

## AFBR-S50MV85G

### Time-of-Flight Sensor Module for Distance and Motion Measurement

### Description

The Broadcom<sup>®</sup> AFBR-S50MV85G is a multi-pixel optical distance and motion measurement sensor module based on the optical Time-of-Flight principle. The technology has been developed with a special focus on applications with the need for the highest speed and accuracy at medium distance ranges, with small size and very low power consumption.

Due to its best-in-class ambient light suppression, use in outside environments is possible in direct sunlight. The sensor accurately measures white, black, colored, as well as metallic and retroreflective surfaces. The module has an integrated infrared laser light source and an integrated clock source. A single power supply of 5V is required. Data is transferred using a digital Serial Peripheral Interface (SPI) using standard 3.3V CMOS levels. For system health monitoring, an additional reference pixel is used in addition to integrated voltage sensors as well as a temperature sensor.

Frame rates of up to 3 kHz are supported, depending on the microcontroller, data streaming mode, and number of pixels used. For frame rates of up to 100 Hz, a dual-frequency mode (2f) is used to achieve an unambiguous range of 50m in short-range mode and 100m in long-range mode.

### Specifications

- Single voltage supply of 5V
- Typical current consumption of 33 mA
- Integrated 850 nm laser light source
- Typical optical peak output power of 40 mW
- Typical optical average output power < 0.6 mW
- Receiver with 32 pixels
- Field-of-View per pixel of 1.55° × 1.55°
- Transmitter beam width of 4° × 4° to illuminate typically 7 to 16 pixels (3 pixels per dimension)
- Distance range up to 10m and beyond
- Operation temperature (ambient): -20°C to +70°C
- SPI digital interface up to 25 MHz
- Size without pins: 12.4 × 7.6 × 7.9 mm<sup>3</sup> (L × W × H)

### Features

- Very fast measurement rates of up to 3 kHz
- Operation up to 200 kLux
- Multipixel for 3D motion detection
- Integrated calibrated clock source
- Accuracy error typically below ±1%
- Unambiguous range up to 100m in 2f mode
- Reference pixel for system health monitoring
- Laser Class 1 eye safe ready

### Applications

- Distance measurement
- Human machine interfaces
- Robotics
- Automation and control
- Security surveillance
- Inventory monitoring
- Augmented reality

# Mechanical Dimensions

Figure 1: Module Side and Top View (Dimensions in mm)

NOTES:

- 1) Dimensions are in millimeters.
- 2) Nominal values rounded to two decimal places - Suppression of following zeros.
- 3) PCB outer dimension
- 4) Housing outer dimension
- 5) Each pin head consists of a metal ring with a diameter of 1.0mm at the insertion point into the sensor PCB (Figure 2).

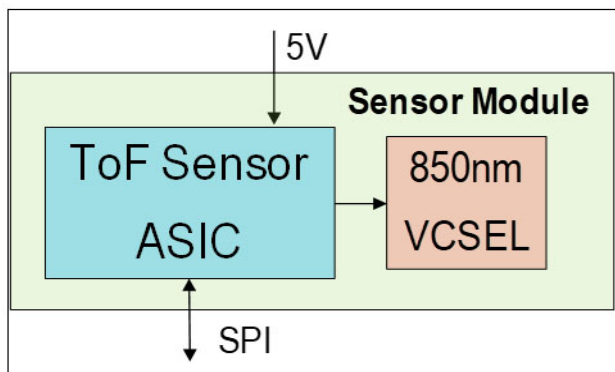

Figure 2: Module Bottom View (Dimensions in mm)

## Functional Description

The integrated Time-of-Flight (ToF) Sensor Module is equipped with an 850 nm vertical-cavity surface-emitting laser (VCSEL) for invisible infrared illumination. The integrated lens for the receiver has a clear aperture of 6 mm in diameter and a Field-of-View (FoV) of 1.55° per pixel.

**Figure 3: Block Diagram of the AFBR-S50MV85G**

The transmitter is aligned with the receiver to illuminate between 7 and 16 pixels simultaneously, depending on the distance and reflectivity of the target object as well as the settings of the software pixel binning algorithm. The binning algorithm can be configured by the user to either allow for more pixels for 3D applications or optimize settings for a highly precise 1D distance measurement, depending on the actual application. In addition the system compensates for parallax errors for very near distances. Basically, no lower distance limit is required. This allows the module to achieve a good pixel intensity for distance measurements over the whole measurement range, as well as deliver context information for the system. Context information includes motion, speed, tilt angles, or lateral alignment precision for small targets or features.

