use is still valid. In this mode, the user reference is ignored.
- Automatic non-revertive mode. The device stays with the currently selected reference as long as it is valid, even if a higher priority reference becomes available. The user reference is ignored in this mode.
- Manual with automatic fallback mode. The device uses the user reference for as long as it is valid. If it becomes invalid, the reference input with the highest priority is chosen in accordance with the priority-based algorithm.
- Manual with holdover mode. The user reference is the active reference until it becomes invalid. At that point, the device automatically goes into holdover.
- Manual mode without holdover. The user reference is the active reference, regardless of whether or not it is valid.

The user also has the option to force the device directly into holdover or free run operation via the user holdover and user free run bits. In free run mode, the free run frequency tuning word register defines the free run output frequency. In holdover mode, the output frequency depends on the holdover control settings (see the Holdover section).

Phase Build-Out Reference Switching

The AD9557 supports phase build-out reference switching, which is the term given to a reference switchover that completely masks any phase difference between the previous reference and the new reference. That is, there is virtually no phase change detectable at the output when a phase build-out switchover occurs.

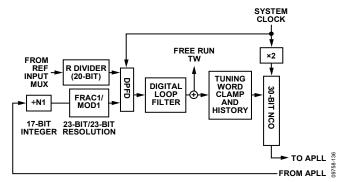

DIGITAL PLL (DPLL) CORE

DPLL Overview

A diagram of the DPLL core of the AD9557 appears in Figure 39. The phase/frequency detector, feedback path, lock detectors, phase offset, and phase slew rate limiting that comprise this second generation DPLL are all digital implementations.

The start of the DPLL signal chain is the reference signal, f_R , which is the frequency of the reference input. A reference prescaler reduces the frequency of this signal by an integer factor, R + 1, where R is the 20-bit value stored in the appropriate profile register and $0 \le R \le 1,048,575$. Therefore, the frequency at the output of the R divider (or the input to the time-to-digital converter (TDC)) is

$$f_{TDC} = \frac{f_R}{R+1}$$

A TDC samples the output of the R divider. The TDC/PFD produces a time series of digital words and delivers them to the digital loop filter. The digital loop filter offers the following advantages:

- Determination of the filter response by numeric coefficients rather than by discrete component values
- The absence of analog components (R/L/C), which eliminates tolerance variations due to aging
- The absence of thermal noise associated with analog components
- The absence of control node leakage current associated with analog components (a source of reference feed-through spurs in the output spectrum of a traditional analog PLL)

The digital loop filter produces a time series of digital words at its output and delivers them to the frequency tuning input of a Σ - Δ modulator (SDM). The digital words from the loop filter steer the DCO frequency toward frequency and phase lock with the input signal (f_{TDC}).

The DPLL includes a feedback divider that causes the digital loop to operate at an integer-plus-fractional multiple. The output of the DPLL is

$$f_{OUT_DPLL} = f_{TDC} \times \left[(N1+1) + \frac{FRAC1}{MOD1} \right]$$

where:

N1 is the 17-bit value stored in the appropriate profile registers (Register 0x0715 to Register 0x0717 for REFA).

FRAC1 and *MOD1* are the 23-bit numerators and denominators of the fractional feedback divider block.

The fractional portion of the feedback divider can be bypassed by setting FRAC1 to 0, but MOD1 must never be 0.

The DPLL output frequency is usually 175 MHz to 200 MHz for optimal performance.

TDC/PFD

The phase-frequency detector (PFD) is an all-digital block. It compares the digital output from the TDC (which relates to the active reference edge) with the digital word from the feedback block. It uses a digital code pump and digital integrator (rather than a conventional charge pump and capacitor) to generate the error signal that steers the DCO frequency toward phase lock.

Programmable Digital Loop Filter

The AD9557 loop filter is a third-order digital IIR filter that is analogous to the third-order analog loop shown in Figure 40.

Figure 40. Third-Order Analog Loop Filter

The AD9557 loop filter block features a simplified architecture in which the user enters the desired loop characteristics directly into the profile registers. This architecture makes the calculation of individual coefficients unnecessary in most cases, while still offering complete flexibility.

The AD9557 has two preset digital loop filters: high (88.5°) phase margin and normal (70°) phase margin. The loop filter coefficients are stored in Register 0x0317 to Register 0x0322 for high phase margin and Register 0x0323 to Register 0x032E for normal phase margin. The high phase margin loop filter is intended for applications in which the closed-loop transfer function must not have greater than 0.1 dB of peaking.

Bit 0 of Register 0x070E selects which filter is used for Profile A, and Bit 0 of 0x074E selects the filter for Profile B.

The loop bandwidth for Profile A is set in Register 0x070F to Register 0x0711, and the loop bandwidth for Profile B is set in Register 0x074F to Register 0x0751.

The two preset conditions cover all of the intended applications for the AD9557. For special cases where these conditions must be modified, the tools for calculating these coefficients are available by contacting Analog Devices directly.

DPLL Digitally Controlled Oscillator Free Run Frequency

The AD9557 uses an SDM as a DCO. The DCO free run frequency can be calculated from the following equation:

$$f_{dco_freerun} = f_{SYS} \times \frac{2}{8 + \frac{FTW0}{2^{30}}}$$

where:

FTW0 is the value in Register 0x0300 to Register 0x0303. *f*_{SYS} is the system clock frequency.

See the System Clock (SYSCLK) section for information on calculating the system clock frequency.

Adaptive Clocking

The AD9557 can support adaptive clocking applications such as asynchronous mapping and demapping. In these applications,

the output frequency can be dynamically adjusted by up to ± 100 ppm from the nominal output frequency without manually breaking the DPLL loop and reprogramming the device. This function is supported for REFA only, not REFB.

The following registers are used in this function:

- Register 0x0715 to Register 0x0717 (DPLL N1 divider)
- Register 0x0718 to Register 0x071A (DPLL FRAC1 divider)
- Register 0x071B to Register 0x071D (DPLL MOD1 divider)

Writing to these registers requires an I/O update by writing 0x01 to Register 0x0005 before the new values take effect.

To make small adjustments to the output frequency, the user can vary the FRAC1 and issue an I/O update. The advantage to using only FRAC1 to adjust the output frequency is that the DPLL does not briefly enter holdover. Therefore, the FRAC1 bit can be updated as fast as the phase detector frequency of the DPLL.

Writing to the N1 and MOD1 dividers allows larger changes to the output frequency. When the AD9557 detects that the N1 or MOD1 values have changed, it automatically enters and exits holdover for a brief instant without any disturbance in the output frequency. This limits how quickly the output frequency can be adapted.

It is important to realize that the amount of frequency adjustment is limited to ± 100 ppm before the output PLL (APLL) needs a recalibration. Variations that are larger than ± 100 ppm are possible; however, the ability of the AD9557 to maintain lock over temperature extremes may be compromised.

It is also important to remember that the rate of change in output frequency depends on the DPLL loop bandwidth.

DPLL Phase Lock Detector

The DPLL contains an all-digital phase lock detector. The user controls the threshold sensitivity and hysteresis of the phase detector via the profile registers.

The phase lock detector behaves in a manner analogous to water in a tub (see Figure 41). The total capacity of the tub is 4096 units with -2048 denoting empty, 0 denoting the 50% point, and +2048 denoting full. The tub also has a safeguard to prevent overflow. Furthermore, the tub has a low water mark at -1024and a high water mark at +1024. To change the water level, the user adds water with a fill bucket or removes water with a drain bucket. The user specifies the size of the fill and drain buckets via the 8-bit fill rate and drain rate values in the profile registers.

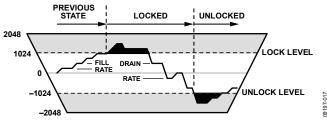

Figure 41. Lock Detector Diagram

The water level in the tub is what the lock detector uses to determine the lock and unlock conditions. When the water level is below the low water mark (-1024), the detector indicates an unlock condition. Conversely, when the water level is above the high water mark (+1024), the detector indicates a lock condition. When the water level is between the marks, the detector simply holds its last condition. This concept appears graphically in Figure 41, with an overlay of an example of the instantaneous water level (vertical) vs. time (horizontal) and the resulting lock/unlock states.

During any given PFD cycle, the detector either adds water with the fill bucket or removes water with the drain bucket (one or the other but not both). The decision of whether to add or remove water depends on the threshold level specified by the user. The phase lock threshold value is a 16-bit number stored in the profile registers and is expressed in picoseconds (ps). Thus, the phase lock threshold extends from 0 ns to ± 65.535 ns and represents the magnitude of the phase error at the output of the PFD.

The phase lock detector compares each phase error sample at the output of the PFD to the programmed phase threshold value. If the absolute value of the phase error sample is less than or equal to the programmed phase threshold value, the detector control logic dumps one fill bucket into the tub. Otherwise, it removes one drain bucket from the tub. Note that it is not the polarity of the phase error sample, but its magnitude relative to the phase threshold value, that determines whether to fill or drain. If more filling is taking place than draining, the water level in the tub eventually rises above the high water mark (+1024), which causes the phase lock detector to indicate lock. If more draining is taking place than filling, the water level in the tub eventually falls below the low water mark (-1024), which causes the phase lock detector to indicate unlock. The ability to specify the threshold level, fill rate, and drain rate enables the user to tailor the operation of the phase lock detector to the statistics of the timing jitter associated with the input reference signal.

Note that when the AD9557 enters the free run or holdover mode, the DPLL phase lock detector indicates an unlocked state. However, when the AD9557 performs a reference switch, the lock detector state prior to the switch is preserved during the transition period.

DPLL Frequency Lock Detector

The operation of the frequency lock detector is identical to that of the phase lock detector. The only difference is that the fill or drain decision is based on the period deviation between the reference and feedback signals of the DPLL instead of the phase error at the output of the PFD.

The frequency lock detector uses a 24-bit frequency threshold register specified in units of picoseconds (ps). Therefore, the

frequency threshold value extends from 0 µs to ±16.777215 µs. It represents the magnitude of the difference in period between the reference and feedback signals at the input to the DPLL. For example, if the reference signal is 1.25 MHz and the feedback signal is 1.38 MHz, the period difference is approximately 75.36 ns ($|1/1,250,000 - 1/1,380,000| \approx 75.36$ ns).

Frequency Clamp

The AD9557 DPLL features a digital tuning word clamp that ensures that the DPLL output frequency stays within a defined range. This feature is very useful to eliminate undesirable behavior in cases where the reference input clocks may be unpredictable. The tuning word clamp is also useful to guarantee that the APLL never loses lock, by ensuring that the APLL VCO frequency stays within its tuning range.

Frequency Tuning Word History

The AD9557 has the ability to track the history of the tuning word samples generated by the DPLL digital loop filter output. It does so by periodically computing the average tuning word value over a user-specified interval. This average tuning word is used during holdover mode to maintain the average frequency when no input references are present.

LOOP CONTROL STATE MACHINE

Switchover

Switchover occurs when the loop controller switches directly from one input reference to another. The AD9557 handles a reference switchover by briefly entering holdover mode, loading the new DPLL parameters, and then immediately recovering. During the switchover event, however, the AD9557 preserves the status of the lock detectors to avoid phantom unlock indications.

Holdover

The holdover state of the DPLL is typically used when none of the input references are present, although the user can also manually engage holdover mode. In holdover mode, the output frequency remains constant. The accuracy of the AD9557 in holdover mode is dependent on the device programming and availability of tuning word history.

Recovery from Holdover

When the AD9557 is in holdover mode and a valid reference becomes available, the device exits holdover operation. The loop state machine restores the DPLL to closed-loop operation, locks to the selected reference, and sequences the recovery of all the loop parameters based on the profile settings for the active reference.

Note that, if the user holdover bit is set, the device does not automatically exit holdover when a valid reference is available. However, automatic recovery can occur after clearing the user holdover bit (Bit 6 in Register 0x0A01).

SYSTEM CLOCK (SYSCLK) SYSTEM CLOCK INPUTS

Functional Description

The SYSCLK circuit provides a low jitter, stable, high frequency clock for use by the rest of the chip. The XOA and XOB pins connect to the internal SYSCLK multiplier. The SYSCLK multiplier can synthesize the system clock by connecting a crystal resonator across the XOA and XOB input pins or by connecting a low frequency clock source. The optimal signal for the system clock input is either a crystal in the 50 MHz range or an ac-coupled square wave with a 1 V p-p amplitude.

System Clock Period

For the AD9557 to accurately measure the frequency of incoming reference signals, the user must enter the system clock period into the nominal system clock period registers (Register 0x0103 to Register 0x0105). The SYSCLK period is entered in units of nanoseconds (ns).

System Clock Details

There are two internal paths for the SYSCLK input signal: low frequency non-XTAL (LF) and crystal resonator (XTAL).

Using a TCXO for the system clock is a common use for the LF path. Applications requiring DPLL loop bandwidths of less than 50 Hz or high stability in holdover require a TCXO. As an alternative to the 49.152 MHz crystal for these applications, the AD9557 reference design uses a 19.2 MHz TCXO, which offers excellent holdover stability and a good combination of low jitter and low spurious content.

The 1.8 V differential receiver connected to the XOA and XOB pins is self-biased to a dc level of approximately 1 V, and ac coupling is strongly recommended. When a 3.3 V CMOS oscillator is in use, it is important to use a voltage divider to reduce the input high voltage to a maximum of 1.8 V. See Figure 34 for details on connecting a 3.3 V CMOS TCXO to the system clock input.

The non-XTAL input path permits the user to provide an LVPECL, LVDS, 1.8 V CMOS, or sinusoidal low frequency clock for multiplication by the integrated SYSCLK PLL. The LF path handles input frequencies from 3.5 MHz up to 100 MHz. However, when using a sinusoidal input signal, it is best to use a frequency that is in excess of 20 MHz. Otherwise, the resulting low slew rate can lead to substandard noise performance. Note that the non-XTAL path includes an optional 2× frequency multiplier to double the rate at the input to the SYSCLK PLL and potentially reduce the PLL in-band noise. However, to avoid exceeding the maximum PFD rate of 150 MHz, the 2× frequency multiplier is only for input frequencies that are below 75 MHz.

The non-XTAL path also includes an input divider (M) that is programmable for divide-by-1, -2, -4, or -8. The purpose of the divider is to limit the frequency at the input to the PLL to less than 150 MHz (the maximum PFD rate). The XTAL path enables the connection of a crystal resonator (typically 10 MHz to 50 MHz) across the XOA and XOB input pins. An internal amplifier provides the negative resistance required to induce oscillation. The internal amplifier expects an AT cut, fundamental mode crystal with a maximum motional resistance of 100 Ω . The following crystals, listed in alphabetical order, may meet these criteria. Analog Devices, Inc., does not guarantee their operation with the AD9557 nor does Analog Devices endorse one crystal supplier over another. The AD9557 reference design uses a 49.152 MHz crystal, which is high performance, low spurious content, and readily available.

- AVX/Kyocera CX3225SB
- ECS ECX-32
- Epson/Toyocom TSX-3225
- Fox FX3225BS
- NDK NX3225SA
- Siward SX-3225
- Suntsu SCM10B48-49.152 MHz

The AD9557 reference design also has a place to mount a 5 mm \times 7 mm TCXO. A TCXO with a CMOS output is strongly recommended instead of a clipped sine wave output. The following TCXOs, listed in alphabetical order, may meet these criteria. Analog Devices does not guarantee their operation with the AD9557 nor does Analog Devices endorse one TCXO supplier over another.

- Vectron TX-700
- Rakon RPT7050J

SYSTEM CLOCK MULTIPLIER

The SYSCLK PLL multiplier is an integer-N design with an integrated VCO. It provides a means to convert a low frequency clock input to the desired system clock frequency, f_{SYS} (750 MHz to 805 MHz). The SYSCLK PLL multiplier accepts input signals of between 3.5 MHz and 600 MHz; however, frequencies that are in excess of 150 MHz require the system clock P divider to ensure compliance with the maximum PFD rate (150 MHz). The PLL contains a feedback divider (N) that is programmable for divide values between 4 and 255.

$$f_{SYS} = f_{OSC} \times \frac{sysclk_Ndiv}{sysclk_Pdiv}$$

where:

*f*_{OSC} is the frequency at the XOA and XOB pins. *sysclk_Ndiv* is the value stored in Register 0x0100. *sysclk_Pdiv* is the system clock P divider that is determined by the setting of Register 0x0101, Bits[2:1].

If the system clock doubler is used, the value of sysclk_Ndiv must be half of its original value.

The system clock multiplier features a simple lock detector that compares the time difference between the reference and feedback edges. The most common cause of the SYSCLK multiplier not locking is a non-50% duty cycle at the SYSCLK input while the system clock doubler is enabled.

System Clock Stability Timer

Because the reference monitors depend on the system clock being at a known frequency, it is important that the system clock be stable before activating the monitors. At initial powerup, the system clock status is not known, and, therefore, it is reported as being unstable. After the device has been programmed, the system clock PLL (if enabled) eventually locks.

When a stable operating condition is detected, a timer is run for the duration that is stored in the system clock stability period registers. If, at any time during this waiting period, the condition is violated, the timer is reset and halted until a stable condition is reestablished. After the specified period elapses, the AD9557 reports the system clock as stable.

OUTPUT PLL (APLL)

A diagram of the output PLL (APLL) is shown in Figure 42.

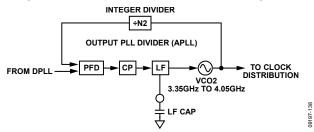

Figure 42. Output PLL Block Diagram

The APLL provides the frequency upconversion from the DPLL output to the 3.35 GHz to 4.05 GHz range, while also providing noise filtering on the DPLL output. The APLL reference input is the output of the DPLL. The feedback divider is an integer divider. The loop filter is partially integrated with the one external 6.8 nF capacitor. The nominal loop bandwidth for this PLL is 250 kHz, with 68 degrees of phase margin.

The frequency wizard that is included in the evaluation software configures the APLL, and the user does not need to make changes to the APLL settings. However, there may be special cases where the user may want to adjust the APLL loop bandwidth to meet a specific phase noise requirement. The easiest way to change the APLL loop bandwidth is to adjust the APLL charge pump current in Register 0x0400. There is sufficient stability (68° of phase margin) in the APLL default settings to permit a broad range of adjustment without causing the APLL to be unstable. Contact Analog Devices directly if more detail is needed.

Calibration of the APLL must be performed at startup and when the nominal input frequency to the APLL changes by more than ± 100 ppm, although the APLL maintains lock over voltage and temperature extremes without recalibration. Calibration centers the dc operating voltage at the input to the APLL VCO.

