

FEATURES

Excellent ac performance

- 3 dB bandwidth
- 800 MHz (200 mV p-p)
- 750 MHz (2 V p-p)
- Slew rate: 2400 V/ μ s

Low power: 75 mW, $V_S = \pm 5$ V

Excellent video performance

- 100 MHz, 0.1 dB gain flatness
- 0.02% differential gain error/0.02° differential phase error
($R_L = 150 \Omega$)

ADV3221 is a pin-for-pin upgrade to the HA4344

Gain = +1 (ADV3221) or gain = +2 (ADV3222)

Low all hostile crosstalk of -85 dB @ 5 MHz, and

-58 dB @ 100 MHz

Latched control lines for synchronous switching

High impedance output disable allows connection of multiple devices without loading the output bus

16-lead SOIC

APPLICATIONS

Routing of high speed signals including

- Video (NTSC, PAL, S, SECAM, YUV, RGB)
- Compressed video (MPEG, wavelet)
- 3-level digital video (HDB3)

Data communications

Telecommunications

GENERAL DESCRIPTION

The ADV3221 and ADV3222 are high speed, high slew rate, buffered 4:1 analog multiplexers. They offer a -3 dB signal bandwidth greater than 800 MHz and channel switch times of less than 20 ns with 1% settling. With lower than -58 dB of crosstalk and -67 dB isolation (at 100 MHz), the ADV3221 and ADV3222 are useful in many high speed applications. The differential gain error of less than 0.02% and differential phase error of less than 0.02°, together with 0.1 dB gain flatness out to 100 MHz while driving a 75 Ω back terminated load, make the ADV3221 and ADV3222 ideal for all types of signal switching.

The ADV3221/ADV3222 include an output buffer that can be placed into a high impedance state. This allows multiple outputs

Figure 1.

09852-001

to be connected together for cascading stages without the off channels loading the output bus. The ADV3221 has a gain of +1, and the ADV3222 has a gain of +2; they both operate on ± 5 V supplies while consuming less than 7.5 mA of idle current. The channel switching is performed via latched control lines, allowing synchronous updating in a multiple ADV3221/ADV3222 environment.

The ADV3221/ADV3222 are offered in a 16-lead SOIC package and are available over the extended industrial temperature range of -40°C to +85°C.

ABSOLUTE MAXIMUM RATINGS

Table 4.

Parameter	Rating
Supply Voltage (V+ – V–)	12 V
Analog Input Voltage	V– to V+
Digital Input Voltage	0 V to V+
Output Voltage (Disabled Output)	(V+ – 1 V) to (V– + 1 V)
Output Short-Circuit Duration	Momentary
Output Short-Circuit Current	50 mA
Storage Temperature Range	–65°C to +150°C
Operating Temperature Range	–40°C to +85°C
Lead Temperature (Soldering, 10 sec)	300°C
Junction Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 5. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
16-Lead Narrow-Body SOIC	81	43	°C/W

POWER DISSIPATION

The ADV3221/ADV3222 are operated with ± 5 V supplies and can drive loads down to 150 Ω , resulting in a wide range of possible power dissipations. For this reason, extra care must be taken to adjust the operating conditions based on ambient temperature.

Packaged in a 16-lead narrow-body SOIC, the ADV3221 and ADV3222 junction-to-ambient thermal impedance (θ_{JA}) is 81°C/W. For long-term reliability, the maximum allowed junction temperature of the die, T_J , should not exceed 125°C. Temporarily exceeding this limit may cause a shift in parametric performance due to a change in stresses exerted on the die by the package. Figure 4 shows the range of the allowed internal die power dissipations that meet these conditions over the –40°C to +85°C ambient temperature range. When using Figure 4, do not include the external load power in the maximum power calculation, but do include the load current through the die output transistors.

Figure 4. Maximum Die Power Dissipation vs. Ambient Temperature

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

THEORY OF OPERATION

The ADV3221/ADV3222 are dual-supply, high performance 4:1 analog multiplexers, optimized for switching between multiple video sources. High peak slew rates enable wide bandwidth operation for large input signals. Internal compensation provides for high phase margin, allowing low overshoot and fast settling for pulsed inputs. Low enabled and disabled power consumption make the ADV3221 and ADV3222 ideal for constructing larger arrays.

