Revision	Details	Date
Rev 1.0	Preliminary datasheet	Jan. 2018

## 128M x 8 bit DDR3 Synchronous DRAM (SDRAM)

Advance (Rev. 1.0, Jan /2018)

### Features

- JEDEC Standard Compliant
- Power supplies:  $V_{DD}$  &  $V_{DDQ} = +1.5V \pm 0.075V$
- Operating temperature range:
  - Commercial :  $T_C = 0 \sim 95^\circ C$
  - Industrial :  $T_C = -40 \sim 95^\circ C$
- Supports JEDEC clock jitter specification
- Fully synchronous operation
- Fast clock rate: 800MHz
- Differential Clock, CK & CK#
- Bidirectional differential data strobe
  - DQS & DQS#
- 8 internal banks for concurrent operation
- 8n-bit prefetch architecture
- Pipelined internal architecture
- Precharge & active power down
- Programmable Mode & Extended Mode registers
- Additive Latency (AL): 0, CL-1, CL-2
- Programmable Burst lengths: 4, 8
- Burst type: Sequential / Interleave
- Output Driver Impedance Control
- Average refresh period
  - 8192 cycles/64ms (7.8us at  $-40^\circ C \leq T_C \leq +85^\circ C$ )
  - 8192 cycles/32ms (3.9us at  $+85^\circ C \leq T_C \leq +95^\circ C$ )
- Write Leveling
- ZQ Calibration
- Dynamic ODT (Rtt\_Nom & Rtt\_WR)
- RoHS compliant
- Auto Refresh and Self Refresh
- 78-ball 8 x 10.5 x 1.0mm FBGA package
  - Pb and Halogen Free

### Overview

The 1Gb Double-Data-Rate-3 DRAMs is double data rate architecture to achieve high-speed operation. It is internally configured as an eight bank DRAM.

The 1Gb chip is organized as 16Mbit x 8 I/Os x 8 bank devices. These synchronous devices achieve high speed double-data-rate transfer rates of up to 1600 Mb/sec/pin for general applications.

The chip is designed to comply with all key DDR3 DRAM key features and all of the control and address inputs are synchronized with a pair of externally supplied differential clocks. Inputs are latched at the cross point of differential clocks (CK rising and CK# falling). All I/Os are synchronized with differential DQS pair in a source synchronous fashion.

These devices operate with a single 1.5V  $\pm 0.075V$  power supply and are available in BGA packages.

**Table 1. Ordering Information**

Product part No	Org	Temperature	Max Clock (MHz)	Package

Figure 2. Block Diagram

**Figure 3. State Diagram**

This simplified State Diagram is intended to provide an overview of the possible state transitions and the commands to control them. In particular, situations involving more than one bank, the enabling or disabling of on-die termination, and some other events are not captured in full detail

**Ball Descriptions**
**Table 3. Ball Details**

Symbol	Type	Description
CK, CK#	Input	<b>Differential Clock:</b> CK and CK# are driven by the system clock. All SDRAM input signals are sampled on the crossing of positive edge of CK and negative edge of CK#. Output (Read) data is referenced to the crossings of CK and CK# (both directions of crossing).
CKE	Input	<b>Clock Enable:</b> CKE activates (HIGH) and deactivates (LOW) the CK signal. If CKE goes LOW synchronously with clock, the internal clock is suspended from the next clock cycle and the state of output and burst address is frozen as long as the CKE remains LOW. When all banks are in the idle state, deactivating the clock controls the entry to the Power Down and Self Refresh modes.
BA0-BA2	Input	<b>Bank Address:</b> BA0-BA2 define to which bank the BankActivate, Read, Write, or Bank Precharge command is being applied.
A0-A13	Input	<b>Address Inputs:</b> A0-A13 is sampled during row address (A0-A13) for Active commands and the column address (A0-A9) for Read/Write commands to select one location out of the memory array in the respective bank. (A10/AP and A12/BC# have additional functions). The address inputs also provide the op-code during Mode Register Set commands.
A10/AP	Input	<b>Auto-Precharge:</b> A10 is sampled during Read/Write commands to determine whether Autoprecharge should be performed to the accessed bank after the Read/Write operation. (HIGH: Autoprecharge; LOW: no Autoprecharge). A10 is sampled during a Precharge command to determine whether the Precharge applies to one bank (A10 LOW) or all banks (A10 HIGH).
A12/BC#	Input	<b>Burst Chop:</b> A12/BC# is sampled during Read and Write commands to determine if burst chop (on the fly) will be performed. (HIGH - no burst chop; LOW - burst chopped).
CS#	Input	<b>Chip Select:</b> CS# enables (sampled LOW) and disables (sampled HIGH) the command decoder. All commands are masked when CS# is sampled HIGH. It is considered part of the command code.
RAS#	Input	<b>Row Address Strobe:</b> The RAS# signal defines the operation commands in conjunction with the CAS# and WE# signals and is latched at the crossing of positive edges of CK and negative edge of CK#. When RAS# and CS# are asserted "LOW" and CAS# is asserted "HIGH" either the BankActivate command or the Precharge command is selected by the WE# signal. When the WE# is asserted "HIGH" the BankActivate command is selected and the bank designated by BA is turned on to the active state. When the WE# is asserted "LOW" the Precharge command is selected and the bank designated by BA is switched to the idle state after the precharge operation.
CAS#	Input	<b>Column Address Strobe:</b> The CAS# signal defines the operation commands in conjunction with the RAS# and WE# signals and is latched at the crossing of positive edges of CK and negative edge of CK#. When RAS# is held "HIGH" and CS# is asserted "LOW" the column access is started by asserting CAS# "LOW". Then, the Read or Write command is selected by asserting WE# "HIGH" or "LOW".
WE#	Input	<b>Write Enable:</b> The WE# signal defines the operation commands in conjunction with the RAS# and CAS# signals and is latched at the crossing of positive edges of CK and negative edge of CK#. The WE# input is used to select the BankActivate or Precharge command and Read or Write command.
DQS, DQS#	Input / Output	<b>Bidirectional Data Strobe:</b> Specifies timing for Input and Output data. Read Data Strobe is edge triggered. Write Data Strobe provides a setup and hold time for data and DM. The data strobes DOS is paired with DQS# to provide differential pair signaling to the system during both reads and writes.
TDQS TDQS#	Output	<b>Termination Data Strobe:</b> When TDQS is enabled, DM is disabled, and the TDQS and TDQS# balls provide termination resistance.

DM	Input	<b>Data Input Mask:</b> Input data is masked when DM is sampled HIGH during a write cycle. DM has an optional use as TDQS on the x8.
DQ0-DQ7	Input / Output	<b>Data I/O:</b> The DQ0-DQ7 input and output data are synchronized with positive and negative edges of DQS and DQS#. The I/Os are byte-maskable during Writes.
ODT	Input	<b>On Die Termination:</b> ODT (registered HIGH) enables termination resistance internal to the DDR3 SDRAM. When enabled, ODT is applied to each DQ, DQS, DQS#, DM/TDQS and TDQS# signal. (When TDQS is enabled via Mode Register A11=1 in MR1) The ODT pin will be ignored if Mode-registers, MR1 and MR2, are programmed to disable RTT.
RESET#	Input	<b>Active Low Asynchronous Reset:</b> Reset is active when RESET# is LOW, and inactive when RESET# is HIGH. RESET# must be HIGH during normal operation. RESET# is a CMOS rail to rail signal with DC high and low at 80% and 20% of VDD.
V <sub>DD</sub>	Supply	<b>Power Supply:</b> +1.5V ±0.075V.
V <sub>SS</sub>	Supply	<b>Ground</b>
V <sub>DDQ</sub>	Supply	<b>DQ Power:</b> +1.5V ±0.075V.
V <sub>SSQ</sub>	Supply	<b>DQ Ground</b>
V <sub>REFCA</sub>	Supply	<b>Reference voltage for CA</b>
V <sub>REFDQ</sub>	Supply	<b>Reference voltage for DQ</b>
ZQ	Supply	<b>Reference pin for ZQ calibration.</b>
NC	-	<b>No Connect:</b> These pins should be left unconnected.

### Operation Mode Truth Table

The following tables provide a quick reference of available DDR3 SDRAM commands, including CKE power-down modes and bank-to-bank commands.

**Table 4. Truth Table (Note (1), (2))**

Command	State	CKE <sub>n-1</sub> <sup>(3)</sup>	CKE <sub>n</sub>	DM	BA0-2	A10/AP	A0-9, 11, 13	A12/BC#	CS#	RAS#	CAS#	WE#

ZQ Calibration Short	Idle	H	H	X	X	L	X	X	L	H	H	L

**NOTE 1:** V=Valid data, X=Don't Care, L=Low level, H=High level

**NOTE 2:** CKEn signal is input level when commands are provided.

**NOTE 3:** CKEn-1 signal is input level one clock cycle before the commands are provided.

**NOTE 4:** These are states of bank designated by BA signal.

**NOTE 5:** DM can be enabled respectively.

## Functional Description

The DDR3 SDRAM is a high-speed dynamic random access memory internally configured as an eight-bank DRAM. The DDR3 SDRAM uses an 8n prefetch architecture to achieve high speed operation. The 8n Prefetch architecture is combined with an interface designed to transfer two data words per clock cycle at the I/O pins. A single read or write operation for the DDR3 SDRAM consists of a single 8n-bit wide, four clock data transfer at the internal DRAM core and two corresponding n-bit wide, one-half clock cycle data transfers at the I/O pins.

Read and write operation to the DDR3 SDRAM are burst oriented, start at a selected location, and continue for a burst length of eight or a 'chopped' burst of four in a programmed sequence. Operation begins with the registration of an Active command, which is then followed by a Read or Write command. The address bits registered coincident with the Active command are used to select the bank and row to be activated (BA0-BA2 select the bank; A0-A13 select the row). The address bit registered coincident with the Read or Write command are used to select the starting column location for the burst operation, determine if the auto precharge command is to be issued (via A10), and select BC4 or BL8 mode 'on the fly' (via A12) if enabled in the mode register.

Prior to normal operation, the DDR3 SDRAM must be powered up and initialized in a predefined manner. The following sections provide detailed information covering device reset and initialization, register definition, command descriptions and device operation.

**Figure 4. Reset and Initialization Sequence at Power-on Ramping**

NOTE 1. From time point "Td" until "Tk" NOP or DES commands must be applied between MRS and ZQCL commands.

∥ TIME BREAK ■ Don't Care

## Power-up and Initialization

The Following sequence is required for POWER UP and Initialization

1. Apply power (RESET# is recommended to be maintained below  $0.2 \times VDD$ , all other inputs may be undefined). RESET# needs to be maintained for minimum 200us with stable power. CKE is pulled "Low" anytime before RESET# being de-asserted (min. time 10ns). The power voltage ramp time between 300mV to VDDmin must be no greater than 200ms; and during the ramp,  $VDD > VDDQ$  and  $(VDD - VDDQ) < 0.3$  Volts.
  - VDD and VDDQ are driven from a single power converter output, AND
  - The voltage levels on all pins other than VDD, VDDQ, VSS, VSSQ must be less than or equal to VDDQ and VDD on one side and must be larger than or equal to VSSQ and VSS on the other side. In addition, VTT is limited to 0.95V max once power ramp is finished, AND
  - Vref tracks VDDQ/2.OR
  - Apply VDD without any slope reversal before or at the same time as VDDQ.
  - Apply VDDQ without any slope reversal before or at the same time as VTT & Vref.
  - The voltage levels on all pins other than VDD, VDDQ, VSS, VSSQ must be less than or equal to VDDQ and VDD on one side and must be larger than or equal to VSSQ and VSS on the other side.
2. After RESET# is de-asserted, wait for another 500us until CKE become active. During this time, the DRAM will start internal state initialization; this will be done independently of external clocks.
3. Clock (CK, CK#) need to be started and stabilized for at least 10ns or 5tCK (which is larger) before CKE goes active. Since CKE is a synchronous signal, the corresponding set up time to clock (tIS) must be meeting. Also a NOP or Deselect command must be registered (with tIS set up time to clock) before CKE goes active. Once the CKE registered "High" after Reset, CKE needs to be continuously registered "High" until the initialization sequence is finished, including expiration of tDLLK and tZQinit.
4. The DDR3 DRAM will keep its on-die termination in high impedance state as long as RESET# is asserted. Further, the DRAM keeps its on-die termination in high impedance state after RESET# deassertion until CKE is registered HIGH. The ODT input signal may be in undefined state until tIS before CKE is registered HIGH. When CKE is registered HIGH, the ODT input signal may be statically held at either LOW or HIGH. If RTT\_NOM is to be enabled in MR1, the ODT input signal must be statically held LOW. In all cases, the ODT input signal remains static until the power up initialization sequence is finished, including the expiration of tDLLK and tZQinit.
5. After CKE being registered high, wait minimum of Reset CKE Exit time, tXPR, before issuing the first MRS command to load mode register. (tXPR=max (tXS, 5tCK))
6. Issue MRS command to load MR2 with all application settings. (To issue MRS command for MR2, provide "Low" to BA0 and BA2, "High" to BA1)
7. Issue MRS Command to load MR3 with all application settings. (To issue MRS command for MR3, provide "Low" to BA2, "High" to BA0 and BA1)
8. Issue MRS Command to load MR1 with all application settings and DLL enabled. (To issue "DLL Enable" command, provide "Low" to A0, "High" to BA0 and "Low" to BA1 and BA2)
9. Issue MRS Command to load MR0 with all application settings and "DLL reset". (To issue DLL reset command provide "High" to A8 and "Low" to BA0-BA2)
10. Issue ZQCL command to starting ZQ calibration.
11. Wait for both tDLLK and tZQinit completed.
12. The DDR3 SDRAM is now ready for normal operation.