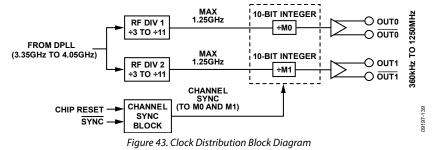

APLL calibration at startup can be accomplished during initial register loading by following the instructions in the Device Register Programming Using a Register Setup File section of this data sheet.

To recalibrate the APLL VCO after the chip has been running, the user must first input the new settings (if any). Ensure that the system clock is still locked and stable, and that the DPLL is in free run mode with the free run tuning word set to the same output frequency that is used when the DPLL is locked.

Take the following steps to calibrate the APLL VCO:

- 1. Ensure that the system clock is locked and stable.
- Ensure that the DPLL is in user free run mode (Register 0x0A01, Bit 5 = 1b), and the free run tuning word is set.
- 3. Write Register 0x0405 = 0x20.
- 4. Write Register 0x0005 = 0x01.
- 5. Write Register 0x0405 = 0x21.
- 6. Write Register 0x0005 = 0x01.
- 7. Monitor the APLL status using Bit 2 in Register 0x0D01.

CLOCK DISTRIBUTION

RF Dividers (RF Divider 2 and RF Divider 1)

The first block in each clock distribution section is the RF divider. The RF dividers divide the VCO output frequency down to a maximum frequency of \leq 1.25 GHz and has special circuitry to maintain a 50% duty cycle for any divide ratio.

The following register addresses contain the RF divider settings:

- RF Divider 1: Register 0x0407, Bits [3:0]
- RF Divider 2: Register 0x0407, Bits [7:4]

In normal operation, the RF dividers do not need to be reset because the APLL VCO calibration (which normally occurs after programming the RF divider) automatically performs an RF divider reset.

However, in cases where the user wants to change either of the RF dividers, but not recalibrate the corresponding APLL VCO afterward, the user must first reset that RF divider by writing 0x0F to the appropriate RF divider register and then issuing an I/O update by writing Register 0x0005 = 0x01. At this point, the user can program the new RF divider value, and issue another I/O update.

Channel Dividers

The channel divider blocks, M0 and M1, are 10-bit integer dividers with a divide range of 1 to 1023. The channel divider block contains duty cycle correction that guarantees 50% duty cycle for both even and odd divide ratios.

OUTPUT POWER-DOWN

The output drivers can be individually powered down.

OUTPUT ENABLE

Each of the output channels offers independent control of enable/ disable functionality via the distribution enable register. The distribution outputs use synchronization logic to control enable/disable activity to avoid the production of runt pulses and ensure that outputs with the same divide ratios become active/inactive in unison.

OUTPUT MODE

The user has independent control of the operating mode of each of the four output channels via the output clock distribution registers (Address 0x0500 to Address 0x0509). The operating mode control includes

- Logic family and pin functionality
- Output drive strength
- Output polarity
- Divide ratio
- Phase of each output channel

OUT0 provides 3.3 V CMOS, in addition to 1.8 V CMOS modes. OUT1 has 1.8 V CMOS, LVDS, and HSTL modes.

All CMOS drivers feature a CMOS drive strength that allows the user to choose between a strong, high performance CMOS driver, or a lower power setting with less EMI and crosstalk. The best setting is application dependent.

For applications where LVPECL levels are required, the user should choose the HSTL mode, and ac-couple the output signal. See the Input/Output Termination Recommendations section for recommended termination schemes.

CLOCK DISTRIBUTION SYNCHRONIZATION

Divider Synchronization

The dividers in the clock distribution channels can be synchronized with each other.

At power-up, the clock dividers are held static until a sync signal is initiated by the channel sync block. The following are possible sources of a sync signal, and these settings are found in Register 0x0500:

- Direct sync via Bit 2 of Register 0x0500
- Direct sync via a sync op code (0xA1) in the EEPROM storage sequence during EEPROM loading
- DPLL phase or frequency lock
- A rising edge of the selected reference input
- The SYNC pin
- A multifunction pin configured for the sync signal

Data Sheet

The APLL lock detect signal gates the sync signal from the channel sync block shown in Figure 43. The channel dividers receive a sync signal from the channel sync block only if the APLL is calibrated and locked, unless the APLL locked controlled sync disable bit (Register 0x0405, Bit 3) is set.

A channel can be programmed to ignore the sync function by setting the mask Channel 1 sync and mask Channel 0 sync bits (Bits[5:4]) in Register 0x0500. When programmed to ignore the sync, the channel ignores both the user initiated sync signal and the zero delay initiated sync signals, and the channel divider starts toggling, provided that the APLL is calibrated and locked, or if the APLL locked controlled sync disable bit (Register 0x0405, Bit 3) is set.

If the output sync function is to be controlled using an M pin, take the following steps:

- 1. Enable the M pins by writing Register 0x0200 = 0x01.
- 2. Issue an I/O update (Register 0x0005 = 0x01).
- 3. Set the appropriate M pin function.

If this process is not followed, a sync pulse is issued automatically.

STATUS AND CONTROL MULTIFUNCTION PINS (M3 TO M0)

The AD9557 has four digital CMOS I/O pins (M3 to M0) that are configurable for a variety of uses. To use these functions, the user must enable them by writing a 0x01 to Register 0x0200. The function of these pins is programmable via the register map. Each pin can control or monitor an assortment of internal functions, based on the contents of Register 0x0201 to Register 0x0204.

To monitor an internal function with a multifunction pin, write a Logic 1 to the most significant bit of the register associated with the desired multifunction pin. The value of the seven least significant bits of the register defines the control function, as shown in Table 124.

To control an internal function with a multifunction pin, write a Logic 0 to the most significant bit of the register associated with the desired multifunction pin. The monitored function depends on the value of the seven least significant bits of the register, as shown in Table 125.

If more than one multifunction pin operates on the same control signal, then internal priority logic ensures that only one multifunction pin serves as the signal source. The selected pin is the one with the lowest numeric suffix. For example, if both M0 and M3 operate on the same control signal, M0 is used as the signal source and the redundant pins are ignored.

At power-up, the multifunction pins can force the device into certain configurations, as defined in the initial pin programming section. This functionality, however, is valid only during powerup or following a reset, after which the pins can be reconfigured via the serial programming port or via the EEPROM.

If the output sync function is to be controlled using an M pin,

- 1. Enable the M pins by writing Register 0x0200 = 0x01.
- 2. Issue an I/O update (Register 0x0005 = 0x01).
- 3. Set the appropriate M pin function.

If this process is not followed, a sync pulse is issued automatically.

IRQ PIN

The AD9557 has a dedicated interrupt request (IRQ) pin. Bits[1:0] of the IRQ pin output mode register (Register 0x0209) control how the IRQ pin asserts an interrupt, based on the value of the two bits, as follows:

- 00: the IRQ pin is high impedance when deasserted and active low when asserted and requires an external pull-up resistor.
- 01: the IRQ pin is high impedance when deasserted and active high when asserted and requires an external pull-down resistor.
- 10: the IRQ pin is Logic 0 when deasserted and Logic 1 when asserted.
- 11: the IRQ pin is Logic 1 when deasserted and Logic 0 when asserted. (This is the default operating mode.)

The AD9557 asserts the IRQ pin when any bit in the IRQ monitor register (Address 0x0D02 to Address 0x0D07) is a Logic 1. Each bit in this register is associated with an internal function that is capable of producing an interrupt. Furthermore, each bit of the IRQ monitor register is the result of a logical AND of the associated internal interrupt signal and the corresponding bit in the IRQ mask register (Address 0x020A to Address 0x020E). That is, the bits in the IRQ mask register have a one-to-one correspondence with the bits in the IRQ monitor register. When an internal function produces an interrupt signal and the associated IRQ mask bit is set, the corresponding bit in the IRQ monitor register is set. The user must be aware that clearing a bit in the IRQ mask register removes only the mask associated with the internal interrupt signal. It does not clear the corresponding bit in the IRQ monitor register.

Note that the IRQ function detects a state change in the function that is being monitored. However, if IRQs are cleared (or if they are enabled for the first time), they do not generate for a preexisting condition. The state must change after the IRQs are enabled. For example, if REFA is already invalid before the REFA invalid IRQ is enabled, the IRQ does not generate.

The IRQ pin is the result of a logical OR of all the IRQ monitor register bits. Thus, the AD9557 asserts the IRQ pin as long as any IRQ monitor register bit is a Logic 1. Note that it is possible to have multiple bits set in the IRQ monitor register. Therefore, when the AD9557 asserts the IRQ pin, it may indicate an interrupt from several different internal functions. The IRQ monitor register provides the user with a means to interrogate the AD9557 to determine which internal function produced the interrupt.

Typically, when the IRQ pin is asserted, the user interrogates the IRQ monitor register to identify the source of the interrupt request. After servicing an indicated interrupt, the user must clear the associated IRQ monitor register bit via the IRQ clearing register (Address 0x0A04 to Address 0x0A09). The bits in the IRQ clearing register have a one-to-one correspondence with the bits in the IRQ monitor register. Note that the IRQ clearing register is autoclearing. The IRQ pin remains asserted until the user clears all of the bits in the IRQ monitor register that indicate an interrupt.

It is also possible to collectively clear all of the IRQ monitor register bits by setting the clear all IRQs bit in the reset function register (Register 0x0A03, Bit 1). Note that this is an autoclearing bit. Setting this bit results in deassertion of the IRQ pin. Alternatively, the user can program any of the multifunction pins to clear all IRQs. This allows the user to clear all IRQs by means of a hardware pin rather than by using a serial I/O port operation.

WATCHDOG TIMER

The watchdog timer is a general-purpose programmable timer. To set the timeout period, the user writes to the 16-bit watchdog timer register (Address 0x0x0210 and Address 0x0211). A value of 0b in this register disables the timer. A nonzero value sets the timeout period in milliseconds (ms), giving the watchdog timer a range of 1 ms to 65.535 sec. The relative accuracy of the timer is approximately 0.1% with an uncertainty of 0.5 ms.

If enabled, the timer runs continuously and generates a timeout event when the timeout period expires. The user has access to the watchdog timer status via the IRQ mechanism and the multifunction pins (M0 to M3). In the case of the multifunction pins, the timeout event of the watchdog timer is a pulse that lasts 32 system clock periods.

There are two ways to reset the watchdog timer (thereby preventing it from causing a timeout event). The first is by writing a Logic 1 to the autoclearing clear watchdog bit in the clear/reset functions register (Register 0x0A03, Bit 0). Alternatively, the user can program any of the multifunction pins to reset the watchdog timer. This allows the user to reset the timer by means of a hardware pin rather than by using a serial I/O port operation.

EEPROM

EEPROM Overview

The AD9557 contains an integrated 2048-byte, electrically erasable, programmable read-only memory (EEPROM). The AD9557 can be configured to perform a download at power-up via the multifunction pins (M2 to M3), but uploads and downloads can also be done on demand via the EEPROM control registers (Address 0x0E00 to Address 0x0E03).

The EEPROM provides the ability to upload and download configuration settings to and from the register map. Figure 44 shows a functional diagram of the EEPROM.

Register 0x0E10 to Register 0x0E3F represent a 53-byte EEPROM storage sequence area (referred to as the "scratch pad" in this section) that enables the user to store a sequence of instructions for transferring data to the EEPROM from the device settings portion of the register map. Note that the default values for these registers provide a sample sequence for saving/retrieving all of the AD9557 EEPROM-accessible registers. Figure 44 shows the connectivity between the EEPROM and the controller that manages data transfer between the EEPROM and the register map.

The controller oversees the process of transferring EEPROM data to and from the register map. There are two modes of operation handled by the controller: saving data to the EEPROM (upload mode) or retrieving data from the EEPROM (download mode). In either case, the controller relies on a specific instruction set.

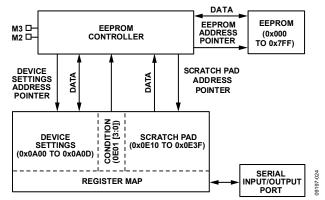

Figure 44. EEPROM Functional Diagram

| Instruction Value (Hex) | Instruction Type | Bytes Required | Description |
|----------------------------|---------------------|-------------------|--|
| 0x00 to 0x7F | Data | 3 | A data instruction tells the controller to transfer data to or from the device settings section of the register map. A data instruction requires two additional bytes that, together, indicate a starting address in the register map. Encoded in the data instruction is the number of bytes to transfer, which is one more than the instruction value. |
| 0x80 | I/O update | 1 | When the controller encounters this instruction while downloading from the EEPROM, it issues a soft I/O update. |
| 0xA0 | Calibrate | 1 | When the controller encounters this instruction while downloading from the EEPROM, it initiates a system clock calibration sequence. |
| 0xA1 | Distribution sync | 1 | When the controller encounters this instruction while downloading from the EEPROM, it issues a sync pulse to the output distribution synchronization. |
| 0xB0 to 0xCF | Condition | 1 | B1 to CF are condition instructions and correspond to Condition 1 through Condition 31, respectively. B0 is the null condition instruction. See the EEPROM Conditional Processing section for details. |
| 0xFE | Pause | 1 | When the controller encounters this instruction in the EEPROM storage sequence area while uploading to the EEPROM, it holds both the scratch pad address pointer and the EEPROM address pointer at its last value. This allows storage of more than one instruction sequence in the EEPROM. Note that the controller does not copy this instruction to the EEPROM during upload. |
| 0xFF | End | 1 | When the controller encounters this instruction in the EEPROM storage sequence area while uploading to the EEPROM, it resets both the register area address pointer and the EEPROM address pointer and then enters an idle state. When the controller encounters this instruction while downloading from the EEPROM, it resets the EEPROM address pointer and then enters an idle state. |

Table 21. EEPROM Controller Instruction Set

EEPROM Instructions

Table 21 lists the EEPROM controller instruction set. The controller recognizes all instruction types, whether it is in upload or download mode, except for the pause instruction, which is recognized only in upload mode.

The I/O update, calibrate, distribution sync, and end instructions are mostly self-explanatory. The others, however, warrant further detail, as described in the following paragraphs.

Data instructions are those that have a value from 0x000 to 0x7FF. A data instruction tells the controller to transfer data between the EEPROM and the register map. The controller requires the following two parameters to carry out the data transfer:

- The number of bytes to transfer
- The register map target address

The controller decodes the number of bytes to transfer directly from the data instruction itself by adding one to the value of the instruction. For example, the 1A data instruction has a decimal value of 26; therefore, the controller knows to transfer 27 bytes (one more than the value of the instruction). When the controller encounters a data instruction, it knows to read the next two bytes in the scratch pad because these contain the register map target address. Note that, in the EEPROM scratch pad, the two registers that comprise the address portion of a data instruction have the MSB of the address in the D7 position of the lower register address. The bit weight increases from left to right, from the lower register address to the higher register address. Furthermore, the starting address always indicates the lowest numbered register map address in the range of bytes to transfer. That is, the controller always starts at the register map target address and counts upward regardless of whether the serial I/O port is operating in I²C, SPI LSB-first, or SPI MSB-first mode.

As part of the data transfer process during an EEPROM upload, the controller calculates a 1-byte checksum and stores it as the final byte of the data transfer. As part of the data transfer process during an EEPROM download, however, the controller again calculates a 1-byte checksum value but compares the newly calculated checksum with the one that was stored during the upload process. If an upload/download checksum pair does not match, the controller sets the EEPROM fault status bit. If the upload/download checksums match for all data instructions encountered during a download sequence, the controller sets the EEPROM complete status bit.

Condition instructions are those that have a value from B0 to CF. The B1 to CF condition instructions represent Condition 1 to Condition 31, respectively. The B0 condition instruction is special because it represents the null condition (see the EEPROM Conditional Processing section). A pause instruction, like an end instruction, is stored at the end of a sequence of instructions in the scratch pad. When the controller encounters a pause instruction during an upload sequence, it keeps the EEPROM address pointer at its last value. This way the user can store a new instruction sequence in the scratch pad and upload the new sequence to the EEPROM. The new sequence is stored in the EEPROM address locations immediately following the previously saved sequence. This process is repeatable until an upload sequence contains an end instruction. The pause instruction is also useful when used in conjunction with condition processing. It allows the EEPROM to contain multiple occurrences of the same registers, with each occurrence linked to a set of conditions (see the EEPROM Conditional Processing section).

EEPROM Upload

To upload data to the EEPROM, the user must first ensure that the write enable bit (Register 0x0E00, Bit 0) is set. Then, on setting the autoclearing save to EEPROM bit (Register 0x0E02, Bit 0), the controller initiates the EEPROM data storage process.

Uploading EEPROM data requires that the user first write an instruction sequence into the scratch pad registers. During the upload process, the controller reads the scratch pad data byteby-byte, starting at Register 0x0E10 and incrementing the scratch pad address pointer, as it goes, until it reaches a pause or end instruction.

As the controller reads the scratch pad data, it transfers the data from the scratch pad to the EEPROM (byte-by-byte) and increments the EEPROM address pointer accordingly, unless it encounters a data instruction. A data instruction tells the controller to transfer data from the device settings portion of the register map to the EEPROM. The number of bytes to transfer is encoded within the data instruction, and the starting address for the transfer appears in the next two bytes in the scratch pad.

When the controller encounters a data instruction, it stores the instruction in the EEPROM, increments the EEPROM address pointer, decodes the number of bytes to be transferred, and increments the scratch pad address pointer. Then it retrieves the next two bytes from the scratch pad (the target address) and increments the scratch pad address pointer by 2. Next, the controller transfers the specified number of bytes from the register map (beginning at the target address) to the EEPROM.

When it completes the data transfer, the controller stores an extra byte in the EEPROM to serve as a checksum for the transferred block of data. To account for the checksum byte, the controller increments the EEPROM address pointer by one more than the number of bytes transferred. Note that, when the controller transfers data associated with an active register, it actually transfers the buffered contents of the register (see the Buffered/Active Registers section for details on the difference between buffered and active registers). This allows the transfer of nonzero autoclearing register contents. AD9557

Note that conditional processing (see the EEPROM Conditional Processing section) does not occur during an upload sequence.

Manual EEPROM Download

A manual EEPROM download transfers data from the EEPROM to the device register map. To download data, the user sets the autoclearing load from the EEPROM bit (Register 0x0E03, Bit 1). This commands the controller to initiate the EEPROM download process. During download, the controller reads the EEPROM data byte-by-byte, incrementing the EEPROM address pointer as it goes, until it reaches an end instruction. As the controller reads the EEPROM data, it executes the stored instructions, which includes transferring stored data to the device settings portion of the register map when it encounters a data instruction.

To ensure robust operation, the EEPROM download must be allowed to complete (Register 0x0D00, Bit 1 returning to 0b) before other register writes are performed. If the EEPROM download is interrupted, the user may need to reset the AD9557 prior to attempting another EEPROM download.