The maximum distance range for detecting black targets with 8% remission is up to 10m within an indoor environment. For harsh outdoor conditions under bright sunlight (for example, 100 kLux with a typical midday sunlight spectrum AM 1.5), the maximum distance range for detecting black targets with 8% remission is reduced to less than 7m. If dual-frequency mode is enabled, the useful distance substantially exceeds 10m for bright or highly reflective targets. This mode is supported for frame rates up to 100 Hz.

There is no processor with firmware on the module. All hardware configuration, calibration, and measurement steps are performed by an external microcontroller using the ToF driver software, which extracts both distance and amplitude values of all used pixels on a per-frame base. The driver software is available as a library independent of the underlying hardware platform within the ARM Cortex-M family. Example software applications such as extraction and graphical display of distance and direction is provided with the Software Developers Kit (SDK).

The ready-to-run binaries of the driver firmware include an Application Programmers Interface (API), which allows the user to configure and customize the device operation, are provided free of charge under a generic End User License Agreement. Additionally, a reference implementation utilizing the driver software binaries with an Arm Cortex M0/M0+, M1, M3, and M4+ 32-bit platform is provided with an open source SDK under the GNU GPL license for evaluation and reference purposes. For detailed instructions on how to install and run the kit, refer to the Getting Started Document.

The module uses an integrated factory-calibrated and temperature-compensated RC oscillator as well as an all-digital PLL for highly precise clock generation. The module is factory calibrated, however in certain applications (cover glass) an additional customer calibration is required. A suitable compensation and calibration functionality is provided along with the software driver and application software package.

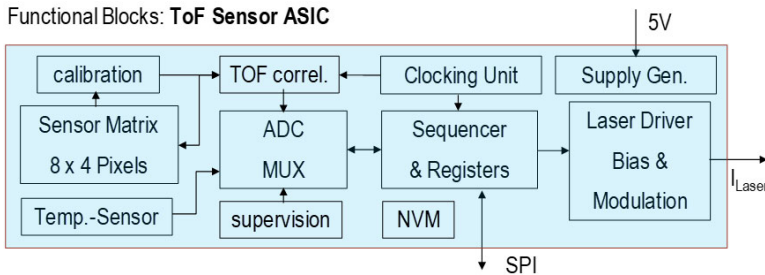

# Description of the Time-of-Flight Sensor ASIC and Detector Matrix

The ToF sensor ASIC includes all required building blocks for clock and supply generation out of a single supplied voltage, analog and digital signal processing, as well as a laser driver.

The receiver sensor consists of 32 pixels, partitioned into eight rows and four lines with a hexagonal structure.

The ToF drive stage allows both driving laser light sources with variable threshold and modulation currents as well as LEDs for up to 55 mA peak current, depending on module configuration.

**Figure 4: Functional Block Diagram of Sensor ASIC within AFBR-S50MV85G**

**Figure 5: Hexagonal Structure of Sensor Matrix (Dimensions in  $\mu\text{m}$ )**

**Figure 6: Field-of-View (FoV) Description of the Sensor**

## Detailed Module Pin Description and Operation

The housing/device includes 4.3 mm long pins and is designed for wave soldering—reflow soldering is not allowed. Because the housing is not hermetic and uses venting holes for pressure balance, no wash or flux clean is allowed. Operation in humid, non-condensing environments is possible (see [Operating Conditions and Electrical Characteristics](#)). The housing provides a robust mechanical, thermal, and electrical connection to the customer PCB. The module uses a 5.0V supply, which is split up into a Laser as well as a Sensor supply rail. Separate local blocking and filtering is recommended to avoid electrical crosstalk from the laser into the sensor supply. All data sheet performance values are based on the internal clock source only. The pins can be described as follows:

### I/O Pin Configuration

Pin Number	Name	Pin Type	Buffer Type	Description
1	SPI_CLK	I	3.3V CMOS	SPI Clock Input for SPI interface clock up to 25 MHz using standard 3.3V CMOS levels.
2	SPI_MOSI	I	3.3V CMOS	SPI Slave Data Input using standard 3.3V CMOS levels.
3	SPI_MISO	O	3.3V, PP	SPI Slave Data Output (Push-Pull) using standard 3.3V CMOS levels with a drive strength of 8 mA.
4	IRQ_n	O	3.3V, OD	Active Low Interrupt Output (Open Drain). Measurement-ready output (Open Drain), using standard 3.3V CMOS levels with a drive strength of 4 mA with an internal pull-up of 50 k $\Omega$ . An external pull-up to 3.3V using a 10 k $\Omega$ resistor is recommended.
5	GNDL	GND	—	Laser Driver Ground, connect with Sensor GND on the PCB.
6	VDDL	PWR	—	Laser Anode Supply, connect with a Ferrite Bead to 5V and buffer with 10 $\mu$ F/100 nF versus GNDL.
7	GND	GND	—	Sensor Ground, connect to a GND plane on the PCB.
8	VDD	PWR	—	Sensor Supply, connect to 5V and buffer with 10 $\mu$ F/100 nF versus GND.
9	GND	GND	—	Sensor Ground, connect to a GND plane on the PCB.
10	CLK+	I/O	3.3V/LVDS	Optional: Clock input/output, single-ended/differential. Reference clock output; do not connect if not used; differential or single-ended.
11	CLK-	I/O	LVDS	Optional Clock input/output, differential. Reference clock output; do not connect if not used; differential only.
12	Test	NU	—	Test pin for factory usage, do not connect.
13	VDD	PWR	—	Sensor Supply, connect to 5V and buffer with 10 $\mu$ F/100 nF versus GND.
14	GND	GND	—	Sensor Ground, connect to a GND plane on the PCB.
15	SPI_CS_n	I	3.3V CMOS	SPI Chip Select (active-low) using standard 3.3V CMOS levels, internal pull up of 50 k $\Omega$ .

## Absolute Maximum Ratings and Regulatory Compliance

Stresses in excess of the absolute maximum ratings can cause catastrophic damage to the device. Limits apply to each parameter in isolation, all other parameters having values within the recommended operation conditions. It should not be assumed that limiting values of more than one parameter can be applied to products at same time. Exposure to the absolute maximum ratings for extended periods can adversely affect device reliability.

### Absolute Maximum Ratings

Description	Symbol	Min.	Typ.	Max.	Units	Notes
Supply voltage sensor	VDD	-0.5	—	5.5	V	
Supply voltage laser	VDDL	-0.5	—	VDD + 1V	V	a
Storage temperature range	T <sub>stor</sub>	-40	—	95	°C	
Maximum operating temperature range	T <sub>amb</sub>	-20	—	70	°C	b
Lead soldering temperature	T <sub>sold</sub>	—	—	260	°C	c
Lead soldering time	tsold	—	—	10	s	c
ESD protection, human body model	ESD_HBM	-1500	—	1500	V	d
Ambient Light illuminance at starting, powering up, and resetting of device	Ev	—	—	100	k Lux	e

- During powering up, VDDL as well as all other signal pins must not exceed VDD by more than 1.0V.
- Operating the product outside the maximum rated ambient operating temperature range will compromise its reliability and may damage the product. Ambient air temperature is defined as the temperature measured with the thermocouple placed close to the sensor.
- The module is Pb-free wave solderable (no clean): JESD22-B106D. The moisture sensitivity level is 3.
- Human Body Model (HBM): JEDEC JS-001-2012.
- 100 kLux (Spectrum AM 1.5) measured on a 90% remission target.

### Regulatory Compliance

Feature	Test Method	Performance and Comments
Electrostatic discharge (ESD) to the electrical pins	JEDEC JS-001-2012	Withstands up to 1500V HBM applied between electrical pins.
RoHS I and II compliance	RoHS Directive 2011/65EU Annex II	
REACH compliance	EC No 1907/2006	
UL-94 flammability	UL-94V-0	
Eye safety	Tested according to the following standards: <ul style="list-style-type: none"> <li>■ EN 61010-1:2010</li> <li>■ EN 60825-1:2014</li> <li>■ EN 06825-2:2004+A1+A2</li> </ul>	Laser class 1 certified by TUV Rheinland Certificate No. R 50459299 <sup>a</sup>

- Laser Class 1 operation depends on correct system integration and configuration of software. Without the correct configuration or before the integration has been completed, the module can emit at higher levels and is rated as Laser Class 3B device.

Figure 7: Laser Safety Warning Sign for Unrecommended/Non-Default Operation

## Operating Conditions and Electrical Characteristics

### Recommended Operating Conditions

Description	Symbol	Min.	Typ.	Max.	Units	Notes
Supply voltage sensor	VDD	4.5	5	5.5	V	a
Supply voltage laser (anode)	VDDL	4.5	5	5.5	V	a
Maximum ripple of supply voltage sensor	VPP	—	—	100	mV <sub>pp</sub>	b
Maximum ripple of supply voltage laser	VPPL	—	—	100	mV <sub>pp</sub>	b
Operation temperature range	T <sub>amb</sub>	-20	25	70	°C	
Relative humidity, non-condensing	RH	—	—	85	%	

a. For operation over full temperature range, it is recommended to limit the range from 4.75V to 5.25V.

b. Ripple to be measured with a bandwidth of at least 200 MHz.

