

**FEATURES**
**Pin-compatible family**
**Excellent dynamic performance**
**AD9736: SFDR = 82 dBc at  $f_{OUT} = 30$  MHz**
**AD9736: SFDR = 69 dBc at  $f_{OUT} = 130$  MHz**
**AD9736: IMD = 87 dBc at  $f_{OUT} = 30$  MHz**
**AD9736: IMD = 82 dBc at  $f_{OUT} = 130$  MHz**
**LVDS data interface with on-chip 100  $\Omega$  terminations**
**Built-in self test**
**LVDS sampling integrity**
**LVDS-to-DAC data transfer integrity**
**Low power: 380 mW ( $I_{FS} = 20$  mA;  $f_{OUT} = 330$  MHz)**
**1.8/3.3 V dual-supply operation**
**Adjustable analog output**
**8.66 mA to 31.66 mA ( $R_L = 25 \Omega$  to  $50 \Omega$ )**
**On-chip 1.2 V reference**
**160-lead chip scale ball grid array (CSP\_BGA) package**
**APPLICATIONS**
**Broadband communications systems**
**Cellular infrastructure (digital predistortion)**
**Point-to-point wireless**
**CMTS/VOD**
**Instrumentation, automatic test equipment**
**Radar, avionics**
**GENERAL DESCRIPTION**

The AD9736, AD9735, and AD9734 are high performance, high frequency DACs that provide sample rates of up to 1200 MSPS, permitting multicarrier generation up to their Nyquist frequency. The AD9736 is the 14-bit member of the family, while the AD9735 and the AD9734 are the 12-bit and 10-bit members, respectively. They include a serial peripheral interface (SPI) port that provides for programming of many internal parameters and enables readback of status registers.

A reduced-specification LVDS interface is utilized to achieve the high sample rate. The output current can be programmed over a range of 8.66 mA to 31.66 mA. The AD973x family is manufactured on a 0.18  $\mu\text{m}$  CMOS process and operates from 1.8 V and 3.3 V supplies for a total power consumption of 380 mW in bypass mode. It is supplied in a 160-lead chip scale ball grid array for reduced package parasitics.

**FUNCTIONAL BLOCK DIAGRAM**

Figure 1.

**PRODUCT HIGHLIGHTS**

1. Low noise and intermodulation distortion (IMD) features enable high quality synthesis of wideband signals at intermediate frequencies up to 600 MHz.
2. Double data rate (DDR) LVDS data receivers support the maximum conversion rate of 1200 MSPS.
3. Direct pin programmability of basic functions or SPI port access offers complete control of all AD973x family functions.
4. Manufactured on a CMOS process, the AD973x family uses a proprietary switching technique that enhances dynamic performance.
5. The current output(s) of the AD9736 family are easily configured for single-ended or differential circuit topologies.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

### THERMAL RESISTANCE

$\theta_{JA}$  is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

Package Type	$\theta_{JA}$ <sup>1</sup>	Unit
160-Lead Ball, CSP_BGA	31.2	°C/W

<sup>1</sup> $\theta_{JA}$  measurement in still air.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 2. AD9736 Digital LVDS Input, Clock I/O (Top View)

Table 6. AD9736 Pin Function Descriptions

Pin No.	Mnemonic	Description
A1, A2, A3, B1, B2, B3, C1, C2, C3, D2, D3	CVDD18	1.8 V Clock Supply.
A4, A5, A6, A9, A10, A11, B4, B5, B6, B9, B10, B11, C4, C5, C6, C9, C10, C11, D4, D5, D6, D9, D10, D11	AVSS	Analog Supply Ground.
A7, B7, C7, D7	IOUTB	DAC Negative Output. 10 mA to 30 mA full-scale output current.
A8, B8, C8, D8	IOUTA	DAC Positive Output. 10 mA to 30 mA full-scale output current.
A12, A13, B12, B13, C12, C13, D12, D13	AVDD33	3.3 V Analog Supply.
A14	DNC	Do Not Connect.
B14	I120	Nominal 1.2 V Reference. Tie to analog ground via 10 kΩ resistor to generate a 120 μA reference current.
C14	VREF	Band Gap Voltage Reference I/O. Tie to analog ground via 1 nF capacitor; output impedance is approximately 5 kΩ.
D1, E2, E3, E4, F2, F3, F4, G1, G2, G3, G4	CVSS	Clock Supply Ground.
D14	IPTAT	Factory Test Pin. Output current, proportional to absolute temperature, is approximately 10 μA at 25°C with a slope of approximately 20 nA/°C.
E1, F1	DACCLK-/DACCLK+	Negative/Positive DAC Clock Input (DACCLK).
E11, E12, F11, F12, G11, G12	AVSS	Analog Supply Ground Shield. Tie to AVSS at the DAC.
E13	IRQ/UNSIGNED	If PIN_MODE = 0, IRQ: Active low open-drain interrupt request output, pull up to DVDD33 with 10 kΩ resistor. If PIN_MODE = 1, UNSIGNED: Digital input pin where 0 = twos complement input data format, 1 = unsigned.
E14	RESET/PD	If PIN_MODE = 0, RESET: 1 resets the AD9736. If PIN_MODE = 1, PD: 1 puts the AD9736 in the power-down state.
F13	CSB/2x	See the Serial Peripheral Interface section and the Pin Mode Operation section for pin description.
F14	SDIO/FIFO	See the Pin Mode Operation section for pin description.
G13	SCLK/FSC0	See the Pin Mode Operation section for pin description.
G14	SDO/FSC1	See the Pin Mode Operation section for pin description.
H1, H2, H3, H4, H11, H12, H13, H14, J1, J2, J3, J4, J11, J12, J13, J14	DVDD18	1.8 V Digital Supply.

Pin No.	Mnemonic	Description
K1, K2, K3, K4, K11, K12, L2, L3, L4, L5, L6, L9, L10, L11, L12, M3, M4, M5, M6, M9, M10, M11, M12	DVSS	Digital Supply Ground.
K13, K14	DB<13>-/DB<13>+	Negative/Positive Data Input Bit 13 (MSB). Conforms to IEEE-1596 reduced range link.
L1	PIN_MODE	0 = SPI Mode. SPI is enabled. 1 = PIN Mode. SPI is disabled; direct pin control.
L7, L8, M7, M8, N7, N8, P7, P8	DVDD33	3.3 V Digital Supply.
L13, L14	DB<12>-/DB<12>+	Negative/Positive Data Input Bit 12. Conforms to IEEE-1596 reduced range link.
M2, M1	DB<0>-/DB<0>+	Negative/Positive Data Input Bit 0 (LSB). Conforms to IEEE-1596 reduced range link.
M13, M14	DB<11>-/DB<11>+	Negative/Positive Data Input Bit 11. Conforms to IEEE-1596 reduced range link.
N1, P1	DB<1>-/DB<1>+	Negative/Positive Data Input Bit 1. Conforms to IEEE-1596 reduced range link.
N2, P2	DB<2>-/DB<2>+	Negative/Positive Data Input Bit 2. Conforms to IEEE-1596 reduced range link.
N3, P3	DB<3>-/DB<3>+	Negative/Positive Data Input Bit 3. Conforms to IEEE-1596 reduced range link.
N4, P4	DB<4>-/DB<4>+	Negative/Positive Data Input Bit 4. Conforms to IEEE-1596 reduced range link.
N5, P5	DB<5>-/DB<5>+	Negative/Positive Data Input Bit 5. Conforms to IEEE-1596 reduced range link.
N6, P6	DATACLK_OUT-/ DATACLK_OUT+	Negative/Positive Data Output Clock. Conforms to IEEE-1596 reduced range link.
N9, P9	DATACLK_IN-/ DATACLK_IN+	Negative/Positive Data Input Clock. Conforms to IEEE-1596 reduced range link.
N10, P10	DB<6>-/DB<6>+	Negative/Positive Data Input Bit 6. Conforms to IEEE-1596 reduced range link.
N11, P11	DB<7>-/DB<7>+	Negative/Positive Data Input Bit 7. Conforms to IEEE-1596 reduced range link.
N12, P12	DB<8>-/DB<8>+	Negative/Positive Data Input Bit 8. Conforms to IEEE-1596 reduced range link.
N13, P13	DB<9>-/DB<9>+	Negative/Positive Data Input Bit 9. Conforms to IEEE-1596 reduced range link.
N14, P14	DB<10>-/DB<10>+	Negative/Positive Data Input Bit 10. Conforms to IEEE-1596 reduced range link.

Figure 3. AD9735 Digital LVDS Input, Clock I/O (Top View)

Table 7. AD9735 Pin Function Descriptions

Pin No.	Mnemonic	Description
A1, A2, A3, B1, B2, B3, C1, C2, C3, D2, D3	CVDD18	1.8 V Clock Supply.
A4, A5, A6, A9, A10, A11, B4, B5, B6, B9, B10, B11, C4, C5, C6, C9, C10, C11, D4, D5, D6, D9, D10, D11	AVSS	Analog Supply Ground.
A7, B7, C7, D7	IOUTB	DAC Negative Output. 10 mA to 30 mA full-scale output current.
A8, B8, C8, D8	IOUTA	DAC Positive Output. 10 mA to 30 mA full-scale output current.
A12, A13, B12, B13, C12, C13, D12, D13	AVDD33	3.3 V Analog Supply.
A14	DNC	Do Not Connect.
B14	I120	Nominal 1.2 V Reference. Tie to analog ground via 10 kΩ resistor to generate a 120 μA reference current.
C14	VREF	Band Gap Voltage Reference I/O. Tie to analog ground via 1 nF capacitor; output impedance approximately 5 kΩ.
D1, E2, E3, E4, F2, F3, F4, G1, G2, G3, G4	CVSS	Clock Supply Ground.
D14	IPTAT	Factory Test Pin; Output current, proportional to absolute temperature, is approximately 10 μA at 25°C with a slope of approximately 20 nA/°C.
E1, F1	DACCLK-/DACCLK+	Negative/Positive DAC Clock Input (DACCLK).
E11, E12, F11, F12, G11, G12	AVSS	Analog Supply Ground Shield. Tie to AVSS at the DAC.
E13	IRQ/UNSIGNED	If PIN_MODE = 0, IRQ: Active low open-drain interrupt request output, pull up to DVDD33 with 10 kΩ resistor. If PIN_MODE = 1, UNSIGNED: Digital input pin where 0 = twos complement input data format, 1 = unsigned.
E14	RESET/PD	If PIN_MODE = 0, RESET: 1 resets the AD9735. If PIN_MODE = 1, PD: 1 puts the AD9735 in the power-down state.
F13	CSB/2×	See the Serial Peripheral Interface section and the Pin Mode Operation section for pin description.
F14	SDIO/FIFO	See the Pin Mode Operation section for pin description.
G13	SCLK/FSC0	See the Pin Mode Operation section for pin description.
G14	SDO/FSC1	See the Pin Mode Operation section for pin description.
H1, H2, H3, H4, H11, H12, H13, H14, J1, J2, J3, J4, J11, J12, J13, J14	DVDD18	1.8 V Digital Supply.
K1, K2, K3, K4, K11, K12, L2, L3, L4, L5, L6, L9, L10, L11, L12, M3, M4, M5, M6, M9, M10, M11, M12	DVSS	Digital Supply Ground.