Note that conditional processing (see the EEPROM Conditional Processing section) is applicable only when downloading.

Automatic EEPROM Download

Following a power-up, an assertion of the $\overrightarrow{\text{RESET}}$ pin, or a soft reset (Register 0x0000, Bit 5 = 1), if the PINCONTROL pin is low, and M3 and M2 are either high or low (see Table 22), the instruction sequence stored in the EEPROM executes automatically with one of eight conditions. If M3 and M2 are left floating and the PINCONTROL pin is low, the EEPROM is bypassed and the factory defaults are used. In this way, a previously stored set of register values downloads automatically on power-up or with a hard or soft reset. See the EEPROM Conditional Processing section for details regarding conditional processing and the way it modifies the download process.

To ensure robust operation, the automatic EEPROM download must be initiated by the power-on reset (POR) pulse, and not by the RESET pin. Holding the RESET pin low during power-up is not recommended because the reset caused by the rising edge of the RESET pin may interrupt the EEPROM download initiated by the POR pulse.

| Table 22. | EEPROM | Setup |
|-----------|--------|-------|
|-----------|--------|-------|

| - | | | | |
|------|------|----|--------------|-------------------------|
| M3 | M2 | ID | FNCINIT[7:3] | EEPROM Download? |
| Low | Low | 1 | 00001b | Yes, EEPROM Condition 1 |
| Low | Open | 2 | 00010b | Yes, EEPROM Condition 2 |
| Low | High | 3 | 00011b | Yes, EEPROM Condition 3 |
| Open | Low | 4 | 00100b | Yes, EEPROM Condition 4 |
| Open | Open | 0 | n/a | No |

| High | Open | 7 | 00111b | Yes, EEPROM Condition 7 |
| High | High | 8 | 01000b | Yes, EEPROM Condition 8 |

EEPROM Conditional Processing

The condition instructions allow conditional execution of EEPROM instructions during a download sequence. This allows the user to store different AD9557 configurations in the EEPROM. During EEPROM loading, the state of the M pins (or the value of Register 0x0E01) determine which configuration is loaded. During an upload (to EEPROM) sequence, however, they are stored as is and have no effect on the upload process.

Note that, during EEPROM downloads, the condition instructions themselves and the end instruction always execute unconditionally.

Conditional processing makes use of two elements: the condition (from Condition 1 to Condition 8) and the condition tag board. The relationships among the condition, the condition tag board, and the EEPROM controller appear schematically in Figure 45.

The condition is a 5-bit value with 32 possibilities. Condition = 0 is the null condition. When the null condition is in effect (which is normally the case), the EEPROM controller executes all instructions unconditionally. Condition 9 through Condition 31 are not accessible using the M pins. The remaining eight possibilities (that is, Condition = 1 through Condition = 8) modify the way the EEPROM controller handles a download sequence. The condition originates from one of two sources (see Figure 45), as follows:

- FNCINIT, Bits[7:3], which is the state of the M2 to M3 multifunction pins at power-up (see Table 22)
- Register 0x0E01, Bits[3:0]

If Register 0x0E01, Bits[3:0] $\neq 0$, then the condition is the value that is stored in Register 0x0E01, Bits[3:0]; otherwise, the

condition is FNCINIT, Bits[7:3]. Note that a nonzero condition that is present in Register 0x0E01, Bits[3:0] takes precedence over FNCINIT, Bits[7:3].

The condition tag board is a table maintained by the EEPROM controller. When the controller encounters a condition instruction, it decodes the B1 through CF instructions as condition = 1 through condition = 8, respectively, and tags that particular condition in the condition tag board. However, the B0 condition instruction decodes as the null condition, for which the controller clears the condition tag board, and subsequent download instructions execute unconditionally (until the controller encounters a new condition instruction).

During download, the EEPROM controller executes or skips instructions depending on the value of the condition and the contents of the condition tag board. Note, however, that the condition instructions and the end instruction always execute unconditionally during download. If Condition = 0, all instructions during download execute unconditionally. If Condition $\neq 0$ and there are any tagged conditions in the condition tag board, the controller executes instructions only if the condition is tagged. If the condition is not tagged, the controller skips instructions until it encounters a condition instruction that decodes as a tagged condition. Note that the condition tag board allows multiple conditions to be tagged at any given moment. This conditional processing mechanism enables the user to have one download instruction sequence with many possible outcomes depending on the value of the condition and the order in which the controller encounters condition instructions.

09197-025

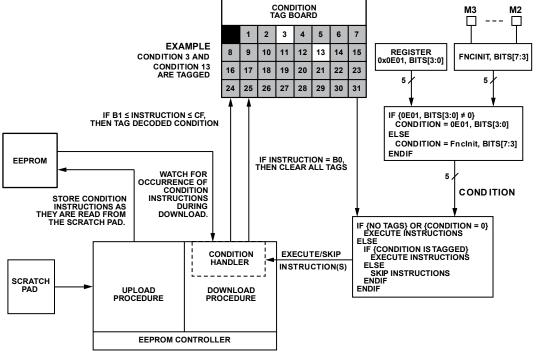

Figure 45. EEPROM Conditional Processing

Table 23 lists a sample EEPROM download instruction sequence. It illustrates the use of condition instructions and how they alter the download sequence. The table begins with the assumption that no conditions are in effect. That is, the most recently executed condition instruction is either B0 or no conditional instructions have been processed.

| Table 23. EEI | ROM Conditional | Processing Example |
|---------------|-----------------|--------------------|
| | | |

| Instruction | Action |
|-------------|---|
| 0x08 | Transfer the system clock register contents, |
| 0x01 | regardless of the current condition. |
| 0x00 | |
| 0xB1 | Tag Condition 1. |
| 0x19 | Transfer the clock distribution register contents |
| 0x04 | only if tag condition $= 1$. |
| 0x00 | |
| 0xB2 | Tag Condition 2. |
| 0xB3 | Tag Condition 3. |
| 0x07 | Transfer the reference input register contents |
| 0x05 | only if tag condition = 1, 2, or 3. |
| 0x00 | |
| 0x0A | Calibrate the system clock only if tag condition = 1, 2, or 3. |
| 0xB0 | Clear the tag condition board. |
| 0x80 | Execute an I/O update, regardless of the value of the tag condition. |
| 0x0A | Calibrate the system clock, regardless of the value of the tag condition. |

Storing Multiple Device Setups in EEPROM

Conditional processing makes it possible to create a number of different device setups, store them in EEPROM, and download a specific setup on demand. To do so, first program the device control registers for a specific setup. Then, store an upload sequence in the EEPROM scratch pad with the following general form:

- 1. Condition instruction (B1 to CF) to identify the setup with a specific condition (1 to 31)
- 2. Data instructions (to save the register contents), along with any required calibrate and/or I/O update instructions
- 3. Pause instruction (FE)

With the upload sequence written to the scratch pad, perform an EEPROM upload (Register 0x0E02, Bit 0).

Reprogram the device control registers for the next desired setup. Then store a new upload sequence in the EEPROM scratch pad with the following general form:

- 1. Condition instruction (B0)
- 2. The next desired condition instruction (B1 to CF, but different from the one used during the previous upload to identify a new setup)
- 3. Data instructions (to save the register contents) along with any required calibrate and/or I/O update instructions
- 4. Pause instruction (FE)

With the upload sequence written to the scratch pad, perform an EEPROM upload (Register 0x0E02, Bit 0).

Repeat the process of programming the device control registers for a new setup, storing a new upload sequence in the EEPROM scratch pad (Step 1 through Step 4), and executing an EEPROM upload (Register 0x0E02, Bit 0) until all of the desired setups have been uploaded to the EEPROM.

Note that, on the final upload sequence stored in the scratch pad, the pause instruction (FE) must be replaced with an end instruction (FF).

To download a specific setup on demand, first store the condition associated with the desired setup in Register 0x0E01, Bits[3:0]. Then perform an EEPROM download (Register 0x0E03, Bit 1). Alternatively, to download a specific setup at power-up, apply the required logic levels necessary to encode the desired condition on the M2 and M3 multifunction pins. Then power up the device; an automatic EEPROM download occurs. The condition (as established by the M2 to M3 multifunction pins) guides the download sequence and results in a specific setup.

Keep in mind that the number of setups that can be stored in the EEPROM is limited. The EEPROM can hold a total of 2048 bytes. Each nondata instruction requires one byte of storage. Each data instruction, however, requires N + 4 bytes of storage, where N is the number of transferred register bytes and the other four bytes include the data instruction itself (one byte), the target address (two bytes), and the checksum calculated by the EEPROM controller during the upload sequence (one byte).

Programming the EEPROM to Configure an M Pin to Control Synchronization of Clock Distribution

A special EEPROM loading sequence is required to use the EEPROM to load the registers and to use an M pin to enable/disable outputs.

To control the output sync function by using an M pin, perform the following steps:

- 1. Enable the M pins by writing Register 0x0200 = 0x01.
- 2. Issue an I/O update (Register 0x0005 = 0x01).
- 3. Set the appropriate M pin function (see the Clock Distribution Synchronization section for details).

If this sequence is not performed, a sync pulse is issued automatically.

The following changes write Register 0x0200 first and then issue an I/O update before writing the remaining M pin configuration registers in Register 0x0201 to Register 0x0208. The default EEPROM loading sequence from Register 0x0E10 to Register 0x0E16 is unchanged. The following steps must be inserted into the EEPROM storage sequence:

- 1. Register 0x0E17 = 0x00. Write one byte at Register 0x0200.
- 2. Register 0x0E18 = 0x02.
- 3. Register 0x0E19 = 0x00.
- Register 0x0E1A = 0x80. EEPROM command for an I/O update.
- 5. Register 0x0E1B = 0x10. Transfer 17 bytes to EEPROM.
- 6. Register 0x0E1C = 0x02. Transfer starts at Address 0x0201.
- 7. Register 0x0E1D = 0x01.

The rest of the EEPROM loading sequence is the same as the default EEPROM loading sequence, except that the register address of the EEPROM storage sequence is shifted down four bytes from the default. For example,

- Register 0x0E1E = default value of Register 0x0E1A = 0x2E
- Register 0x0E1F = default value of Register 0x0E1B = 0x03
- Register 0x0E20 = default value of Register 0x0E1C = 0x00
- ...
- Register 0x0E40 = default value of Register 0x0E1C = 0x3C = 0xFF
- (end of data)

SERIAL CONTROL PORT

The AD9557 serial control port is a flexible, synchronous serial communications port that provides a convenient interface to many industry-standard microcontrollers and microprocessors. The serial control port is compatible with most synchronous transfer formats, including I²C, Motorola SPI, and Intel SSR protocols. The serial control port allows read/write access to the AD9557 register map.

In SPI mode, single or multiple byte transfers are supported. The SPI port configuration is programmable via Register 0x0000. This register is integrated into the SPI control logic rather than in the register map and is distinct from the I²C Register 0x0000. It is also inaccessible to the EEPROM controller.

Although the AD9557 supports both the SPI and I²C serial port protocols, only one or the other is active following power-up (as determined by the M0 and M1 multifunction pins during the start-up sequence). That is, the only way to change the serial port protocol is to reset the device (or cycle the device power supply).

SPI/I²C PORT SELECTION

Because the AD9557 supports both SPI and I²C protocols, the active serial port protocol depends on the logic state of the PINCONTROL, M1, and M0 pins. The PINCONTROL pin must be low, and the state of the M0 and M1 pins determines the I²C address, or if SPI mode is enabled. See Table 24 for the I²C address assignments.

Table 24. SPI/I²C Serial Port Setup

SPI SERIAL PORT OPERATION

Pin Descriptions

The serial clock pin (SCLK) serves as the serial shift clock. This pin is an input. SCLK synchronizes serial control port read and write operations. The rising edge of SCLK registers write data bits, and the falling edge registers read data bits. The SCLK pin supports a maximum clock rate of 40 MHz.

The serial data input/output pin (SDIO) is a dual-purpose pin and acts as either an input only (unidirectional mode) or as both an input and an output (bidirectional mode). The AD9557 default SPI mode is bidirectional. The SDO (serial data output) pin is useful only in unidirectional I/O mode. It serves as the data output pin for read operations.

The chip select pin (\overline{CS}) is an active low control that gates read and write operations. This pin is internally connected to a 30 k Ω pull-up resistor. When \overline{CS} is high, the SDO and SDIO pins go into a high impedance state.

SPI Mode Operation

The SPI port supports both 3-wire (bidirectional) and 4-wire (unidirectional) hardware configurations and both MSB-first and LSB-first data formats. Both the hardware configuration and data format features are programmable. By default, the AD9557 uses the bidirectional MSB-first mode. The reason that bidirectional is the default mode is so that the user can still write to the device, if it is wired for unidirectional operation, to switch to unidirectional mode.

Assertion (active low) of the $\overline{\text{CS}}$ pin initiates a write or read operation to the AD9557 SPI port. For data transfers of three bytes or fewer (excluding the instruction word), the device supports the $\overline{\text{CS}}$ stalled high mode (see Table 25). In this mode, the $\overline{\text{CS}}$ pin can be temporarily deasserted on any byte boundary, allowing time for the system controller to process the next byte. $\overline{\text{CS}}$ can be deasserted only on byte boundaries, however. This applies to both the instruction and data portions of the transfer.

During stall high periods, the serial control port state machine enters a wait state until all data is sent. If the system controller decides to abort a transfer midstream, then the state machine must be reset either by completing the transfer or by asserting the \overline{CS} pin for at least one complete SCLK cycle (but less than eight SCLK cycles). Deasserting the \overline{CS} pin on a nonbyte boundary terminates the serial transfer and flushes the buffer.

In streaming mode (see Table 25), any number of data bytes can be transferred in a continuous stream. The register address is automatically incremented or decremented. \overline{CS} must be deasserted at the end of the last byte that is transferred, thereby ending the streaming mode.

| Table 25. | Byte | Transfer | Count |
|-----------|------|----------|-------|
| | | | |

| W1 | WO | Bytes to Transfer | Bytes to Transfer | | | |
|----|----|-------------------|-------------------|--|--|--|
| 0 | 0 | 1 | | | | |
| 0 | 1 | 2 | | | | |
| 1 | 0 | 3 | | | | |
| 1 | 1 | Streaming mode | | | | |

Communication Cycle—Instruction Plus Data

The SPI protocol consists of a two-part communication cycle. The first part is a 16-bit instruction word that is coincident with the first 16 SCLK rising edges and a payload. The instruction word provides the AD9557 serial control port with information regarding the payload. The instruction word includes the R/\overline{W} bit that indicates the direction of the payload transfer (that is, a read or write operation). The instruction word also indicates the number of bytes in the payload and the starting register address of the first payload byte.

Write

If the instruction word indicates a write operation, the payload is written into the serial control port buffer of the AD9557. Data bits are registered on the rising edge of SCLK. The length of the transfer (1, 2, or 3 bytes or streaming mode) depends on the W0 and W1 bits (see Table 25) in the instruction byte. When not streaming, \overline{CS} can be deasserted after each sequence of eight bits to stall the bus (except after the last byte, where it ends the cycle). When the bus is stalled, the serial transfer resumes when \overline{CS} is asserted. Deasserting the \overline{CS} pin on a nonbyte boundary resets the serial control port. Reserved or blank registers are not skipped over automatically during a write sequence. Therefore, the user must know what bit pattern to write to the reserved registers to preserve proper operation of the device. Generally, it does not matter what data is written to blank registers, but it is customary to write 0s.

Most of the serial port registers are buffered (see the Buffered/Active Registers section for details on the difference between buffered and active registers). Therefore, data written into buffered registers does not take effect immediately. An additional operation is required to transfer buffered serial control port contents to the registers that actually control the device. This is accomplished with an I/O update operation, which is performed in one of two ways. One is by writing a Logic 1 to Register 0x0005, Bit 0 (this bit is autoclearing). The other is to use an external signal via an appropriately programmed multifunction pin. The user can change as many register bits as desired before executing an I/O update. The I/O update operation transfers the buffer register contents to their active register counterparts.

Read

The AD9557 supports the long instruction mode only. If the instruction word indicates a read operation, the next N \times 8 SCLK cycles clock out the data from the address specified in the instruction word. N is the number of data bytes read and depends on the W0 and W1 bits of the instruction word. The readback data is valid on the falling edge of SCLK. Blank registers are not skipped over during readback.

A readback operation takes data from either the serial control port buffer registers or the active registers, as determined by Register 0x0004, Bit 0.

SPI Instruction Word (16 Bits)

The MSB of the 16-bit instruction word is R/W, which indicates whether the instruction is a read or a write. The next two bits, W1 and W0, indicate the number of bytes in the transfer (see Table 25). The final 13 bits are the register address (A12 to A0), which indicates the starting register address of the read/write operation (see Table 27).

SPI MSB-/LSB-First Transfers

The AD9557 instruction word and payload can be MSB first or LSB first. The default for the AD9557 is MSB first. The LSBfirst mode can be set by writing a 1 to Register 0x0000, Bit 6. Immediately after the LSB-first bit is set, subsequent serial control port operations are LSB first.

When MSB-first mode is active, the instruction and data bytes must be written from MSB to LSB. Multibyte data transfers in MSB-first format start with an instruction byte that includes the register address of the most significant payload byte. Subsequent data bytes must follow, in order, from high address to low address. In MSB-first mode, the serial control port internal address generator decrements for each data byte of the multibyte transfer cycle.

When Register 0x0000, Bit 6 = 1 (LSB first), the instruction and data bytes must be written from LSB to MSB. Multibyte data transfers in LSB-first format start with an instruction byte that includes the register address of the least significant payload byte, followed by multiple data bytes. The serial control port internal byte address generator increments for each byte of the multibyte transfer cycle.

For multibyte MSB-first (default) I/O operations, the serial control port register address decrements from the specified starting address toward Address 0x0000. For multibyte LSB-first I/O operations, the serial control port register address increments from the starting address toward Address 0x1FFF. Reserved addresses are not skipped during multibyte I/O operations; therefore, the user must write the default value to a reserved register and 0s to unmapped registers. Note that it is more efficient to issue a new write command than to write the default value to more than two consecutive reserved (or unmapped) registers.