### Electrical Characteristics

Description	Symbol	Min.	Typ.	Max.	Units	Notes
SPI slave interface clock frequency	f <sub>SPI</sub>	1	12	25	MHz	
Low level input voltage	VIL	-0.3	—	0.8	V	
High level input voltage	VIH	2	—	3.6	V	
Low level output voltage	VOL	—	—	0.8	V	
High level output voltage	VOH	2.8	—	—	V	
Output current of SDO	I <sub>SDO</sub>	3	—	8	mA	
Peak laser current	I <sub>VDDL_peak</sub>	—	55	60	mA	
Average laser current	<I <sub>VDDL</sub> >	0.1	1	2	mA	a
Average sensor current	<I <sub>VDD</sub> >	—	32	40	mA	
Active system power consumption	P <sub>diss,total</sub>	—	165	230	mW	b
Power up time	t <sub>poweron</sub>	—	—	1	ms	c
Initialization time	T <sub>init</sub>	—	300	—	ms	d

a. Assumes Laser Class 1 operation.

b. Assumes a constantly active device and no use of standby modes between two frames.

c. Time until the device is ready to accept commands.

d. Initialization/boot-up time from first access to start of measurement.

## Optical Module Performance Summary

AFBR-S50MV85G is one of the most flexible Time-of-Flight measuring modules available in the market. It provides an excellent sensitivity combined with a very wide dynamic range, best-in-class ambient light suppression, and support for short measurement cycles. In contrast to typical laser ranging sensors, several pixels are operated simultaneously to allow for 3D object movement extractions. Of course all those performance parameters typically cannot be optimized at the same time. Therefore useful configurations for certain applications are supported and can be selected on-the-fly in the driver Software in order to allow for a combination and time interleaved operation of different modes.

## Optical and Sensor Characteristics

Description	Symbol	Min.	Typ.	Max.	Units	Notes
Emission wavelength	$\lambda$	840	850	865	nm	
Beam divergence $1/e_2$ full width	$\Theta_{full}$	3.5	4.0	4.5	°	a
Light spot diameter at 100 mm distance	$D_{100}$	6	7	8	mm	
Light spot diameter at 1000 mm distance	$D_{1000}$	61	70	80	mm	
Light spot diameter at 10,000 mm distance	$D_{10000}$	610	700	780	mm	
Pixel FoV at 100 mm distance	$D_{pix_{100}}$	—	2.7	—	mm	
Pixel FoV at 1000 mm distance	$D_{pix_{1000}}$	—	27	—	mm	
Pixel FoV at 10,000 mm distance	$D_{pix_{10000}}$	—	270	—	mm	
Number of actively illuminated pixels	$\#Pix_{illum}$	7	9	16	#	
Number of available pixels	$\#Pix$	—	32	—	#	
Pitch of detector pixels	$d_{Pix}$	—	150	—	$\mu m$	
Avalanche gain of detector pixels	M	15	50	100	#	b
Bit clock	$f_{bit}$	48	96	192	MHz	
Actual laser pulse length (pattern)	$t_{pulse}$	10.4	20.8	41.6	ns	
Number of configurable phase shifts	$\#ph$	1	4	16	#	
Analog integration time per phase	$t_{int}$	0.01	10	40	$\mu s$	
Digital averaging depth per phase	$\#S$	1	6	1024	#	
Frame Rate (all pixels, max. $t_{int}$ 20 $\mu s$ )	$f_{frame\_max}$	—	100	1000	Hz	c
Frame Rate (16 Pixels, max. $t_{int}$ 10 $\mu s$ )	$f_{frame\_max}$	—	100	2000	Hz	d
Frame Rate (8 Pixels, $t_{int}$ max. 5 $\mu s$ )	$f_{frame\_max}$	—	100	3000	Hz	e
Measurement range	$d_{meas}$	10	—	10,000	mm	f
Distance resolution	$\Delta d_{res}$	—	0.1	—	mm	
Precision	$\sigma$	0.5	5	—	mm	g
Absolute accuracy of zero point (offset)	$\Delta d_{abs}$	-10	—	10	mm	
Relative distance accuracy	$\Delta d_{rel}$	—	$\pm 1$	—	%	h
Ambient light illuminance suppression	$E_{AL}$	—	100,000	200,000	lx	i
Eye Safety IEC 60825-1:2014	Class	—	1	—	—	j

- Using optics and laser optimized for the simultaneous use of minimum 7 pixels.
- APD gain is configurable depending on application scenario and can be changed on-the-fly.
- Maximum 40 ns pulses, all pixels active, SPI clock minimum 12 MHz, analog integration time limited by eye safety.