### Reset Procedure at Stable Power

The following sequence is required for RESET at no power interruption initialization.

1. Asserted RESET below  $0.2 \cdot V_{DD}$  anytime when reset is needed (all other inputs may be undefined). RESET needs to be maintained for minimum 100ns. CKE is pulled "Low" before RESET being de-asserted (min. time 10ns).
2. Follow Power-up Initialization Sequence step 2 to 11.
3. The Reset sequence is now completed. DDR3 SDRAM is ready for normal operation.

**Figure 5. Reset Procedure at Power Stable Condition**

**NOTE 1.** From time point "Td" until "Tk" NOP or DES commands must be applied between MRS and ZQCL commands.

∥ TIME BREAK  Don't Care

## Register Definition

### Programming the Mode Registers

For application flexibility, various functions, features, and modes are programmable in four Mode Registers, provided by the DDR3 SDRAM, as user defined variables and they must be programmed via a Mode Register Set (MRS) command. As the default values of the Mode Registers are not defined, contents of Mode Registers must be fully initialized and/or re-initialized, i.e., written, after power up and/or reset for proper operation. Also the contents of the Mode Registers can be altered by re-executing the MRS command during normal operation. When programming the mode registers, even if the user chooses to modify only a sub-set of the MRS fields, all address fields within the accessed mode register must be redefined when the MRS command is issued. MRS command and DLL Reset do not affect array contents, which mean these commands can be executed any time after power-up without affecting the array contents.

The mode register set command cycle time,  $t_{MRD}$  is required to complete the write operation to the mode register and is the minimum time required between two MRS commands shown in Figure of  $t_{MRD}$  timing.

**Figure 6.  $t_{MRD}$  timing**

The MRS command to Non-MRS command delay,  $t_{MOD}$ , is required for the DRAM to update the features except DLL reset, and is the minimum time required from an MRS command to a non-MRS command excluding NOP and DES shown in Figure of  $t_{MOD}$  timing.

**Figure 7.  $t_{MOD}$  timing**

The mode register contents can be changed using the same command and timing requirements during normal operation as long as the DRAM is in idle state, i.e., all banks are in the precharged state with  $t_{RP}$  satisfied, all data bursts are completed and CKE is high prior to writing into the mode register. The mode registers are divided into various fields depending on the functionality and/or modes.

## Mode Register MR0

The mode-register MR0 stores data for controlling various operating modes of DDR3 SDRAM. It controls burst length, read burst type, CAS latency, test mode, DLL reset, WR, and DLL control for precharge Power-Down, which include various vendor specific options to make DDR3 DRAM useful for various applications. The mode register is written by asserting low on CS#, RAS#, CAS#, WE#, BA0, BA1, and BA2, while controlling the states of address pins according to the following figure.

**Table 5. Mode Register Bitmap**

Note 1. Reserved for future use and must be set to 0 when programming the MR.

Note 2. WR (write recovery for autoprecharge) min in clock cycles is calculated by dividing tWR (ns) by tCK (ns) and rounding up to the next integer WRmin [cycles] = Roundup (tWR / tCK). The value in the mode register must be programmed to be equal or larger than WRmin. The programmed WR value is used with tRP to determine tDAL.

### - CAS Latency

The CAS Latency is defined by MR0 (bit A2, A4~A6) as shown in the MR0 Definition figure. CAS Latency is the delay, in clock cycles, between the internal Read command and the availability of the first bit of output data. DDR3 SDRAM does not support any half clock latencies. The overall Read Latency (RL) is defined as Additive Latency (AL) + CAS Latency (CL); RL = AL + CL.

### - Test Mode

The normal operating mode is selected by MR0 (bit7=0) and all other bits set to the desired values shown in the MR0 definition figure. Programming bit A7 to a '1' places the DDR3 SDRAM into a test mode that is only used by the DRAM manufacturer and should not be used. No operations or functionality is guaranteed if A7=1.

### - Burst Length, Type, and Order

Accesses within a given burst may be programmed to sequential or interleaved order. The burst type is selected via bit A3 as shown in the MR0 Definition as above figure. The ordering of access within a burst is determined by the burst length, burst type, and the starting column address. The burst length is defined by bits A0-A1. Burst lengths options include fix BC4, fixed BL8, and on the fly which allow BC4 or BL8 to be selected coincident with the registration of a Read or Write command via A12/BC#

**Table 6. Burst Type and Burst Order**

Burst Length	Read Write	Starting Column Address			Sequential A3=0	Interleave A3=1	Note
		A2	A1	A0			
4 Chop	Read	0	0	0	0, 1, 2, 3, T, T, T, T	0, 1, 2, 3, T, T, T, T	1, 2, 3
		0	0	1	1, 2, 3, 0, T, T, T, T	1, 0, 3, 2, T, T, T, T	
		0	1	0	2, 3, 0, 1, T, T, T, T	2, 3, 0, 1, T, T, T, T	
		0	1	1	3, 0, 1, 2, T, T, T, T	3, 2, 1, 0, T, T, T, T	
		1	0	0	4, 5, 6, 7, T, T, T, T	4, 5, 6, 7, T, T, T, T	
		1	0	1	5, 6, 7, 4, T, T, T, T	5, 4, 7, 6, T, T, T, T	
		1	1	0	6, 7, 4, 5, T, T, T, T	6, 7, 4, 5, T, T, T, T	
		1	1	1	7, 4, 5, 6, T, T, T, T	7, 6, 5, 4, T, T, T, T	
	Write	0	V	V	0, 1, 2, 3, X, X, X, X	0, 1, 2, 3, X, X, X, X	1, 2, 4, 5
		1	V	V	4, 5, 6, 7, X, X, X, X	4, 5, 6, 7, X, X, X, X	
8	Read	0	0	0	0, 1, 2, 3, 4, 5, 6, 7	0, 1, 2, 3, 4, 5, 6, 7	2
		0	0	1	1, 2, 3, 0, 5, 6, 7, 4	1, 0, 3, 2, 5, 4, 7, 6	
		0	1	0	2, 3, 0, 1, 6, 7, 4, 5	2, 3, 0, 1, 6, 7, 4, 5	
		0	1	1	3, 0, 1, 2, 7, 4, 5, 6	3, 2, 1, 0, 7, 6, 5, 4	
		1	0	0	4, 5, 6, 7, 0, 1, 2, 3	4, 5, 6, 7, 0, 1, 2, 3	
		1	0	1	5, 6, 7, 4, 1, 2, 3, 0	5, 4, 7, 6, 1, 0, 3, 2	
		1	1	0	6, 7, 4, 5, 2, 3, 0, 1	6, 7, 4, 5, 2, 3, 0, 1	
		1	1	1	7, 4, 5, 6, 3, 0, 1, 2	7, 6, 5, 4, 3, 2, 1, 0	
	Write	V	V	V	0, 1, 2, 3, 4, 5, 6, 7	0, 1, 2, 3, 4, 5, 6, 7	2, 4

Note 1. In case of burst length being fixed to 4 by MR0 setting, the internal write operation starts two clock cycles earlier than for the BL8 mode. This means that the starting point for tWR and tWTR will be pulled in by two clocks. In case of burst length being selected on-the-fly via A12/BC#, the internal write operation starts at the same point in time like a burst of 8 write operation. This means that during on-the-fly control, the starting point for tWR and tWTR will not be pulled in by two clocks.

Note 2. 0~7 bit number is value of CA[2:0] that causes this bit to be the first read during a burst.

Note 3. T: Output driver for data and strobcs are in high impedance.

Note 4. V: a valid logic level (0 or 1), but respective buffer input ignores level on input pins.

Note 5. X: Don't Care.

### - DLL Reset

The DLL Reset bit is self-clearing, meaning it returns back to the value of '0' after the DLL reset function has been issued. Once the DLL is enabled, a subsequent DLL Reset should be applied. Anytime the DLL reset function is used, tDLLK must be met before any functions that require the DLL can be used (i.e. Read commands or ODT synchronous operations.)

### - Write Recovery

The programmed WR value MR0 (bits A9, A10, and A11) is used for the auto precharge feature along with tRP to determine tDAL. WR (write recovery for auto-precharge) min in clock cycles is calculated by dividing tWR (ns) by tCK (ns) and rounding up to the next integer: WR min [cycles] = Roundup (tWR [ns]/tCK [ns]). The WR must be programmed to be equal or larger than tWR (min).

### - Precharge PD DLL

MR0 (bit A12) is used to select the DLL usage during precharge power-down mode. When MR0 (A12=0), or 'slow-exit', the DLL is frozen after entering precharge power-down (for potential power savings) and upon exit requires tXPDLL to be met prior to the next valid command. When MR0 (A12=1), or 'fast-exit', the DLL is maintained after entering precharge power-down and upon exiting power-down requires tXP to be met prior to the next valid command.

## Mode Register MR1

The Mode Register MR1 stores the data for enabling or disabling the DLL, output strength, Rtt\_Nom impedance, additive latency, WRITE leveling enable and Qoff. The Mode Register 1 is written by asserting low on CS#, RAS#, CAS#, WE#, high on BA0 and low on BA1 and BA2, while controlling the states of address pins according to the following figure.

**Table 7. Extended Mode Register EMR (1) Bitmap**

Note 1. Reserved for future use and must be set to 0 when programming the MR.

Note 2. Outputs disabled - DQs, DQSs, DQS#s.

Note 3. In Write leveling Mode (MR1 [bit7] = 1) with MR1 [bit12] = 1, all RTT\_Nom settings are allowed; in Write Leveling Mode (MR1 [bit7] = 1) with MR1 [bit12]=0, only RTT\_Nom settings of RZQ/2, RZQ/4 and RZQ/6 are allowed.

Note 4. If RTT\_Nom is used during Writes, only the values RZQ/2, RZQ/4 and RZQ/6 are allowed.

### - DLL Enable/Disable

The DLL must be enabled for normal operation. DLL enable is required during power up initialization, and upon returning to normal operation after having the DLL disabled. During normal operation (DLL-on) with MR1 (A0=0), the DLL is automatically disabled when entering Self-Refresh operation and is automatically re-enabled upon exit of Self-Refresh operation. Any time the DLL is enabled and subsequently reset, tDLLK clock cycles must occur before a Read or synchronous ODT command can be issued to allow time for the internal clock to be synchronized with the external clock. Failing to wait for synchronization to occur may result in a violation of the tDQSCK, tAON, or tAOF parameters. During tDLLK, CKE must continuously be registered high. DDR3 SDRAM does not require DLL for any Write operation, except when RTT\_WR is enabled and the DLL is required for proper ODT operation. For more detailed information on DLL Disable operation are described in DLL-off Mode. The direct ODT feature is not supported during DLL-off mode. The on-die termination resistors must be disabled by continuously registering the ODT pin low and/or by programming the RTT\_Nom bits MR1{A9,A6,A2} to {0,0,0} via a mode register set command during DLL-off mode.

The dynamic ODT feature is not supported at DLL-off mode. User must use MRS command to set Rtt\_WR, MR2 {A10, A9} = {0, 0}, to disable Dynamic ODT externally

### - Output Driver Impedance Control

The output driver impedance of the DDR3 SDRAM device is selected by MR1 (bit A1 and A5) as shown in MR1 definition figure.

### - ODT Rtt Values

DDR3 SDRAM is capable of providing two different termination values (Rtt\_Nom and Rtt\_WR). The nominal termination value Rtt\_Nom is programmable in MR1. A separate value (Rtt\_WR) may be programmable in MR2 to enable a unique Rtt value when ODT is enabled during writes. The Rtt\_WR value can be applied during writes even when Rtt\_Nom is disabled.

### - Additive Latency (AL)

Additive Latency (AL) operation is supported to make command and data bus efficient for sustainable bandwidth in DDR3 SDRAM. In this operation, the DDR3 SDRAM allows a read or write command (either with or without auto-precharge) to be issued immediately after the active command. The command is held for the time of the Additive Latency (AL) before it is issued inside the device. The Read Latency (RL) is controlled by the sum of the AL and CAS Latency (CL) register settings. Write Latency (WL) is controlled by the sum of the AL and CAS Write Latency (CWL) register settings. A summary of the AL register options are shown in MR.