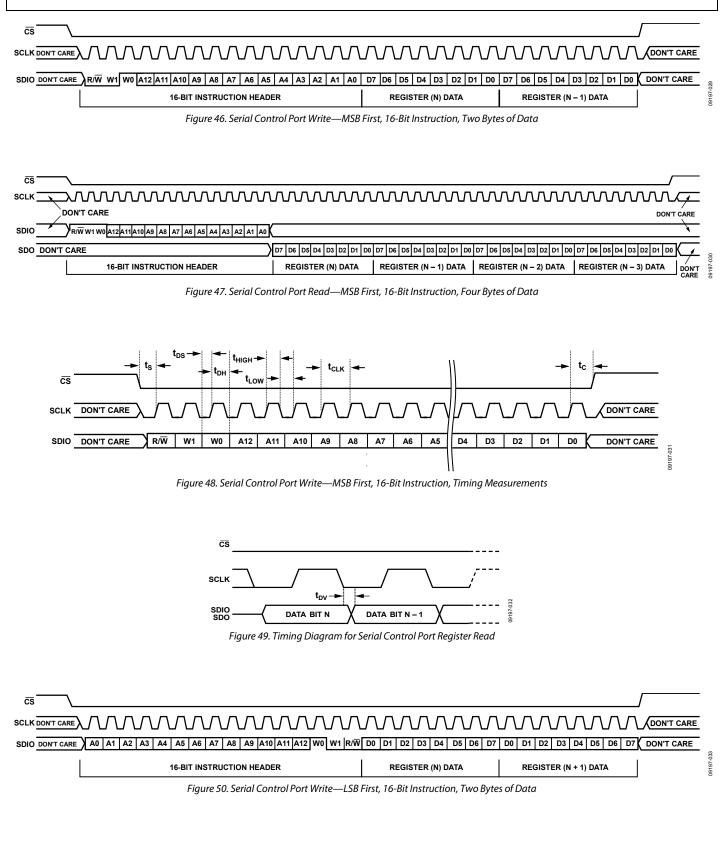

Table 26. Streaming Mode (No Addresses Are Skipped)

| Write Mode | Address Direction | Stop Sequence |
|------------|-------------------|---------------|
| LSB First | Increment | 0x0000 0x1FFF |
| MSB First | Decrement | 0x1FFF 0x0000 |

Data Sheet

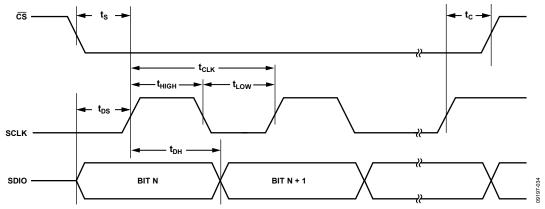

Figure 51. Serial Control Port Timing—Write

Table 28. Serial Control Port Timing

| Parameter | Description |
|-------------------|--|
| t _{DS} | Setup time between data and the rising edge of SCLK |
| t _{DH} | Hold time between data and the rising edge of SCLK |
| t _{clk} | Period of the clock |
| ts | Setup time between the CS falling edge and the SCLK rising edge (start of the communication cycle) |
| tc | Setup time between the SCLK rising edge and \overline{CS} rising edge (end of the communication cycle) |
| t _{HIGH} | Minimum period that SCLK needs to be in a logic high state |
| t _{LOW} | Minimum period that SCLK needs to be in a logic low state |
| t _{DV} | SCLK to valid SDIO and SDO (see Figure 49) |

I²C SERIAL PORT OPERATION

The I²C interface has the advantage of requiring only two control pins and is a de facto standard throughout the I2C industry. However, its disadvantage is programming speed, which is 400 kbps maximum. The AD9557 I²C port design is based on the I²C fast mode standard; therefore, it supports both the 100 kHz standard mode and 400 kHz fast mode. Fast mode imposes a glitch tolerance requirement on the control signals. That is, the input receivers ignore pulses of less than 50 ns duration.

The AD9557 I²C port consists of a serial data line (SDA) and a serial clock line (SCL). In an I²C bus system, the AD9557 is connected to the serial bus (data bus SDA and clock bus SCL) as a slave device; that is, no clock is generated by the AD9557. The AD9557 uses direct 16-bit memory addressing instead of traditional 8-bit memory addressing.

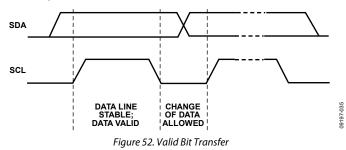

The AD9557 allows up to seven unique slave devices to occupy the I²C bus. These are accessed via a 7-bit slave address that is transmitted as part of an I²C packet. Only the device that has a matching slave address responds to subsequent I²C commands. Table 24 lists the supported device slave addresses.

I²C Bus Characteristics

A summary of the various I²C protocols appears in Table 29.

| Table 29. I ² C Bus Abbreviation Definitions | | | | |
|---|----------------|--|--|--|
| Abbreviation | Definition | | | |
| S | Start | | | |
| Sr | Repeated start | | | |
| Р | Stop | | | |
| A | Acknowledge | | | |
| Ā | Nonacknowledge | | | |
| W | Write | | | |
| R | Read | | | |

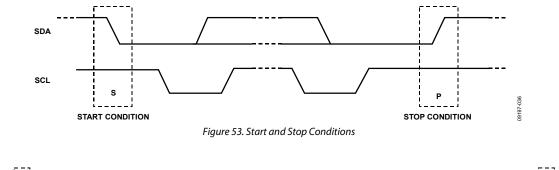

The transfer of data is shown in Figure 52. One clock pulse is generated for each data bit transferred. The data on the SDA line must be stable during the high period of the clock. The high or low state of the data line can change only when the clock signal on the SCL line is low.

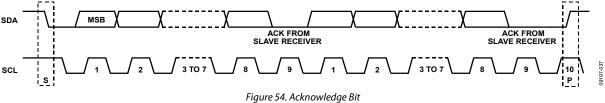

Start/stop functionality is shown in Figure 53. The start condition is characterized by a high-to-low transition on the SDA line while SCL is high. The start condition is always generated by the master to initialize a data transfer. The stop condition is characterized by a low-to-high transition on the SDA line while SCL is high. The stop condition is always generated by the master to terminate a data transfer. Every byte on the SDA line must be eight bits long. Each byte must be followed by an acknowledge bit; bytes are sent MSB first.

The acknowledge bit (A) is the ninth bit attached to any 8-bit data byte. An acknowledge bit is always generated by the receiving device (receiver) to inform the transmitter that the byte has been received. It is done by pulling the SDA line low during the ninth clock pulse after each 8-bit data byte.

The nonacknowledge bit (\overline{A}) is the ninth bit attached to any 8bit data byte. A nonacknowledge bit is always generated by the receiving device (receiver) to inform the transmitter that the byte has not been received. It is done by leaving the SDA line high during the ninth clock pulse after each 8-bit data byte.

Rev. C | Page 51 of 95

Data Transfer Process

The master initiates data transfer by asserting a start condition. This indicates that a data stream follows. All I²C slave devices connected to the serial bus respond to the start condition.

The master then sends an 8-bit address byte over the SDA line, consisting of a 7-bit slave address (MSB first) plus an R/W bit. This bit determines the direction of the data transfer, that is, whether data is written to or read from the slave device (0 = write, 1 = read).

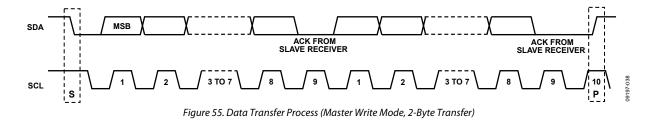

The peripheral whose address corresponds to the transmitted address responds by sending an acknowledge bit. All other devices on the bus remain idle while the selected device waits for data to be read from or written to it. If the R/\overline{W} bit is 0, the master (transmitter) writes to the slave device (receiver). If the R/\overline{W} bit is 1, the master (receiver) reads from the slave device (transmitter).

The format for these commands is described in the Data Transfer Format section.

Data is then sent over the serial bus in the format of nine clock pulses: one data byte (eight bits) from either master (write mode) or slave (read mode) followed by an acknowledge bit from the receiving device. The number of bytes that can be transmitted per transfer is unrestricted. In write mode, the first two data bytes immediately after the slave address byte are the internal memory (control registers) address bytes, with the high address byte first. This addressing scheme gives a memory address of up to $2^{16} - 1 = 65,535$. The data bytes after these two memory address bytes are register data written to or read from the control registers. In read mode, the data bytes after the slave address byte are register data written to or read from the control registers.

When all data bytes are read or written, stop conditions are established. In write mode, the master (transmitter) asserts a stop condition to end data transfer during the 10th clock pulse following the acknowledge bit for the last data byte from the slave device (receiver). In read mode, the master device (receiver) receives the last data byte from the slave device (transmitter) but does not pull SDA low during the ninth clock pulse. This is known as a nonacknowledge bit. By receiving the nonacknowledge bit, the slave device knows that the data transfer is finished and enters idle mode. The master then takes the data line low during the low period before the 10th clock pulse, and high during the 10th clock pulse to assert a stop condition.

A start condition can be used in place of a stop condition. Furthermore, a start or stop condition can occur at any time, and partially transferred bytes are discarded.

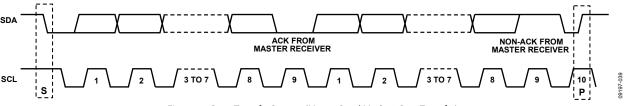

Figure 56. Data Transfer Process (Master Read Mode, 2-Byte Transfer)

Data Transfer Format

Write byte format—the write byte protocol is used to write a register address to the RAM, starting from the specified RAM address.

| S | Slave address | W | Α | RAM address high byte | Α | RAM address low byte | Α | RAM Data 0 | A | RAM Data 1 | Α | RAM Data 2 | A | Ρ |
|---|------------------|---|---|--------------------------|---|-------------------------|---|---------------|---|---------------|---|---------------|---|---|
|---|------------------|---|---|--------------------------|---|-------------------------|---|---------------|---|---------------|---|---------------|---|---|

Send byte format—the send byte protocol is used to set up the register address for subsequent reads.

| | S | Slave address | W | Α | RAM address high byte | Α | RAM address low byte | Α | Ρ |
|--|---|---------------|---|---|-----------------------|---|----------------------|---|---|
|--|---|---------------|---|---|-----------------------|---|----------------------|---|---|

Receive byte format—the receive byte protocol is used to read the data byte(s) from RAM, starting from the current address.

| S | Slave address | R | Α | RAM Data 0 | Α | RAM Data 1 | Α | RAM Data 2 | Ā | Ρ |
|---|---------------|---|---|------------|---|------------|---|------------|---|---|
|---|---------------|---|---|------------|---|------------|---|------------|---|---|

Read byte format-the combined format of the send byte and the receive byte.

| Γ | S | Slave | W | Α | RAM | Α | RAM | Α | Sr | Slave | R | Α | RAM | Α | RAM | Α | RAM | Ā | Ρ |
|---|---|---------|---|---|-----------|---|----------|---|----|---------|---|---|--------|---|--------|---|--------|---|---|

| | | | | | High Byte | | Low Byte | | | | | | | | | | | | |

I²C Serial Port Timing

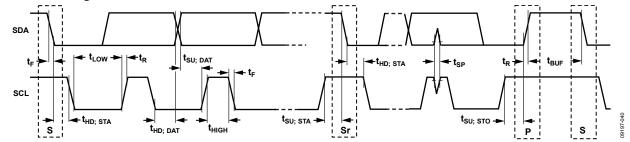

Figure 57. I²C Serial Port Timing

Table 30. I²C Timing Definitions

| Parameter | Description |
|------------------|---|
| f _{SCL} | Serial clock |
| tbuf | Bus free time between stop and start conditions |
| thd; sta | Repeated hold time start condition |
| tsu; sta | Repeated start condition setup time |
| tsu; sto | Stop condition setup time |
| thd; dat | Data hold time |
| tsu; dat | Date setup time |
| t _{LOW} | SCL clock low period |
| tніgн | SCL clock high period |
| t _R | Minimum/maximum receive SCL and SDA rise time |
| t _F | Minimum/maximum receive SCL and SDA fall time |
| t _{sp} | Pulse width of voltage spikes that must be suppressed by the input filter |

PROGRAMMING THE I/O REGISTERS

The register map spans an address range from 0x0000 through 0x0E3C. Each address provides access to 1 byte (eight bits) of data. Each individual register is identified by its four-digit hexadecimal address (for example, Register 0x0A10). In some cases, a group of addresses collectively defines a register.

In general, when a group of registers defines a control parameter, the LSB of the value resides in the D0 position of the register with the lowest address. The bit weight increases right to left, from the lowest register address to the highest register address.

Note that the EEPROM storage sequence registers (Address 0x0E10 to Address 0x0E3C) are an exception to the above convention (see the EEPROM Instructions section).

BUFFERED/ACTIVE REGISTERS

There are two copies of most registers: buffered and active. The value in the active registers is the one that is in use. The buffered registers are the ones that take effect the next time the user writes 0x01 to the I/O update register (Register 0x0005). Buffering the registers allows the user to update a group of registers (like the digital loop filter coefficients) at the same time, which avoids the potential of unpredictable behavior in the device. Registers with an L in the option column are live, meaning that they take effect the moment the serial port transfers that data byte.

AUTOCLEAR REGISTERS

An A in the option column of the register map identifies an autoclear register. Typically, the active value for an autoclear register takes effect following an I/O update. The bit is cleared by the internal device logic upon completion of the prescribed action.

REGISTER ACCESS RESTRICTIONS

Read and write access to the register map may be restricted depending on the register in question, the source and direction of access, and the current state of the device. Each register can be classified into one or more access types. When more than one type applies, the most restrictive condition is the one that applies.

Whenever access is denied to a register, all attempts to read the register return a 0 byte, and all attempts to write to the register are ignored. Access to nonexistent registers is handled in the same way as for a denied register.

Regular Access

Registers with regular access do not fall into any other category. Both read and write access to registers of this type can be from either the serial ports or the EEPROM controller. However, only one of these sources can have access to a register at any given time (access is mutually exclusive). When the EEPROM controller is active, in either load or store mode, it has exclusive access to these registers.

Read-Only Access

An R in the option column of the register map identifies readonly registers. Access is available at all times, including when the EEPROM controller is active. Note that read-only registers (R) are inaccessible to the EEPROM, as well.

Exclusion from EEPROM Access

An E in the option column of the register map identifies a register with contents that are inaccessible to the EEPROM. That is, the contents of this type of register cannot be transferred directly to the EEPROM or vice versa. Note that read-only registers (R) are inaccessible to the EEPROM, as well.

THERMAL PERFORMANCE

Table 31. Thermal Parameters for the 40-Lead LFCSP Package

| Symbol | Thermal Characteristic Using a JEDEC51-7 Plus JEDEC51-5 2S2P Test Board ¹ | Value ² | Unit |
|-----------------|---|--------------------|------|
| θ _{JA} | Junction-to-ambient thermal resistance, 0.0 m/sec airflow per JEDEC JESD51-2 (still air) | 30.2 | °C/W |
| θјма | Junction-to-ambient thermal resistance, 1.0 m/sec airflow per JEDEC JESD51-6 (moving air) | 26.4 | °C/W |
| θјма | Junction-to-ambient thermal resistance, 2.5 m/sec airflow per JEDEC JESD51-6 (moving air) | 23.6 | °C/W |
| Өлв | Junction-to-board thermal resistance, 0.0 m/sec airflow per JEDEC JESD51-8 (still air) | 16.3 | °C/W |
| θις | Junction-to-case thermal resistance (die-to-heat sink) per MIL-Std 883, Method 1012.1 | 2.2 | °C/W |
| ψ_{JT} | Junction-to-top-of-package characterization parameter, 0 m/sec airflow per JEDEC JESD51-2 (still air) | 0.2 | °C/W |

¹ The exposed pad on the bottom of the package must be soldered to ground to achieve the specified thermal performance.

² Results are from simulations. The PCB is a JEDEC multilayer type. Thermal performance for actual applications requires careful inspection of the conditions in the application to determine if they are similar to those assumed in these calculations.

The AD9557 is specified for a case temperature (T_{CASE}). To ensure that T_{CASE} is not exceeded, an airflow source can be used. Use the following equation to determine the junction temperature on the application PCB:

 $T_J = T_{CASE} + (\Psi_{JT} \times PD)$

where:

 T_J is the junction temperature (°C).

 T_{CASE} is the case temperature (°C) measured by the user at the top center of the package.

 Ψ_{JT} is the value as indicated in Table 31.

PD is the power dissipation (see Table 3).

Values of θ_{JA} are provided for package comparison and PCB design considerations. θ_{JA} can be used for a first order approximation of T_J by the equation:

 $T_J = T_A + (\theta_{JA} \times PD)$

where T_A is the ambient temperature (°C).

Values of θ_{IC} are provided for package comparison and PCB design considerations when an external heat sink is required.

Values of θ_{IB} are provided for package comparison and PCB design considerations.

POWER SUPPLY PARTITIONS

The AD9557 power supplies are divided into four groups: DVDD3, DVDD, AVDD3, and AVDD. All power and ground pins must be connected, even if certain blocks of the chip are powered down.

This section recommends the use of ferrite beads. Most users report that the use of bypass capacitors together with ferrite beads is the best arrangement, although some have reported that ferrite beads alone are superior.

RECOMMENDED CONFIGURATION FOR 3.3 V SWITCHING SUPPLY

A popular power supply arrangement is to power the AD9557 with the output of a 3.3 V switching power supply.

When the AD9557 is powered using 3.3 V switching power supplies, all of the 3.3 V supplies can be connected to the 3.3 V switcher output, and a 0.1 μ F bypass capacitor must be placed adjacent to each 3.3 V power supply pin.

CONFIGURATION FOR 1.8 V SUPPLY

When 1.8 V supplies are preferred, it is recommended that an LDO regulator, such as the ADP222, be used to generate the 1.8 V supply from the 3.3 V supply.

The ADP222 offers excellent power supply rejection in a small $(2 \text{ mm} \times 2 \text{ mm})$ package. It has two 1.8 V outputs. One output can be used for the DVDD pins (Pin 6, Pin 34, and Pin 35), and the other output can drive the AVDD pins.

The ADP7104 is another good choice for converting 3.3 V to 1.8 V. The close-in noise of the ADP7104 is lower than that of the ADP222; therefore, it may be better suited for applications where close-in phase noise is critical and the AD9557 DPLL loop bandwidth is <50 Hz. In such cases, all 1.8 V supplies can be connected to one ADP7104.

Use of Ferrite Beads on 1.8 V Supplies

To ensure the best output to output isolation, use one ferrite bead for each of the following AVDD pins: Pin 11, Pin 17, and Pin 18. The ferrite beads must be placed in between the 1.8 V LDO output and each pin listed previously. Ferrite beads that have low (<0.7 Ω) dc resistance and approximately 600 Ω impedance at 100 MHz are suitable for this application.