- d. Maximum 40 ns pulses, 16 pixels active, SPI clock minimum 24 MHz, analog integration time limited by eye safety.
- e. Maximum 40 ns pulses, 8 pixels active, SPI clock minimum 24 MHz, analog integration time limited by eye safety.
- f. Maximum measurement range depends on target remission, ambient light, and sensor configuration.
- g. Depending on remission and distance of object, pulse length, and integration time (see [Figure 5](#) and [Figure 6](#)).
- h. Best accuracy values are achieved in short range mode and individual crosstalk calibration (API) for Broadcom default pixel binning settings with amplitudes larger 100 LSB at 25°C 1 kLux background light.
- i. Maximum value is 200 kLux (AM 1.5) on a 45% remission target or 100 kLux on a 90% remission target.
- j. Laser class depends on the software configuration; default operation is for IEC Laser Class 1. The customer must follow and fulfill the Broadcom SW and HW design recommendations to achieve Laser Class 1. Without the correct configuration or before the integration has been completed, the module can emit at higher levels and must be rated as a Laser Class 3B device.

## Example Characteristics

To show the dependency of distance measurement repeatability per pixel (1-sigma distance precision) on various factors including environmental as well as configuration options, a set of example precision characteristics are presented. The characteristics are valid for well-illuminated pixels only. AFBR-S50MV85G has a contiguous cluster of at least seven well-illuminated pixels simultaneously. Repeatability error is referred to as precision. Precision values as well as the maximum usable distance depend on the target reflectivity or remission (undirected reflectivity with lambertian characteristics), in combination with ambient light illumination of the target.

The average output power is selected to meet Laser Class 1 eye safety. The laser pulse lengths can be chosen either to allow for high precision and accuracy (short-range mode) or maximum sensitivity at the expense of larger distance noise (long-range mode). The native unambiguous range is 6.25m for short-range mode and 12.5m for long-range mode. It is extended by a factor of eight to 50m and 100m, respectively, if dual-frequency mode is selected. Dual-frequency mode is supported for frame rates up to 100 Hz.

By default, short-range mode is selected with dual-frequency mode enabled. [Figure 8](#) through [Figure 11](#) show the typical precision values per pixel as a function of target distance and target remission (8% for black, 18% for grey, and 90% for white) at different ambient light levels. In case of ambient light, both precision as well as the maximum usable range are degraded. For distances beyond the detection limit of objects with 8% remission, the background color is changed from green to blue.

By changing the sensor configuration in the software, this limit can be further increased if required, on the expense of precision and maximum possible frame rates.

The following general trends apply to all scenarios:

- Precision scales with the square root of frame rate. Because frame rate mainly determines the number of analog measurements per frame, and not the length of each individual analog measurement, it does not directly affect the detection limit or maximum usable range. For example, lowering the frame rate from 100 Hz to 25 Hz reduces the precision error by a factor of two.
- Precision also scales with pulse length (the shorter the pulses, the smaller the error), but short pulses also degrade the detection limit due to additional noise of the larger bandwidth.
- The influence of ambient light can be efficiently compensated to ensure that no overflow happens, it also does not change the detector efficiency; however the remaining additional shot noise degrades both detection limit as well as repeatability error.

In long-range mode with 40 ns pulse length, the native unambiguous range increases to 12.5m and sensitivity increases as well on the expense of precision. [Figure 12](#) through [Figure 15](#) illustrate the performance of long-range mode.

In general, it is recommended to use short-range mode, however in case dual-frequency mode must be disabled, for example when frame rates in excess of 100 Hz are required, long-range mode is preferred because of the larger unambiguous range. The figures in this section only illustrate some of the typical applications supported by the two standard configurations. There are many more configurations possible. To achieve optimum precision values, the APD gain (multiplication factor, M) is automatically adjusted by the ToF driver software according to the current illumination conditions. By default, the gain stage *medium high* is selected, which typically corresponds to  $M = 50$ .

**NOTE:** In the near infrared, most objects show different (often higher) remission values than in the visible range. Objects appearing deep black in the visible spectrum can easily have a remission value of 10% or higher in the 850 nm wavelength range.