### - Write leveling

For better signal integrity, DDR3 memory module adopted fly-by topology for the commands, addresses, control signals, and clocks. The fly-by topology has benefits from reducing number of stubs and their length but in other aspect, causes flight time skew between clock and strobe at every DRAM on DIMM. It makes difficult for the Controller to maintain tDQSS, tDSS, and tDSH specification. Therefore, the controller should support 'write leveling' in DDR3 SDRAM to compensate for skew.

### - Output Disable

The DDR3 SDRAM outputs maybe enable/disabled by MR1 (bit 12) as shown in MR1 definition. When this feature is enabled (A12=1) all output pins (DQs, DQS, DQS#, etc.) are disconnected from the device removing any loading of the output drivers. This feature may be useful when measuring modules power for example. For normal operation A12 should be set to '0'.

### - TDQS enable

TDQS (Termination Data Strobe) is a feature of DDR3 SDRAM that provides additional termination resistance outputs that may be useful in some system configurations. In contrast to the RDQS function of DDR2 SDRAM, TDQS provides the termination resistance function only. The data strobe function of RDQS is not provided by TDQS. The TDQS and DM functions share the same pin. When the TDQS function is enabled via the mode register, the DM function is not supported. When the TDQS function is disabled, the DM function is provided and the TDQS# pin is not used. The TDQS function is available in X8 DDR3 SDRAM only.

## Mode Register MR2

The Mode Register MR2 stores the data for controlling refresh related features, Rtt\_WR impedance, and CAS write latency. The Mode Register 2 is written by asserting low on CS#, RAS#, CAS#, WE#, high on BA1 and low on BA0 and BA2, while controlling the states of address pins according to the table below.

**Table 8. Extended Mode Register EMR (2) Bitmap**

BA2	BA1	BA0	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0	Address Field
0 <sup>**</sup>	1	0	0 <sup>**</sup>			Rtt_WR		0 <sup>**</sup>	SRT	0	CWL			PASR			Mode Register (2)

BA1	BA0	MRS mode
0	0	MR0
0	1	MR1
1	0	MR2
1	1	MR3

A10	A9	RTT_WR <sup>**2</sup>
0	0	Dynamic ODT off (Write does not affect Rtt value)
0	1	RZQ/4
1	0	RZQ/2
1	1	Reserved

A7	Self-Refresh Temperature (SRT) Range
0	Normal operating temperature range
1	Extended (optional) operating temperature range

A2	A1	A0	Partial Array Self-Refresh (Optional)
0	0	0	Full Array
0	0	1	Half Array (BA[2:0]=000,001,010,&011)
0	1	0	Quarter Array (BA[2:0]=000,&001)
0	1	1	1/8 <sup>th</sup> Array (BA[2:0]=000)
1	0	0	3/4 Array (BA[2:0]=010,011,100,101,110,&111)
1	0	1	Half Array (BA[2:0]=100,101,110,&111)
1	1	0	Quarter Array (BA[2:0]=110,&111)
1	1	1	1/8 <sup>th</sup> Array (BA[2:0]=111)

A5	A4	A3	CAS write Latency (CWL)
0	0	0	5 (tCK(avg) ≥ 2.5ns)
0	0	1	6 (2.5ns > tCK(avg) ≥ 1.875ns)
0	1	0	7 (1.875ns > tCK(avg) ≥ 1.5ns)
0	1	1	8 (1.5ns > tCK(avg) ≥ 1.25ns)
1	0	0	9 (1.25ns > tCK(avg) ≥ 1.07ns)
1	0	1	Reserved
1	1	0	Reserved
1	1	1	Reserved

Note 1. BA2 and A8, A11~ A13 are RFU and must be programmed to 0 during MRS.

Note 2. The Rtt\_WR value can be applied during writes even when Rtt\_Nom is disabled.  
 During write leveling, Dynamic ODT is not available.

### - Partial Array Self-Refresh (PASR)

If PASR (Partial Array Self-Refresh) is enabled, data located in areas of the array beyond the specified address range will be lost if Self-Refresh is entered. Data integrity will be maintained if tREFI conditions are met and no Self-Refresh command is issued.

### - CAS Write Latency (CWL)

The CAS Write Latency is defined by MR2 (bits A3-A5) shown in MR2. CAS Write Latency is the delay, in clock cycles, between the internal Write command and the availability of the first bit of input data. DDR3 DRAM does not support any half clock latencies. The overall Write Latency (WL) is defined as Additive Latency (AL) + CAS Write Latency (CWL);  $WL=AL+CWL$ .

For more information on the supported CWL and AL settings based on the operating clock frequency, refer to "Standard Speed Bins". For detailed Write operation refer to "WRITE Operation".

### - Dynamic ODT (Rtt\_WR)

DDR3 SDRAM introduces a new feature "Dynamic ODT". In certain application cases and to further enhance signal integrity on the data bus, it is desirable that the termination strength of the DDR3 SDRAM can be changed without issuing an MRS command. MR2 Register locations A9 and A10 configure the Dynamic ODT settings.

DDR3 SDRAM introduces a new feature "Dynamic ODT". In certain application cases and to further enhance signal integrity on the data bus, it is desirable that the termination strength of the DDR3 SDRAM can be changed without issuing an MRS command. MR2 Register locations A9 and A10 configure the Dynamic ODT settings. In Write leveling mode, only RTT\_Nom is available. For details on Dynamic ODT operation, refer to "Dynamic ODT".

### - Self-Refresh Temperature (SRT)

Mode register MR2[7] is used to disable/enable the SRT function. When SRT is disabled, the self refresh mode's refresh rate is assumed to be at the normal 85°C limit (sometimes referred to as 1x refresh rate). In the disabled mode, SRT requires the user to ensure the DRAM never exceeds a TC of 85°C while in self refresh mode.

When SRT is enabled, the DRAM self refresh is changed internally from 1x to 2x, regardless of the case temperature. This enables the user to operate the DRAM beyond the standard 85°C limit up to the optional extended temperature range of 95°C while in self refresh mode. The standard self refresh current test specifies test conditions to normal case temperature (85°C) only, meaning if SRT is enabled, the standard self refresh current specifications do not apply (see Extended Temperature Usage).

### Extended Temperature Usage

DDR3 SDRAM supports the optional extended case temperature (TC) range of 0°C to 95°C. The extended temperature range DRAM must be refreshed externally at 2x (double refresh) anytime the case temperature is above 85°C (and does not exceed 95°C). The external refresh requirement is accomplished by reducing the refresh period from 64ms to 32ms. Thus, SRT must be enabled when TC is above 85°C or self refresh cannot be used until TC is at or below 85°C.

**Table 9. Self-Refresh mode summary**

MR2 A[7]	Self-Refresh operation	Allowed Operating Temperature Range for Self-Refresh mode
0	Self-Refresh rate appropriate for the Normal Temperature Range	Normal (0 ~ 85C)
1	Self-Refresh appropriate for either the Normal or Extended Temperature Ranges. The DRAM must support Extended Temperature Range. The value of the SRT bit can effect self-refresh power consumption, please refer to the IDD table for details.	Normal and Extended (0 ~ 95C)

### Mode Register MR3

The Mode Register MR3 controls Multi-purpose registers. The Mode Register 3 is written by asserting low on CS#, RAS#, CAS#, WE#, high on BA1 and BA0, and low on BA2 while controlling the states of address pins according to the table below

**Table 10. Extended Mode Register EMR (3) Bitmap**

Note 1. BA2, A3 - A13 are RFU and must be programmed to 0 during MRS.

Note 2. The predefined pattern will be used for read synchronization.

Note 3. When MPR control is set for normal operation (MR3 A[2] = 0) then MR3 A[1:0] will be ignored.

**Table 11. Absolute Maximum DC Ratings**

Symbol	Parameter	Values	Unit	Note
V <sub>DD</sub>	Voltage on VDD pin relative to V <sub>SS</sub>	-0.4 ~ 1.8	V	1,3
V <sub>DDQ</sub>	Voltage on VDDQ pin relative to V <sub>SS</sub>	-0.4 ~ 1.8	V	1,3
V <sub>IN</sub> , V <sub>OUT</sub>	Voltage on any pin relative to V <sub>SS</sub>	-0.4 ~ 1.8	V	1
T <sub>STG</sub>	Storage temperature	-55 ~ 100	°C	1,2

Note 1. Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Note 2. Storage Temperature is the case surface temperature on the center/top side of the DRAM.

Note 3. VDD and VDDQ must be within 300mV of each other at all times; and Vref must be not greater than 0.6VDDQ, when VDD and VDDQ are less than 500mV; Vref may be equal to or less than 300mV.

**Table 12. Temperature Range**

Symbol	Parameter	Values	Unit	Note
T <sub>OPER</sub>	Commercial Operating Temperature Range	0 ~ 95	°C	1-3
	Industrial Operating Temperature Range	-40 ~ 95	°C	1-4

Note 1. Operating temperature is the case surface temperature on center/top of the DRAM.

Note 2. The operating temperature range is the temperature where all DRAM specification will be supported. Outside of this temperature range, even if it is still within the limit of stress condition, some deviation on portion of operating specification may be required. During operation, the DRAM case temperature must be maintained between 0-85°C under all other specification parameter. Supporting 0 - 85 °C with full JEDEC AC & DC specifications.

Note 3. Some applications require operation of the DRAM in the Extended Temperature Range between 85 °C and 95 °C case temperature. Full specifications are guaranteed in this range, but the following additional apply.

- a. Refresh commands must be doubled in frequency, therefore, reducing the Refresh interval tREFI to 3.9us. It is also possible to specify a component with 1x refresh (tREFI to 7.8us) in the Extended Temperature Range.
- b. If Self-Refresh operation is required in the Extended Temperature Range, then it is mandatory to either use the Manual Self-Refresh mode with Extended Temperature Range capability (MR2 A6=0 and MR2 A7=1) or enable the optional Auto Self-Refresh mode (MR2 A6=1 and MR2 A7=0).

Note 4. During Industrial Temperature Operation Range, the DRAM case temperature must be maintained between -40°C~95°C under all operating Conditions.

**Table 13. Recommended DC Operating Conditions**

Symbol	Parameter	Min.	Typ.	Max.	Unit	Note
V <sub>DD</sub>	Power supply voltage	1.425	1.5	1.575	V	1,2
V <sub>DDQ</sub>	Power supply voltage for output	1.425	1.5	1.575	V	1,2

Note 1. Under all conditions VDDQ must be less than or equal to VDD.

Note 2. VDDQ tracks with VDD. AC parameters are measured with VDD and VDDQ tied together.

**Table 14. Single-Ended AC and DC Input Levels for Command and Address**

Symbol	Parameter	DDR3-1600		Unit	Note
		Min.	Max.		
V <sub>IH.CA</sub> (DC100)	DC input logic high	V <sub>REF</sub> +0.1	V <sub>DD</sub>	V	1,5
V <sub>IL.CA</sub> (DC100)	DC input logic low	V <sub>SS</sub>	V <sub>REF</sub> -0.1	V	1,6
V <sub>IH.CA</sub> (AC175)	AC input logic high	V <sub>REF</sub> +0.175	-	V	1,2
V <sub>IL.CA</sub> (AC175)	AC input logic low	-	V <sub>REF</sub> -0.175	V	1,2
V <sub>IH.CA</sub> (AC150)	AC input logic high	V <sub>REF</sub> +0.15	-	V	1,2
V <sub>IL.CA</sub> (AC150)	AC input logic low	-	V <sub>REF</sub> -0.15	V	1,2
V <sub>IH.CA</sub> (AC135)	AC input logic high	-	-	V	1,2
V <sub>IL.CA</sub> (AC135)	AC input logic low	-	-	V	1,2
V <sub>IH.CA</sub> (AC125)	AC input logic high	-	-	V	1,2
V <sub>IL.CA</sub> (AC125)	AC input logic low	-	-	V	1,2
V <sub>RefCA</sub> (DC)	Reference Voltage for ADD, CMD inputs	0.49xV <sub>DD</sub>	0.51xV <sub>DD</sub>	V	3,4

Note 1. For input only pins except RESET#. Vref = VrefCA(DC).

Note 2. See "Overshoot and Undershoot Specifications".

Note 3. The ac peak noise on Vref may not allow Vref to deviate from VrefCA(DC) by more than ±1% VDD.

Note 4. For reference: approx. VDD/2 ±15 mV.