Pin 6 and Pin 35 are 1.8 V digital supplies, and while they are not susceptible to external noise, they are themselves a source of digital noise. Therefore, a ferrite bead is recommended for each of these pins. Pin 34 and Pin 35 can be joined together a powered from one power supply.

See Table 2 for the current consumed by each group. Refer to Figure 20, Figure 21, and Figure 22 for information on the power consumption vs. output frequency.

PIN PROGRAM FUNCTION DESCRIPTION

The AD9557 supports both hard pin and soft pin program function, with the on-chip ROM containing the predefined configurations. When a pin program function is enabled and initiated, the selected, predefined configuration is transferred from the ROM to the corresponding registers to configure the device into the desired state.

OVERVIEW OF ON-CHIP ROM FEATURES Input/Output Frequency Translation Configuration

The AD9557 has one on-chip ROM that contains a total of 256 different input-output frequency translation configurations for independent selection of 16 input frequencies and 16 output frequencies. Each input/output frequency translation configuration assumes that all input frequencies are the same and all the output frequencies are the same. Each configuration reprograms the following registers/parameters:

- Reference input period register
- Reference divider R register
- Digital PLL feedback divider register (Fractional Part FRAC1, Modulus Part MOD1 and Integer Part N1) free run
- Tuning word register
- Output PLL feedback divider N2 register
- RF divider register
- Clock distribution channel divider register

All configurations are set to support one single system clock frequency as 786.432 MHz ($16 \times$ the default 49.152 MHz system clock reference frequency).

Four Different System Clock PLL Configurations

- REF = 49.152 MHz XO (×2 on, N = 8)
- REF = 49.152 MHz XTAL (×2 on, N = 8)
- REF = 24.756 MHz XTAL (×2 on, N = 16)
- REF = 98.304 MHz XO (×2 off, N = 8)

Four Different DPLL Loop Bandwidths

• 1 Hz, 10 Hz, 50 Hz, 100 Hz

DPLL Phase Margin

- Normal phase margin (70°)
- High phase margin (88.5°)

The ROM also contains an APLL VCO calibration bit. This bit is used to program Register 0x0405, Bit 0 (from 0) to 1 to generate a low-high transition to automatically initiate APLL VCO calibration.

HARD PIN PROGRAMMING MODE

The state of the PINCONTROL pin at power-up controls whether or not the chip is in hard pin programming mode. Setting the PINCONTROL pin high disables the I²C protocol, although the register map can be accessed via the SPI protocol.

The M0 pin selects one of three input frequencies, and the M3 to M1 pins select one of 16 possible output frequencies. See Table 32 and Table 33 for details.

The system clock configuration is controlled by the state of the IRQ pin at startup (see Table 34). The digital PLL loop bandwidth, reference input frequency accuracy tolerance ranges, and DPLL phase margin selection are not available in hard pin programming mode unless the user uses the serial port to change their default values.

When in hard pin programming mode, the user must set Register 0x0200, Bit 0 = 1 to activate the IRQ, REF status, and PLL lock status signals at the multifunction pins.

SOFT PIN PROGRAMMING MODE OVERVIEW

The soft pin programming function is controlled by a dedicated register section (Address 0x0C00 to Address 0x0C08). The purpose of soft pin programming is to use the register bits to mimic the hard pins for the configuration section. When in soft pin programming mode, both the SPI and I²C ports are available.

- Address 0x0C00, Bit 0 enables accessibility to Address 0x0C01 and Address 0x0C02 (Soft Pin Section 1). This bit must be set in soft pin mode.
- Address 0x0C03, Bit 0 enables accessibility to Address 0x0C04 to Address 0x0C06 (Soft Pin Section 2). This bit must be set in soft pin mode.
- Address 0x0C01, Bits[3:0] select one of 16 input frequencies.
- Address 0x0C01, Bits[7:4] select one of 16 output frequencies.
- Address 0x0C02, Bits[1:0] select the system clock configuration.
- Address 0x0C06, Bits[1:0] select one of four input frequency tolerance ranges.
- Address 0x0C06, Bits[3:2] select one of four DPLL loop bandwidths.
- Address 0x0C06, Bit 4 selects the DPLL phase margin.
- Address 0x0C04, Bits[3:0] scale the REFA and REFB input frequency down by divide-by-1, -4, -8, or -16 independently. For example, when Address 0x0C01[3:0] = 0101 to select 622.08 MHz input frequency for both REFA and REFB, setting Address 0x0C04[1:0] = 0x01 scales down the REFA input frequency to 155.52 MHz (= 622.08 MHz/4). This is done by internally scaling the R divider for REFA up by 4× and the REFA period up by 4×.
- Address 0x0C05, Bits[3:0] scale the Channel 0 and Channel 1 output frequency down by divide-by-1, divide-by-4, divide-by-8, or divide-by-16.

REGISTER MAP

Register addresses that are not listed in Table 35 are not used, and writing to those registers has no effect. The user should write the default value to sections of registers marked reserved. R means read only. A means autoclear. E means excluded from EEPROM loading. L means live (I/O update not required for register to take effect or for a read-only register to be updated).

REGISTER MAP BIT DESCRIPTIONS

SERIAL PORT CONFIGURATION (REGISTER 0x0000 TO REGISTER 0x0005)

Table 36. Serial Configuration (Note that the Contents of Register 0x0000 are Not Stored to the EEPROM)

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------------------|---|
| 0x0000 | 7 | SDO enable | Enables SPI port SDO pin. |
| | | | 1 = 4-wire (SDO pin enabled). |
| | | | 0 (default) = 3-wire. |
| | 6 | LSB first/increment address | Bit order for SPI port. |
| | | | 1 = least significant bit and byte first. |
| | | | Register addresses are automatically incremented in multibyte transfers. |
| | | | 0 (default) = most significant bit and byte first. |
| | | | Register addresses are automatically decremented in multibyte transfers. |
| | 5 | Soft reset | Device reset (invokes an EEPROM download or pin program ROM download if EEPROM or pin program is enabled. See the EEPROM and Pin Configuration and Function Descriptions for details. |
| | [4:0] | Reserved | Reserved. |

Table 37. Readback Control

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------|---|
| 0x0004 | [7:1] | Reserved | Reserved. |
| | 0 | Read buffer register | For buffered registers, serial port read-back reads from actual (active) registers instead of the buffer. |
| | | | 1 = reads buffered values that take effect on next assertion of I/O update. 0 (default) = reads values currently applied to the device's internal logic. |

Table 38. Soft I/O Update

| Address | Bits | Bit Name | Description |
|---------|-------|------------|--|
| 0x0005 | [7:1] | Reserved | Reserved. |
| | 0 | I/O update | Writing a 1 to this bit transfers the data in the serial I/O buffer registers to the device's internal control registers of the device. Unless a register is marked as live (as indicated by an L in the Opt column of the register map), the user must write to this bit before any register settings can take effect and before a read-only register can be updated with the most current value. This is an autoclearing bit. |

Table 39. User Scratch Pad

| Address | Bits | Bit Name | Description |
|---------|-------|------------------------|--|
| 0x0006 | [7:0] | User scratch pad[7:0] | User programmable EEPROM ID registers. These registers enable users to write a unique code of their choosing to keep track of revisions to the EEPROM register loading. It has |
| 0x0007 | [7:0] | User scratch pad[15:8] | no effect on part operation. 0 = default. |

SILICON REVISION (REGISTER 0x000A)

Table 40. Silicon Revision

| Address | Bits | Bit Name | Description |
|---------|-------|------------------|--|
| 0x000A | [7:0] | Silicon revision | This read-only register identifies the revision level of the AD9557. |

CLOCK PART SERIAL ID (REGISTER 0x000C TO REGISTER 0x000D)

Table 41. Clock Part Family ID

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------------|--|
| 0x000C | [7:0] | Clock part family ID[7:0] | This read-only register (along with Register 0x000D) uniquely identifies an AD9557 or AD9558. No other part in the Analog Devices AD95xx family has a value of 0x0001 in these two registers. Default: 0x01 for the AD9557 and AD9558. |
| 0x000D | [7:0] | Clock part family ID[15:8] | This register is a continuation of Register 0x000C. Default: 0x00 for the AD9557 and AD9558. |

SYSTEM CLOCK (REGISTER 0x0100 TO REGISTER 0x0108)

Table 42. System Clock PLL Feedback Divider (N3 Divider)

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------|--|
| 0x0100 | [7:0] | SYSCLK N3 divider | System clock PLL feedback divider value: $4 \le N3 \le 255$ (default: 0x08). |

Table 43. SYSCLK Configuration

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------|---|
| 0x0101 | [7:5] | Reserved | Reserved. |
| | 4 | Load from ROM (read only) | This read-only bit is set if the PINCONTROL pin was high during the last RESET or power-on. |
| | | | 0 = The PINCONTROL pin was low at power-on (or reset). |
| | | | 1 = The PINCONTROL pin was high at power-on (or reset). |
| | 3 | SYSCLK XTAL enable | Enables the crystal maintaining amplifier for the system clock input. 1 (default) = crystal mode (crystal maintaining amplifier enabled). 0 = external XO or other system clock source. |
| | [2:1] | SYSCLK P divider | System clock input divider. 00 (default) = 1. 01 = 2. 10 = 4. 11 = 8. |
| | 0 | SYSCLK doubler enable | Enable clock doubler on system clock input to reduce noise. 0 = disable. 1 (default) = enable. |

Table 44. Nominal System Clock Period¹

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------------------|--|
| 0x0103 | [7:0] | Nominal system clock period (fs) | System clock period, Bits[7:0]. Default: 0x0E. |
| 0x0104 | [7:0] | | System clock period, Bits[15:8]. Default: 0x67. |
| 0x0105 | [7:5] | Reserved | Reserved. |
| | [4:0] | Nominal system clock period (fs) | System clock period, Bits[20:16]. Default: 0x13. |

 1 Note that the default setting for system clock period is 1.271566 ns, which is the period of 786.432 MHz (= 49.152 MHz \times 16).

Table 45. System Clock Stability Period

| Address | Bits | Bit Name | Description |
|---------|-------|------------------------------------|---|
| 0x0106 | [7:0] | System clock stability period (ms) | System clock period, Bits[7:0]. Default: 0x32 (0x000032 = 50 ms). |
| 0x0107 | [7:0] | | System clock period, Bits[15:8]. Default: 0x00. |
| 0x0108 | [7:5] | Reserved | Reserved. |
| | 4 | Reset SYSCLK stability timer | This autoclearing bit resets the system clock stability timer. |
| | [3:0] | System clock stability period | System clock period, Bits[19:16]. Default: 0x00. |

GENERAL CONFIGURATION (REGISTER 0x0200 TO REGISTER 0x0214)

Multifunction Pin Control (M3 to M0) and IRQ Pin Control (Register 0x0200 to Register 0x0209)

Note that the default setting for the M3 to M0 multifunction pins and the IRQ pin is that of a 3-level logic input at startup. Setting Bit 1 in Register 0x0200 to 1 enables normal M3 to M0 pin functionality.

| Address | Bits | Bit Name | Description |
|---------|-------|------------------------------------|---|
| 0x0200 | [7:1] | Reserved | Reserved. |
| | 0 | Enable M pins and IRQ pin function | 0 (default) = disables the function of the M pins and the IRQ pin control register (Address 0x0201 to Address 0x0209); the M pins and IRQ pin are in 3-level logic input state. 1 = the M pins and IRQ pin are out of 3-level logic input state and enable the binary function of the M pins and the IRQ pin control registers (Address 0x0201 to Address 0x0209). |
| 0x0201 | 7 | M0 output/input | In/out control for M0 pin. 0 = input (2-level logic control pin). 1 (default) = output (2-level logic status pin). |
| | [6:0] | Function | See Table 124 and Table 125. Default: 0xB0 = REFA valid. |
| 0x0202 | 7 | M1 output/input | In/out control for M1 pin (same as M0). |
| | [6:0] | Function | See Table 124 and Table 125. Default: 0xB1 = REFB valid. |
| 0x0203 | 7 | M2 output/input | In/out control for M2 pin (same as M0). |
| | [6:0] | Function | See Table 124 and Table 125. Default: 0xC0 = REFA active. |
| 0x0204 | 7 | M3 output/input | In/out control for M3 pin (same as M0). |
| | [6:0] | Function | See Table 124 and Table 125. Default: 0xC1 = REFB active. |
| 0x0205 | [7:0] | Reserved | Reserved. |
| 0x0206 | [7:0] | Reserved | Reserved. |
| 0x0207 | [7:0] | Reserved | Reserved. |
| 0x0208 | [7:0] | Reserved | Reserved. |

Table 46. Multifunction Pins (M0 to M3) Control

Table 47. IRQ Pin Output Mode

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------------------|--|
| 0x0209 | [7:5] | Reserved | Reserved |
| | [4:3] | Status signal at IRQ pin[1:0] | This selection is valid only when Address 0x0209, Bit 2 = 1 |
| | | | 00 = DPLL phase locked |
| | | | 01 = DPLL frequency locked |
| | | | 10 = system clock PLL locked |
| | | | 11 (default) = (DPLL phase locked) AND (system clock PLL locked) AND (APLL locked) |
| | 2 | Use IRQ pin for status signal | 0 = uses IRQ pin to monitor IRQ event |
| | | | 1 (default) = uses IRQ pin to monitor internal status signals |
| | [1:0] | IRQ pin driver type | Select the output mode of the IRQ pin |
| | | | 00 = NMOS, open drain (requires an external pull-up resistor) |
| | | | 01 = PMOS, open drain (requires an external pull-down resistor) |
| | | | 10 (default) = CMOS, active high |
| | | | 11 = CMOS, active low |

IRQ MASK (REGISTER 0x020A TO REGISTER 0x020F)

The IRQ mask register bits form a one-to-one correspondence with the bits of the IRQ monitor register (0x0D02 to 0x0D09). When set to Logic 1, the IRQ mask bits enable the corresponding IRQ monitor bits to indicate an IRQ event. The default for all IRQ mask bits is Logic 0, which prevents the IRQ monitor from detecting any internal interrupts.

Table 48. IRQ Mask for SYSCLK

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------|--|
| 0x020A | [7:6] | Reserved | Reserved |
| | 5 | SYSCLK unlocked | Enables IRQ for indicating a SYSCLK PLL state transition from locked to unlocked |
| | 4 | SYSCLK locked | Enables IRQ for indicating a SYSCLK PLL state transition from unlocked to locked |
| | 3 | APLL unlocked | Enables IRQ for indicating a APLL state transition from locked to unlocked |
| | 2 | APLL locked | Enables IRQ for indicating a APLL state transition from unlocked to locked |
| | 1 | APLL cal complete | Enables IRQ for indicating that APLL (LCVCO) calibration has completed |
| | 0 | APLL cal started | Enables IRQ for indicating that APLL (LCVCO) calibration has begun |

Table 49. IRQ Mask for Distribution Sync, Watchdog Timer, and EEPROM

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------|--|
| 0x020B | [7:5] | Reserved | Reserved |
| | 4 | Pin program end | Enables IRQ for indicating successful completion of an pin program ROM load |
| | 3 | Sync distribution | Enables IRQ for indicating a distribution sync event |
| | 2 | Watchdog timer | Enables IRQ for indicating expiration of the watchdog timer |
| | 1 | EEPROM fault | Enables IRQ for indicating a fault during an EEPROM load or save operation |
| | 0 | EEPROM complete | Enables IRQ for indicating successful completion of an EEPROM load or save operation |

Table 50. IRQ Mask for the Digital PLL

| Address | Bits | Bit Name | Description |
|---------|------|--------------------|--|
| 0x020C | 7 | Switching | Enables IRQ for indicating that the DPLL is switching to a new reference |
| | 6 | Closed | Enables IRQ for indicating that the DPLL has entered closed-loop operation |
| | 5 | Freerun | Enables IRQ for indicating that the DPLL has entered free run mode |
| | 4 | Holdover | Enables IRQ for indicating that the DPLL has entered holdover mode |
| 3 Fre | | Frequency unlocked | Enables IRQ for indicating that the DPLL lost frequency lock |
| | 2 | Frequency locked | Enables IRQ for indicating that the DPLL has acquired frequency lock |
| | 1 | Phase unlocked | Enables IRQ for indicating that the DPLL lost phase lock |
| | 0 | Phase locked | Enables IRQ for indicating that the DPLL has acquired phase lock |

Table 51. IRQ Mask for History Update, Frequency Limit and Phase Slew Limit

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------|---|
| 0x020D | [7:5] | Reserved | Reserved |
| | 4 | History updated | Enables IRQ for indicating the occurrence of a tuning word history update |
| | 3 | Frequency unclamped | Enables IRQ for indicating a frequency limit state transition from clamped to unclamped |
| | 2 | Frequency clamped | Enables IRQ for indicating a state transition of the frequency limiter from unclamped to clamped |
| | 1 | Phase slew unlimited | Enables IRQ for indicating a state transition of the phase slew limiter from slew limiting to not slew limiting |
| | 0 | Phase slew limited | Enables IRQ for indicating a state transition of the phase slew limiter from not slew limiting to slew limiting |

Table 52. IRQ Mask for Reference Inputs

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------|---|
| 0x020E | 7 | Reserved | Reserved |
| | 6 | REFB validated | Enables IRQ for indicating that REFB has been validated |
| | 5 | REFB fault cleared | Enables IRQ for indicating that REFB has been cleared of a previous fault |
| | 4 | REFB fault | Enables IRQ for indicating that REFB has been faulted |
| | 3 | Reserved | Reserved |
| | 2 | REFA validated | Enables IRQ for indicating that REFA has been validated |
| | 1 | REFA fault cleared | Enables IRQ for indicating that REFA has been cleared of a previous fault |
| | 0 | REFA fault | Enables IRQ for indicating that REFA has been faulted |
| 0x020F | [7:0] | Reserved | Reserved |

Table 53. Watchdog Timer 11

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------|---|
| 0x0210 | [7:0] | Watchdog timer (ms) | Watchdog timer bits[7:0] Default: 0x00 |
| 0x0211 | [7:0] | | Watchdog timer bits[15:8] Default: 0x00 |

¹Note that the watchdog timer is expressed in units of milliseconds (ms). The default value is 0 (disabled).

DPLL CONFIGURATION (REGISTER 0x0300 TO REGISTER 0x032E)

Table 54. Free Run Frequency Tuning Word¹

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------------------|---|
| 0x0300 | [7:0] | 30-bit free run frequency tuning word | Free run frequency tuning word bits[7:0]; default: 0x11 |
| 0x0301 | [7:0] | | Free run frequency tuning word bits[15:8]; default: 0x15 |
| 0x0302 | [7:0] | | Free run frequency tuning word bits[23:9]; default: 0x64 |
| 0x0303 | [7:6] | Reserved | Reserved |
| | [5:0] | 30-bit free run frequency word | Free run frequency tuning word bits[29:24]: default: 0x1B |

¹ Note that the default free run tuning word is 0x1B641511, which is used for 8 kHz/19.44 MHz = 622.08 MHz translation.