Pin No.	Mnemonic	Description
K13, K14	DB<11>-/DB<11>+	Negative/Positive Data Input Bit 11 (MSB). Conforms to IEEE-1596 reduced range link.
L1	PIN_MODE	0 = SPI Mode. SPI is enabled. 1 = PIN Mode. SPI disabled; direct pin control.
L7, L8, M7, M8, N7, N8, P7, P8 L13, L14	DVDD33	3.3 V Digital Supply.
M1, M2	DB<10>-/DB<10>+	Negative/Positive Data Input Bit 10. Conforms to IEEE-1596 reduced range link.
M13, M14	NC	No Connect.
N1, P1	DB<9>-/DB<9>+	Negative/Positive Data Input Bit 9. Conforms to IEEE-1596 reduced range link.
N2, P2	NC	No Connect.
N3, P3	DB<0>-/DB<0>+	Negative/Positive Data Input Bit 0 (LSB). Conforms to IEEE-1596 reduced range link.
N4, P4	DB<1>-/DB<1>+	Negative/Positive Data Input Bit 1. Conforms to IEEE-1596 reduced range link.
N5, P5	DB<2>-/DB<2>+	Negative/Positive Data Input Bit 2. Conforms to IEEE-1596 reduced range link.
N6, P6	DB<3>-/DB<3>+	Negative/Positive Data Input Bit 3. Conforms to IEEE-1596 reduced range link.
N9, P9	DATACLK_OUT-/ DATACLK_OUT+	Negative/Positive Data Output Clock. Conforms to IEEE-1596 reduced range link.
N10, P10	DATACLK_IN-/ DATACLK_IN+	Negative/Positive Data Input Clock. Conforms to IEEE-1596 reduced range link.
N11, P11	DB<4>-/DB<4>+	Negative/Positive Data Input Bit 4. Conforms to IEEE-1596 reduced range link.
N12, P12	DB<5>-/DB<5>+	Negative/Positive Data Input Bit 5. Conforms to IEEE-1596 reduced range link.
N13, P13	DB<6>-/DB<6>+	Negative/Positive Data Input Bit 6. Conforms to IEEE-1596 reduced range link.
N14, P14	DB<7>-/DB<7>+	Negative/Positive Data Input Bit 7. Conforms to IEEE-1596 reduced range link.
	DB<8>-/DB<8>+	Negative/Positive Data Input Bit 8. Conforms to IEEE-1596 reduced range link.

Table 8. AD9734 Pin Function Descriptions

Pin No.	Mnemonic	Description
A1, A2, A3, B1, B2, B3, C1, C2, C3, D2, D3	CVDD18	1.8 V Clock Supply.
A4, A5, A6, A9, A10, A11, B4, B5, B6, B9, B10, B11, C4, C5, C6, C9, C10, C11, D4, D5, D6, D9, D10, D11	AVSS	Analog Supply Ground.
A7, B7, C7, D7	IOUTB	DAC Negative Output. 10 mA to 30 mA full-scale output current.
A8, B8, C8, D8	IOUTA	DAC Positive Output. 10 mA to 30 mA full-scale output current.
A12, A13, B12, B13, C12, C13, D12, D13	AVDD33	3.3 V Analog Supply.
A14	DNC	Do Not Connect.
B14	I120	Nominal 1.2 V Reference. Tie to analog ground via 10 kΩ resistor to generate a 120 μA reference current.
C14	VREF	Band Gap Voltage Reference I/O. Tie to analog ground via 1 nF capacitor; output impedance approximately 5 kΩ.
D1, E2, E3, E4, F2, F3, F4, G1, G2, G3, G4	CVSS	Clock Supply Ground.
D14	IPTAT	Factory Test Pin. Output current, proportional to absolute temperature, is approximately 10 μA at 25°C with a slope of approximately 20 nA/°C.
E1, F1	DACCLK-/DACCLK+	Negative/Positive DAC Clock Input (DACCLK).
E11, E12, F11, F12, G11, G12	AVSS	Analog Supply Ground Shield. Tie to AVSS at the DAC.
E13	IRQ/UNSIGNED	If PIN_MODE = 0, IRQ: Active low open-drain interrupt request output, pull up to DVDD33 with 10 kΩ resistor. If PIN_MODE = 1, UNSIGNED: Digital input pin where 0 = twos complement input data format, 1 = unsigned.
E14	RESET/PD	If PIN_MODE = 0, RESET: 1 resets the AD9734. If PIN_MODE = 1, PD: 1 puts the AD9734 in the power-down state.
F13	CSB/2×	See the Serial Peripheral Interface section and the Pin Mode Operation section for pin description.
F14	SDIO/FIFO	See the Pin Mode Operation section for pin description.
G13	SCLK/FSC0	See the Pin Mode Operation section for pin description.
G14	SDO/FSC1	See the Pin Mode Operation section for pin description.
H1, H2, H3, H4, H11, H12, H13, H14, J1, J2, J3, J4, J11, J12, J13, J14	DVDD18	1.8 V Digital Supply.
K1, K2, K3, K4, K11, K12, L2, L3, L4, L5, L6, L9, L10, L11, L12, M3, M4, M5, M6, M9, M10, M11, M12	DVSS	Digital Supply Ground.
K13, K14	DB<9>-/DB<9>+	Negative/Positive Data Input Bit 9 (MSB). Conforms to IEEE-1596

Pin No.	Mnemonic	Description
L1	PIN_MODE	reduced range link. 0 = SPI Mode. SPI is enabled. 1 = PIN Mode. SPI is disabled; direct pin control.
L7, L8, M7, M8, N7, N8, P7, P8 L13, L14	DVDD33 DB<8>-/DB<8>+	3.3 V Digital Supply. Negative/Positive Data Input Bit 8. Conforms to IEEE-1596 reduced range link.
M1, M2 M13, M14	NC DB<7>-/DB<7>+	No Connect. Negative/Positive Data Input Bit 7. Conforms to IEEE-1596 reduced range link.
N1, P1	NC	No Connect.
N2, P2	NC	No Connect.
N3, P3	NC	No Connect.
N4, P4	DB<0>-/DB<0>+	Negative/Positive Data Input Bit 0 (LSB). Conforms to IEEE-1596 reduced range link.
N5, P5	DB<1>-/DB<1>+	Negative/Positive Data Input Bit 1. Conforms to IEEE-1596 reduced range link.
N6, P6	DATACLK_OUT-/ DATACLK_OUT+	Negative/Positive Data Output Clock. Conforms to IEEE-1596 reduced range link.
N9, P9	DATACLK_IN-/ DATACLK_IN+	Negative/Positive Data Input Clock. Conforms to IEEE-1596 reduced range link.
N10, P10	DB<2>-/DB<2>+	Negative/Positive Data Input Bit 2. Conforms to IEEE-1596 reduced range link.
N11, P11	DB<3>-/DB<3>+	Negative/Positive Data Input Bit 3. Conforms to IEEE-1596 reduced range link.
N12, P12	DB<4>-/DB<4>+	Negative/Positive Data Input Bit 4. Conforms to IEEE-1596 reduced range link.
N13, P13	DB<5>-/DB<5>+	Negative/Positive Data Input Bit 5. Conforms to IEEE-1596 reduced range link.
N14, P14	DB<6>-/DB<6>+	Negative/Positive Data Input Bit 6. Conforms to IEEE-1596 reduced range link.

## TERMINOLOGY

### Linearity Error (Integral Nonlinearity or INL)

The maximum deviation of the actual analog output from the ideal output, determined by a straight line drawn from zero to full scale.

### Differential Nonlinearity (DNL)

The measure of the variation in analog value, normalized to full scale, associated with a 1 LSB change in digital input code.

### Monotonicity

A DAC is monotonic if the output either increases or remains constant as the digital input increases.

### Offset Error

The deviation of the output current from the ideal of zero. For IOUTA, 0 mA output is expected when the inputs are all 0s. For IOUTB, 0 mA output is expected when all inputs are set to 1s.

### Gain Error

The difference between the actual and ideal output span. The actual span is determined by the output when all inputs are set to 1s minus the output when all inputs are set to 0s.

### Output Compliance Range

The range of allowable voltage at the output of a current output DAC. Operation beyond the maximum compliance limits can cause either output stage saturation or breakdown, resulting in nonlinear performance.

### Temperature Drift

Specified as the maximum change from the ambient (25°C) value to the value at either  $T_{MIN}$  or  $T_{MAX}$ . For offset and gain drift, the drift is reported in ppm of full-scale range (FSR) per °C. For reference drift, the drift is reported in ppm per °C.

### Power Supply Rejection

The maximum change in the full-scale output as the supplies are varied from nominal to minimum and maximum specified voltages.

### Settling Time

The time required for the output to reach and remain within a specified error band about its final value, measured from the start of the output transition.

### Glitch Impulse

Asymmetrical switching times in a DAC give rise to undesired output transients that are quantified by a glitch impulse. It is specified as the net area of the glitch in pV-s.

### Spurious-Free Dynamic Range

The difference, in dB, between the rms amplitude of the output signal and the peak spurious signal over the specified bandwidth.

### Total Harmonic Distortion (THD)

The ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal. It is expressed as a percentage or in decibels (dB).

### Multitone Power Ratio

The spurious-free dynamic range containing multiple carrier tones of equal amplitude. It is measured as the difference between the rms amplitude of a carrier tone to the peak spurious signal in the region of a removed tone.

## SPI REGISTER DETAILS

Reading these registers returns previously written values for all defined register bits, unless otherwise noted. Reset value for write registers in **bold** text.