## Typical Precision in Short-Range Mode, Indoor (Approximately 1 kLux)

Figure 8: Short-Range Mode Up to 4m at Frame Rate of 100 Hz and Laser Class 1, 1 kLux

## Digital Interface Characteristics

Register access is performed with a standard four-wire serial peripheral interface (SPI), which is available in all common microcontrollers. It can be run with up to 25 MHz clock frequency.

The default mode is SPI Mode 3, which translates into clock polarity CPOL = 1 (base value of clock is high) and clock phase CPHA = 1 (data output on falling edge, data is captured on rising edge). The chunk size is 8 bits (8 address bits, multiples of 8 data bits) and the endianness is big endian (most significant bit first). The timing relations are sketched in the following diagram.

Figure 16: SPI Timing Diagram

## SPI Slave Interface Timing Parameters

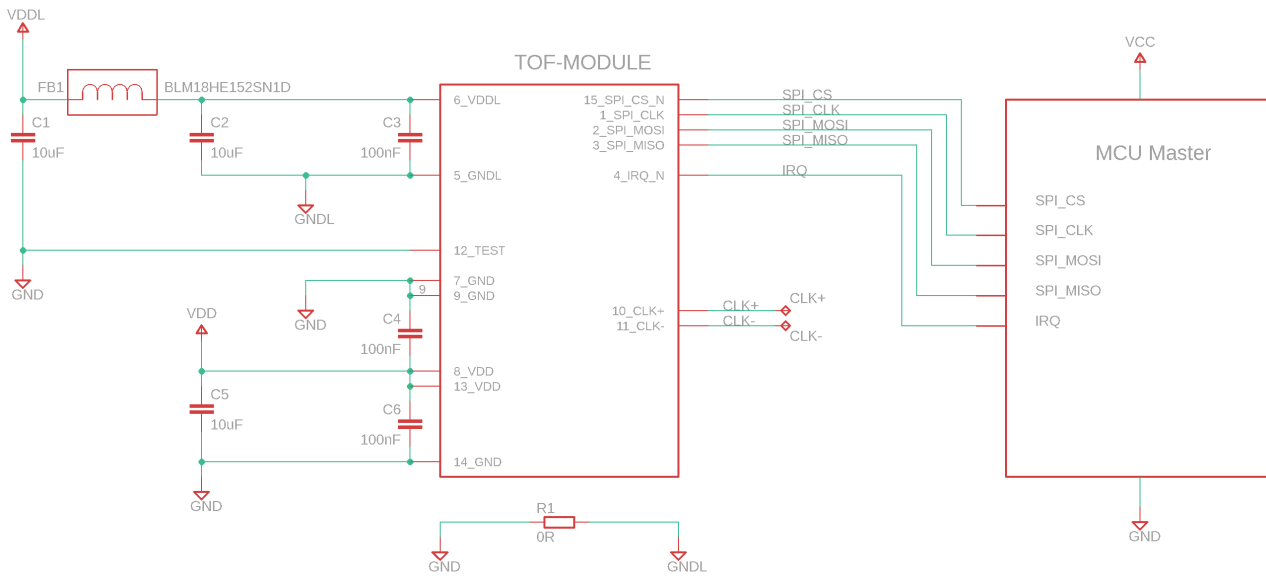

Description	Symbol	Min.	Typ.	Max.	Units	Notes
SPI clock frequency	$f_{\text{SPI}}$	1	12	25	MHz	—
SPI clock high period	$T_{\text{hCK}}$	—	40	—	ns	—
SPI clock low period	$T_{\text{ICK}}$	—	40	—	ns	—
Input logic low hysteresis	$V_{\text{IL}}$	—	—	1	V	—
Input logic high hysteresis	$V_{\text{IH}}$	2.18	—	—	V	—

Data output enable time	$t_{\text{enSO}}$	1.7	—	—	ns	—
Data output disable time	$t_{\text{disSO}}$	—	—	18.6	ns	—

# Application Circuit and Layout Recommendations

The ToF sensor module requires local power supply filtering to limit voltage ripple based on dynamic variations of current consumption and respective noise coupling into the module, as well as coupling back into the application circuit using the supply rails VDD and VDDL. The main noise source is the laser driver, which generates pulses of the order of 50 mA for a few nanosecond lengths, mainly drawn from the VDDL supply rail. The respective noisy GND is denoted as GNDL. The short pulses should be buffered with a 100 nF ceramic capacitor placed close to the VDDL and the GNDL pin with a sufficiently high frequency response (impedance of less than 0.5Ω between 10 MHz and 200 MHz, such as in the X7R type in a 0603 SMD package). Because the pulses are grouped into bursts, another larger capacitor referenced to GNDL should be used to stabilize the supply, followed by a bead and another 10 μF capacitor referenced to GND (pi filter) to block noise in both directions. At this point VDD and VDDL can be combined on the PCB to a single 5V supply rail. Because a similar switching noise must be filtered for the sensor supply VDD, both VDD supply pins should be buffered against GND with 100 nF. GNDL can be directly connected to a highly conductive GND plane.