Note 5. VIH(dc) is used as a simplified symbol for VIH.CA(DC100)

Note 6. VIL(dc) is used as a simplified symbol for VIL.CA(DC100)

Note 7. VIH(ac) is used as a simplified symbol for VIH.CA(AC175), VIH.CA(AC150), VIH.CA(AC135), and VIH.CA(AC125); VIH.CA(AC175) value is used when Vref + 0.175V is referenced, VIH.CA(AC150) value is used when Vref + 0.150V is referenced, VIH.CA(AC135) value is used when Vref + 0.135V is referenced, and VIH.CA(AC125) value is used when Vref + 0.125V is referenced.

Note 8. VIL(ac) is used as a simplified symbol for VIL.CA(AC175), VIL.CA(AC150), VIL.CA(AC135), and VIL.CA(AC125); VIL.CA(AC175) value is used when Vref - 0.175V is referenced, VIL.CA(AC150) value is used when Vref - 0.150V is referenced, VIL.CA(AC135) value is used when Vref - 0.135V is referenced, and VIL.CA(AC125) value is used when Vref - 0.125V is referenced.

**Table 15. Single-Ended AC and DC Input Levels for DQ and DM**

Symbol	Parameter	DDR3-1600		Unit	Note
		Min.	Max.		
V <sub>IH.DQ</sub> (DC100)	DC input logic high	V <sub>REF</sub> +0.1	V <sub>DD</sub>	V	1,5
V <sub>IL.DQ</sub> (DC100)	DC input logic low	V <sub>SS</sub>	V <sub>REF</sub> -0.1	V	1,6
V <sub>IH.DQ</sub> (AC150)	AC input logic high	V <sub>REF</sub> +0.15	-	V	1,2
V <sub>IL.DQ</sub> (AC150)	AC input logic low	-	V <sub>REF</sub> -0.15	V	1,2
V <sub>IH.DQ</sub> (AC135)	AC input logic high	-	-	V	1,2
V <sub>IL.DQ</sub> (AC135)	AC input logic low	-	-	V	1,2
V <sub>RefDQ</sub> (DC)	Reference Voltage for DQ, DM inputs	0.49xV <sub>DD</sub>	0.51xV <sub>DD</sub>	V	3,4

Note 1. Vref = VrefDQ(DC).

Note 2. See "Overshoot and Undershoot Specifications".

Note 3. The ac peak noise on Vref may not allow Vref to deviate from VrefDQ(DC) by more than ±1% VDD.

Note 4. For reference: approx. VDD/2 ±15 mV.

Note 5. VIH(dc) is used as a simplified symbol for VIH.DQ(DC100)

Note 6. VIL(dc) is used as a simplified symbol for VIL.DQ(DC100)

Note 7. VIH(ac) is used as a simplified symbol for VIH.DQ(AC150), VIH.DQ(AC135) and VIH.DQ(AC150) value is used when Vref + 0.150V is referenced, VIH.DQ(AC135) value is used when Vref + 0.135V is referenced.

Note 8. VIL(ac) is used as a simplified symbol for VIL.DQ(AC150), VIL.DQ(AC135) and VIL.DQ(AC150) value is used when Vref - 0.150V is referenced, VIL.DQ(AC135) value is used when Vref - 0.135V is referenced.

**Table 16. Differential AC and DC Input Levels**

Symbol	Parameter	Values		Unit	Note
		Min.	Max.		
V <sub>IHdiff</sub>	Differential input high	+ 0.2	Note 3	V	1
V <sub>ILdiff</sub>	Differential input logic low	Note 3	- 0.2	V	1
V <sub>IHdiff(ac)</sub>	Differential input high ac	2 x (V <sub>IH(ac)</sub> - V <sub>REF</sub> )	Notes 3	V	2
V <sub>ILdiff(ac)</sub>	Differential input low ac	Note 3	2 x (V <sub>IL(ac)</sub> - V <sub>REF</sub> )	V	2

Note 1. Used to define a differential signal slew-rate.

Note 2. For CK - CK# use V<sub>IH</sub>/V<sub>IL</sub>(ac) of ADD/CMD and V<sub>REFCA</sub>; for DQS, DQS# use V<sub>IH</sub>/V<sub>IL</sub>(ac) of DQs and V<sub>REFDQ</sub>; if a reduced ac-high or ac-low level is used for a signal group, then the reduced level applies also here.

Note 3. These values are not defined; however, the single-ended signals CK, CK#, DQS, DQS# need to be within the respective limits (V<sub>IH</sub>(dc) max, V<sub>IL</sub>(dc)min) for single-ended signals as well as the limitations for overshoot and undershoot.

**Table 17. Capacitance (V<sub>DD</sub> = 1.5V, T<sub>OPER</sub> = 25 °C)**

Symbol	Parameter	DDR3-1600		Unit	Note
		Min.	Max.		
C <sub>IO</sub>	Input/output capacitance, (DQ, DM, DQS, DQS#)	1.4	2.3	pF	1, 2, 3
C <sub>CK</sub>	Input capacitance, CK and CK#	0.8	1.4	pF	2, 3
C <sub>DCK</sub>	Input capacitance delta, CK and CK#	0	0.15	pF	2, 3, 4
C <sub>DDQS</sub>	Input/output capacitance delta, DQS and DQS#	0	0.15	pF	2, 3, 5
C <sub>I</sub>	Input capacitance, (CTRL, ADD, CMD input-only pins)	0.75	1.3	pF	2, 3, 6
C <sub>DI_CTRL</sub>	Input capacitance delta, (All CTRL input-only pins)	-0.4	0.2	pF	2, 3, 7, 8
C <sub>DI_ADD_CMD</sub>	Input capacitance delta, (All ADD, CMD input-only pins)	-0.4	0.4	pF	2, 3, 9, 10
C <sub>DIO</sub>	Input/output capacitance delta, (DQ, DM, DQS, DQS#)	-0.5	0.3	pF	2, 3, 11
C <sub>ZQ</sub>	Input/output capacitance of ZQ pin	-	3	pF	2, 3, 12

Note 1. Although the DM pins have different functions, the loading matches DQ and DQS.

Note 2. This parameter is not subject to production test. It is verified by design and characterization. V<sub>DD</sub>=V<sub>DDQ</sub>=1.5V, V<sub>BIAS</sub>=V<sub>DD</sub>/2 and ondie termination off.

Note 3. This parameter applies to monolithic devices only; stacked/dual-die devices are not covered here.

Note 4. Absolute value of C<sub>CK</sub>-C<sub>CK#</sub>.

Note 5. Absolute value of C<sub>IO</sub>(DQS)-C<sub>IO</sub>(DQS#).

Note 6. C<sub>I</sub> applies to ODT, CS#, CKE, A0-A13, BA0-BA2, RAS#, CAS#, WE#.

Note 7. C<sub>DI\_CTRL</sub> applies to ODT, CS# and CKE.

Note 8. C<sub>DI\_CTRL</sub>=C<sub>I</sub>(CTRL)-0.5\*(C<sub>I</sub>(CK)+C<sub>I</sub>(CK#)).

Note 9. C<sub>DI\_ADD\_CMD</sub> applies to A0-A13, BA0-BA2, RAS#, CAS# and WE#.

Note 10. C<sub>DI\_ADD\_CMD</sub>=C<sub>I</sub>(ADD\_CMD) - 0.5\*(C<sub>I</sub>(CK)+C<sub>I</sub>(CK#)).

Note 11. C<sub>DIO</sub>=C<sub>IO</sub>(DQ,DM) - 0.5\*(C<sub>IO</sub>(DQS)+C<sub>IO</sub>(DQS#)).

Note 12. Maximum external load capacitance on ZQ pin: 5 pF.

**Table 18. IDD specification parameters and test conditions ( $V_{DD} = 1.5V \pm 0.075V$ ,  $T_{OPER} = 0\sim 95^{\circ}C$  (Commercial),  $T_{OPER} = -40\sim 95^{\circ}C$  (Industrial))**

I <sub>DD8</sub>	10	mA

Note 1. Burst Length: BL8 fixed by MRS: set MR0 A[1,0]=00B.

Note 2. Output Buffer Enable: set MR1 A[12] = 0B; set MR1 A[5,1] = 01B; RTT\_Nom enable: set MR1 A[9,6,2] = 011B; RTT\_Wr enable: set MR2 A[10,9] = 10B.

Note 3. Pecharge Power Down Mode: set MR0 A12=0B for Slow Exit or MR0 A12=1B for Fast Exit.

Note 4. Self-Refresh Temperature Range (SRT): set MR2 A7=0B for normal or 1B for extended temperature range.

Note 5. Read Burst Type: Nibble Sequential, set MR0 A[3] = 0B.

Note 6. Supporting 0 - 85 °C with full JEDEC AC & DC specifications. This is the minimum requirements for all operating temperature options. However, for applications operating in Extended Temperature 85°C ~ 95°C, some optional spec are required.

$t_{PRPDEN}$	Timing of PRE or PREA command to Power Down entry		1	-	$t_{CK}$	20
$t_{RDPDEN}$	Timing of RD/RDA command to Power Down entry		RL+4+1	-	$t_{CK}$	
$t_{WRPDEN}$	Timing of WR command to Power Down entry (BL8OTF, BL8MRS, BC4OTF)		WL+4+ ( $t_{WR}/t_{CK}$ )	-	$t_{CK}$	9
$t_{WRAPDEN}$	Timing of WRA command to Power Down entry (BL8OTF, BL8MRS,BC4OTF)		WL+4+ WR+1	-	$t_{CK}$	10

$t_{WRPDEN}$	Timing of WR command to Power Down entry (BC4MRS)	WL+2+ ( $t_{WR}/t_{CK}$ )	-	$t_{CK}$	9
$t_{WRAPDEN}$	Timing of WRA command to Power Down entry (BC4MRS)	WL+2+ WR+1	-	$t_{CK}$	10
$t_{REFPDEN}$	Timing of REF command to Power Down entry	1	-	$t_{CK}$	20, 21
$t_{MRSPDEN}$	Timing of MRS command to Power Down entry	$t_{MOD(min)}$	-		
ODTLon	ODT turn on Latency	WL - 2 = CWL + AL - 2		$t_{CK}$	
ODTLoff	ODT turn off Latency	WL - 2 = CWL + AL - 2			
ODTH4	ODT high time without write command or with write command and BC4	4	-	$t_{CK}$	
ODTH8	ODT high time with Write command and BL8	6	-	$t_{CK}$	
$t_{AONPD}$	Asynchronous RTT turn-on delay (Power- Down with DLL frozen)	2	8.5	ns	
$t_{AOPFD}$	Asynchronous RTT turn-off delay (Power- Down with DLL frozen)	2	8.5	ns	
$t_{AON}$	RTT turn-on	-225	225	ps	7
$t_{AOF}$	RTT_Nom and RTT_WR turn-off time from ODTLoff reference	0.3	0.7	$t_{CK}$	8
$t_{ADC}$	RTT dynamic change skew	0.3	0.7	$t_{CK}$	
$t_{WLMRD}$	First DQS/DQS# rising edge after write leveling mode is programmed	40	-	$t_{CK}$	3
$t_{WLDQSEN}$	DQS/DQS# delay after write leveling mode is programmed	25	-	$t_{CK}$	3
$t_{WLS}$	Write leveling setup time from rising CK, CK# crossing to rising DQS, DQS# crossing	165	-	ps	
$t_{WLH}$	Write leveling hold time from rising DQS, DQS# crossing to rising CK, CK# crossing	165	-	ps	
$t_{WLO}$	Write leveling output delay	0	7.5	ns	
$t_{WLOE}$	Write leveling output error	0	2	ns	
$t_{RFC}$	REF command to ACT or REF command time	110	-	ns	
$t_{REFI}$	Average periodic refresh interval	-40°C to 85°C	-	7.8	$\mu$ s
		85°C to 95°C	-	3.9	$\mu$ s

Note 1. Actual value dependant upon measurement level.

Note 2. Commands requiring a locked DLL are: READ (and RAP) and synchronous ODT commands.

Note 3. The max values are system dependent.

Note 4. WR as programmed in mode register.

Note 5. Value must be rounded-up to next higher integer value.

Note 6. There is no maximum cycle time limit besides the need to satisfy the refresh interval,  $t_{REFI}$ .

Note 7. For definition of RTT turn-on time  $t_{AON}$  See "Timing Parameters".

Note 8. For definition of RTT turn-off time  $t_{AOF}$  See "Timing Parameters".

Note 9.  $t_{WR}$  is defined in ns, for calculation of  $t_{WRPDEN}$  it is necessary to round up  $t_{WR} / t_{CK}$  to the next integer.

Note 10. WR in clock cycles as programmed in MR0.

Note 11. The maximum read postamble is bound by  $t_{DQSCK(min)}$  plus  $t_{QSH(min)}$  on the left side and  $t_{HZ(DQS)max}$  on the right side. See "Clock to Data Strobe Relationship".

Note 12. Output timing deratings are relative to the SDRAM input clock. When the device is operated with input clock jitter, this parameter needs to be derated by t.b.d.