### MODE REGISTER (REG. 0)

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x00	MODE	SDIO_DIR	LSB/MSB	RESET	LONG_INS	2× MODE	FIFO MODE	DATAFRMT	PD

Table 10. Mode Register Bit Descriptions

Bit Name	Read/Write	Description
SDIO_DIR	WRITE	<b>0</b> , input only per SPI standard. 1, bidirectional per SPI standard.
LSB/MSB	WRITE	<b>0</b> , MSB first per SPI standard. 1, LSB first per SPI standard. NOTE: Only change LSB/MSB order in single-byte instructions to avoid erratic behavior due to bit order errors.
RESET	WRITE	<b>0</b> , execute software reset of SPI and controllers, reload default register values except Registers 0x00 and 0x04. 1, set software reset, write 0 on the next (or any following) cycle to release the reset.
LONG_INS	WRITE	<b>0</b> , short (single-byte) instruction word. 1, long (two-byte) instruction word, not necessary since the maximum internal address is REG31 (0x1F).
2×_MODE	WRITE	<b>0</b> , disable 2× interpolation filter. 1, enable 2× interpolation filter.
FIFO_MODE	WRITE	<b>0</b> , disable FIFO synchronization. 1, enable FIFO synchronization.
DATAFRMT	WRITE	<b>0</b> , signed input DATA with midscale = 0x0000. 1, unsigned input DATA with midscale = 0x2000.
PD	WRITE	<b>0</b> , enable LVDS Receiver, DAC, and clock circuitry. 1, power down LVDS Receiver, DAC, and clock circuitry.

### INTERRUPT REQUEST REGISTER (IRQ) (REG. 1)

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x01	IRQ	LVDS	SYNC	CROSS	RESERVED	IE_LVDS	IE_SYNC	IE_CROSS	RESERVED

Table 11. Interrupt Register Bit Descriptions

Bit Name	Read/Write	Description
LVDS	WRITE READ	Don't care. 0, no active LVDS receiver interrupt. 1, interrupt in LVDS receiver occurred.
SYNC	WRITE READ	Don't care. 0, no active SYNC logic interrupt. 1, interrupt in SYNC logic occurred.
CROSS	WRITE READ	Don't care. 0, no active CROSS logic interrupt. 1, interrupt in CROSS logic occurred.
IE_LVDS	WRITE	<b>0</b> , reset LVDS receiver interrupt and disable future LVDS receiver interrupts. 1, enable LVDS receiver interrupt to activate IRQ pin.
IE_SYNC	WRITE	<b>0</b> , reset SYNC logic interrupt and disable future SYNC logic interrupts. 1, enable SYNC logic interrupt to activate IRQ pin.
IE_CROSS	WRITE	<b>0</b> , reset CROSS logic interrupt and disable future CROSS logic interrupts. 1, enable CROSS logic interrupt to activate IRQ pin.

**FULL SCALE CURRENT (FSC) REGISTERS (REG. 2, REG. 3)**

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x02	FSC_1	SLEEP	–	–	–	–	–	FSC<9>	FSC<8>
0x03	FSC_2	FSC<7>	FSC<6>	FSC<5>	FSC<4>	FSC<3>	FSC<2>	FSC<1>	FSC<0>

Table 12. Full Scale Current Output Register Bit Descriptions

Bit Name	Read/Write	Description
SLEEP	WRITE	<b>0</b> , enable DAC output. <b>1</b> , set DAC output current to 0 mA.
FSC<9:0>	WRITE	0x000, 10 mA full-scale output current. <b>0x200</b> , 20 mA full-scale output current. 0x3FF, 30 mA full-scale output current.

**LVDS CONTROLLER (LVDS\_CNT) REGISTERS (REG. 4, REG. 5, REG. 6)**

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x04	LVDS_CNT1	MSD<3>	MSD<2>	MSD<1>	MSD<0>	MHD<3>	MHD<2>	MHD<1>	MHD<0>
0x05	LVDS_CNT2	SD<3>	SD<2>	SD<1>	SD<0>	LCHANGE	ERR_HI	ERR_LO	CHECK
0x06	LVDS_CNT3	LSURV	LAUTO	LFLT<3>	LFLT<2>	LFLT<1>	LFLT<0>	LTRH<1>	LTRH<0>

Table 13. LVDS Controller Register Bit Descriptions

Bit Name	Read/Write	Description
MSD<3:0>	WRITE READ	<b>0x0</b> , set setup delay for the measurement system. If ( LAUTO = 1), the latest measured value for the setup delay. If ( LAUTO = 0), readback of the last SPI write to this bit.
MHD<3:0>	WRITE READ	<b>0x0</b> , set hold delay for the measurement system. If ( LAUTO = 1), the latest measured value for the hold delay. If ( LAUTO = 0), readback of the last SPI write to this bit.
SD<3:0>	WRITE READ	<b>0x0</b> , set sample delay. If ( LAUTO = 1), the result of a measurement cycle is stored in this register. If ( LAUTO = 0), readback of the last SPI write to this bit.
LCHANGE	READ	<b>0</b> , no change from previous measurement. <b>1</b> , change in value from the previous measurement. NOTE: The average filter and the threshold detection are not applied to this bit.
ERR_HI	READ	One of the 15 LVDS inputs is above the input voltage limits of the IEEE reduced link specification.
ERR_LO	READ	One of the 15 LVDS inputs is below the input voltage limits of the IEEE reduced link specification.
CHECK	READ	<b>0</b> , phase measurement—sampling in the previous or following DATA cycle. <b>1</b> , phase measurement—sampling in the correct DATA cycle.
LSURV	WRITE	<b>0</b> , the controller stops after completion of the current measurement cycle. <b>1</b> , continuous measurements are taken and an interrupt is issued if the clock alignment drifts beyond the threshold value.
LAUTO	WRITE	<b>0</b> , sample delay is not automatically updated. <b>1</b> , continuously starts measurement cycles and updates the sample delay according to the measurement. NOTE: LSURV (Reg. 6, Bit 7) must be set to 1 and the LVDS IRQ (Reg. 1, Bit 3) must be set to 0 for AUTO mode.
LFLT<3:0>	WRITE	<b>0x0</b> , average filter length, Delay = Delay + Delta Delay/2 <sup>LFLT &lt;3:0&gt;</sup> , values greater than 12 (0x0C) are clipped to 12.
LTRH<2:0>	WRITE	<b>000</b> , set auto update threshold values.

**SYNC CONTROLLER (SYNC\_CNT) REGISTERS (REG. 7, REG. 8)**

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x07	SYNC_CNT1	FIFOSTAT3	FIFOSTAT2	FIFOSTAT1	FIFOSTAT0	VALID	SCHANGE	PHOF<1>	PHOF<0>
0x08	SYNC_CNT2	SSURV	SAUTO	SFLT<3>	SFLT<2>	SFLT<1>	SFLT<0>	RESERVED	STRH<0>

**Table 14. Sync Controller Register Bit Descriptions**

Bit Name	Read/Write	Description
FIFOSTAT<2:0>	READ	Position of FIFO read counter ranges from 0 to 7.
FIFOSTAT<3>	READ	0, SYNC logic OK. 1, error in SYNC logic.
VALID	READ	0, FIFOSTAT<3:0> is not valid yet. 1, FIFOSTAT<3:0> is valid after a reset.
SCHANGE	READ	0, no change in FIFOSTAT<3:0>. 1, FIFOSTAT<3:0> has changed since the previous measurement cycle when SSURV = 1 (surveillance mode active).
PHOF<1:0>	WRITE READ	<b>00</b> , change the readout counter. Current setting of the readout counter (PHOF<1:0>) in surveillance mode (SSURV = 1) after an interrupt. Current calculated optimal readout counter value in AUTO mode (SAUTO = 1).
SSURV	WRITE	<b>0</b> , the controller stops after completion of the current measurement cycle. 1, continuous measurements are taken and an interrupt is issued if the readout counter drifts beyond the threshold value.
SAUTO	WRITE	<b>0</b> , readout counter (PHOF<3:0>) is not automatically updated. 1, continuously starts measurement cycles and updates the readout counter according to the measurement. NOTE: SSURV (Reg. 8, Bit 7) must be set to 1 and the SYNC IRQ (Reg. 1, Bit 2) must be set to 0 for AUTO mode.
SFLT<3:0>	WRITE	<b>0x0</b> , average filter length, $FIFOSTAT = FIFOSTAT + \Delta FIFOSTAT/2 \wedge SFLT<3:0>$ ; values greater than 12 (0x0C) are not valid.
STRH<0>	WRITE	<b>0</b> , if FIFOSTAT<2:0> = 0 or 7, a sync interrupt is generated. 1, if FIFOSTAT<2:0> = 0, 1, 6 or 7, a sync interrupt is generated.

**CROSS CONTROLLER (CROS\_CNT) REGISTERS (REG. 10, REG. 11)**

ADDR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x0A	CROS_CNT1	-	-	UPDEL<5>	UPDEL<4>	UPDEL<3>	UPDEL<2>	UPDEL<1>	UPDEL<0>

**Table 17. BIST Control Register Bit Descriptions**

Bit Name	Read/Write	Description
SEL<1:0>	WRITE	00, write result of the LVDS Phase 1 BIST to BIST<31:0>. 01, write result of the LVDS Phase 2 BIST to BIST<31:0>. 10, write result of the SYNC Phase 1 BIST to BIST<31:0>. 11, write result of the SYNC Phase 2 BIST to BIST<31:0>.
SIG_READ	WRITE	0, no action. 1, enable BIST signature readback.
LVDS_EN	WRITE	0, no action. 1, enable LVDS BIST.
SYNC_EN	WRITE	0, no action. 1, enable SYNC BIST.
CLEAR	WRITE	0, no action. 1, clear all BIST registers.
BIST<31:0>	READ	Results of the built-in self test.

**CONTROLLER CLOCK PREDIVIDER (CCLK\_DIV) READING REGISTER (REG. 22)**

ADR	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0x16	CCLK_DIV	RESERVED	RESERVED	RESERVED	RESERVED	CCD<3>	CCD<2>	CCD<1>	CCD<0>

Table 18. Controller Clock Predivider Register Bit Descriptions

Bit Name	Read/Write	Description
CCD<3:0>	WRITE	<p><b>0x0</b>, controller clock = DACCLK/16.  <b>0x1</b>, controller clock = DACCLK/32.  <b>0x2</b>, controller clock = DACCLK/64 ...  <b>0xF</b>, controller clock = DACCLK/524288.</p> <p>NOTE: The 100 MHz to 1.2 GHz DACCLK must be divided to less than 10 MHz for correct operation. CCD&lt;3:0&gt; must be programmed to divide the DACCLK so that this relationship is not violated. Controller clock = <math>\text{DACCLK}/(2^{(\text{CCD}&lt;3:0&gt; + 4)})</math>.</p>

## THEORY OF OPERATION

The AD9736, AD9735, and AD9734 are 14-bit, 12-bit, and 10-bit DACs that run at an update rate up to 1.2 GSPS. Input data can be accepted up to the full 1.2 GSPS rate, or a 2× interpolation filter can be enabled (2× mode) allowing full speed operation with a 600 MSPS input data rate. The DATA and DATACLK\_IN inputs are parallel LVDS, meeting the IEEE reduced swing LVDS specifications with the exception of input hysteresis. The DATACLK\_IN input runs at one-half the input DATA rate in a double data rate (DDR) format. Each edge of DATACLK\_IN transfers DATA into the AD9736, as shown in Figure 79.