Table 55. Digital Oscillator Control

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------|---------------------------------------|
| 0x0304 | [7:6] | Reserved | Default: 00b |
| | 5 | DCO 4-level output | 0 (default) = DCO 3-level output mode |
| | | | 1 = enables DCO 4-level output mode |
| | 4 | Reserved | Reserved (must be set to 1b) |
| | [3:0] | Reserved | Reserved (default: 0x0) |

Table 56. DPLL Frequency Clamp

| Address | Bits | Bit Name | Description |
|---------|-------|--|---|
| 0x0306 | [7:0] | Lower limit of pull-in range (expressed as a 20-bit frequency tuning word) | Lower limit pull-in range bits[7:0] Default: 0x51 |
| 0x0307 | [7:0] | | Lower limit pull-in range bits[15:8] Default: 0xB8 |
| 0x0308 | [7:4] | Reserved | Default: 0x0 |
| | [3:0] | Lower limit of pull-in range | Lower limit pull-in range bits[19:16] Default: 0x2 |
| 0x0309 | [7:0] | Upper limit of pull-in range (expressed as a 20-bit frequency tuning word) | Upper limit pull-in range bits[7:0] Default: 0x3E |
| 0x030A | [7:0] | | Upper limit pull-in range bits[15:8] Default: 0x0A |
| 0x030B | [7:4] | Reserved | Default: 0x0 |
| | [3:0] | Upper limit of pull-in range | Upper limit pull-in range bits[19:16] Default: 0xB |

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------------------------|--|
| 0x030C | [7:0] | Fixed phase lock offset (signed; ps) | Fixed phase lock offset bits[7:0] Default: 0x00 |
| 0x030D | [7:0] | | Fixed phase lock offset bits[15:8] Default 0x00 |
| 0x030E | [7:0] | | Fixed phase lock offset bits[23:16] Default: 0x00 |
| 0x030F | [7:6] | Reserved | Reserved; default: 0x0 |
| | [5:0] | Fixed phase lock offset (signed; ps) | Fixed phase lock offset bits[29:24] Default: 0x00 |

Table 57. Fixed Closed-Loop Phase Lock Offset

Table 58. Incremental Closed-Loop Phase Lock Offset Step Size¹

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------------------|---|
| 0x0310 | [7:0] | Incremental phase lock offset | Incremental phase lock offset step size bits[7:0]. |
| | | step size (ps) | Default: 0x00. |
| | | | This controls the static phase offset of the DPLL while it is locked. |
| 0x0311 | [7:0] | | Incremental phase lock offset step size bits[15:8] Default: 0x00. |
| | | | This controls the static phase offset of the DPLL while it is locked. |

¹ Note that the default incremental closed-loop phase lock offset step size value is 0x0000 = 0 (0 ns).

Table 59. Phase Slew Rate Limit

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------------------|--|
| 0x0312 | [7:0] | Phase slew rate limit (µs/sec) | Phase slew rate limit bits[7:0]. Default: 0x00. This register controls the maximum allowable phase slewing during transients and reference switching. The default phase slew rate limit is 0, or disabled. Minimum useful value is 310 µs/sec. |
| 0x0313 | [7:0] | | Phase slew rate limit bits[15:8]. Default: 0x00. |

Table 60. History Accumulation Timer

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------------|--|
| 0x0314 | [7:0] | History accumulation timer (ms) | History accumulation timer bits[7:0]. Default: 0x0A. For Register 0x0314 and Register 0x0315, 0x000A = 10 ms. Maximum is 65 sec. This register controls the amount of tuning word averaging used to determine the tuning word used in holdover. Never program a timer value of zero. The default value is 0x000A = 10 decimal, which equates to 10 ms. |
| 0x0315 | [7:0] | | History accumulation timer bits[15:8]. Default: 0x00. |

Table 61. History Mode

| Address | Bits | Bit Name | Description | | | |
|--------------|------|------------------------|---|--|--|--|
| 0x0316 [7:5] | | Reserved | Reserved. | | | |
| | 4 | Single sample fallback | Controls holdover history. If tuning word history is not available for the reference that was active just prior to holdover, then: 0 (default) = uses the free run frequency tuning word register value. 1 = uses the last tuning word from the DPLL. | | | |
| | 3 | Persistent history | Controls holdover history initialization. When switching to a new reference: 0 (default) = clear the tuning word history. 1 = retain the previous tuning word history. | | | |

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------|---|
| | [2:0] | Incremental average | History mode value from 0 to 7 (default: 0). |
| | | | When set to non-zero, causes the first history accumulation to update prior to the |
| | | | first complete averaging period. After the first full interval, updates occur only at |
| | | | the full period. |
| | | | 0 (default) = update only after the full interval has elapsed. |
| | | | 1 = update at 1/2 the full interval. |
| | | | 2 = update at 1/4 and 1/2 of the full interval. |
| | | | 3 = update at 1/8, 1/4, and 1/2 of the full interval. |
| | | | |
| | | | 7 = update at 1/256, 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, and 1/2 of the full interval. |

| Table 62. Base Digital Loo | p Filter with High Phase Mar | gin (PM = 88.5°, BW = 0.1 Hz | , Third Pole Frequency = $10 \text{ Hz}, \text{N1} = 1)^1$ |

OUTPUT CLOCK DISTRIBUTION (REGISTER 0x0500 TO REGISTER 0x0515)

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------------|---|
| 0x0500 | [7:6] | Reserved | Reserved. |
| | 5 | Mask Channel 1 sync | Masks the synchronous reset to the Channel 1 divider. 0 (default) = unmasked. The output drivers do not toggle until a SYNC pulse occurs. |
| | | | 1 = masked. Setting this bit asynchronously releases Channel 1 from the static sync state thus allowing the Channel 1 divider to toggle. Channel 1 ignores all sync events while this bit is set. Setting this bit does not enable the output drivers connected to this channel. In addition, the output distribution sync also depends on the setting of Register 0x0405, Bit 3. |
| | 4 | Mask Channel 0 sync | Masks the synchronous reset to the Channel 0 divider. |
| | | | 0 (default) = unmasked. The output drivers do not toggle until a SYNC pulse occurs. 1 = masked. Setting this bit asynchronously releases Channel 0 from the static sync state |
| | | | thus allowing the Channel 0 divider to toggle. Channel 0 ignores all sync events while this |
| | | | bit is set. Setting this bit does not enable the output drivers connected to this channel. In addition, the output distribution sync also depends on the setting of Register 0x0405, Bit 3. |
| | 3 | Reserved | Reserved. |
| | 2 | Sync source selection | Selects the sync source for the clock distribution output channels. |
| | | | 0 (default) = direct. The sync pulse occurs on the next I/O update. 1 = active reference. |
| | | | Note that the output distribution sync also depends on the APLL being calibrated and locked, unless Register $0x0405$, Bit $3 = 1b$. |
| | [1:0] | Automatic sync mode | Autosync mode. |
| | | | 00 = disabled. A sync command must be issued manually or by using the sync mask bits in this register (Bits[5:4]). |
| | | | 01 = sync on DPLL frequency lock. |
| | | | 10 (default) = sync on DPLL phase lock. |
| | | | 11 = reserved. |

Table 67. Distribution Output Synchronization Settings

Table 68. Distribution OUT0 Setting

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------------|--|
| 0x0501 | 7 | Enable 3.3 V CMOS driver | 0 (default) = disables 3.3 V CMOS driver, and OUT0 logic is controlled by Register 0x0501[6:4] |
| | | | 1 = enables 3.3 V CMOS driver as operating mode of OUT0. |
| | | | This bit should be set to 1b only if Bits[6:4] are in CMOS mode. |
| | [6:4] | OUT0 format | These bits set the OUT0 driver mode. |
| | | | 000 = PD, tristate. |
| | | | 001 (default) = HSTL. |
| | | | 010 = LVDS. |
| | | | 011 = reserved. |
| | | | 100 = CMOS, both outputs active. |
| | | | 101 = CMOS, P output active, N output power-down. |
| | | | 110 = CMOS, N output active, P output power-down. |
| | | | 111 = reserved. |
| | [3:2] | OUT0 polarity | Controls the OUT0 polarity. |
| | | | 00 (default) = positive, negative. |
| | | | 01 = positive, positive. |
| | | | 10 = negative, positive. |
| | | | 11 = negative, negative. |
| | 1 | OUT0 drive strength | Controls the output drive capability of OUT0. |
| | | | 0 (default) = CMOS: low drive strength; LVDS: 3.5 mA nominal. |
| | | | 1 = CMOS: normal drive strength; LVDS: 4.5 mA nominal (LVDS boost mode). |
| | | | Note that this is only in 3.3 V CMOS mode for CMOS strength. 1.8 V CMOS has only the low drive strength. |
| | 0 | Enable OUT0 | Enables/disables (1b/0b) OUT0 1.8 V driver (default is disabled). |
| | | | This bit does not enable/disable OUT0 if Bit 7 of this register is set to 1. |

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------------|---|
| 0x0502 | [7:0] | Channel 0 divider | 10-bit Channel 0 divider, Bits[7:0] (LSB). |
| | | | Division equals Channel 0 divider, Bits[9:0] + 1. |
| | | | ([9:0] = 0 is divide-by-1, [9:0] = 1 is divide-by-2[9:0] = 1023 is divide-by-1024) |
| 0x0503 | [7:4] | Reserved | Reserved |
| | 3 | Channel 0 PD | 0 (default) = normal operation. |
| | | | 1 = powers down Channel 0. |
| | 2 | Select RF divider for Channel 2 | 1 = selects RF Divider 2 as prescaler for Channel 0 divider. |
| | | | 0 (default) =selects RF Divider 1 as prescaler for Channel 0 divider. |
| | [1:0] | Channel 0 divider | 10-bit channel divider, Bits[9:8] (MSB). |
| 0x0504 | [7:6] | Reserved | Reserved. |
| | [5:0] | Channel 0 divider phase | Divider initial phase after sync relative to the divider input clock (from the RF divider |
| | | | output). LSB is $\frac{1}{2}$ of a period of the divider input clock. |
| | | | Phase = 0 is no phase offset. |
| | | | Phase = 1 is $\frac{1}{2}$ a period offset. |

Table 69. Distribution Channel 0 Divider Setting

Table 70. Distribution OUT1 Setting

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------|---|
| 0x0505 | 7 | Reserved | Reserved. |
| | [6:4] | OUT1 format | These bits set the OUT1 driver mode. |
| | | | 000 = PD, tristate. |
| | | | 001 (default) = HSTL. |
| | | | 010 = LVDS. |
| | | | 011 = reserved. |
| | | | 100 = CMOS, both outputs active. |
| | | | 101 = CMOS, P output active, N output PD. |
| | | | 110 = CMOS, N output active, P output PD. |
| | | | 111 = reserved. |
| | [3:2] | OUT1 polarity | These bits configure the OUT1 polarity in CMOS mode and are active only in CMOS mode. |
| | | | 00 (default) = positive, negative. |
| | | | 01 = positive, positive. |
| | | | 10 = negative, positive. |
| | | | 11 = negative, negative. |
| | 1 | OUT1 drive strength | Controls the output drive capability of OUT1. |
| | | | 0 (default) = LVDS: 3.5 mA nominal. |
| | | | 1 = LVDS: 4.5 mA nominal (LVDS boost mode). |
| | | | No CMOS control because OUT1 is 1.8 V CMOS only. |
| | 0 | Enable OUT1 | Setting this bit enables the OUT1 driver (default is disabled). |
| 0x0506 | [7:0] | Reserved | Reserved. |

Table 71. Distribution Channel 1 Divider Setting

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------|--|
| 0x0507 | [7:0] | Channel 1 divider | The same control for Channel 1 divider as in Register 0x0502 for Channel 0 divider |
| 0x0508 | [7:0] | Channel 1 divider | The same control for Channel 1 divider as in Register 0x0503 for Channel 0 divider |
| 0x0509 | [7:0] | Channel 1 divider | The same control for Channel 1 divider as in Register 0x0504 for Channel 0 divider |

REFERENCE INPUTS (REGISTER 0x0600 TO REGISTER 0x0602)

Table 72. Reference Power-Down¹

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------|--|
| 0x0600 | [7:2] | Reserved | Reserved. |
| | 1 | REFB power-down | Powers down REFB input receiver. 0 (default) = not powered down. 1 = powered down. |
| | 0 | REFA power-down | Powers down REFA input receiver. 0 (default) = not powered down. 1 = powered down. |

¹When all bits are set, the reference receiver section enters a deep sleep mode.

Table 73. Reference Logic Family

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------|--|
| 0x0601 | [7:4] | Reserved | Reserved. |
| | [3:2] | REFB logic type | Selects logic family for REFB input receiver; only REFB_P is used in CMOS mode. 00 (default) = differential. 01 = 1.2 V to 1.5 V CMOS. 10 = 1.8 V to 2.5 V CMOS. 11 = 3.0 V to 3.3 V CMOS. |
| | [1:0] | REFA logic type | The REFA logic type settings are the same as Register 0x0601[3:2] for REFB. |

Table 74. Reference Priority Setting

| Address | Bits | Bit Name | Description |
|---------|-------|---------------|---|
| 0x0602 | [7:4] | Reserved | Reserved. |
| | [3:2] | REFB priority | User assigned priority level (0 to 3) of the reference associated with REFB, which ranks that reference relative to the others. 00 (default) = 0. 01 = 1. 10 = 2. 11 = 3. |
| | [1:0] | REFA priority | The REFA priority settings are the same as in Register 0x0602[3:2] for REFB. |

DPLL PROFILE REGISTERS (REGISTER 0x0700 TO REGISTER 0x0766)

Note that the default value of the REFA profile is as follows: input frequency = 19.44 MHz, output frequency = 622.08 MHz/155.52 MHz, loop bandwidth = 400 Hz, normal phase margin, inner tolerance = 5%, and outer tolerance = 10%.

The default value of REFB profile is as follows: input frequency = 8 kHz, output frequency = 622.08 MHz/155.52 MHz, loop bandwidth = 100 Hz, normal phase margin, inner tolerance = 5%, and outer tolerance = 10%.

REFA Profile (Register 0x0700 to Register 0x0726)

| Table 75. Reference Period—REFA Pr | ofile |
|------------------------------------|-------|
|------------------------------------|-------|

| Address | Bits | Bit Name | Description |
|---------|-------|-------------------------------|--|
| 0x0700 | [7:0] | Nominal reference period (fs) | Nominal reference period bits[7:0] (default: 0xC9) |
| 0x0701 | [7:0] | | Nominal reference period bits[15:8] (default: 0xEA) |
| 0x0702 | [7:0] | | Nominal reference period bits[23:16] (default: 0x10) |
| 0x0703 | [7:0] | | Nominal reference period bits[31:24] (default: 0x03) |
| 0x0704 | [7:0] | | Nominal reference period bits[39:32] (default: 0x00) |
| | | | Default for Register 0x0700 to Register 0x0704 = 0x000310EAC9 = 51.44 ns (1/19.44 MHz) |

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------|--|
| 0x0705 | [7:0] | Inner tolerance | Input reference frequency monitor inner tolerance bits [7:0] (default: 0x14). |
| 0x0706 | [7:0] | | Input reference frequency monitor inner tolerance bit [15:8] (default: 0x00). |
| 0x0707 | [7:4] | Reserved | Reserved. |
| | [3:0] | Inner tolerance | Input reference frequency monitor inner tolerance bits[19:16]. Default for Register 0x0705 to Register 0x0707 = 0x000014 = 20 (5% or 50,000 ppm). The Stratum 3 clock requires inner tolerance of ±9.2 ppm and outer tolerance of ±12 ppm; an SMC clock requires an outer tolerance of ±48 ppm. The allowable range for the inner tolerance is 0x0000A (10%) to 0xFFFFF (1 ppm). The tolerance of the input frequency monitor is only as accurate as the system clock frequency. |
| 0x0708 | [7:0] | Outer tolerance | Input reference frequency monitor outer tolerance bits [7:0] (default: 0x0A). |
| 0x0709 | [7:0] | | Input reference frequency monitor outer tolerance bits[15:8] (default: 0x00). |
| 0x070A | [7:4] | Reserved | Reserved. |
| | [3:0] | Outer tolerance | Input reference frequency monitor outer tolerance bits[19:16]. Default for Register 0x0708 to Register 0x070A = 0x00000A = 10 (10% or 100,000 ppm). The Stratum 3 clock requires an inner tolerance of \pm 9.2 ppm and outer tolerance of \pm 12 ppm; an SMC clock requires an outer tolerance of \pm 48 ppm. The outer tolerance register setting should always be smaller than the inner tolerance. |

Table 76. Reference Period Tolerance—REFA Profile

| Table 77. Reference Validation Timer—REFA Profile | | | | |
|---|-------|-----------------------|---|--|
| Address | Bits | Bit Name | Description | |
| 0x070B | [7:0] | Validation timer (ms) | Validation timer bits[7:0] (default: 0x0A). This is the amount of time a reference input must be valid before it is declared valid by the reference input monitor (default: 10 ms). | |
| 0x070C | [7:0] | | Validation timer bits[15:8] (default: 0x00). | |

Table 78. Reserved Register

| Address | Bits | Bit Name | Description |
|---------|-------|----------|---------------|
| 0x070D | [7:0] | Reserved | Default: 0x00 |

Table 79. DPLL Base Loop Filter Selection—REFA Profile

| Address | Bits | Bit Name | Description | |
|---------|-------|------------------------------|--|--|
| 0x070E | [7:1] | Reserved | Default: 0x00 | |
| | 0 | Sel high PM base loop filter | 0 = base loop filter with normal (70°) phase margin (default) 1 = base loop filter with high (88.5°) phase margin (\leq 0.1 dB peaking in the closed-loop transfer function for loop bandwidths \leq 2 kHz; setting this bit is also recommended for loop bandwidths > 2kHz) | |

Table 80. DPLL Loop BW Scaling Factor—REFA Profile¹

| Address | Bits | Bit Name | Description |
|---------|-------|-----------------------------|---|
| 0x070F | [7:0] | DPLL loop BW scaling factor | Digital PLL loop bandwidth scaling factor, Bits[7:0] (default: 0xF4). |
| 0x0710 | [7:0] | (unit of 0.1 Hz) | Digital PLL loop bandwidth scaling factor, Bits[15:8] (default: 0x01). The default for Register 0x070F to Register 0x0710 = 0x01F4 = 500 (50 Hz loop bandwidth. The loop bandwidth should always be less than the DPLL phase detector frequency divided by 20. |
| 0x0711 | [7:1] | Reserved | Default: 0x00. |
| | 0 | BW scaling factor | Digital PLL loop bandwidth scaling factor, Bit 16 (default: 0b). |

¹Note that the default DPLL loop bandwidth is 50.4 Hz.