Note 13. Value is only valid for RON34.

Note 14. Single ended signal parameter.

Note 15.  $t_{REFI}$  depends on TOPER.

Note 16.  $t_{IS(base)}$  and  $t_{IH(base)}$  values are for 1V/ns CMD/ADD single-ended slew rate and 2V/ns CK, CK# differential slew rate. Note for DQ and DM signals,  $V_{REF(DC)} = V_{REFDQ(DC)}$ . For input only pins except RESET#,  $V_{REF(DC)} = V_{REFCA(DC)}$ . See "Address / Command Setup, Hold and Derating".

Note 17.  $t_{DS(base)}$  and  $t_{DH(base)}$  values are for 1V/ns DQ single-ended slew rate and 2V/ns DQS, DQS# differential slew rate. Note for DQ and DM signals,  $V_{REF(DC)} = V_{REFDQ(DC)}$ . For input only pins except RESET#,  $V_{REF(DC)} = V_{REFCA(DC)}$ . See "Data Setup, Hold and Slew Rate Derating".

Note 18. Start of internal write transaction is defined as follows:

- For BL8 (fixed by MRS and on- the-fly): Rising clock edge 4 clock cycles after WL.
- For BC4 (on- the- fly): Rising clock edge 4 clock cycles after WL.
- For BC4 (fixed by MRS): Rising clock edge 2 clock cycles after WL.

Note 19. The maximum read preamble is bound by  $t_{LZ(DQS)min}$  on the left side and  $t_{DQSCK(max)}$  on the right side. See "Clock to Data Strobe Relationship".

- Note 20. CKE is allowed to be registered low while operations such as row activation, precharge, autoprecharge or refresh are in progress, but power-down IDD spec will not be applied until finishing those operations.
- Note 21. Although CKE is allowed to be registered LOW after a REFRESH command once tREFPDEN(min) is satisfied, there are cases where additional time such as tXPDLL(min) is also required. See "Power-Down clarifications-Case 2".
- Note 22. Defined between end of MPR read burst and MRS which reloads MPR or disables MPR function.
- Note 23. One ZQCS command can effectively correct a minimum of 0.5 % (ZQ Correction) of RON and RTT impedance error within 64 nCK for all speed bins assuming the maximum sensitivities specified in the 'Output Driver Voltage and Temperature Sensitivity' and 'ODT Voltage and Temperature Sensitivity' tables. The appropriate interval between ZQCS commands can be determined from these tables and other application-specific parameters. One method for calculating the interval between ZQCS commands, given the temperature (Tdriftrate) and voltage (Vdriftrate) drift rates that the SDRAM is subject to in the application, is illustrated. The interval could be defined by the following formula:

$$\frac{ZQCorrection}{(TSens \times Tdriftrate) + (VSens \times Vdriftrate)}$$

Where TSens = max(dRTTdT, dRONdTM) and VSens = max(dRTTdV, dRONdVM) define the SDRAM temperature and voltage sensitivities.  
 For example, if TSens = 1.5% / °C, VSens = 0.15% / mV, Tdriftrate = 1 °C / sec and Vdriftrate = 15 mV / sec, then the interval between ZQCS commands is calculated as:

$$\frac{0.5}{(1.5 \times 1) + (0.15 \times 15)} = 0.133 \approx 128ms$$

- Note 24. n = from 13 cycles to 50 cycles. This row defines 38 parameters.
- Note 25. tCH(abs) is the absolute instantaneous clock high pulse width, as measured from one rising edge to the following falling edge.
- Note 26. tCL(abs) is the absolute instantaneous clock low pulse width, as measured from one falling edge to the following rising edge.
- Note 27. The tIS(base) AC150 specifications are adjusted from the tIS(base) specification by adding an additional 100ps of derating to accommodate for the lower alternate threshold of 150 mV and another 25 ps to account for the earlier reference point [(175 mv - 150 mV) / 1 V/ns].
- Note 28. Pulse width of a input signal is defined as the width between the first crossing of Vref(dc) and the consecutive crossing of Vref(dc).
- Note 29. tDQSL describes the instantaneous differential input low pulse width on DQS - DQS#, as measured from one falling edge to the next consecutive rising edge.
- Note 30. tDQSH describes the instantaneous differential input high pulse width on DQS - DQS#, as measured from one rising edge to the next consecutive falling edge.
- Note 31. tDQSH,act + tDQSL,act = 1 tCK,act ; with tXYZ,act being the actual measured value of the respective timing parameter in the application.
- Note 32. tDSH,act + tDSS,act = 1 tCK,act ; with tXYZ,act being the actual measured value of the respective timing parameter in the application.
- Note 33. The CL and CWL settings result in tCK requirements. When making a selection of tCK, both CL and CWL requirement settings need to be fulfilled.

### - Multi-Purpose Register (MPR)

The Multi Purpose Register (MPR) function is used to Read out a predefined system timing calibration bit sequence.

**Figure 8. MPR Block Diagram**

To enable the MPR, a MODE Register Set (MRS) command must be issued to MR3 Register with bit A2 = 1. Prior to issuing the MRS command, all banks must be in the idle state (all banks precharged and tRP met). Once the MPR is enabled, any subsequent RD or RDA commands will be redirected to the Multi Purpose Register. The resulting operation, when a RD or RDA command is issued, is defined by MR3 bits A[1:0] when the MPR is enabled as shown in table 20. When the MPR is enabled, only RD or RDA commands are allowed until a subsequent MRS command is issued with the MPR disabled (MR3 bit A2 = 0). Note that in MPR mode RDA has the same functionality as a READ command which means the auto precharge part of RDA is ignored. Power-Down mode, Self-Refresh and any other non-RD/RDA command is not allowed during MPR enable mode. The RESET function is supported during MPR enable mode.

**Table 20. MPR MR3 Register Definition**

MR3 A[2]	MR3 A[1:0]	Function
MPR	MPR-Loc	
0b	Don't care (0b or 1b)	Normal operation, no MPR transaction. All subsequent Reads will come from DRAM array. All subsequent Write will go to DRAM array.
1b	See the table 20	Enable MPR mode, subsequent RD/RDA commands defined by MR3 A[1:0].

### - MPR Functional Description

- One bit wide logical interface via all DQ pins during READ operation.
- Register Read on x8:
- DQ[0] drive information from MPR.
- DQ[7:1] either drive the same information as DQ [0], or they drive 0b.
- Addressing during for Multi Purpose Register reads for all MPR agents:
- BA [2:0]: don't care
- A[1:0]: A[1:0] must be equal to '00'b. Data read burst order in nibble is fixed
- A[2]: For BL=8, A[2] must be equal to 0b, burst order is fixed to [0,1,2,3,4,5,6,7], \*) For Burst Chop 4 cases, the burst order is switched on nibble base A [2]=0b, Burst order: 0,1,2,3 \*) A[2]=1b, Burst order: 4,5,6,7 \*)
- A[9:3]: don't care
- A10/AP: don't care
- A12/BC: Selects burst chop mode on-the-fly, if enabled within MR0.
- A11 (if available): don't care
- Regular interface functionality during register reads:
- Support two Burst Ordering which are switched with A2 and A[1:0]=00b.
- Support of read burst chop (MRS and on-the-fly via A12/BC)
- All other address bits (remaining column address bits including A10, all bank address bits) will be ignored by the DDR3 SDRAM.
- Regular read latencies and AC timings apply.
- DLL must be locked prior to MPR Reads.

**NOTE:** \*) Burst order bit 0 is assigned to LSB and burst order bit 7 is assigned to MSB of the selected MPR agent.

**Table 21. MPR MR3 Register Definition**

MR3 A[2]	MR3 A[1:0]	Function	Burst Length	Read Address A[2:0]	Burst Order and Data Pattern
1b	00b	Read Predefined Pattern for System Calibration	BL8	000b	Burst order 0, 1, 2, 3, 4, 5, 6, 7 Pre-defined Data Pattern [0, 1, 0, 1, 0, 1, 0, 1]
			BC4	000b	Burst order 0, 1, 2, 3 Pre-defined Data Pattern [0, 1, 0, 1]
			BC4	100b	Burst order 4, 5, 6, 7 Pre-defined Data Pattern [0, 1, 0, 1]
1b	01b	RFU	BL8	000b	Burst order 0, 1, 2, 3, 4, 5, 6, 7
			BC4	000b	Burst order 0, 1, 2, 3
			BC4	100b	Burst order 4, 5, 6, 7
1b	10b	RFU	BL8	000b	Burst order 0, 1, 2, 3, 4, 5, 6, 7
			BC4	000b	Burst order 0, 1, 2, 3
			BC4	100b	Burst order 4, 5, 6, 7
1b	11b	RFU	BL8	000b	Burst order 0, 1, 2, 3, 4, 5, 6, 7
			BC4	000b	Burst order 0, 1, 2, 3
			BC4	100b	Burst order 4, 5, 6, 7

### No Operation (NOP) Command

The No operation (NOP) command is used to instruct the selected DDR3 SDRAM to perform a NOP (CS# low and RAS#, CAS# and WE# high). This prevents unwanted commands from being registered during idle or wait states. Operations already in progress are not affected.

### Deselect Command

The Deselect function (CS# HIGH) prevents new commands from being executed by the DDR3 SDRAM. The DDR3 SDRAM is effectively deselected. Operations already in progress are not affected.

### DLL- Off Mode

DDR3 DLL-off mode is entered by setting MR1 bit A0 to "1"; this will disable the DLL for subsequent operations until A0 bit set back to "0". The MR1 A0 bit for DLL control can be switched either during initialization or later.

The DLL-off Mode operations listed below are an optional feature for DDR3. The maximum clock frequency for DLL-off Mode is specified by the parameter tCKDLL\_OFF. There is no minimum frequency limit besides the need to satisfy the refresh interval, tREFI.

Due to latency counter and timing restrictions, only one value of CAS Latency (CL) in MR0 and CAS Write Latency (CWL) in MR2 are supported. The DLL-off mode is only required to support setting of both CL=6 and CWL=6.

DLL-off mode will affect the Read data Clock to Data Strobe relationship (tDQSCK) but not the data Strobe to Data relationship (tDQSQ, tQH). Special attention is needed to line up Read data to controller time domain. Comparing with DLL-on mode, where tDQSCK starts from the rising clock edge (AL+CL) cycles after the Read command, the DLL-off mode tDQSCK starts (AL+CL-1) cycles after the read command. Another difference is that tDQSCK may not be small compared to tCK (it might even be larger than tCK) and the difference between tDQSCKmin and tDQSCKmax is significantly larger than in DLL-on mode.

The timing relations on DLL-off mode READ operation have shown at the following Timing Diagram (CL=6, BL=8)

**Figure 9. DLL-off mode READ Timing Operation**

**NOTE 1.** The tDQSCK is used here for DQS, DQS# and DQ to have a simplified diagram; the DLL\_off shift will affect both timings in the same way and the skew between all DQ and DQS, DQS# signals will still be tDQSQ.

■ TRANSITIONING DATA ■ Don't Care

## DLL on/off switching procedure

DDR3 DLL-off mode is entered by setting MR1 bit A0 to "1"; this will disable the DLL for subsequent operation until A0 bit set back to "0".

## DLL "on" to DLL "off" Procedure

To switch from DLL "on" to DLL "off" requires the frequency to be changed during Self-Refresh outlined in the following procedure:

1. Starting from Idle state (all banks pre-charged, all timing fulfilled, and DRAMs On-die Termination resistors, RTT, must be in high impedance state before MRS to MR1 to disable the DLL).
2. Set MR1 Bit A0 to "1" to disable the DLL.
3. Wait tMOD.
4. Enter Self Refresh Mode; wait until (tCKSRE) satisfied.
5. Change frequency, in guidance with "Input Clock Frequency Change" section.
6. Wait until a stable clock is available for at least (tCKSRX) at DRAM inputs.
7. Starting with the Self Refresh Exit command, CKE must continuously be registered HIGH until all tMOD timings from any MRS command are satisfied. In addition, if any ODT features were enabled in the mode registers when Self Refresh mode was entered, the ODT signal must continuously be registered LOW until all tMOD timings from any MRS command are satisfied. If both ODT features were disabled in the mode registers when Self Refresh mode was entered, ODT signal can be registered LOW or HIGH.
8. Wait tXS, and then set Mode Registers with appropriate values (especially an update of CL, CWL, and WR may be necessary. A ZQCL command may also be issued after tXS).
9. Wait for tMOD, and then DRAM is ready for next command.