The DACCLK−/DACCLK+ inputs (Pin E1 and Pin F1) directly drive the DAC core to minimize clock jitter. The DACCLK signal is also divided by 2 (1× and 2× mode), then output as the DATACLK\_OUT. The DATACLK\_OUT signal clocks the data source. The DAC expects DDR LVDS data (DB<13:0>) aligned with the DDR input clock (DATACLK\_IN) from a circuit similar to the one shown in Figure 96. Table 19 shows the clock relationships.

**Table 19. AD973x Clock Relationship**

MODE	DACCLK	DATACLK_OUT	DATACLK_IN	DATA
1×	1.2 GHz	600 MHz	600 MHz	1.2 GSPS
2×	1.2 GHz	600 MHz	300 MHz	600 MSPS

Maintaining correct alignment of data and clock is a common challenge with high speed DACs, complicated by changes in temperature and other operating conditions. Using the DATACLK\_OUT signal to generate the data allows most of the internal process, temperature, and voltage delay variation to be cancelled. The AD973x further simplifies this high speed data capture problem with two adaptive closed-loop timing controllers.

One timing controller manages the LVDS data and data clock alignment (LVDS controller), and the other manages the LVDS data and DACCLK alignment (sync controller).

The LVDS controller locates the data transitions and delays the DATACLK\_IN so that its transition is in the center of the valid data window. The sync controller manages the FIFO that moves data from the LVDS DATACLK\_IN domain to the DACCLK domain.

Both controllers can operate in manual mode under external processor control, in surveillance mode where error conditions generate external interrupts, or in automatic mode where errors are automatically corrected.

The LVDS and sync controllers include moving average filtering for noise immunity and variable thresholds to control activity. Normally, the controllers are set to run in automatic mode, making any necessary adjustments without dropping or duplicating samples sent to the DAC. Both controllers require initial calibration prior to entering automatic update mode.

The AD973x analog output changes 35 DACCLK cycles after the input data changes in 1× mode with the FIFO disabled. The FIFO adds up to eight additional cycles of delay. This delay is read from the SPI port. Internal clock delay variation is less than a single DACCLK cycle at 1.2 GHz (833 ps).

Stopping the AD973x DATACLK\_IN while the DACCLK is still running can lead to unpredictable output signals. This occurs because the internal digital signal path is interleaved. The last two samples clocked into the DAC continue to be clocked out by DACCLK even after DATACLK\_IN has stopped. The resulting output signal is at a frequency of one-half  $f_{DAC}$ , and the amplitude depends on the difference between the last two samples.

Control of the AD973x functions is via the serially programmed registers listed in Table 9. Optionally, a limited number of functions can be directly set by external pins in pin mode.

## SERIAL PERIPHERAL INTERFACE

The AD973x serial port is a flexible, synchronous serial communications port, allowing easy interface to many industry-standard microcontrollers and microprocessors. The serial I/O is compatible with most synchronous transfer formats, including both the Motorola SPI® and Intel® SSR protocols. The interface allows read/write access to all registers that configure the AD973x. Single- or multiple-byte transfers are supported, as well as most significant bit first (MSB-first) or least significant bit first (LSB-first) transfer formats. The AD973x serial interface port can be configured as a single pin I/O (SDIO) or two unidirectional pins for in/out (SDIO/SDO).

Figure 68. AD973x SPI Port

The AD973x can optionally be configured via external pins rather than the serial interface. When the PIN\_MODE input (Pin L1) is high, the serial interface is disabled and its pins are reassigned for direct control of the DAC. Specific functionality is described in the Pin Mode Operation section.

### GENERAL OPERATION OF THE SERIAL INTERFACE

There are two phases to a communication cycle with the AD973x. Phase 1 is the instruction cycle, which is the writing of an instruction byte into the AD973x, coincident with the first eight SCLK rising edges. The instruction byte provides the AD973x serial port controller with information regarding the data transfer cycle, which is Phase 2 of the communication cycle. The Phase 1 instruction byte defines whether the upcoming data transfer is read or write, the number of bytes in the data transfer, and the starting register address for the first byte of the data transfer. The first eight SCLK rising edges of each communication cycle are used to write the instruction byte into the AD973x.

The remaining SCLK edges are for Phase 2 of the communication cycle. Phase 2 is the actual data transfer between the AD973x and the system controller. Phase 2 of the communication cycle is a transfer of 1, 2, 3, or 4 data bytes as determined by the instruction byte. Using one multibyte transfer is the preferred method. Single-byte data transfers are useful to reduce CPU overhead when register access requires one byte only. Registers change immediately upon writing to the last bit of each transfer byte.

CSB (Chip Select) can be raised after each sequence of 8 bits (except the last byte) to stall the bus. The serial transfer resumes when CSB is lowered. Stalling on nonbyte boundaries resets the SPI.

### SHORT INSTRUCTION MODE (8-BIT INSTRUCTION)

The short instruction byte is shown in the following table:

**MSB**

**LSB**

I7	I6	I5	I4	I3	I2	I1	I0
R/W	N1	N0	A4	A3	A2	A1	A0

R/W, Bit 7 of the instruction byte, determines whether a read or a write data transfer occurs after the instruction byte write. Logic high indicates read operation. Logic 0 indicates a write operation. N1, N0, Bit 6, and Bit 5 of the instruction byte determine the number of bytes to be transferred during the data transfer cycle. The bit decodes are shown in Table 20.

A4, A3, A2, A1, A0, Bit 4, Bit 3, Bit 2, Bit 1, and Bit 0 of the instruction byte, determine which register is accessed during the data transfer portion of the communications cycle. For multibyte transfers, this address is the starting byte address. The remaining register addresses are generated by the AD973x, based on the LSBFIRST bit (Reg. 0, Bit 6).

Table 20. Byte Transfer Count

N1	N2	Description
0	0	Transfer 1 byte
0	1	Transfer 2 bytes
1	0	Transfer 3 bytes
1	1	Transfer 4 bytes

### LONG INSTRUCTION MODE (16-BIT INSTRUCTION)

The long instruction bytes are shown in the following table:

**MSB**

**LSB**

I15	I14	I13	I12	I11	I10	I9	I8
R/W	N1	N0	A12	A11	A10	A9	A8
I7	I6	I5	I4	I3	I2	I1	I0
A7	A6	A5	A4	A3	A2	A1	A0

If LONG\_INS = 1 (Reg. 0, Bit 4), the instruction byte is extended to 2 bytes where the second byte provides an additional 8 bits of address information. Address 0x00 to Address 0x1F are equivalent in short and long instruction modes. The AD973x does not use any addresses greater than 31 (0x1F), so always set LONG\_INS = 0.

### SERIAL INTERFACE PORT PIN DESCRIPTIONS

#### SCLK—Serial Clock

The serial clock pin is used to synchronize data to and from the AD973x and to run the internal state machines. The maximum frequency of SCLK is 20 MHz. All data input to the AD973x is registered on the rising edge of SCLK. All data is driven out of the AD973x on the rising edge of SCLK.

**CSB—Chip Select**

Active low input starts and gates a communication cycle. It allows more than one device to be used on the same serial communications lines. The SDO and SDIO pins go to a high impedance state when this input is high. Chip select should stay low during the entire communication cycle.

**SDIO—Serial Data I/O**

Data is always written into the AD973x on this pin. However, this pin can be used as a bidirectional data line. The configuration of this pin is controlled by SDIO\_DIR at Reg. 0, Bit 7. The default is Logic 0, which configures the SDIO pin as unidirectional.

**SDO—Serial Data Out**

Data is read from this pin for protocols that use separate lines for transmitting and receiving data. In the case where the AD973x operates in a single bidirectional I/O mode, this pin does not output data and is set to a high impedance state.

**MSB/LSB TRANSFERS**

The AD973x serial port can support both MSB-first or LSB-first data formats. This functionality is controlled by LSBFIRST at Reg. 0, Bit 6. The default is MSB first (LSBFIRST = 0).

When LSBFIRST = 0 (MSB first), the instruction and data bytes must be written from the most significant bit to the least significant bit. Multibyte data transfers in MSB-first format start with an instruction byte that includes the register address of the most significant data byte. Subsequent data bytes should follow in order from high address to low address. In MSB-first mode, the serial port internal byte address generator decrements for each data byte of the multibyte communication cycle.

When LSBFIRST = 1 (LSB first), the instruction and data bytes must be written from least significant bit to most significant bit. Multibyte data transfers in LSB-first format start with an instruction byte that includes the register address of the least significant data byte followed by multiple data bytes. The serial port internal byte address generator increments for each byte of the multibyte communication cycle.

The AD973x serial port controller data address decrements from the data address written toward 0x00 for multibyte I/O operations if the MSB-first mode is active. The serial port controller address increments from the data address written toward 0x1F for multibyte I/O operations if the LSB-first mode is active.

**NOTES ON SERIAL PORT OPERATION**

The AD973x serial port configuration is controlled by Reg. 0, Bit 4, Bit 5, Bit 6, and Bit 7. Note that the configuration changes immediately upon writing to the last bit of the register.

For multibyte transfers, writing to this register can occur during the middle of the communication cycle. Care must be taken to compensate for this new configuration for the remaining bytes of the current communication cycle. The same considerations apply to setting the software reset, RESET (Reg. 0, Bit 5). All registers are set to their default values except Reg. 0 and Reg. 4, which remain unchanged.

Use of only single-byte transfers when changing serial port configurations or initiating a software reset is highly recommended. In the event of unexpected programming sequences, the AD973x SPI can become inaccessible. For example, if user code inadvertently changes the LONG\_INS bit or the LSBFIRST bit, the following bits experience unexpected results. The SPI can be returned to a known state by writing an incomplete byte (1 to 7 bits) of all 0s followed by 3 bytes of 0x00. This returns to MSB-first short instructions (Reg. 0 = 0x00), so the device can be reinitialized.

Figure 73. Timing Diagram for SPI Register Write

Figure 74. Timing Diagram for SPI Register Read

After the last instruction bit is written to the SDIO pin, the driving signal must be set to a high impedance in time for the bus to turn around. The serial output data from the AD973x is enabled by the falling edge of SCLK. This causes the first output data bit to be shorter than the remaining data bits, as shown in Figure 74.

To assure proper reading of data, read the SDIO or SDO pin prior to changing the SCLK from low to high. Due to the more complex multibyte protocol, multiple AD973x devices cannot be daisy-chained on the SPI bus. Multiple DACs should be controlled by independent CSB signals.

**PIN MODE OPERATION**

When the PIN\_MODE input (Pin L1) is set high, the SPI port is disabled. The SPI port pins are remapped, as shown in Table 21. The function of these pins is described in Table 22. The remaining PIN\_MODE register settings are shown in Table 9.