There is no need to place an external oscillator, coils, or other active components except for a microcontroller unit (MCU) for module configuration and data processing. Shortcuts with the conductive ring at pin head must be avoided. The following images show an example schematic for the application board integration and layout proposal based on a 2-layer application PCB.

**Figure 17: Application Schematic**

**Figure 18: Application Layout (the Top Layer of a 2-Layer PCB Design)**

## Driver Software and Software Development Kit (SDK) Overview

The driver software contains all necessary parts for the sensor operation within a low-cost embedded system. It controls the light source, evaluates distances and infrared amplitudes, regulates integration times, calibrates absolute distances and temperature effects, and chooses the optimal pixels depending on the application (either distance measurement or multi-pixel applications). The module software package, containing the driver software core binaries including the API layers as well as example applications, is provided free-of-charge under a generic end-user license agreement. The core binaries are embedded in a reference application that runs on the NXP/Freescale KL46Z, Cortex-M0+ platform. The reference application is distributed under the open source GNU GPL license. The driver software was developed with a focus on portability to any low-power Arm Cortex-M, 32-bit based operation-system-less microcontroller platform. All calculations are based on fixed-point arithmetic and no floating point unit is required.

In addition, a Windows GUI software is provided for evaluation and graphical display of measurement results, as well as easy configuration management. The GUI connects to the reference application using a generic Systems Communication Interface (SCI) that sends and receives data packages over an USB connection. For a detailed description, refer to the API reference manual supplied with each software release.

**Figure 19: Driver Software Block Diagram**

This diagram shows the software architecture overview for the basic implementation of the ToF driver core into user hardware and software. The precompiled core is embedded into open source API layers providing an interface to the user application. A hardware interface declares the required hardware access for the ToF driver core to the underlying hardware and peripherals. The latter is required to connect the core to the AFBR-S50 ToF sensor hardware using SPI and GPIO interfaces.

The ToF driver core provides functionality to take care of device control and communication, sensor calibrations, and measurement data evaluations. The API layers surrounding the core and providing a user and hardware interfaces to access the core from the application code and drive the required peripherals, respectively. The ToF driver core and API are implemented hardware independent and can be ported to any Cortex-Mx based microcontroller platform.

The ToF driver core is designed as an interrupt driven architecture. This allows operating the device in the background while concurrently executing heavy evaluation functionality in the foreground. No operation system is required because the background task is executed directly in the interrupt callbacks. The callbacks executed from the interrupt service routines are kept small in order to not result in a delayed or stalled system.