**Figure 10. DLL Switch Sequence from DLL-on to DLL-off**

**NOTES:**

1. Starting with Idle State, RTT in Hi-Z state
2. Disable DLL by setting MR1 Bit A0 to 1
3. Enter SR
4. Change Frequency
5. Clock must be stable tCKSRX
6. Exit SR
7. Update Mode registers with DLL off parameters setting
8. Any valid command

⋈ TIME BREAK    ■ Don't Care

### DLL “off” to DLL “on” Procedure

To switch from DLL “off” to DLL “on” (with requires frequency change) during Self-Refresh:

1. Starting from Idle state (all banks pre-charged, all timings fulfilled and DRAMs On-die Termination resistors (RTT) must be in high impedance state before Self-Refresh mode is entered).
2. Enter Self Refresh Mode, wait until tCKSRE satisfied.
3. Change frequency, in guidance with “Input clock frequency change” section.
4. Wait until a stable clock is available for at least (tCKSRX) at DRAM inputs.
5. Starting with the Self Refresh Exit command, CKE must continuously be registered HIGH until tDLLK timing from subsequent DLL Reset command is satisfied. In addition, if any ODT features were enabled in the mode registers when Self Refresh mode was entered, the ODT signal must continuously be registered LOW until tDLLK timings from subsequent DLL Reset command is satisfied. If both ODT features are disabled in the mode registers when Self Refresh mode was entered, ODT signal can be registered LOW or HIGH.
6. Wait tXS, then set MR1 Bit A0 to “0” to enable the DLL.
7. Wait tMRD, then set MR0 Bit A8 to “1” to start DLL Reset.
8. Wait tMRD, then set Mode registers with appropriate values (especially an update of CL, CWL, and WR may be necessary. After tMOD satisfied from any proceeding MRS command, a ZQCL command may also be issued during or after tDLLK).
9. Wait for tMOD, then DRAM is ready for next command (remember to wait tDLLK after DLL Reset before applying command requiring a locked DLL!). In addition, wait also for tZQoper in case a ZQCL command was issued.

**Figure 11. DLL Switch Sequence from DLL-off to DLL on**

**NOTES:**

1. Starting with Idle State
2. Enter SR
3. Change Frequency
4. Clock must be stable tCKSRX
5. Exit SR
6. Set DLL on by MR1 A0 = 0
7. Start DLL Reset by MR0 A8=1
8. Update Mode registers
9. Any valid command

}} TIME BREAK █ Don't Care

### Jitter Notes

- Note 1. Unit 'tCK(avg)' represents the actual tCK(avg) of the input clock under operation. Unit 'nCK' represents one clock cycle of the input clock, counting the actual clock edges.ex) tMRD = 4 [nCK] means; if one Mode Register Set command is registered at T<sub>m</sub>, another Mode Register Set command may be registered at T<sub>m</sub>+4, even if (T<sub>m</sub>+4 - T<sub>m</sub>) is 4 x tCK(avg) + tERR(4per),min.
- Note 2. These parameters are measured from a command/address signal (CKE, CS#, RAS#, CAS#, WE#, ODT, BAO, A0, A1, etc.) transition edge to its respective clock signal (CK/CK#) crossing. The spec values are not affected by the amount of clock jitter applied (i.e. tJIT(per), tJIT(cc), etc.), as the setup and hold are relative to the clock signal crossing that latches the command/address. That is, these parameters should be met whether clock jitter is present or not.
- Note 3. These parameters are measured from a data strobe signal (DQS, DQS#) crossing to its respective clock signal (CK, CK#) crossing. The spec values are not affected by the amount of clock jitter applied (i.e. tJIT(per), tJIT(cc), etc.), as these are relative to the clock signal crossing. That is, these parameters should be met whether clock jitter is present or not.
- Note 4. These parameters are measured from a data signal (DM, DQ0, DQ1, etc.) transition edge to its respective data strobe signal (DQS, DQS#) crossing.
- Note 5. For these parameters, the DDR3 SDRAM device supports tnPARAM [nCK] = RU{ tPARAM [ns] / tCK(avg) [ns] }, which is in clock cycles, assuming all input clock jitter specifications are satisfied.
- Note 6. When the device is operated with input clock jitter, this parameter needs to be derated by the actual tERR(mper),act of the input clock, where 2 <= m <= 12. (output deratings are relative to the SDRAM input clock.)
- Note 7. When the device is operated with input clock jitter, this parameter needs to be derated by the actual tJIT(per),act of the input clock. (output deratings are relative to the SDRAM input clock.)

**Table 22. Input clock jitter spec parameter**

Parameter	Symbol	-12		Unit
		Min.	Max.	
Clock period jitter	t <sub>JIT</sub> (per)	-70	70	ps
Clock period jitter during DLL locking period	t <sub>JIT</sub> (per,lck)	-60	60	ps
Cycle to cycle clock period jitter	t <sub>JIT</sub> (cc)	140		ps
Cycle to cycle clock period jitter during DLL locking period	t <sub>JIT</sub> (cc,lck)	120		ps
Cumulative error across 2 cycles	t <sub>ERR</sub> (2per)	-103	103	ps
Cumulative error across 3 cycles	t <sub>ERR</sub> (3per)	-122	122	ps
Cumulative error across 4 cycles	t <sub>ERR</sub> (4per)	-136	136	ps
Cumulative error across 5 cycles	t <sub>ERR</sub> (5per)	-147	147	ps
Cumulative error across 6 cycles	t <sub>ERR</sub> (6per)	-155	155	ps
Cumulative error across 7 cycles	t <sub>ERR</sub> (7per)	-163	163	ps
Cumulative error across 8 cycles	t <sub>ERR</sub> (8per)	-169	169	ps
Cumulative error across 9 cycles	t <sub>ERR</sub> (9per)	-175	175	ps
Cumulative error across 10 cycles	t <sub>ERR</sub> (10per)	-180	180	ps
Cumulative error across 11 cycles	t <sub>ERR</sub> (11per)	-184	184	ps
Cumulative error across 12 cycles	t <sub>ERR</sub> (12per)	-188	188	ps
Cumulative error across n cycles, n=13...50, inclusive	t <sub>ERR</sub> (nper)	$t_{ERR(nper)}_{min} = (1+0.68\ln(n)) * t_{JIT(per)}_{min}$ $t_{ERR(nper)}_{max} = (1+0.68\ln(n)) * t_{JIT(per)}_{max}$		ps

### Input Clock frequency change

Once the DDR3 SDRAM is initialized, the DDR3 SDRAM requires the clock to be “stable” during almost all states of normal operation. This means once the clock frequency has been set and is to be in the “stable state”, the clock period is not allowed to deviate except for what is allowed for by the clock jitter and SSC (spread spectrum clocking) specification.

The input clock frequency can be changed from one stable clock rate to another stable clock rate under two conditions: (1) Self-Refresh mode and (2) Precharge Power-Down mode. Outside of these two modes, it is illegal to change the clock frequency.

For the first condition, once the DDR3 SDRAM has been successfully placed in to Self-Refresh mode and  $t_{CKSRE}$  has been satisfied, the state of the clock becomes a don't care. Once a don't care, changing the clock frequency is permissible, provided the new clock frequency is stable prior to  $t_{CKSRX}$ . When entering and exiting Self-Refresh mode of the sole purpose of changing the clock frequency, the Self-Refresh entry and exit specifications must still be met. The DDR3 SDRAM input clock frequency is allowed to change only within the minimum and maximum operating frequency specified for the particular speed grade.

The second condition is when the DDR3 SDRAM is in Precharge Power-Down mode (either fast exit mode or slow exit mode). If the  $RTT\_Nom$  feature was enabled in the mode register prior to entering Precharge power down mode, the ODT signal must continuously be registered LOW ensuring  $RTT$  is in an off state. If the  $RTT\_Nom$  feature was disabled in the mode register prior to entering Precharge power down mode,  $RTT$  will remain in the off state. The ODT signal can be registered either LOW or HIGH in this case. A minimum of  $t_{CKSRE}$  must occur after  $CKE$  goes LOW before the clock frequency may change. The DDR3 SDRAM input clock frequency is allowed to change only within the minimum and maximum operating frequency specified for the particular speed grade. During the input clock frequency change, ODT and  $CKE$  must be held at stable LOW levels. Once the input clock frequency is changed, stable new clocks must be provided to the DRAM  $t_{CKSRX}$  before precharge Power Down may be exited; after Precharge Power Down is exited and  $t_{XP}$  has expired, the DLL must be RESET via MRS. Depending on the new clock frequency additional MRS commands may need to be issued to appropriately set the  $WR$ ,  $CL$ , and  $CWL$  with  $CKE$  continuously registered high. During DLL re-lock period, ODT must remain LOW and  $CKE$  must remain HIGH. After the DLL lock time, the DRAM is ready to operate with new clock frequency.

**Figure 12. Change Frequency during Precharge Power-down**

**NOTES**

1. Applicable for both SLOW EXIT and FAST EXIT Precharge Power-down.
2.  $t_{AOFPD}$  and  $t_{AOF}$  must be satisfied and outputs High-Z prior to T1; refer to ODT timing section for exact requirements
3. If the  $RTT\_NOM$  feature was enabled in the mode register prior to entering Precharge power down mode, the ODT signal must continuously be registered LOW ensuring  $RTT$  is in an off state, as shown in Figure 9. If the  $RTT\_NOM$  feature was disabled in the mode register prior to entering Precharge power down mode,  $RTT$  will remain in the off state. The ODT signal can be registered either LOW or HIGH in this case.

### Write Leveling

For better signal integrity, DDR3 memory adopted fly by topology for the commands, addresses, control signals, and clocks. The fly by topology has benefits from reducing number of stubs and their length but in other aspect, causes flight time skew between clock and strobe at every DRAM on DIMM. It makes it difficult for the Controller to maintain tDQSS, tDSS, and tDSH specification. Therefore, the controller should support “write leveling” in DDR3 SDRAM to compensate the skew.

The memory controller can use the “write leveling” feature and feedback from the DDR3 SDRAM to adjust the DQS – DQS# to CK – CK# relationship. The memory controller involved in the leveling must have adjustable delay setting on DQS – DQS# to align the rising edge of DQS – DQS# with that of the clock at the DRAM pin. DRAM asynchronously feeds back CK – CK#, sampled with the rising edge of DQS – DQS#, through the DQ bus. The controller repeatedly delays DQS – DQS# until a transition from 0 to 1 is detected. The DQS – DQS# delay established through this exercise would ensure tDQSS specification.

Besides tDQSS, tDSS, and tDSH specification also needs to be fulfilled. One way to achieve this is to combine the actual tDQSS in the application with an appropriate duty cycle and jitter on the DQS- DQS# signals. Depending on the actual tDQSS in the application, the actual values for tDQSL and tDQSH may have to be better than the absolute limits provided in “AC Timing Parameters” section in order to satisfy tDSS and tDSH specification.

DQS/DQS# driven by the controller during leveling mode must be determined by the DRAM based on ranks populated. Similarly, the DQ bus driven by the DRAM must also be terminated at the controller.

One or more data bits should carry the leveling feedback to the controller across the DRAM configurations x8. Therefore, a separate feedback mechanism should be available for each byte lane.

**Figure 13. Write Leveling Concept**

### DRAM setting for write leveling and DRAM termination function in that mode

DRAM enters into Write leveling mode if A7 in MR1 set “High” and after finishing leveling, DRAM exits from write leveling mode if A7 in MR1 set “Low”. Note that in write leveling mode, only DQS/DQS# terminations are activated and deactivated via ODT pin not like normal operation.

**Table 23. DRAM termination function in the leveling mode**

ODT pin at DRAM	DQS, DQS# termination	DQs termination
De-asserted	off	off
Asserted	on	off

**Note 1:** In write leveling mode with its output buffer disabled (MR1[bit7]=1 with MR1[bit12]=1) all RTT\_Nom settings are allowed; in Write Leveling Mode with its output buffer enabled (MR1[bit7]=1 with MR1[bit12]=0) only RTT\_Nom settings of RZQ/2, RZQ/4, and RZQ/6 are allowed.