Table 21. SPI\_MODE vs. PIN\_MODE Inputs

Pin Number	PIN_MODE = 0	PIN_MODE = 1
E13	IRQ	UNSIGNED
F13	CSB	2x
G13	SCLK	FSC0
E14	RESET	PD
F14	SDIO	FIFO
G14	SDO	FSC1

Table 22. PIN\_MODE Input Functions

Mnemonic	Function
UNSIGNED	0, twos complement input data format 1, unsigned input data format
2x	0, interpolation disabled 1, interpolation = 2x enabled
FSC1, FSC0	00, sleep mode 01, 10 mA full-scale output current 10, 20 mA full-scale output current 11, 30 mA full-scale output current
PD	0, chip enabled 1, chip in power-down state
FIFO	0, input FIFO disabled 1, input FIFO enabled

Care must be taken when using PIN\_MODE because only the control bits shown in Table 22 can be changed. If the remaining register default values are not suitable for the desired operation, PIN\_MODE cannot be used. If the FIFO is enabled, the controller clock must be less than 10 MHz. This limits the DAC clock to 160 MHz.

**RESET OPERATION**

The RESET pin forces all SPI register contents to their default values (see Table 9), which places the DAC in a known state. The software reset bit forces all SPI register contents, except Reg. 0 and Reg. 4, to their default values.

The internal reset signal is derived from a logical OR operation on the RESET pin state and from the software reset state. This internal reset signal drives all SPI registers to their default values, except Reg. 0 and Reg. 4, which are unaffected. The data registers are not affected by either reset.

The software reset is asserted by writing 1 to Reg. 0, Bit 5. It may be cleared on the next SPI write cycle or a later write cycle.

**PROGRAMMING SEQUENCE**

The AD973x registers should be programmed in this order:

1. Reset hardware.
2. Make changes to SPI port configuration, if necessary.
3. Input format, if unsigned.
4. Interpolation, if in 2x mode.
5. Calibrate and set the LVDS controller.
6. Enable the FIFO.
7. Calibrate and set the sync controller.

Step 1 through Step 4 are required, while Step 5 through Step 7 are optional. The LVDS controller can help assure proper data reception in the DAC with changes in temperature and voltage. The sync controller manages the FIFO to assure proper transfer of the received data to the DAC core with changes in temperature and voltage. The DAC is intended to operate with both controllers active unless data and clock alignment is managed externally.

**INTERPOLATION FILTER**

In 2x mode, the input data is interpolated by a factor of 2 so that it aligns with the DAC update rate. The interpolation filter is a hard-coded, 55-tap, symmetric FIR with a 0.001 dB pass-band flatness and a stop-band attenuation of about 90 dB. The transition band runs from 20% of  $f_{DAC}$  to 30% of  $f_{DAC}$ . The FIR response is shown in Figure 75 where the frequency axis is normalized to  $f_{DAC}$ . Figure 76 shows the pass-band flatness and Table 23 shows the 16-bit filter coefficients.

**Table 23. FIR Interpolation Filter Coefficients**

Coefficient Number	Coefficient Number	Tap Weight
1	55	-7
2	54	0
3	53	+24
4	52	0
5	51	-62
6	50	0
7	49	+135
8	48	0
9	47	-263

Figure 76. Interpolation Filter Pass-Band Flatness

**DATA INTERFACE CONTROLLERS**

Two internal controllers are utilized in the operation of the AD973x. The first controller helps maintain optimum LVDS data sampling; the second controller helps maintain optimum synchronization between the DACCLK and the incoming data. The LVDS controller is responsible for optimizing the sampling of the data from the LVDS bus (DB13:0), while the sync controller resolves timing problems between the DAC\_CLK (CLK+, CLK-) and the DATACLK. A block diagram of these controllers is shown in Figure 77.

Figure 77. Data Controllers

The controllers are clocked with a divided-down version of the DAC\_CLK. The divide ratio is set utilizing the controller clock predivider bits (CCD<3:0>) located at Reg. 22, Bits 3:0 to generate the controller clock as follows:

$$\text{Controller Clock} = \text{DAC\_CLK} / (2^{(\text{CCD}\langle 3:0 \rangle + 4)})$$

Note that the controller clock cannot exceed 10 MHz for correct operation. Until CCD<3:0> is properly programmed to meet this requirement, the DAC output may not be stable. This means the FIFO cannot be enabled in PIN\_MODE unless the DACCLK is less than 160 MHz.

Figure 75. Interpolation Filter Response

The LVDS and sync controllers are independently operated in three modes via SPI port Reg. 6 and Reg. 8:

- Manual mode
- Surveillance mode
- Auto mode

In manual mode, all of the timing measurements and updates are externally controlled via the SPI.

In surveillance mode, each controller takes measurements and calculates a new optimal value continuously. The result of the measurement is passed through an averaging filter before evaluating the results for increased noise immunity. The filtered result is compared to a threshold value set via Reg. 6 and Reg. 8 of the SPI port. If the error is greater than the threshold, an interrupt is triggered and the controller stops.

Reg. 1 of the SPI port controls the interrupts with Bit 3 and Bit 2 enabling the respective interrupts and Bit 7 and Bit 6 indicating the respective controller interrupt. If an interrupt is enabled, it also activates the AD973x IRQ pin. To clear an interrupt, the interrupt enable bit of the respective controller must be set to 0 for at least 1 controller clock cycle (controller clock <10 MHz).

Auto mode is almost identical to surveillance mode. Instead of triggering an interrupt and stopping the controller, the controller automatically updates its settings to the newly calculated optimal value and continues to run.

**LVDS SAMPLE LOGIC**

A simplified diagram of the AD973x LVDS data sampling engine is shown in Figure 78 and the timing diagram is shown in Figure 79.

The incoming LVDS data is latched by the data sampling signal (DSS), which is derived from DATACLK\_IN. The LVDS controller delays DATACLK\_IN to create the data sampling signal (DSS), which is adjusted to sample the LVDS data in the center of the valid data window. The skew between the DATACLK\_IN and the LVDS data bits (DB<13:0>) must be minimal for proper operation. Therefore, it is recommended that the DATACLK\_IN be generated in the same manner as the LVDS data bits (DB<13:0>) with the same driver and data lines (that is, it should just be another LVDS data bit running a constant 01010101... sequence, as shown in Figure 96).

If the DATACLK\_IN signal is stopped, the DACCLK continues to generate an output signal based on the last two values clocked into the registers that drive D1 and D2, as shown in Figure 78. If these two registers are not equal, a large output at a frequency of one-half f<sub>DAC</sub> can be generated at the DAC output.

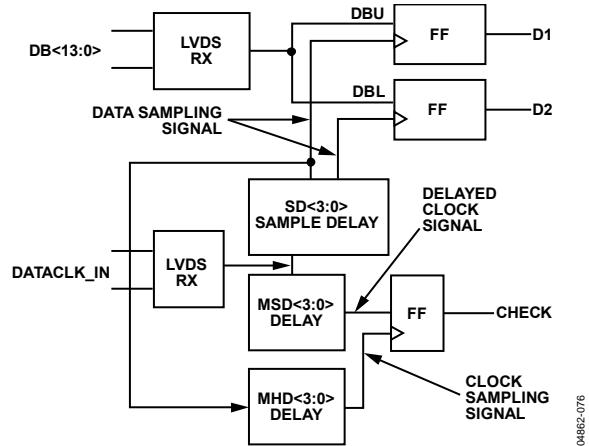

Figure 78. Internal LVDS Data Sampling Logic

Figure 79. Internal LVDS Data Sampling Logic Timing

**LVDS SAMPLE LOGIC CALIBRATION**

The internal DSS delay must be calibrated to optimize the data sample timing. Once calibrated, the AD973x generates an IRQ or automatically corrects its timing if temperature or voltage variations change the timing too much. This calibration is done using the delayed clock sampling signal (CSS) to sample the delayed clock signal (DCS). The LVDS sampling logic finds the edges of the DATACLK\_IN signal and, from this measurement, the center of the valid data window is located.

The internal delay line that derives the delayed DSS from DATACLK\_IN is controlled by SD3:0 (Reg. 5, Bits 7:4), while the DCS is controlled by MSD3:0 (Reg. 4, Bits 7:4), and the CSS is controlled by MHD3:0 (Reg. 4, Bits 3:0).

DATACLK\_IN transitions must be time aligned with the LVDS data (DB<13:0>) transitions. This allows the CSS, derived from the DATACLK\_IN, to find the valid data window of DB<13:0> by locating the DATACLK\_IN edges. The latching (rising) edge of CSS is initially placed using Bits SD<3:0> and can then be shifted to the left using MSD<3:0> and to the right using MHD<3:0>. When CSS samples the DCS and the result is 1 (which can be read back via the check bit at Reg. 5, Bit 0), the sampling occurs in the correct data cycle.

To find the leading edge of the data cycle, increment the measured setup delay until the check bit goes low. To find the trailing edge, increment the measured hold delay (MHD) until check goes low. Always set MHD = 0 when incrementing MSD and vice versa.

The incremental units of SD, MSD, and MHD are in units of real time, not fractions of a clock cycle. The nominal step size is 80 ps.

**OPERATING THE LVDS CONTROLLER IN MANUAL MODE VIA THE SPI PORT**

The manual operation of the LVDS controller allows the user to step through both the setup and hold delays to calculate the optimal sampling delay (that is, the center of the data eye).

With SD<3:0> and MHD<3:0> set to 0, increment the setup time delay (MSD<3:0>, Reg. 4, Bits 7:4) until the check bit (Reg. 5, Bit 0) goes low and record this value. This locates the leading DATACLK\_IN (and data) transition, as shown in Figure 80.

With SD<3:0> and MSD<3:0> set to 0, increment the hold time delay (MHD<3:0>, Reg. 4, Bits 3:0) until the check bit (Reg. 5, Bit 0) goes low and record this value. This locates the trailing DATACLK\_IN (and DB<13:0>) transition, as shown in Figure 81.

Once both DATACLK\_IN edges are located, the sample delay (SD<3:0>, Reg. 5, Bits 7:4) must be updated by

$$Sample\ Delay = (MHD - MSD)/2$$

After updating SD<3:0>, verify that the sampling signal is in the middle of the valid data window by adjusting both MHD and MSD with the new sample delay until the check bit goes low. The new MHD and MSD values should be equal to or within one unit delay if SD<3:0> was set correctly.

MHD and MSD may not be equal to or within one unit delay if the external clock jitter and noise exceeds the internal delay resolution. Differences of 2, 3, or more are possible and can require more filtering to provide stable operation.

The sample delay calibration should be performed prior to enabling surveillance mode or auto mode.