The ADV3221/ADV3222 are organized as four input transconductance stages tied in parallel with a single output transimpedance stage followed by a unity-gain buffer. Internal voltage feedback sets the gain. The ADV3221 is configured as a gain of 1, while the ADV3222 uses a resistive feedback network and ground buffer to realize gain-of-two operation (see Figure 60).

Figure 60. Conceptual Diagram of ADV3222

When not in use, the output can be placed in a low power, high impedance disabled mode via the $\overline{\text{CS}}$ logic input. This is useful when paralleling multiple ADV3221/ADV3222 devices in a system to create larger switching arrays.

Switching between the inputs is controlled with the A0, A1, and $\overline{\text{CS}}$ logic inputs, which are latched through two stages of asynchronous latches. $\overline{\text{CK1}}$ controls the first stage latch, and $\overline{\text{CK2}}$ controls the second stage latch. The latch state is dependent on the level of the CK1 and CK2 signals, and it is not edge triggered. When using multiple ADV3221/ADV3222 devices in a switch design, this double buffered logic allows the use of the CK2 signal to simultaneously update all ADV3221/ADV3222 devices in a system. The A0 and A1 logic inputs select which input is connected to the output (A1 is the most significant bit, A0 is the least significant bit), and the $\overline{\text{CS}}$ logic input determines whether the output is enabled or disabled.

APPLICATIONS INFORMATION

The ADV3221 and ADV3222 are high speed multiplexers used to switch video or RF signals. The low output impedance of the ADV3221/ADV3222 allows the output environment to be optimized for use in 75 Ω or 50 Ω systems by choosing the appropriate series termination resistor. For composite video applications, the ADV3222 (gain of +2) is typically used to provide compensation for the loss of the output termination.

CK1/CK2 OPERATION

The ADV3221/ADV3222 provide a double latched architecture for the A0, A1 (channel selection) and \overline{CS} (output enable) logic. This allows for simultaneous update of multiple devices in bank switching applications or large multiplexer systems consisting of multiple devices connected to common output busses.

Holding $\overline{CK1}$ and $\overline{CK2}$ low places the ADV3221/ADV3222 in a transparent mode. In transparent mode, all logic changes to A0, A1, and \overline{CS} immediately affects the input selection and output enable/disable.

CIRCUIT LAYOUT

Use of proper high speed design techniques is important to ensure optimum performance. Use a low inductance ground plane for power supply bypassing and to provide high quality return paths for the input and output signals. For best performance, it is recommended that power supplies be bypassed with 0.1 μF ceramic capacitors as close to the body of the device as possible. To provide stored energy for lower frequency, high current output driving, place 10 μF tantalum capacitors farther from the device.

The input and output signal paths should be stripline or microstrip controlled impedance. Video systems typically use 75 Ω characteristic impedance, whereas RF systems typically use 50 Ω . Various calculators are available to calculate the trace geometry required to produce the proper characteristic impedance.

TERMINATION

For a controlled impedance situation, termination resistors are required at the inputs and output of the device. The input termination should be a shunt resistor to ground with a value matching the characteristic impedance of the input trace. To reduce reflections, place the input termination resistor as close to the device input pin as possible. To minimize the input-to-input crosstalk, it is important to utilize a low inductance shield between input traces to isolate each input. Consideration of ground current paths must be taken to minimize loop currents in the shields to prevent them from providing a coupling medium for crosstalk.

For proper matching, the output series termination resistor should be the same value as the characteristic impedance of the output trace and placed as close to the output of the device as possible. This placement reduces the high frequency effect of series parasitic inductance, which can affect gain flatness and -3 dB bandwidth.

CAPACITIVE LOAD

A high frequency output can have difficulties when driving a large capacitive load, usually resulting in peaking in the frequency domain or overshoot in the time domain. If these effects become too large, oscillation can result.

The response of the device under various capacitive loads is shown in Figure 6 through Figure 12, and in Figure 15. If a condition arises where excessive load capacitance is encountered and the overshoot is too great or the device oscillates, a small series resistor of a few tens of ohms can be used to improve the performance.