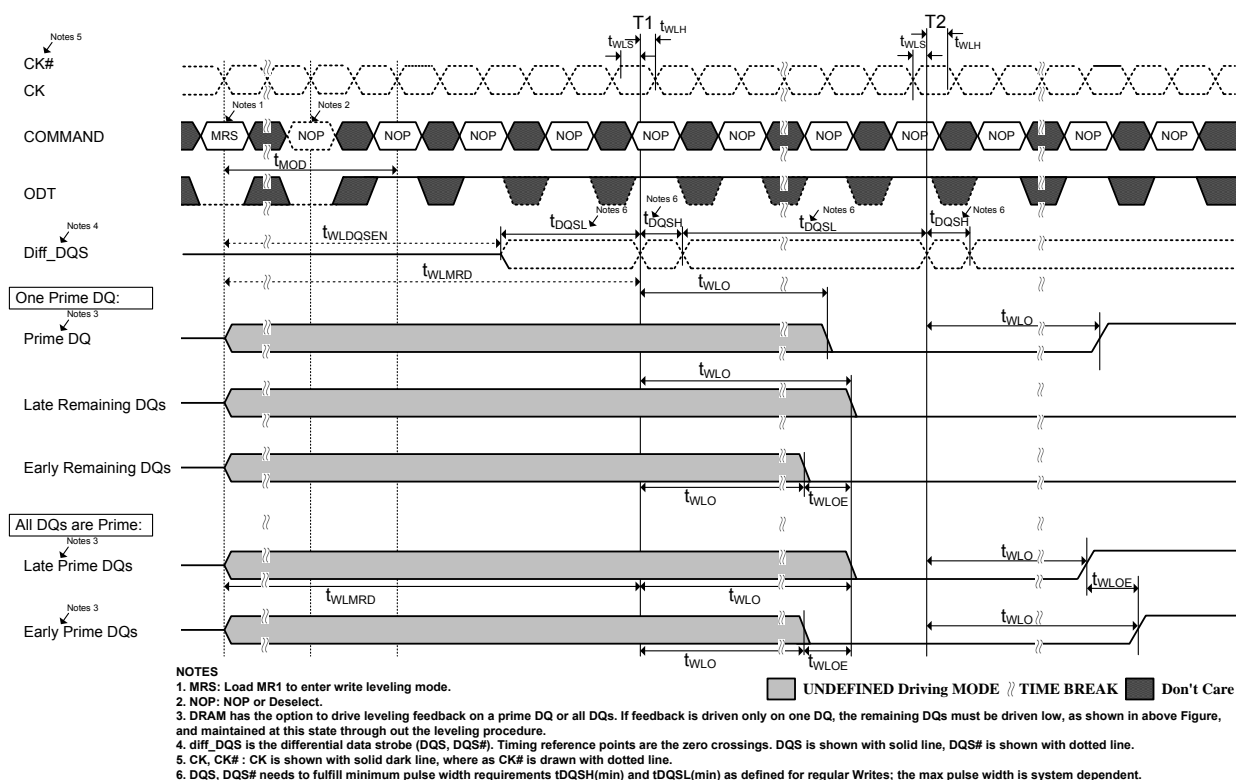

### Procedure Description

Memory controller initiates Leveling mode of all DRAMs by setting bit 7 of MR1 to 1. With entering write leveling mode, the DQ pins are in undefined driving mode. During write leveling mode, only NOP or Deselect commands are allowed. As well as an MRS command to exit write leveling mode. Since the controller levels one rank at a time, the output of other rank must be disabled by setting MR1 bit A12 to 1. Controller may assert ODT after tMOD, time at which DRAM is ready to accept the ODT signal.

Controller may drive DQS low and DQS# high after a delay of tWLDQSEN, at which time DRAM has applied on-die termination on these signals. After tDQSL and tWLMRD controller provides a single DQS, DQS# edge which is used by the DRAM to sample CK – CK# driven from controller. tWLMRD(max) timing is controller dependent.

DRAM samples CK – CK# status with rising edge of DQS and provides feedback on all the DQ bits asynchronously after tWLO timing. There is a DQ output uncertainty of tWLOE defined to allow mismatch on DQ bits; there are no read strobes (DQS/DQS#) needed for these DQs. Controller samples incoming DQ and decides to increment or decrement DQS – DQS# delay setting and launches the next DQS/DQS# pulse after some time, which is controller dependent. Once a 0 to 1 transition is detected, the controller locks DQS – DQS# delay setting and write leveling is achieved for the device.

**Figure 14. Timing details of Write Leveling sequence (DQS – DQS# is capturing CK – CK# low at T1 and CK – CK# high at T2)**

## Write Leveling Mode Exit

The following sequence describes how Write Leveling Mode should be exited:

1. After the last rising strobe edge (see  $\sim T_0$ ), stop driving the strobe signals (see  $\sim T_{c0}$ ). Note: From now on, DQ pins are in undefined driving mode, and will remain undefined, until  $t_{MOD}$  after the respective MR command ( $T_{e1}$ ).
2. Drive ODT pin low ( $t_{IS}$  must be satisfied) and keep it low (see  $T_{b0}$ ).
3. After the RTT is switched off, disable Write Level Mode via MRS command (see  $T_{c2}$ ).
4. After  $t_{MOD}$  is satisfied ( $T_{e1}$ ), any valid command may be registered. (MR commands may be issued after  $t_{MRD}$  ( $T_{d1}$ )).

**Figure 15. Timing details of Write Leveling exit**

## ACTIVE Command

The ACTIVE command is used to open (or activate) a row in a particular bank for subsequent access. The value on the BA0-BA2 inputs selects the bank, and the addresses provided on inputs A0-A13 selects the row. These rows remain active (or open) for accesses until a precharge command is issued to that bank. A PRECHARGE command must be issued before opening a different row in the same bank.

## PRECHARGE Command

The PRECHARGE command is used to deactivate the open row in a particular bank or the open row in all banks. The bank(s) will be available for a subsequent row activation a specified time ( $t_{RP}$ ) after the PRECHARGE command is issued, except in the case of concurrent auto precharge, where a READ or WRITE command to a different bank is allowed as long as it does not interrupt the data transfer in the current bank and does not violate any other timing parameters. Once a bank has been precharged, it is in the idle state and must be activated prior to any READ or WRITE commands being issued to that bank. A PRECHARGE command is allowed if there is no open row in that bank (idle bank) or if the previously open row is already in the process of precharging. However, the precharge period will be determined by the last PRECHARGE command issued to the bank.

## READ Operation

### Read Burst Operation

During a READ or WRITE command DDR3 will support BC4 and BL8 on the fly using address A12 during the READ or WRITE (AUTO PRECHARGE can be enabled or disabled).

A12=0, BC4 (BC4 = burst chop, tCCD=4)

A12=1, BL8

A12 will be used only for burst length control, not a column address.

**Figure 16. READ Burst Operation RL=5 (AL=0, CL=5, BL=8)**

**NOTES:**

1. BL8, RL = 5, AL = 0, CL = 5.
2. Dout n = data-out from column n.
3. NOP commands are shown for ease of illustration; other commands may be valid at these times.
4. BL8 setting activated by either MR0[A1:0 = 00] or MR0[A1:0 = 01] and A12 = 1 during READ command at T0.

TRANSITIONING DATA Don't Care

**Figure 17. READ Burst Operation RL=9 (AL=4, CL=5, BL=8)**

**NOTES:**

1. BL8, RL = 9, AL = (CL-1), CL = 5.
2. Dout n = data-out from column n.
3. NOP commands are shown for ease of illustration; other commands may be valid at these times.
4. BL8 setting activated by either MR0[A1:0 = 00] or MR0[A1:0 = 01] and A12 = 1 during READ command at T0.

TRANSITIONING DATA Don't Care

## READ Timing Definitions

Read timing is shown in the following figure and is applied when the DLL is enabled and locked.

Rising data strobe edge parameters:

$t_{DQSCK, min}$ / $t_{DQSCK, max}$  describes the allowed range for a rising data strobe edge relative to CK, CK#.  $t_{DQSCK}$  is the actual position of a rising strobe edge relative to CK, CK#.  $t_{QSH}$  describes the DQS, DQS# differential output high time.  $t_{DQSQ}$  describes the latest valid transition of the associated DQ pins.  $t_{QH}$  describes the earliest invalid transition of the associated DQ pins.

Falling data strobe edge parameters:

$t_{QSL}$  describes the DQS, DQS# differential output low time.  $t_{DQSQ}$  describes the latest valid transition of the associated DQ pins.  $t_{QH}$  describes the earliest invalid transition of the associated DQ pins.

$t_{DQSQ}$ ; both rising/falling edges of DQS, no tAC defined.

**Figure 18. READ timing Definition**

## Read Timing; Clock to Data Strobe relationship

Clock to Data Strobe relationship is shown in the following figure and is applied when the DLL is enabled and locked.

Rising data strobe edge parameters:

$t_{DQSCk}$  min/max describes the allowed range for a rising data strobe edge relative to CK and CK#.  $t_{DQSCk}$  is the actual position of a rising strobe edge relative to CK and CK#.  $t_{QSH}$  describes the data strobe high pulse width.

Falling data strobe edge parameters:

$t_{QSL}$  describes the data strobe low pulse width.

**Figure 19. Clock to Data Strobe relationship**

**NOTES:**

1. Within a burst, rising strobe edge is not necessarily fixed to be always at  $t_{DQSCk}(\text{min})$  or  $t_{DQSCk}(\text{max})$ . Instead, rising strobe edge can vary between  $t_{DQSCk}(\text{min})$  and  $t_{DQSCk}(\text{max})$ .
2. Notwithstanding note 1, a rising strobe edge with  $t_{DQSCk}(\text{max})$  at  $T(n)$  can not be immediately followed by a rising strobe edge with  $t_{DQSCk}(\text{min})$  at  $T(n+1)$ . This is because other timing relationships ( $t_{QSH}$ ,  $t_{QSL}$ ) exist: if  $t_{DQSCk}(n+1) < 0: t_{DQSCk}(n) < 1.0 t_{CK} - (t_{QSH}(\text{min}) + t_{QSL}(\text{min})) - |t_{DQSCk}(n+1)|$
3. The DQS, DQS# differential output high time is defined by  $t_{QSH}$  and the DQS, DQS# differential output low time is defined by  $t_{QSL}$ .
4. Likewise,  $t_{LZ}(\text{DQS})\text{min}$  and  $t_{HZ}(\text{DQS})\text{min}$  are not tied to  $t_{DQSCk}(\text{min})$  (early strobe case) and  $t_{LZ}(\text{DQS})\text{max}$  and  $t_{HZ}(\text{DQS})\text{max}$  are not tied to  $t_{DQSCk}(\text{max})$  (late strobe case).
5. The minimum pulse width of read preamble is defined by  $t_{RPRE}(\text{min})$ .
6. The maximum read postamble is bound by  $t_{DQSCk}(\text{min})$  plus  $t_{QSH}(\text{min})$  on the left side and  $t_{HZ}(\text{DQS})\text{max}$  on the right side.
7. The minimum pulse width of read postamble is defined by  $t_{RPST}(\text{min})$ .
8. The maximum read preamble is bound by  $t_{LZ}(\text{DQS})\text{min}$  on the left side and  $t_{DQSCk}(\text{max})$  on the right side.

## Read Timing; Data Strobe to Data Relationship

The Data Strobe to Data relationship is shown in the following figure and is applied when the DLL is enabled and locked.

Rising data strobe edge parameters:

- tDQSQ describes the latest valid transition of the associated DQ pins.
- tQH describes the earliest invalid transition of the associated DQ pins.

Falling data strobe edge parameters:

- tDQSQ describes the latest valid transition of the associated DQ pins.
- tQH describes the earliest invalid transition of the associated DQ pins.
- tDQSQ; both rising/falling edges of DQS, no tAC defined

tDQSQ; both rising/falling edges of DQS, no tAC defined

**Figure 20. Data Strobe to Data Relationship**

**NOTES:**

1. BL = 8, RL = 5 (AL = 0, CL = 5)
2. DOUT n = data-out from column n.
3. NOP commands are shown for ease of illustration; other commands may be valid at these times.
4. BL8 setting activated by either MR0[A1:0 = 00] or MR0[A1:0 = 01] and A12 = 1 during READ command at T0.
5. Output timings are referenced to VDDQ/2, and DLL on for locking.
6. tDQSQ defines the skew between DQS, DQS# to Data and does not define DQS, DQS# to Clock.
7. Early Data transitions may not always happen at the same DQ. Data transitions of a DQ can vary (either early or late) within a burst.

■ TRANSITIONING DATA ■ Don't Care

## Write Operation

### DDR3 Burst Operation

During a READ or WRITE command, DDR3 will support BC4 and BL8 on the fly using address A12 during the READ or WRITE (Auto Precharge can be enabled or disabled).

A12=0, BC4 (BC4 = Burst Chop, tCCD=4)

A12=1, BL8

A12 is used only for burst length control, not as a column address.

### WRITE Timing Violations

Generally, if timing parameters are violated, a complete reset/initialization procedure has to be initiated to make sure the DRAM works properly. However, it is desirable for certain minor violations that the DRAM is guaranteed not to “hang up” and errors be limited to that particular operation.

For the following, it will be assumed that there are no timing violations with regard to the Write command itself (including ODT, etc.) and that it does satisfy all timing requirements not mentioned below.

### Data Setup and Hold Violations

Should the strobe timing requirements (tDS, tDH) be violated, for any of the strobe edges associated with a write burst, then wrong data might be written to the memory location addressed with the offending WRITE command.

Subsequent reads from that location might result in unpredictable read data, however, the DRAM will work properly otherwise.