Figure 80. Setup Delay Measurement

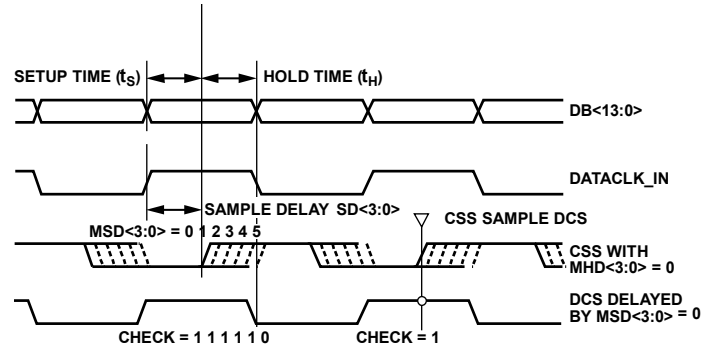

Figure 81. Hold Delay Measurement

**OPERATING THE LVDS CONTROLLER IN SURVEILLANCE AND AUTO MODE**

In surveillance mode, the controller searches for the edges of the data eye in the same manner as in the manual mode of operation and triggers an interrupt if the clock sampling signal (CSS) has moved more than the threshold value set by LTRH<1:0> (Reg. 6, Bits 1:0).

There is an internal filter that averages the setup and hold time measurements to filter out noise and glitches on the clock lines.

$$Average\ Value = (MHD - MSD)/2$$

$$New\ Average = Average\ Value + (\Delta\ Average/2 \wedge LFLT<3:0>)$$

If an accumulating error in the average value causes it to exceed the threshold value (LTHR<1:0>), an interrupt is issued.

The maximum allowable value for LFLT<3:0> is 12. If LFLT<3:0> is too small, clock jitter and noise can cause erratic behavior. In most cases, LFLT can be set to the maximum value.

In surveillance mode, the ideal sampling point should first be found using manual mode and then applied to the sample delay registers. Set the threshold and filter values depending on how far the CSS signal is allowed to drift before an interrupt occurs. Then, set the surveillance bit high (Reg. 6, Bit 7) and monitor the interrupt signal either via the SPI port (Reg. 1, Bit 7) or the IRQ pin.

In auto mode, follow the same steps to set up the sample delay, threshold, and filter length. To run the controller in auto mode, both the LAUTO (Reg. 6, Bit 6) and LSURV (Reg. 6, Bit 7) bits need to be set to 1. In auto mode, the LVDS interrupt should be set low (Reg. 1, Bit 3) to allow the sample delay to be automatically updated if the threshold value is exceeded.

## SYNC LOGIC AND CONTROLLER

A FIFO structure is utilized to synchronize the data transfer between the DACCLK and the DATACLK\_IN clock domains. The sync controller writes data from DB<13:0> into an 8-word memory register based on a cyclic write counter clocked by the DSS, which is a delayed version of DACCLK\_IN. The data is read out of the memory based on a second cyclic read counter clocked by DACCLK. The 8-word FIFO shown in Figure 82 provides sufficient margin to maintain proper timing under most conditions. The sync logic is designed to prevent the read and write pointers from crossing. If the timing drifts far enough to require an update of the phase offset (PHOF<1:0>), two samples are duplicated or dropped. Figure 83 shows the timing diagram for the sync logic.

Figure 82. Sync Logic Block Diagram

### SYNC LOGIC AND CONTROLLER OPERATION

The relationship between the readout pointer and the write pointer initially is unknown because the startup relationship between DACCLK and DATACLK\_IN is unknown. The sync logic measures the relative phase between the two counters with the zero detect block and the flip-flop in Figure 82. The relative phase is returned in FIFOSTAT<2:0> (Reg. 7, Bits 6:4), and sync logic errors are indicated by FIFOSTAT<3> (Reg. 7, Bit 7). If FIFOSTAT<2:0> returns a value of 0 or 7, the memory is sampling in a critical state (read and write pointers are close to crossing).

If the FIFOSTAT<2:0> returns a value of 3 or 4, the memory is sampling at the optimal state (read and write pointers are farthest apart). If FIFOSTAT<2:0> returns a critical value, the pointer can be adjusted with the phase offset PHOF<1:0> (Reg. 7, Bits 1:0). Due to the architecture of the FIFO, the phase offset can only adjust the read pointer in steps of 2.

### OPERATION IN MANUAL MODE

To start operating the DAC in manual mode, allow DACCLK and DATACLK\_IN to stabilize, then enable FIFO mode (Reg. 0, Bit 2). Read FIFOSTAT<2:0> (Reg. 7, Bits 6:4) to determine if adjustment is needed. For example, if FIFOSTAT<2:0> = 6, the timing is not yet critical, but it is not optimal.

To return to an optimal state (FIFOSTAT<2:0> = 4), the PHOF<1:0> (Reg. 7, Bits 1:0) needs to be set to 1. Setting PHOF<1:0> = 1 effectively increments the read pointer by 2. This causes the write pointer value to be captured two clocks later, decreasing FIFOSTAT<2:0> from 6 to 4.

### OPERATION IN SURVEILLANCE AND AUTO MODES

Once FIFOSTAT<2:0> is manually placed in an optimal state, the AD973x sync logic can run in surveillance or auto mode. To start, turn on surveillance mode by setting SSURV = 1 (Reg. 8, Bit 7), then enable the sync interrupt (Reg. 1, Bit 2). If STRH<0> = 0 (Reg. 8, Bit 0), an interrupt occurs if FIFOSTAT<2:0> = 0 or 7. If STRH<0> = 1 (Reg. 8, Bit 0), an interrupt occurs if FIFOSTAT<2:0> = 0, 1, 6, or 7. The interrupt is read at Reg. 1, Bit 6 at the AD973x IRQ pin.

To enter auto mode, complete the preceding steps then set SAUTO = 1 (Reg. 8, Bit 6). Next, set the sync interrupt = 0 (Reg. 1, Bit 2), to allow the phase offset (PHOF<1:0>) to be automatically updated if FIFOSTAT<2:0> violates the threshold value. The FIFOSTAT signal is filtered to improve noise immunity and reduce unnecessary phase offset updates. The filter operates with the following algorithm:

$$FIFOSTAT = FIFOSTAT + \Delta FIFOSTAT / 2 \wedge SFLT<3:0>$$

where:

$$0 \leq SFLT<3:0> \leq 12$$

Values greater than 12 are set to 12. If SFLT<3:0> is too small, clock jitter and noise can cause erratic behavior. Normally, SFLT can be set to the maximum value.

### FIFO BYPASS

When the FIFO\_MODE bit (Reg. 1, Bit 2) is set to 0, the FIFO is bypassed with a mux. When the FIFO is enabled, the pipeline delay through the AD973x increases by the delta between the FIFO read pointer and write pointer plus 4 more clock periods.

Figure 83. Sync Logic Timing Diagram

# DIGITAL BUILT-IN SELF TEST (BIST)

## OVERVIEW

The AD973x includes an internal signature generator that processes incoming data to create unique signatures. These signatures are read back from the SPI port, allowing verification of correct data transfer into the AD973x. BIST vectors provided on the AD973x-EB evaluation board CD check the full width data input or individual bits for PCB debug, utilizing the procedure in the AD973x BIST Procedure section. Alternatively, any vector can be used provided the expected signature is calculated in advance.

The MATLAB® routine, in the Generating Expected Signatures section, calculates the expected signature. BIST verifies correct data transfer because not all errors are always evident on a spectrum analyzer. There are four BIST signature generators that can be read back using Reg. 18 to Reg. 21, based on the setting of the BIST selection bits (Reg. 17, Bits 7:6), as shown in Table 24. The BIST signature returned from the AD973x depends on the digital input during the test. Because the filters in the DAC have memory, it is important to put the correct idle value on the DATA input to flush the memory prior to reading the BIST signature.

Placing the idle value on the data input also allows the BIST to be set up while the DAC clock is running. The idle value should be all 0s in unsigned mode (0x0000) and all 0s except for the MSB in twos complement mode (0x2000).

The BIST consists of two stages; the first stage is after the LVDS receiver and the second stage is after the FIFO. The first BIST stage verifies correct sampling of the data from the LVDS bus while the second BIST stage verifies correct synchronization between the DAC\_CLK domain and the DATACLK\_IN domain. The BIST vector is generated using 32-bit LFSR signature logic. Because the internal architecture is a 2-bus parallel system, there are two 32-bit LFSR signature logic blocks on both the LVDS and SYNC blocks. Figure 84 shows where the LVDS and SYNC phases are located.

Table 24. BIST Selection Bits

Bit	SEL<1>	SEL<0>
LVDS Phase 1	0	0
LVDS Phase 2	0	1
SYNC Phase 1	1	0
SYNC Phase 2	1	1

Figure 84. Block Diagram Showing LVDS and SYNC Phase 1 and SYNC Phase 2

048662-082

**AD973x BIST PROCEDURE**

1. Set RESET pin = 1.
2. Set input DATA = 0x0000 for unsigned (0x2000 for twos complement).
3. Enable DATACLK\_IN if it is not already running.
4. Run for at least 16 DATACLK\_IN cycles.
5. Set RESET pin = 0.
6. Run for at least 16 DATACLK\_IN cycles.
7. Set RESET pin = 1.
8. Run for at least 16 DATACLK\_IN cycles.
9. Set RESET pin = 0.
10. Set desired operating mode (1× mode and signed data are default values and expected for the supplied BIST vectors).
11. Set CLEAR (Reg. 17, Bit 0), SYNC\_EN (Reg. 17, Bit 1), and LVDS\_EN (Reg. 17, Bit 2) high.
12. Wait 50 DATACLK\_IN cycles to allow 0s to propagate through and clear sync signatures.
13. Set CLEAR low.
14. Read all signature registers (Reg. 21, Reg. 20, Reg. 19, and Reg. 18) for each of the four SEL (Reg. 17, Bits 7:6) values and verify they are all 0x00.

**LVDS Phase 1**

- a. Reg. 17 set to 0x26 (SEL1 = 0, SEL0 = 0, SIG\_READ = 1, LVDS\_EN = 1, SYNC\_EN = 1).
- b. Read Reg. 20, Reg. 19, Reg. 18, and Reg. 17.

**LVDS Phase 2**

- a. Reg. 17 set to 0x66 (SEL1 = 0, SEL0 = 1, SIG\_READ = 1, LVDS\_EN = 1, SYNC\_EN = 1).
- b. Read Reg. 20, Reg. 19, Reg. 18, and Reg. 17.

**SYNC Phase 1**

- a. Reg. 17 set to 0xA6 (SEL1 = 1, SEL0 = 0, SIG\_READ = 1, LVDS\_EN = 1, SYNC\_EN = 1).
- b. Read Reg. 20, Reg. 19, Reg. 18, and Reg. 17.