Table 81. R Divider—REFA Profile

| Address | Bits | Bit Name | Description | |
|---------|-------|------------------|---|--|
| 0x0712 | [7:0] | R divider | DPLL integer reference divider (minus 1), Bits[7:0] (default: 0xC5) | |
| 0x0713 | [7:0] | | DPLL integer reference divider, Bits[15:8] (default: 0x00) | |
| 0x0714 | [7:5] | Reserved | Default: 0x0 | |
| | 4 | Enable REFA div2 | Enables the reference input divide-by-2 for REFA 0 = bypass the divide-by-2 (default) 1 = enable the divide-by-2 | |
| | [3:0] | R divider | DPLL integer reference divider, Bits[19:16] (default: 0x0) The default for Register 0x0712 to Register 0x0714 = 0x000C5 = 197 (which equals R = 198) | |

| Address | Bits | Bit Name | Description | |
|---------|-------|-----------------|---|--|
| 0x0715 | [7:0] | Integer Part N1 | DPLL integer feedback divider (minus 1), Bits[7:0] (default: 0x6B) | |
| 0x0716 | [7:0] | | DPLL integer feedback divider, Bits[15:8] (default: 0x07) | |
| 0x0717 | [7:1] | Reserved | Default: 0x00 | |
| | 0 | Integer Part N1 | DPLL integer feedback divider, Bit 16 (default: 0b) The default for Register 0x0715 to Register 0x717 = 0x0076B = (which equals N1 = 1900) | |

Table 83. Fractional Part of Fractional Feedback Divider FRAC1—REFA Profile

| Address | Bits | Bit Name | Description |
|---------|-------|--|---|
| 0x0718 | [7:0] | Digital PLL fractional | The numerator of the fractional-N feedback divider, Bits[7:0] (default: 0x04) |
| 0x0719 | [7:0] | feedback divider—FRAC1 | The numerator of the fractional-N feedback divider, Bits[15:8] (default: 0x00) |
| 0x071A | 7 | Reserved Default: 0b | |
| | [6:0] | Digital PLL fractional feedback divider—FRAC1 | The numerator of the fractional-N feedback divider, Bits[22:16] (default: 0x00) |

Table 84. Modulus of Fractional Feedback Divider MOD1–REFA Profile

| Address | Bits | Bit Name | Description |
|---------|-------|--|---|
| 0x071B | [7:0] | Digital PLL feedback | The denominator of the fractional-N feedback divider, Bits[7:0] (default: 0x05) |
| 0x071C | [7:0] | divider modulus—MOD1 | The denominator of the fractional-N feedback divider, Bits[15:8] (default: 0x00) |
| 0x071D | 7 | Reserved Default: 0b | |
| | [6:0] | Digital PLL feedback divider modulus—MOD1 | The denominator of the fractional-N feedback divider, Bits[22:16] (default: 0x00) |

Table 85. Phase and Frequency Lock Detector Controls—REFA Profile

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------|---|
| 0x071E | [7:0] | Phase lock threshold | Phase lock threshold, Bits[7:0] (default: 0xBC); default of 0x02BC = 700 ps |
| 0x071F | [7:0] | | Phase lock threshold, Bits[15:8] (default: 0x02) |
| 0x0720 | [7:0] | Phase lock fill rate | Phase lock fill rate, Bits[7:0] (default: 0x0A = 10 code/PFD cycle) |
| 0x0721 | [7:0] | Phase lock drain rate | Phase lock drain rate, Bits[7:0] (default: 0x0A = 10 code/PFD cycle) |
| 0x0722 | [7:0] | Frequency lock threshold | Frequency lock threshold, Bits[7:0] (default: 0xBC); default of 0x02BC = 700 ps |
| 0x0723 | [7:0] | | Frequency lock threshold, Bits[15:8] (default: 0x02) |
| 0x0724 | [7:0] | | Frequency lock threshold, Bits[23:16] (default: 0x00) |
| 0x0725 | [7:0] | Frequency lock fill rate | Frequency lock fill rate, Bits[7:0] (default: 0x0A = 10 code/PFD cycle) |
| 0x0726 | [7:0] | Frequency lock drain rate | Frequency lock drain rate, Bits[7:0] (default: 0x0A = 10 code/PFD cycle) |

REFB Profile (Register 0x0740 to Register 0x0766)

The REFB profile registers, Register 0x0740 to Register 0x0766, are identical to the REFA profile registers, Register 0x0700 to Register 0x0726.

OPERATIONAL CONTROLS (REGISTER 0x0A00 TO REGISTER 0x0A0D)

Table 86. General Power-Down

| Address | Bits | Bit Name | Description |
|--|------|--|--|

| 3TDC power-downPlaces the time-to-digital converter in deep sleep me2APLL power-downPlaces the Output PLL in deep sleep mode (default is | | Places reference clock inputs in deep sleep mode (default is not powered down) | |
| | | TDC power-down | Places the time-to-digital converter in deep sleep mode (default is not powered down) |
| | | APLL power-down | Places the Output PLL in deep sleep mode (default is not powered down) |
| | | Clock dist power-down | Places the clock distribution outputs in deep sleep mode (default is not powered down) |
| | 0 | Full power-down | Places the entire device in deep sleep mode (default is not powered down) |

Table 87. Loop Mode

| Address | Bits | Bit Name | Description | |
|---------|-------|--|---|---|
| 0x0A01 | 7 | Reserved | Reserved. | |
| | 6 | User holdover | Forces the device into holdover mode (default is not forced holdover mode). If a tuning word history is available, then the history tuning word specifies the DCO output frequency. Otherwise, the free run frequency tuning word register specifies the DCO output frequency. The phase and frequency lock detectors are forced into the unlocked state. | |
| | 5 | User freerun | Forces the device into user free run mode (default is not forced user free run mode). The free run frequency tuning word register specifies the DCO output frequency. When the user freerun bit is set, it overrides the user holdover bit (Address 0x0A01, Bit 6). | |
| | [4:2] | REF switchover mode | Selects the operating mode of the reference sv | vitching state machine. |
| | | | Reference Switchover Mode, Bits[2:0]; Register 0x0A01[4:2] | Reference Selection Mode |
| | | | 000 (default) | Automatic revertive mode |
| | | | 001 | Automatic non-revertive mode |
| | | | 010 | Manual reference select (with automatic fallback mode) |
| | | | 011 | Manual reference select mode (with auto-holdover) |
| | | | 100 | Full manual mode (no auto-holdover) |
| | | | 101 | Not used |
| | | | 110 | Not used |
| | | | 111 | Not used |
| | 1 | Reserved | Reserved. | |
| | 0 | User reference in manual switchover mode | Input reference when reference switchover mode (Register 0x0A01, Bits[4:2]) = 100. 0 (default) = Input Reference A. 1 = Input Reference B. | |

Table 88. Cal/Sync

| Address | Bits | Bit Name | Description |
|---------|-------|------------------------------|--|
| 0x0A02 | [7:2] | Reserved | Default: 0x00 |
| | 1 | Soft sync clock distribution | Setting this bit initiates synchronization of the clock distribution output (default: 0b). Nonmasked outputs stall when value is 1b, restart is initialized on 1b to 0b transition. |
| | 0 | Reserved | Default: 0b. |

Reset Functions (Register 0x0A03)

Table 89. Reset Functions

| Address | Bits | Bit Name | Description |
|-------------|------|----------------------|--|
| 0x0A03 | 7 | Reserved | Default: 0b. |
| (autoclear) | 6 | Clear LF | Setting this bit clears the digital loop filter (intended as a debug tool). |
| | 5 | Clear CCI | Setting this bit clears the CCI filter (intended as a debug tool). |
| | 4 | Reserved | Default: 0b. |
| | 3 | Clear auto sync | Setting this bit resets the automatic synchronization logic (see Register 0x0500). |
| | 2 | Clear TW history | Setting this bit resets the tuning word history logic (part of holdover functionality). |
| | 1 | Clear all IRQs | Setting this bit clears the entire IRQ monitor register (Register 0x0D02 to Register 0x0D07). It is the equivalent of setting all the bits of the IRQ clearing register (Register 0x0A04 to 0x0A0D). |
| | 0 | Clear watchdog timer | Setting this bit resets the watchdog timer (see Register 0x0210 and Register 0x0211). If the timer times out, it simply starts a new timing cycle. If the timer has not yet timed out, it restarts at time zero without causing a timeout event. Continuously resetting the watchdog timer at intervals of less than its timeout period prevents the watchdog timer from generating a timeout event. |

IRQ Clearing (Register 0x0A04 to Register 0x0A09)

The IRQ clearing registers are identical in format to the IRQ monitor registers (Register 0x0D02 to Register 0x0D09). When set to Logic 1, an IRQ clearing bit resets the corresponding IRQ monitor bit, thereby canceling the interrupt request for the indicated event. The IRQ clearing register is an autoclearing register.

Table 90. IRQ Clearing for SYSCLK

| Address | Bits | Bit Name | Description | | | |
|---|-------|--------------------------------------|-------------------------------------|--|--|--|
| 0x0A04 | [7:6] | Reserved | Reserved | | | |

Incremental Phase Offset Control and Manual Reference Validation (Register 0x0A0A to Register 0x0A0D)

Table 95. Incremental Phase Offset Control

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------------|--|
| 0x0A0A | [7:3] | Reserved | Reserved |
| | 2 | Reset phase offset | Resets the incremental phase offset to zero. This is an autoclearing bit. |
| | 1 | Decrement phase offset | Decrements the incremental phase offset by the amount specified in the Incremental phase lock offset step size register (Register 0x0312 to Register 0x0313). This is an autoclearing bit. |
| | 0 | Increment phase offset | Increments the incremental phase offset by the amount specified in the Incremental phase lock offset step size register (Register 0x0312 to Register 0x0313). This is an autoclearing bit. |

Table 96. Manual Reference Validation

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------|--|
| 0x0A0B | [7:2] | Reserved | Reserved. |
| | 1 | Force Timeout B | Setting this autoclearing bit emulates timeout of the validation timer for Reference B and allows the user to make REFB valid immediately. |
| | 0 | Force Timeout A | Setting this autoclearing bit emulates timeout of the validation timer for Reference A and allows the user to make REFA valid immediately. |
| 0x0A0C | [7:2] | Reserved | Reserved. |
| | 1 | Ref Mon Override B | Overrides the reference monitor REF FAULT signal for Reference B. Setting this bit forces REFB to be invalid and is a useful way to force a reference switch away from REFB (default: 0b). |
| | 0 | Ref Mon Override A | Overrides the reference monitor REF FAULT signal for Reference A. Setting this bit forces REFA to be invalid and is a useful way to force a reference switch away from REFA (default: 0). |
| 0x0A0D | [7:2] | Reserved | Reserved. |
| | 1 | Ref Mon Bypass B | Setting this bit bypasses the reference monitor for Reference B and starts the REFB validation timer. By first setting this bit, and then setting the Force Timeout B bit, REFB is valid for use by the DPLL. However, the user should not set this bit at exactly the same time as the force timeout bit (default: 0). |
| | 0 | Ref Mon Bypass A | Setting this bit bypasses the reference monitor for Reference A and starts the REFA validation timer. By first setting this bit, and then setting the Force Timeout B bit, REFA is valid for use by the DPLL. However, the user should not set this bit at exactly the same time as the force timeout bit (default: 0). |

QUICK IN/OUT FREQUENCY SOFT PIN CONFIGURATION (REGISTER 0x0C00 TO REGISTER 0x0C08)

| Address | Bits | Bit Name | Descriptio | n | | | | | |

Table 97. Soft Pin Program Setting

AD9557

| Address | Bits | Bit Name | Description | |
|---------|-------|--|--|--|
| 0x0C06 | [7:5] | Reserved | Reserved | |
| | 4 | Sel high PM base loop filter | 0 = base loop filter with normal (70°) phase margin (default). 1 = base loop filter with high (88.5°) phase margin. (<0.1 dB peaking in closed-loop transfer function). | |
| | [3:2] | DPLL loop BW | Scales the DPLL loop BW while in soft pin mode. 00 (default) = 50 Hz. 01 = 1 Hz. 10 = 10 Hz. 11 = 100 Hz. | |
| | [1:0] | Reference input frequency tolerance | Scales the input frequency tolerance while in soft pin mode. 00 (default) = outer tolerance: 10%; inner tolerance: 8% (for general conditions). 01 = outer tolerance: 12 ppm; inner tolerance: 9.6 ppm (for Stratum 3). 10 = outer tolerance: 48 ppm; inner tolerance: 38 ppm (for SMC clock standard). 11 = outer tolerance: 200 ppm; inner tolerance: 160 ppm (for XTAL system clock). | |
| 0x0C07 | [7:1] | Reserved | Reserved. | |
| 0 | | Soft pin start transfer | Autoclearing register. 1 = initiates ROM download without resetting the part/register map. After ROM download is complete, this register is reset. | |
| 0x0C08 | [7:1] | Reserved | Reserved. | |
| | 0 | Soft pin reset | Autoclearing register; resets the part like soft reset (Register 0x0000, Bit 5), except that this reset function initiates a soft pin ROM download without resetting the part/register map. After ROM download is complete, this register is pulled back to zero. | |

STATUS READBACK (REGISTER 0x0D00 TO REGISTER 0x0D14)

All bits in Register 0x0D00 to Register 0x0D14 are read only. To show the latest status, Register 0x0D08 through Register 0x0D14 require an I/O update (Register 0x0005 = 0x01) immediately before being read. However, Register 0x0D00 through Register 0x0D07 are live.

Table 98. EEPROM Status

| Address | Bits | Bit Name | Description |
|---------|-------|------------------------------|--|
| 0x0D00 | [7:4] | Reserved | Reserved. |
| | 3 | Pin program ROM load process | The control logic sets this bit when data is being read from the ROM. |
| | 2 | Fault detected | An error occurred while saving data to or loading data from the EEPROM. |
| | 1 | Load in progress | The control logic sets this bit while data is being read from the EEPROM. |
| | 0 | Save in progress | The control logic sets this bit while data is being written to the EEPROM. |

Table 99. SYSCLK Status

| Address | Bits | Bit Name | Description |
|---------|------|---------------------------|---|
| 0x0D01 | 7 | Raw SYSCLK lock detect | Indicates the status of the system clock PLL (not latched by SYSCLK gating circuit). 0 = system clock PLL is unlocked. 1 = system clock PLL is locked. |
| | 6 | DPLL_APLL_Lock | Indicates the status of the DPLL and APLL. 0 = either the DPLL or the APLL is unlocked. 1 = both the DPLL and APLL are locked. |
| | 5 | All PLLs locked | Indicates the status of the system clock PLL, APLL, and DPLL. 0 = system clock PLL or APLL or DPLL is unlocked. 1 = all three PLLs (system clock PLL, APLL, and DPLL) are locked. |
| | 4 | APLL VCO status | 1 = OK. 0 = off/clocks are missing. |
| | 3 | APLL cal in process | The control logic holds this bit set while the amplitude calibration of the APLL VCO is in progress. |
| | 2 | APLL lock | Indicates the status of the APLL. 0 = APLL unlocked. 1 = APLL locked. |
| | 1 | System clock stable | The control logic sets this bit when the device considers the system clock to be stable (see the System Clock Stability Timer section). 0 = not stable (the system clock stability timer has not expired yet). 1 = stable (the system clock stability timer has expired). |
| | 0 | SYSCLK lock detect | Indicates the status of the system clock PLL (latched by SYSCLK gating circuit). 0 = system clock PLL unlocked. 1 = system clock PLL locked. |

IRQ Monitor (Register 0x0D02 to Register 0x0D07

If not masked via the IRQ mask registers (Register 0x0209 and Register 0x020A), the appropriate IRQ monitor bit is set to Logic 1 when the indicated event occurs. These bits are cleared only via the IRQ clearing registers (Register 0x0A04 to Register 0A0B), the reset all IRQs bit (Register 0x0A03, Bit 1), or a device reset.

| Table 100. IRQ Monitor | for SYSCLK |
|------------------------|------------|
|------------------------|------------|

| Address | Bits | Bit Name | Description |
|---------|-------|------------------|--|
| 0x0D02 | [7:6] | Reserved | Reserved. |
| | 5 | SYSCLK unlocked | Indicates a SYSCLK PLL state transition from locked to unlocked |
| | 4 | SYSCLK locked | Indicates a SYSCLK PLL state transition from unlocked to locked |
| | 3 | APLL unlocked | Indicates an output PLL state transition from locked to unlocked |
| | 2 | APLL locked | Indicates an output PLL state transition from unlocked to locked |
| | 1 | APLL cal ended | Indicates that APLL calibration is complete |
| | 0 | APLL cal started | Indicates that APLL in APLL calibration has begun |

Table 101. IRQ Monitor for Distribution Sync, Watchdog Timer and EEPROM

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------------|---|
| 0x0D03 | [7:5] | Reserved | Reserved |
| | 4 | Pin program end | Indicates successful completion of a ROM load operation |
| | 3 | Output distribution sync | Indicates a distribution sync event |
| | 2 | Watchdog timer | Indicates expiration of the watchdog timer |
| | 1 | EEPROM fault | Indicates a fault during an EEPROM load or save operation |
| | 0 | EEPROM complete | Indicates successful completion of an EEPROM load or save operation |

Table 102. IRQ Monitor for the Digital PLL

| Address | Bits | Bit Name | Description |
|---------|------|--------------------|---|
| 0x0D04 | 7 | Switching | Indicates that the DPLL is switching to a new reference |
| | 6 | Closed | Indicates that the DPLL has entered closed-loop operation |
| | 5 | Freerun | Indicates that the DPLL has entered free run mode |
| | 4 | Holdover | Indicates that the DPLL has entered holdover mode |
| | 3 | Frequency unlocked | Indicates that the DPLL has lost frequency lock |
| | 2 | Frequency locked | Indicates that the DPLL has acquired frequency lock |
| | 1 | Phase unlocked | Indicates that the DPLL has lost phase lock |
| | 0 | Phase locked | Indicates that the DPLL has acquired phase lock |