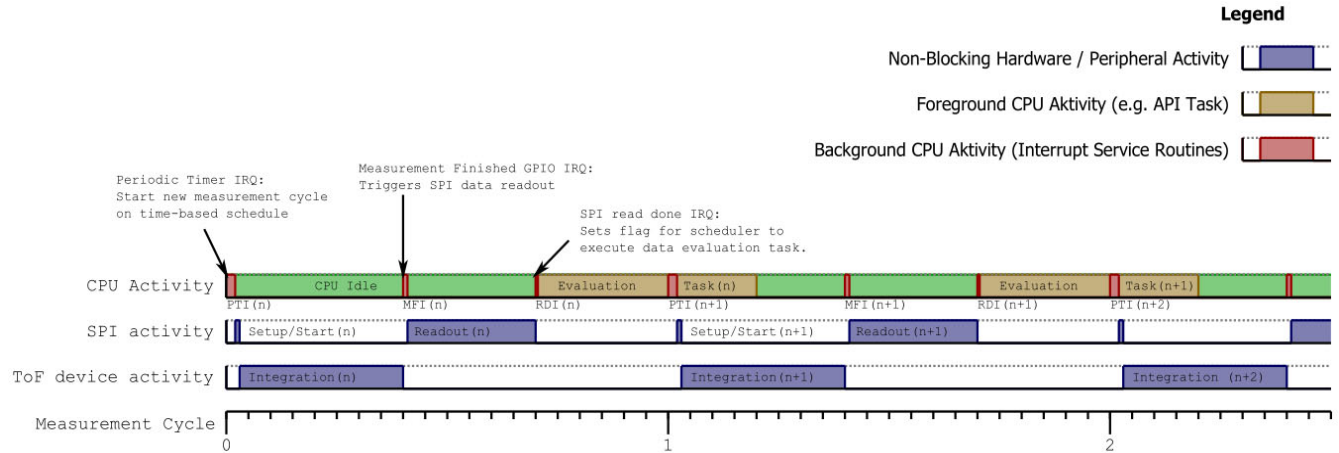

The device measurement cycle is triggered either by a periodic interrupt timer (PIT) or by a user call to the corresponding asynchronous API function. The core manages and updates the device configuration dynamically to adapt to changing ambient situations (for example, distance, reflectivity, background light, temperature, and so on) and trigger the device measurement cycle afterwards. After the measurement cycle has been performed autonomously on the chip, the raw data is read and the user application is informed by invoking a callback.

To avoid loading the interrupt service routines with a heavy workload, the user application must call the evaluation and calibration task from the foreground or main thread to perform calculations and obtain calibrated measurement results like range-per-pixel in meter units. This can be done by calling the evaluation task function from a simple main loop, using a basic preemptive task scheduler or even a real time operation system (RTOS). The core separates the measurement cycle into two main tasks:

1. The device communication with the ToF hardware is performed using a standard SPI interface plus a single IRQ line to obtain the data ready event. The communication is fully automated in the background within small interrupt service routines. The only action the user application might need to take is on the trigger of a new measurement cycle. This can also be done from a periodic interrupt timer. The device is dynamically updated with new configuration parameters (obtained by evaluation of the previous results or user request) before the measurement data acquisition is started. After the measurement cycle is finished, the pending IRQ from the device initiates the data read-out and a callback function is invoked to inform the user application of the data ready event.
2. The data evaluation and calibration of the raw data is performed by a simple function call from the main thread to the API. Afterwards, useful information such as range values, signal strength, or ambient light level are available for further usage in the user application.

The following figure shows an example of the software API measurement task timing.

**Figure 20: Software Timing Diagram**

A periodic timer interrupt (PTI) triggers the measurements in the background on a time-based schedule. After the device configuration is updated, the integration cycle starts. The device acquires all measurement data autonomously and raises the measurement finished interrupt (MFI) using a GPIO line upon finishing. The data is ready to read via the SPI interface. After the SPI communication is done, the user application is informed about the new data using a callback from the SPI read done interrupt (RDI). The user application is now responsible for calling the evaluation and calibration task for the received measurement data from the foreground or main task. Meanwhile, the PTI triggers the next measurement frame independently of the current user application state.

**NOTE:** The length of the evaluation task depends on the platform and chosen algorithms, and might be longer than the bare measurement frame time. This would lead to a delay of the measurement start and a slower frame rate.

In addition, there are several utility functions for calibration (for example, crosstalk/cover glass correction) and configuration (for example, frame rate, dynamic integration time adaption, pixel binning for 1D measurement) provided that help to achieve best sensor performance for a vast variety of application scenarios.

To be portable, the API requires the following interfaces to peripherals, which must be implemented by the user for the platform of choice:

- **SPI with GPIO:** Communication with the device is done using a standard four-wire SPI interface. An EEPROM is implemented in the chip that can be accessed via SPI pins using a not-SPI-compatible protocol that is implemented in software using a bit banging algorithm. Therefore, SPI pins must be accessible as GPIO pins too.
- **GPIO IRQ:** A single GPIO interrupt input line is required for the measurement finished interrupt.
- **Timer 1 (mandatory):** To obey the eye-safety limits, a highly accurate and independent hardware timer is required for time measurement occasions.
- **Timer 2 (optional):** To maintain a fixed frame rate and trigger measurements independently in the background, an additional periodic interrupt timer can be used.
- **Non-Volatile Memory (optional):** To permanently store user calibration and configuration data, a non-volatile memory like flash might be implemented.

In case the software stalls or the SPI interface is disturbed or breached, there is no risk of uncontrolled activity of the module. Because the measurement of each frame must be started by the software individually, the module will stop all activities automatically as soon as the SPI Chip Select is enabled, or latest after the current frame CPU measurement has been completed.

## Software and Application Support

Contact your local sales representative to get the latest SDK and associated documentation. Evaluation kits that include Windows-based evaluation software are also available.

For additional information, refer to the [AFBR-S50MV85G Product Page](#).

## Packaging and Ordering Information

The modules are shipped in tubes of 60 pieces each. The minimum order quantity is one tube. Including plugs, the tube length is 50 cm.

**Figure 21: Packing Details**

For checking availability and inventory at distribution channels, check inventory on the [AFBR-S50MV85G Product Page](#).