**SYNC Phase 2**

- a. Reg. 17 set to 0xE6 (SEL1 = 1, SEL0 = 1, SIG\_READ = 1, LVDS\_EN = 1, SYNC\_EN = 1).
- b. Read Reg. 20, Reg. 19, Reg. 18, and Reg. 17.

15. Clock the BIST vector into the AD973x.
16. After the BIST vector is clocked into the part, hold DATA = 0x0000 for unsigned (0x2000 for twos complement); otherwise, the additional nonzero data changes the signature.

17. Read all signature registers (Reg. 21, Reg. 20, Reg. 19, and Reg. 18, as described in Step 14) for each of the four SEL (Reg. 17, Bits 7:6) values, and verify that they match the expected signatures shown in Table 25.
18. Flush the BIST circuitry. This must be done once before valid data can be read. Loop back to Step 11 and rerun the test to obtain the correct result.
19. Each time BIST mode is entered, this flush needs to be performed once. Multiple BIST runs can be performed without reflashing as long as the device remains in BIST mode.

**AD973x EXPECTED BIST SIGNATURES**

The BIST vectors provided on the AD973x-EB CD are in signed mode, so no programming is necessary for the part to pass the BIST. The BIST vector is for 1×, no FIFO, and signed data.

For testing all 14 input bits, use the vector all\_bits\_unsnew.txt and verify against the signatures in Table 25.

**Table 25. Expected BIST Data Readback for All Bits**

LVDS Phase 1	LVDS Phase 2	SYNC Phase 1	SYNC Phase 2
CF71487C	66DF5250	CF71487C	66DF5250

For individual bit tests, use the vectors named bit*n*.txt (where *n* is the desired bit number being tested) and compare them against the values in Table 26.

**Table 26. Expected BIST Data Readback for Individual Bits**

Vector	Bit Number	LVDS Rise Expected	LVDS Fall Expected
bit0.txt	0	AABF0A00	2A400500
bit1.txt	1	2BBF0A00	6B400500
bit2.txt	2	29BE0A00	E9400500
bit3.txt	3	2DBC0A00	ED410500
bit4.txt	4	25B80A00	E5430500
bit5.txt	5	35B00A00	F5470500
bit6.txt	6	15A00A00	D54F0500
bit7.txt	7	55800A00	955F0500
bit8.txt	8	D5C00A00	157F0500
bit9.txt	9	D5410A00	153E0500
bit10.txt	10	D5430B00	15BC0500
bit11.txt	11	D5470900	15B80400
bit12.txt	12	D54F0D00	15B00600
bit13.txt	13	D55F0500	15A00200

Note the following for Table 26:

- The term *rise* refers to Phase 1 and *fall* refers to Phase 2.
- Byte order is Decimal Register Address 21, Address 20, Address 19, and Address 18.
- SYNC phase should always equal LVDS phase in 1× mode.

## GENERATING EXPECTED SIGNATURES

The following MATLAB code duplicates the internal logic of the AD973x. To use it, save this code in a file called `bist.m`.

```

--- begin bist.m ---
function [ ret1 , ret2 ] = bist(vec)
ret1 = bist1(vec(1:2:length(vec)-1));
ret2 = bist1(vec(2:2:length(vec)));
function ret = bist1(v)
sum = zeros(1,32);
for i = 1 :length(v)
if v(i) ~= 0
su(1) = ~xor(sum(32) ,bitget(v(i),1));
su(2) = ~xor(sum(1) ,bitget(v(i),2));
su(3) = ~xor(sum(2) ,bitget(v(i),3));
su(4) = ~xor(sum(3) ,bitget(v(i),4));
su(5) = ~xor(sum(4) ,bitget(v(i),5));
su(6) = ~xor(sum(5) ,bitget(v(i),6));
su(7) = ~xor(sum(6) ,bitget(v(i),7));
su(8) = ~xor(sum(7) ,bitget(v(i),8));
su(9) = ~xor(sum(8) ,bitget(v(i),9));
su(10) = ~xor(sum(9) ,bitget(v(i),10));
su(11) = ~xor(sum(10) ,bitget(v(i),11));
su(12) = ~xor(sum(11) ,bitget(v(i),12));
su(13) = ~xor(sum(12) ,bitget(v(i),13));
su(14) = ~xor(sum(13) ,bitget(v(i),14));
su(15) = sum(14); su(16) = sum(15);
su(17) = sum(16); su(18) = sum(17);
su(19) = sum(18); su(20) = sum(19);
su(21) = sum(20); su(22) = sum(21);
su(23) = sum(22); su(24) = sum(23);
su(25) = sum(24); su(26) = sum(25);
su(27) = sum(26); su(28) = sum(27);
su(29) = sum(28); su(30) = sum(29);
su(31) = sum(30); su(32) = sum(31);
sum = su;
end
end % for ret = dec2hex( 2.^[0:31]* sum',8);
--- end bist.m ---

```

To generate the expected BIST signatures, follow this procedure:

1. Start MATLAB and type the following at the command prompt:
 

```
t = round(randn(1,100) × 213/8+213);
[ b1 b2 ] = bist(t)
```
2. The first statement creates a random vector of 14-bit words, with a length of 100.
3. Set **t** equal to any desired vector, or take this random vector and input it to the AD973x.
4. Alter the command **randn(1,100)** to change the vector length as desired.
5. Type **b1** at the command line to see the calculated signature for the LVDS BIST, Phase 1.
6. Type **b2** to see the value for LVDS BIST, Phase 2.

The values returned for **b1** and **b2** each are 32-bit hex values. They correspond to Reg. 18, Reg. 19, Reg. 20, and Reg. 21, where **b1** is the value read for SEL<1:0> = 0, 0 (see Table 17) and **b2** is the value read for SEL<1:0> = 0, 1.

When the DAC is in 1× mode, the signature at SYNC BIST, Phase 1 should equal the signature at LVDS BIST, Phase 1. The same is true for Phase 2.

## CROSS CONTROLLER REGISTERS

The AD973x differential output stage is adjustable to equalize the charge injection into the positive and negative outputs. This adjustment impacts certain performance characteristics, such as harmonic distortion or IMD. System performance can be enhanced by adjusting the cross controller.

If the system is calibrated after manufacture, adjust the cross controller offsets to provide optimum performance. To start, increment DNDEL<5:0> (Reg. 11, Bits 5:0) while observing HD2 (second harmonic distortion) and/or IMD to find the desired optimum. If DNDEL does not influence the performance, set it to 0 and increment UPDEL<5:0> (Reg. 10, Bits 5:0). Based on system characterization, set one of these controls to the maximum value to yield the best performance.

Figure 85 shows the effect of UPDEL and DNDEL.

04862-093

Figure 85. Effect of UPDEL and DNDEL

## ANALOG CONTROL REGISTERS

The AD973x includes some registers for optimizing its analog performance. These registers include temperature trim for the band gap, noise reduction in the output current mirror, and output current mirror headroom adjustments.

### BAND GAP TEMPERATURE CHARACTERISTIC TRIM BITS

Using TRMBG<2:0> (Reg. 14, Bits 2:0), the temperature characteristic of the internal band gap can be trimmed to minimize the drift over temperature, as shown in Figure 86.

Figure 86. Band Gap Temperature Characteristic for Various TRMBG Values

The temperature changes are sensitive to process variations, and Figure 86 may not be representative of all fabrication lots. Optimum adjustment requires measurement of the device operation at two temperatures and development of a trim algorithm to program the correct TRMBG<2:0> values in external nonvolatile memory.

### MIRROR ROLL-OFF FREQUENCY CONTROL

With MSEL <1:0> (Reg. 14, Bits 7:6), the user can adjust the noise contribution of the internal current mirror to optimize the 1/f noise. Figure 87 shows MSEL vs. the 1/f noise with 20 mA full-scale current into a 50 Ω resistor.

Figure 87. 1/f Noise with Respect to MSEL Bits

### HEADROOM BITS

HDRM<7:0> (Reg. 15, Bits 7:0) are for internal evaluation. Changing the default reset values is not recommended.

### VOLTAGE REFERENCE

The AD973x output current is set by a combination of digital control bits and the I120 reference current, as shown in Figure 88.

Figure 88. Voltage Reference Circuit

The reference current is obtained by forcing the band gap voltage across an external 10 kΩ resistor from I120 (Pin B14) to ground. The 1.2 V nominal band gap voltage ( $V_{REF}$ ) generates a 120 μA reference current in the 10 kΩ resistor. This current is adjusted digitally by FSC<9:0> (Reg. 2, Reg. 3) to set the output full-scale current  $I_{FS}$ :

$$I_{FS} = \frac{V_{REF}}{R} \times \left( 72 + \left( \frac{192}{1024} \times FSC <9:0> \right) \right)$$

The full-scale output current range is approximately 10 mA to 30 mA for register values from 0x000 to 0x3FF. The default value of 0x200 generates 20 mA full scale. The typical range is shown in Figure 89.

Figure 89.  $I_{FS}$  vs. DAC Gain Code

Always connect a 10 k $\Omega$  resistor from the I120 pin to ground and use the digital controls to vary the full-scale current. The AD973x is not a multiplying DAC. Applying an analog signal to I120 is not supported.

VREF (Pin C14) must be bypassed to ground with a 1 nF capacitor. The band gap voltage is present on this pin and can be buffered for use in external circuitry. The typical output impedance is near 5 k $\Omega$ . If desired, an external reference can be used to overdrive the internal reference by connecting it to the VREF pin.

IPTAT (Pin D14) is used for factory testing. Leave this pin floating.

## APPLICATIONS INFORMATION

### DRIVING THE DACCLK INPUT

The DACCLK input requires a low jitter differential drive signal. It is a PMOS input differential pair powered from the 1.8 V supply, so it is important to maintain the specified 400 mV input common-mode voltage. Each input pin can safely swing from 200 mV p-p to 800 mV p-p about the 400 mV common-mode voltage. While these input levels are not directly LVDS compatible, DACCLK can be driven by an offset ac-coupled LVDS signal, as shown in Figure 90.

Figure 90. LVDS DACCLK Drive Circuit

If a clean sine clock is available, it can be transformer-coupled to DACCLK, as shown in Figure 107. Use of a CMOS or TTL clock can also be acceptable for lower sample rates. It is routed through a CMOS to LVDS translator, then ac-coupled, as described previously. Alternatively, it can be transformer-coupled and clamped, as shown in Figure 91.

Figure 91. TTL or CMOS DACCLK Drive Circuit

A simple bias network for generating  $V_{CM}$  is shown in Figure 92. It is important to use CVDD18 and CVSS for the clock bias circuit. Any noise or other signal that is coupled onto the clock is multiplied by the DAC digital input signal and may degrade the DAC performance.