Table 103. IRQ Monitor for History Update, Frequency Limit and Phase Slew Limit

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------|---|
| 0x0D05 | [7:5] | Reserved | Reserved |
| | 4 | History updated | Indicates the occurrence of a tuning word history update |
| | 3 | Frequency unclamped | Indicates a frequency limiter state transition from clamped to unclamped |
| | 2 | Frequency clamped | Indicates a frequency limiter state transition from unclamped to clamped |
| | 1 | Phase slew unlimited | Indicates a phase slew limiter state transition from slew limiting to not slew limiting |
| | 0 | Phase slew limited | Indicates a phase slew limiter state transition from not slew limiting to slew limiting |

Table 104. IRQ Monitor for Reference Inputs

DPLL Status, Input Reference Status, Holdover History, and DPLL Lock Detect Tub Levels (Register 0x0D08 to Register 0x0D14)

| Table 105 | Table 105. DPLL Status | | | |
|-----------|------------------------|---------------------------|---|--|
| Address | Bits | Bit Name | Description | |
| 0x0D08 | 7 | Reserved | Reserved | |
| | 6 | Offset slew limiting | The current closed-loop phase offset is rate limited | |
| | 5 | Frequency lock | The DPLL has achieved frequency lock | |
| | 4 | Phase lock | The DPLL has achieved phase lock | |
| | 3 | Loop switching | The DPLL is in the process of a reference switchover | |
| | 2 | Holdover | The DPLL is in holdover mode | |
| | 1 | Active | The DPLL is active (that is, operating in a closed-loop condition) | |
| | 0 | Freerun | The DPLL is free run (that is, operating in an open-loop condition) | |
| 0x0D09 | [7:6] | Reserved | Default: 0b | |
| | 5 | Frequency clamped | The upper or lower frequency tuning word clamp is in effect | |
| | 4 | History available | There is sufficient tuning word history available for holdover operation | |
| | [3:2] | Active reference priority | Priority value of the currently active reference 00 = highest priority 11 = lowest priority | |
| | 1 | Reserved | Default: 0b | |
| | 0 | Current active reference | Index of the currently active reference 0 = Reference A 1 = Reference B | |

Tabl

Table 106. Reserved Register

| Address | Bits | Bit Name | Description |
|---------|-------|----------|-------------|
| 0x0D0A | [7:0] | Reserved | Reserved |

Table 107. Input Reference Status¹

| Address | Bits | Bit Name | Description |
|---------|-------|----------|---|
| 0x0D0B | 7 | B valid | REFB is valid for use. (It is unfaulted, and its validation timer has expired.) |
| | 6 | B fault | REFB is not valid for use. |
| | 5 | B fast | This bit indicates that the frequency of REFB is higher than allowed by its profile settings. |
| | 4 | B slow | This bit indicates that the frequency of REFB is lower than allowed by its profile settings. |
| | 3 | A valid | REFA is valid for use. (It is unfaulted, and its validation timer has expired.) |
| | 2 | A fault | REFA is not valid for use. |
| | 1 | A fast | This bit indicates that the frequency of REFA is higher than allowed by its profile settings. |
| | 0 | A slow | This bit indicates that the frequency of REFA is lower than allowed by its profile settings. |
| 0x0D0C | [7:0] | Reserved | Reserved. |

¹Note that the user must issue an I/O update by writing 0x01 to Register 0x0005 to update the status of these registers. Also note that if the fast and slow bits are both set, it means that the clock is missing on that reference input.

Table 108. Holdover History¹

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------|----------------------------------|
| 0x0D0D | [7:0] | Tuning word readback | Tuning word readback bits[7:0] |
| 0x0D0E | [7:0] | | Tuning word readback bits[15:8] |
| 0x0D0F | [7:0] | | Tuning word readback bits[23:9] |
| 0x0D10 | [7:0] | | Tuning word readback bits[31:24] |

¹ Note that these registers contain the current 30-bit DCO frequency tuning word that is generated by the tuning word history logic.

| Address | Bits | Bit Name | Description |
|---------|-------|---------------|---|
| 0x0D11 | [7:0] | Phase tub | Read-only digital PLL lock detect bathtub level[7:0] (see the DPLL Frequency Lock Detector section). |
| 0x0D12 | [7:4] | | Reserved. |
| | [3:0] | | Read-only digital PLL lock detect bathtub level[11:8] (see the DPLL Frequency Lock Detector section). |
| 0x0D13 | [7:0] | Frequency tub | Read-only digital PLL lock detect bathtub level[7:0] (see the DPLL Phase Lock Detector section). |
| 0x0D14 | [7:4] | Reserved | Reserved. |
| | [3:0] | Frequency tub | Read-only digital PLL lock detect bathtub level[11:8] (see the DPLL Phase Lock Detector section). |

Table 109. Digital PLL Lock Detect Tub Levels

EEPROM CONTROL (REGISTER 0x0E00 TO REGISTER 0x0E3C)

Table 110. EEPROM Control

| Address | Bits | Bit Name | Description |
|---------|-------|---------------------|--|
| 0x0E00 | [7:1] | Reserved | Reserved. |
| | 0 | Write enable | EEPROM write enable/protect. This bit is live, meaning that the user does not need to issue an I/O update after writing it. 0 (default) = EEPROM write protected 1 = EEPROM write enabled. |
| 0x0E01 | [7:4] | Reserved | Reserved. |
| | [3:0] | Conditional value | When set to a non-zero value, establishes the condition for EEPROM downloads. This register is live, meaning that the user does not need to issue an I/O update after writing it. Default: 0x0. |
| 0x0E02 | [7:1] | Reserved | Reserved. |
| | 0 | Save to EEPROM | Uploads data to the EEPROM. This is an auto-clearing live bit, meaning that the EEPROM load begins immediately after writing this bit (I/O update not needed). To ensure robust operation, the EEPROM upload must be allowed to complete (Register 0x0D00, Bit 1 returning to 0b) before other register writes are performed. If the EEPROM download is interrupted, the user may need to reset the AD9557 prior to attempting another EEPROM operation. |
| 0x0E03 | [7:2] | Reserved | Reserved. |
| | 1 | Load from EEPROM | Downloads data from the EEPROM. This is an auto-clearing live bit, meaning that the EEPROM load begins immediately after writing this bit (I/O update not needed). To ensure robust operation, the EEPROM download must be allowed to complete (Register 0x0D00, Bit 1 returning to 0b) before other register writes are performed. If the EEPROM download is interrupted, the user may need to reset the AD9557 prior to attempting another EEPROM operation. |
| | 0 | Reserved | Reserved. |

EEPROM STORAGE SEQUENCE (REGISTER 0x0E10 TO REGISTER 0x0E3C)

The default settings of Register 0x0E10 to Register 0x0E3C contain the default EEPROM instruction sequence. The tables in this section provide descriptions of the register defaults, assuming that the controller has been instructed to carry out an EEPROM storage sequence in which all of the registers are stored and loaded by the EEPROM.

| Address | Bits | Bit Name | Description | |
|---------|-------|--------------|--|--|
| 0x0E10 | [7:0] | EEPROM ID | The default value of this register is 0x01, which the controller interprets as a data instruction. Its decimal value is 1, so this tells the controller to transfer two bytes of data (1 + 1), beginning at the address specified by the next two bytes. The controller stores 0x01 in the EEPROM and increments the EEPROM address pointer. | |
| 0x0E11 | [7:0] | | The default value of these two registers is 0x0006. Note that Register 0x0E11 and Register 0x0E12 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this | |
| 0x0E12 | [7:0] | | case, 0x0006). The controller stores 0x0006 in the EEPROM and increments the EEPROM pointer by 2. It then transfers two bytes from the register map (beginning at Address 0x0006) to the EEPROM and increments the EEPROM address pointer by 3 (two data bytes and one checksum byte). The two bytes transferred correspond to the system clock parameters in the register map. | |
| 0x0E13 | [7:0] | System clock | The default value of this register is 0x08, which the controller interprets as a data instruction. Its decimal value is 8, so this tells the controller to transfer nine bytes of data (8 + 1), beginning at the address specified by the next two bytes. The controller stores 0x08 in the EEPROM and increments the EEPROM address pointer. | |

Table 111. EEPROM Storage Sequence for System Clock Settings

| Address | Bits | Bit Name | Description |
|---------|-------|------------|--|
| 0x0E14 | [7:0] | | The default value of these two registers is 0x0100. Note that Register 0x0E14 and Register 0x0E15 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this |
| 0x0E15 | [7:0] | | case, 0x0100). The controller stores 0x0100 in the EEPROM and increments the EEPROM pointer by 2. It then transfers nine bytes from the register map (beginning at Address 0x0100) to the EEPROM and increments the EEPROM address pointer by 10 (nine data bytes and one checksum byte). The nine bytes transferred correspond to the system clock parameters in the register map. |
| 0x0E16 | [7:0] | I/O update | The default value of this register is 0x80, which the controller interprets as an I/O update instruction. The controller stores 0x80 in the EEPROM and increments the EEPROM address pointer. |

Table 112. EEPROM Storage Sequence for General Configuration Settings

| Address | Bits | Bit Name | Description |
|---------|-------|----------|--|
| 0x0E17 | [7:0] | General | The default value of this register is 0x11, which the controller interprets as a data instruction. Its decimal value is 17, so this tells the controller to transfer 18 bytes of data (17 + 1), beginning at the address specified by the next two bytes. The controller stores 0x11 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E18 | [7:0] | | The default value of these two registers is 0x0200. Note that Register 0x0E18 and Register 0x0E19 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this |
| 0x0E19 | [7:0] | | case, 0x0200). The controller stores 0x0200 in the EEPROM and increments the EEPROM pointer by 2. It then transfers 18 bytes from the register map (beginning at Address 0x0200) to the EEPROM and increments the EEPROM address pointer by 19 (18 data bytes and one checksum byte). The 18 bytes transferred correspond to the general configuration parameters in the register map. |

Table 113. EEPROM Storage Sequence for DPLL Settings

| Address | Bits | Bit Name | Description |
|---------|-------|----------|--|
| 0x0E1A | [7:0] | DPLL | The default value of this register is 0x2E, which the controller interprets as a data instruction. Its decimal value is 46, so this tells the controller to transfer 47 bytes of data (46 + 1), beginning at the address specified by the next two bytes. The controller stores 0x2E in the EEPROM and increments the EEPROM address pointer. |
| 0x0E1B | [7:0] | | The default value of these two registers is 0x03. Note that Register 0x0E1B and Register 0x0E1C are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this case, 0x0300). The controller stores 0x0300 in the EEPROM and increments the EEPROM pointer by |
| 0x0E1C | [7:0] | | 2. It then transfers 47 bytes from the register map (beginning at Address 0x0300) to the EEPROM and increments the EEPROM address pointer by 48 (47 data bytes and one checksum byte). The 47 bytes transferred correspond to the DPLL parameters in the register map. |

Table 114. EEPROM Storage Sequence for APLL Settings

| Address | Bits | Bit Name | Description |
|---------|-------|----------|---|
| 0x0E1D | [7:0] | APLL | The default value of this register is 0x08, which the controller interprets as a data instruction. Its decimal value is 8, so this tells the controller to transfer nine bytes of data (8 + 1), beginning at the address specified by the next two bytes. The controller stores 0x08 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E1E | [7:0] | | The default value of these two registers is 0x0400. Note that Register 0x0E1E and Register 0x0E1F are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this case, 0x0400). The controller stores 0x0400 in the EEPROM and increments the EEPROM pointer by 2. |
| 0x0E1F | [7:0] | | It then transfers nine bytes from the register map (beginning at Address 0x0400) to the EEPROM and increments the EEPROM address pointer by 10 (nine data bytes and one checksum byte). The nine bytes transferred correspond to APLL parameters in the register map. |

| Address | Bits | Bit Name | Description |
|---------|-------|--------------------|--|
| 0x0E20 | [7:0] | Clock distribution | The default value of this register is 0x15, which the controller interprets as a data instruction. Its decimal value is 21, so this tells the controller to transfer 22 bytes of data (21+1), beginning at the address specified by the next two bytes. The controller stores 0x15 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E21 | [7:0] | | The default value of these two registers is 0x0500. Note that Register 0x0E21 and Register 0x0E22 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this case, 0x0500). The controller stores 0x0500 in the EEPROM and increments the EEPROM pointer by |
| 0x0E22 | [7:0] | | 2. It then transfers 22 bytes from the register map (beginning at Address 0x0500) to the EEPROM and increments the EEPROM address pointer by 23 (22 data bytes and one checksum byte). The 22 bytes transferred correspond to the clock distribution parameters in the register map. |
| 0x0E23 | [7:0] | I/O update | The default value of this register is 0x80, which the controller interprets as an I/O update instruction. The controller stores 0x80 in the EEPROM and increments the EEPROM address pointer. |

Table 116. EEPROM Storage Sequence for Reference Input Settings

| Address | Bits | Bit Name | Description |
|---------|-------|------------------|---|
| 0x0E24 | [7:0] | Reference inputs | The default value of this register is 0x03, which the controller interprets as a data instruction. Its decimal value is 3, so this tells the controller to transfer four bytes of data (3 + 1), beginning at the address specified by the next two bytes. The controller stores 0x03 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E25 | [7:0] | | The default value of these two registers is 0x0600. Note that Register 0x0E25 and Register 0x0E26 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this |
| 0x0E26 | [7:0] | | case, 0x0600). The controller stores 0x0600 in the EEPROM and increments the EEPROM pointer by 2. It then transfers four bytes from the register map (beginning at Address 0x0600) to the EEPROM and increments the EEPROM address pointer by 5 (four data bytes and one checksum byte). The four bytes transferred correspond to the reference inputs parameters in the register map. |

Table 117. Reserved

| Address | Bits | Bit Name | Description |
|---------|-------|----------|-------------|
| 0x0E27 | [7:0] | Reserved | Reserved. |
| 0x0E28 | [7:0] | Reserved | Reserved. |
| 0x0E29 | [7:0] | | |

Table 118. EEPROM Storage Sequence for REFA Profile Settings

| Address | Bits | Bit Name | Description |
|---------|-------|--------------|--|
| 0x0E2A | [7:0] | REFA profile | The default value of this register is 0x26, which the controller interprets as a data instruction. Its decimal value is 38, so this tells the controller to transfer 39 bytes of data (38 + 1), beginning at the address specified by the next two bytes. The controller stores 0x26 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E2B | [7:0] | | The default value of these two registers is 0x0700. Note that Register 0x0E2B and Register 0x0E2C are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this |
| 0x0E2C | [7:0] | | case, 0x0700). The controller stores 0x0700 in the EEPROM and increments the EEPROM pointer by 2. It then transfers 39 bytes from the register map (beginning at Address 0x0700) to the EEPROM and increments the EEPROM address pointer by 40 (39 data bytes and one checksum byte). The 39 bytes transferred correspond to the REFA profile parameters in the register map. |

| Table 119. | EEPRO | OM Storage Sequence | e for REFB | Profile Settings | |
|------------|-------|---------------------|------------|------------------|--|
| | | | | | |

| Address | Bits | Bit Name | Description | | | |
|---------------------|-------|--------------|---|--|--|--|
| 0x0E2D | [7:0] | REFB profile | The default value of this register is 0x26, which the controller interprets as a data instruction. Its decimal value is 38, so this tells the controller to transfer 39 bytes of data (38 + 1), beginning at the address specified by the next two bytes. The controller stores 0x26 in the EEPROM and increments the EEPROM address pointer. | | | |
| 0x0E2E | [7:0] | | The default value of these two registers is 0x0740. Note that Register 0x0E2E and Register 0x0E2F are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address (in this case, 0x0740). The controller stores 0x0740 in the EEPROM and increments the EEPROM pointer by 2. | | | |
| 0x0E2F | [7:0] | | It then transfers 39 bytes from the register map (beginning at Address 0x0740) to the EEPROM and increments the EEPROM address pointer by 40 (39 data bytes and one checksum byte). The 39 bytes transferred correspond to the REFB Profile parameters in the register map. | | | |
| 0x0E30 to 0x0E35 | [7:0] | Reserved | Reserved. | | | |
| 0x0E36 | [7:0] | I/O update | The default value of this register is 0x80, which the controller interprets as an I/O update instruction. The controller stores 0x80 in the EEPROM and increments the EEPROM address pointer. | | | |

Table 120. EEPROM Storage Sequence for Operational Control Settings

| Address | Bits | Bit Name | Description |
|---------|-------|----------------------|--|
| 0x0E37 | [7:0] | Operational controls | The default value of this register is 0x0D, which the controller interprets as a data instruction. Its decimal value is 13, so this tells the controller to transfer 14 bytes of data (13 + 1), beginning at the address specified by the next two bytes. The controller stores 0x0D in the EEPROM and increments the EEPROM address pointer. |
| 0x0E38 | [7:0] | | The default value of these two registers is 0x0A00. Note that Register 0x0E38 and Register 0x0E39 are the most significant and least significant bytes of the target address, respectively. Because the previous register contains a data instruction, these two registers define a starting address |
| 0x0E39 | [7:0] | | (in this case, 0x0A00). The controller stores 0x0A00 in the EEPROM and increments the EEPROM pointer by 2. It then transfers 14 bytes from the register map (beginning at Address 0x0A00) to the EEPROM and increments the EEPROM address pointer by 15 (14 data bytes and one checksum byte). The 14 bytes transferred correspond to the operational controls parameters in the register map. |

Table 121. EEPROM Storage Sequence for APLL Calibration

| Address | Bits | Bit Name | Description |
|---------|-------|----------------|--|
| 0x0E3A | [7:0] | Calibrate APLL | The default value of this register is 0xA0, which the controller interprets as a calibrate instruction. The controller stores 0xA0 in the EEPROM and increments the EEPROM address pointer. |
| 0x0E3B | [7:0] | I/O update | The default value of this register is 0x80, which the controller interprets as an I/O update instruction. The controller stores 0x80 in the EEPROM and increments the EEPROM address pointer. |

Table 122. EEPROM Storage Sequence for End of Data

| Address | Bits | Bit Name | Description |
|---------|-------|-------------|---|
| 0x0E3C | [7:0] | End of data | The default value of this register is 0xFF, which the controller interprets as an end instruction. The controller stores this instruction in the EEPROM, resets the EEPROM address pointer, and enters an idle state. Note that if this is a pause rather than an end instruction, the controller actions are the same except that the controller increments the EEPROM address pointer rather than resetting it. |

Table 123. Available for Additional EEPROM Instructions

| Address | Bits | Bit Name | Description |
|--------------------|-------|----------|--|
| 0x0E3D to 0xE45 | [7:0] | Unused | This area is available for additional EEPROM instructions. |

| Register Value | Output Function | Equivalent Status Register |
|----------------|---|----------------------------|
| 0x80 | Static Logic 0 | None |
| 0x81 | Static Logic 1 | None |