Figure 92. DACCLK  $V_{CM}$  Generator Circuit

## DAC OUTPUT DISTORTION SOURCES

The second harmonic is mostly due to an imbalance in the output load. The dc transfer characteristic of the DAC is capable of second harmonic distortion of at least  $-75$  dBc. Output load imbalance or digital data noise coupling onto DACCLK causes additional second harmonic distortion.

The DAC architecture inherently generates third harmonics, the levels of which depend on the output frequency and amplitude generated. If any output signal is rectified and coupled back onto the DAC clock, it can generate additional third-harmonic energy.

The distortion components should be identical in amplitude and phase at both AD973x outputs. Even though each single-ended output includes a large amount of second-harmonic energy, a careful differential-to-single-ended conversion can remove most of it. Optimum performance at high intermediate frequency (IF) output is obtained with the output circuit shown in Figure 93.

This is the configuration implemented on the evaluation board (Figure 107). The  $20\ \Omega$  series resistors allow the DAC to drive a less reactive load, which improves distortion. Further improvement is realized by adding the Balun T3 to help provide an equal load to both DAC outputs.

Figure 93. IF Signal Output Circuit

Because T1 has a differential input, but a single-ended output, Pin 4 of T1 has a higher capacitance to ground due to parasitics to Pin 3. T1 Pin 6 has lower parasitic capacitance to ground because it drives  $50\ \Omega$  at Pin 1. This presents an unbalanced load to the DAC output, so T3 is added to improve the load balancing. Refer to Figure 107 for the transformer part numbers.

### DC-COUPLED DAC OUTPUT

In some cases, it may be desirable to dc-couple the AD973x output. The best method for doing this is shown in Figure 94. This circuit can be used with voltage or current feedback amplifiers. Because the DAC output current is driving a virtual ground, this circuit may offer enhanced settling times. The settling time is limited by the op amp rather than by the DAC. This circuit is intended for use where the amplifiers can be powered by a bipolar supply.

Figure 94. Op Amp I to V Conversion Output Circuit

04862-992

An alternate circuit is shown in Figure 95. It suffers from dc offset at the output unless the DAC load resistors are small, relative to the amplifier gain and feedback resistors.

Figure 95. Differential Op Amp Output Circuit

04862-993

### DAC DATA SOURCES

The circuit shown in Figure 96 allows optimum data alignment when running the AD973x at full speed. This circuit can be easily implemented in the FPGA or ASIC used to drive the digital input. It is important to use the DATACLK\_OUT signal because it helps to cancel some of the timing errors. In this configuration, DATACLK\_OUT generates the DDR LVDS DATACLK\_IN to drive the AD973x. The circuit aligns the DATACLK\_IN and the digital input data (DB<13:0>) as required by the AD973x. The LVDS controller in the AD973x uses DATACLK\_IN to generate the internal DSS to capture the incoming data in the center of the valid data window.

To operate in 2x mode, the circuit in Figure 96 must be modified to include a divide-by-2 block in the path of DATACLK\_OUT. Without this additional divider, the data and DATACLK\_IN runs 2x too fast. DATACLK\_OUT is always DACCLK/2.

Contact FPGA vendors directly regarding the maximum output data rates supported by their products.

## INPUT DATA TIMING

The AD973x is intended to operate with the LVDS and sync controllers running to compensate for timing drift due to voltage and temperature variations. In this mode, the key to correct data capture is to present valid data for a minimum amount of time. The AD973x minimum valid data time is measured by increasing the input data rate to the point of failure. The nominal supply voltages are used and the temperature is set to the worst case of 85°C. The input data is verified via the BIST signature registers, because the DAC output does not run as fast as the input data logic. The following example explains how the minimum data valid period is calculated for the typical performance case.

These factors must be considered in determining the minimum valid data window at the receiver input:

- Data rise and fall times: 100 ps (rise + fall)
- Internal clock jitter: 10 ps  
(DATACLK\_OUT + DATACLK\_IN)
- Bit-to-bit skew: 50 ps
- Bit-to-DATACLK\_IN skew: 50 ps
- Internal data sampling signal resolution: 80 ps

For nominal silicon, the BIST typically indicates failure at 2.15 GSPS or a DACCLK period of 465 ps. The valid data window is calculated by subtracting all the other variables from the total data period:

$$\text{Minimum Data Valid Time} = \text{DACCLK Period} - \text{Data Rise} - \text{Data Fall} - \text{Jitter} - \text{Bit-to-Bit Skew} - \text{Bit-to-DATACLK\_IN Skew} - \text{Data Sampling Signal Resolution}$$

For the 400 mV p-p LVDS signal case:

$$\text{Minimum Data Valid} = 465 \text{ ps} - 100 \text{ ps} - 10 \text{ ps} - 50 \text{ ps} - 80 \text{ ps} = 465 \text{ ps} - 240 \text{ ps} = 225 \text{ ps}$$

For correct data capture, the input data must be valid for 225 ps. Slower edges, more jitter, or more skew require an increase in the clock period to maintain the minimum data valid period. Table 27 shows the typical minimum data valid period ( $t_{MDE}$ ) for 400 mV p-p differential and 250 mV p-p differential LVDS swings.

The ability of the AD973x to capture incoming data is dependent on the speed of the silicon, which varies from lot to lot. The typical (or average) silicon speed operates with data that is valid for 225 ps at 85°C. Statistically, the worst extreme for slow silicon may require up to a 344 ps valid data period, as specified in Table 2.

**Table 27. Typical Minimum Data Valid Times**

Differential Input Voltage	BIST Max $f_{CLK}$	Min Clock Period	Typ Min Data Valid at Receiver
400 mV	2.15 GHz	465 ps	225 ps
250 mV	2.00 GHz	500 ps	260 ps

At 1.2 GHz, the typical 400 mV p-p minimum data valid period of 225 ps leaves 608 ps for external factors. Under the same conditions, the worst expected minimum data valid period of 344 ps leaves 489 ps for external data uncertainty.

The 100 mV LVDS  $V_{OD}$  threshold test is a dc test to verify that the input logic state changes. It does not indicate the operating speed. The ability of the receiver to recover the data depends on the input signal overdrive. With a 250 mV input, there is a 150 mV overdrive, and with a 400 mV signal, there is a 300 mV overdrive. The relationship between overdrive level and timing is very nonlinear. Higher levels of overdrive result in smaller minimum valid data windows.

For typical silicon, decreasing the LVDS swing from 400 mV p-p to 250 mV p-p requires the minimum data valid period to increase by 15%. This is illustrated in Figure 100.

Figure 100. Typical Minimum Valid Data Time ( $t_{MDE}$ ) vs. LVDS Swing

The minimum valid data window changes with temperature, voltage, and process. The maximum value presented in the specification table was determined from a  $6\sigma$  distribution in the worst-case conditions.

## SYNCHRONIZATION TIMING

When more than one AD973x must be synchronized or when a constant group delay must be maintained, the internal controllers cannot be used. If the FIFO is enabled, the delay between multiple AD973x devices is unknown. If the DATACLK\_OUT from multiple devices is used, there is an uncertainty of two DACCLK periods because the initial phase of DATACLK\_OUT with respect to DACCLK cannot be controlled. This means one DAC must be used to provide DATACLK\_OUT for all synchronized DACs and all timing must be externally managed. The following timing information allows system timing to be calculated so that multiple AD973xs can be synchronized.

DATACLK\_OUT changes relative to the rising edge of DACCLK+ and is delayed, as shown in Figure 101. Because DACCLK is divided by 2 to create DATACLK\_OUT, the phase of DATACLK\_OUT can be 0° or 180°. There is no way to predict or control this relationship. It can be different after each power cycle and is not affected by hardware or software resets.

Figure 101. DACCLK to DATACLK\_OUT Delay

The incoming data is de-interleaved internally as shown in Figure 78. In Figure 78, DBU (upper) and DBL (lower) represent the de-interleaved data paths. Each edge of DATACLK\_IN latches an incoming sample in two alternating registers. The DATACLK\_IN to data setup and hold definitions are illustrated in Figure 102. All the data input must be valid during the setup-and-hold period. External skew effectively increases the setup and hold times that the data source must meet.

Figure 102. Standard Definitions for DATACLK\_IN or DATACLK\_OUT to Data Setup and Hold, SD = 0

While correct DATA\_IN vs. DATACLK\_IN timing is critical, the transition of the incoming data to the DACCLK domain is equally critical. By referencing the incoming DATA and DATACLK\_IN timing to the DATACLK\_OUT signal, some timing uncertainty can be removed. The DATACLK\_OUT timing very closely tracks the timing of the DACCLK-controlled registers. Any variation in the path delay affects both paths in almost the same way. If DATACLK\_OUT is not used, the full DACCLK to DATACLK\_OUT path variation reduces the external timing margin. Figure 101 shows a simplified view of the internal clocking scheme with the relevant delay paths.

The internal architecture is interleaved such that each phase has twice as long to make the transition across the clock domains. This results in an extremely narrow window where the incoming data must be held stable.

Table 28 shows the timing parameters for Figure 101 and Figure 102. These parameters were measured for a sample of five devices from five silicon lots. Worst-case fast and slow skew lots were included in addition to the nominal (or average) lot. The typical -40°C to typical +85°C spread illustrates the variability with temperature for a single lot. Adding in lot-to-lot variation with the fast and slow lots indicates the worst-case spread in timing.

The timing varies such that all of the parameters move in the same direction. For example, if the DATACLK\_IN to data setup time is fast, the hold time is similarly fast. The DACCLK to DATACLK\_OUT delay and the DATACLK\_OUT to data setup and hold is also at the fast end of the range.

Note that the polarities of setup-and-hold values in Table 28 conform to the standard convention of setup time occurring prior to the latching edge and hold time occurring after the latching edge, as shown in Figure 102.

Table 28. AD973x Clock and Data Timing Parameters

Symbol and Definition	Fast -40°C	Typ -40°C	All +25°C	Typ +85°C	Slow +85°C	Unit
t <sub>DDCO</sub> – DACCLK to DATACLK_OUT Delay	+1650	+1800	+1890	+2050	+2350	ps
t <sub>DCISU</sub> – DATACLK_IN to DATA Setup	-100	-120	-150	-170	-220	ps
t <sub>DCIH</sub> – DATACLK_IN to DATA Hold	+210	+220	+240	+280	+360	ps
t <sub>DISU</sub> – DATACLK_OUT to DATA Setup	+1310	+1440	+1611	+1710	+1970	ps
t <sub>DIH</sub> – DATACLK_OUT to DATA Hold	-1250	-1360	-1548	-1640	-1890	ps

### POWER SUPPLY SEQUENCING

The 1.8 V supplies should be enabled prior to enabling the 3.3 V supplies. Do not enable the 3.3 V supplies when the 1.8 V supplies are off.