### Strobe to Strobe and Strobe to Clock Violations

Should the strobe timing requirements (tDQSH, tDQSL, tWPRE, tWPST) or the strobe to clock timing requirements (tDSS, tDSH, tDQSS) be violated, for any of the strobe edges associated with a Write burst, then wrong data might be written to the memory location addressed with the offending WRITE command. Subsequent reads from that location might result in unpredictable read data, however the DRAM will work properly otherwise.

### Write Timing Parameters

This drawing is for example only to enumerate the strobe edges that “belong” to a write burst. No actual timing violations are shown here. For a valid burst all timing parameters for each edge of a burst need to be satisfied (not only for one edge).

### Refresh Command

The Refresh command (REF) is used during normal operation of the DDR3 SDRAMs. This command is not persistent, so it must be issued each time a refresh is required. The DDR3 SDRAM requires Refresh cycles at an average periodic interval of tREFI. When CS#, RAS#, and CAS# are held Low and WE# High at the rising edge of the clock, the chip enters a Refresh cycle. All banks of the SDRAM must be precharged and idle for a minimum of the precharge time tRP(min) before the Refresh Command can be applied. The refresh addressing is generated by the internal refresh controller. This makes the address bits “Don’t Care” during a Refresh command. An internal address counter supplies the address during the refresh cycle. No control of the external address bus is required once this cycle has started. When the refresh cycle has completed, all banks of the SDRAM will be in the precharged (idle) state. A delay between the Refresh Command and the next valid command, except NOP or DES, must be greater than or equal to the minimum Refresh cycle time tRFC(min).

In general, a Refresh command needs to be issued to the DDR3 SDRAM regularly every tREFI interval. To allow for improved efficiency in scheduling and switching between tasks, some flexibility in the absolute refresh interval is provided. A maximum of 8 Refresh commands can be postponed during operation of the DDR3 SDRAM, meaning that at no point in time more than a total of 8 Refresh commands are allowed to be postponed. In case that 8 Refresh commands are postponed in a row, the resulting maximum interval between the surrounding Refresh commands is limited to 9 x tREFI. A maximum of 8 additional Refresh commands can be issued in advance (“pulled in”), with each one reducing the number of regular Refresh commands required later by one. Note that pulling in more than 8 Refresh commands in advance does not further reduce the number of regular Refresh commands required later, so that the resulting maximum interval between two surrounding Refresh command is limited to 9 x tREFI. Before entering Self-Refresh Mode, all postponed Refresh commands must be executed.

## Self-Refresh Operation

The Self-Refresh command can be used to retain data in the DDR3 SDRAM, even if the reset of the system is powered down. When in the Self-Refresh mode, the DDR3 SDRAM retains data without external clocking. The DDR3 SDRAM device has a built-in timer to accommodate Self-Refresh operation. The Self-Refresh Entry (SRE) Command is defined by having CS#, RAS#, CAS#, and CKE held low with WE# high at the rising edge of the clock. Before issuing the Self-Refreshing-Entry command, the DDR3 SDRAM must be idle with all bank precharge state with tRP satisfied. Also, on-die termination must be turned off before issuing Self-Refresh-Entry command, by either registering ODT pin low "ODTL + 0.5tCK" prior to the Self-Refresh Entry command or using MRS to MR1 command. Once the Self-Refresh Entry command is registered, CKE must be held low to keep the device in Self-Refresh mode. During normal operation (DLL on), MR1 (A0=0), the DLL is automatically disabled upon entering Self-Refresh and is automatically enabled (including a DLL-RESET) upon exiting Self-Refresh.

When the DDR3 SDRAM has entered Self-Refresh mode, all of the external control signals, except CKE and RESET#, are "don't care". For proper Self-Refresh operation, all power supply and reference pins (VDD, VDDQ, VSS, VSSQ, VRefCA, and VRefDQ) must be at valid levels. The DRAM initiates a minimum of one Refresh command internally within tCKE period once it enters Self-Refresh mode.

The clock is internally disabled during Self-Refresh operation to save power. The minimum time that the DDR3 SDRAM must remain in Self-Refresh mode is tCKE. The user may change the external clock frequency or halt the external clock tCKSRE after Self-Refresh entry is registered; however, the clock must be restarted and stable tCKSRX before the device can exit Self-Refresh mode.

The procedure for exiting Self-Refresh requires a sequence of events. First, the clock must be stable prior to CKE going back HIGH. Once a Self-Refresh Exit Command (SRX, combination of CKE going high and either NOP or Deselect on command bus) is registered, a delay of at least tXS must be satisfied before a valid command not requiring a locked DLL can be issued to the device to allow for any internal refresh in progress. Before a command which requires a locked DLL can be applied, a delay of at least tXSDLL and applicable ZQCAL function requirements [TBD] must be satisfied. Before a command that requires a locked DLL can be applied, a delay of at least tXSDLL must be satisfied.

Depending on the system environment and the amount of time spent in Self-Refresh, ZQ calibration commands may be required to compensate for the voltage and temperature drift as described in "ZQ Calibration Commands". To issue ZQ calibration commands, applicable timing requirements must be satisfied.

CKE must remain HIGH for the entire Self-Refresh exit period tXSDLL for proper operation except for Self-Refresh re-entry. Upon exit from Self-Refresh, the DDR3 SDRAM can be put back into Self-Refresh mode after waiting at least tXS period and issuing one refresh command (refresh period of tRFC). NOP or deselect commands must be registered on each positive clock edge during the Self-Refresh exit interval tXS. ODT must be turned off during tXSDLL. The use of Self-Refresh mode instructs the possibility that an internally times refresh event can be missed when CKE is raised for exit from Self-Refresh mode. Upon exit from Self-Refresh, the DDR3 SDRAM requires a minimum of one extra refresh command before it is put back into Self-Refresh mode.

## Power-Down Modes

### Power-Down Entry and Exit

Power-Down is synchronously entered when CKE is registered low (along with NOP or Deselect command). CKE is not allowed to go low while mode register set command, MPR operations, ZQCAL operations, DLL locking or read/write operation are in progress. CKE is allowed to go low while any of other operation such as row activation, precharge or auto precharge and refresh are in progress, but power-down IDD spec will not be applied until finishing those operation.

The DLL should be in a locked state when power-down is entered for fastest power-down exit timing. If the DLL is not locked during power-down entry, the DLL must be reset after exiting power-down mode for proper read operation and synchronous ODT operation. DRAM design provides all AC and DC timing and voltage specification as well proper DLL operation with any CKE intensive operations as long as DRAM controller complies with DRAM specifications.

During Power-Down, if all banks are closed after any in progress commands are completed, the device will be in precharge Power-Down mode; if any bank is open after in progress commands are completed, the device will be in active Power-Down mode.

Entering Power-down deactivates the input and output buffers, excluding CK, CK, ODT, CKE, and RESET#. To protect DRAM internal delay on CKE line to block the input signals, multiple NOP or Deselect commands are needed during the CKE switch off and cycle(s) after, this timing period are defined as tCPDED. CKE\_low will result in deactivation of command and address receivers after tCPDED has expired.

**Table 24. Power-Down Entry Definitions**

Status of DRAM	MRS bit A12	DLL	PD Exit	Relevant Parameters
Active (A Bank or more open)	Don't Care	On	Fast	tXP to any valid command.
Precharged (All Banks Precharged)	0	Off	Slow	tXP to any valid command. Since it is in precharge state, commands here will be ACT, AR, MRS/EMRS, PR or PRA. tXPDLL to commands who need DLL to operate, such as RD, RDA or ODT control line.
Precharged (All Banks Precharged)	1	On	Fast	tXP to any valid command.

Also the DLL is disabled upon entering precharge power-down (Slow Exit Mode), but the DLL is kept enabled during precharge power-down (Fast Exit Mode) or active power-down. In power-down mode, CKE low, RESET# high, and a stable clock signal must be maintained at the inputs of the DD3 SDRAM, and ODT should be in a valid state but all other input signals are "Don't care" (If RESET# goes low during Power-Down, the DRAM will be out of PD mode and into reset state).

CKE low must be maintain until tCKE has been satisfied. Power-down duration is limited by 9 times tREFI of the device. The power-down state is synchronously exited when CKE is registered high (along with a NOP or Deselect command). CKE high must be maintained until tCKE has been satisfied. A valid, executable command can be applied with power-down exit latency, tXP and/or tXPDLL after CKE goes high. Power-down exit latency is defined at AC spec table of this datasheet.

### On-Die Termination (ODT)

On-die termination (ODT) is a feature that enables the DRAM to enable/disable and turn on/off termination resistance for each DQ, DQS, DQS#, and DM for the x8 configurations (and TDQS, TDQS# for the x8 configuration, when enabled).

ODT is designed to improve signal integrity of the memory channel by enabling the DRAM controller to independently turn on/off the DRAM's internal termination resistance for any grouping of DRAM devices. ODT is not supported during DLL disable mode (simple functional representation shown below). The switch is enabled by the internal ODT control logic, which uses the external ODT ball and other control information.

**Figure 21. Functional representation of ODT**

The switch is enabled by the internal ODT control logic, which uses the external ODT pin and other control information. The value of  $R_{TT}$  is determined by the settings of Mode Register bits. The ODT pin will be ignored if the Mode Register MR1 and MR2 are programmed to disable ODT and in self-refresh mode.

### ODT Mode Register and ODT Truth Table

The ODT Mode is enabled if either of MR1 {A2, A6, A9} or MR2 {A9, A10} are non-zero. In this case, the value of  $R_{TT}$  is determined by the settings of those bits.

Application: Controller sends WR command together with ODT asserted.

One possible application: The rank that is being written to provides termination.

DRAM turns ON termination if it sees ODT asserted (except ODT is disabled by MR)

DRAM does not use any write or read command decode information.

**Table 25. Termination Truth Table**

ODT pin	DRAM Termination State
0	OFF
1	On, (Off, if disabled by MR1 (A2, A6, A9) and MR2 (A9, A10) in general)

### Synchronous ODT Mode

Synchronous ODT mode is selected whenever the DLL is turned on and locked. Based on the power-down definition, these modes are:

- Any bank active with CKE high
- Refresh with CKE high
- Idle mode with CKE high
- Active power down mode (regardless of MR0 bit A12)
- Precharge power down mode if DLL is enabled during precharge power down by MR0 bit A12

The direct ODT feature is not supported during DLL-off mode. The on-die termination resistors must be disabled by continuously registering the ODT pin low and/or by programming the RTT\_Nom bits MR1{A9,A6,A2} to {0,0,0} via a mode register set command during DLL-off mode.

In synchronous ODT mode, RTT will be turned on ODTLon clock cycles after ODT is sampled high by a rising clock edge and turned off ODTLoff clock cycles after ODT is registered low by a rising clock edge. The ODT latency is tied to the write latency (WL) by: ODTLon = WL - 2; ODTLoff = WL-2.

### ODT Latency and Posted ODT

In synchronous ODT Mode, the Additive Latency (AL) programmed into the Mode Register (MR1) also applies to the ODT signal. The DRAM internal ODT signal is delayed for a number of clock cycles defined by the Additive Latency (AL) relative to the external ODT signal. ODTLon = CWL + AL - 2; ODTLoff = CWL + AL - 2. For details, refer to DDR3 SDRAM latency definitions.

**Table 26. ODT Latency**

Symbol	Parameter	DDR3-1600	Unit
ODTLon	ODT turn on Latency	$WL - 2 = CWL + AL - 2$	tCK
ODTLoff	ODT turn off Latency	$WL - 2 = CWL + AL - 2$	tCK

### Timing Parameters

In synchronous ODT mode, the following timing parameters apply: ODTLon, ODTLoff, tAON min/max, tAOF min/max. Minimum RTT turn-on time (tAON min) is the point in time when the device leaves high impedance and ODT resistance begins to turn on. Maximum RTT turn-on time (tAON max) is the point in time when the ODT resistance is fully on. Both are measured from ODTLon.

Minimum RTT turn-off time (tAOF min) is the point in time when the device starts to turn off the ODT resistance. Maximum RTT turn off time (tAOF max) is the point in time when the on-die termination has reached high impedance. Both are measured from ODTLoff.

When ODT is asserted, it must remain high until ODTH4 is satisfied. If a Write command is registered by the SDRAM with ODT high, then ODT must remain high until ODTH4 (BL=4) or ODTH8 (BL=8) after the write command. ODTH4 and ODTH8 are measured from ODT registered high to ODT registered low or from the registration of a write command until ODT is registered low.

### ODT during Reads

As the DDR3 SDRAM cannot terminate and drive at the same time, RTT must be disabled at least half a clock cycle before the read preamble by driving the ODT pin low appropriately. RTT may not be enabled until the end of the post-amble as shown in the following figure. DRAM turns on the termination when it stops driving which is determined by tHZ. If DRAM stops driving early (i.e. tHZ is early), then tAONmin time may apply. If DRAM stops driving late (i.e. tHZ is late), then DRAM complies with tAONmax timing. Note that ODT may be disabled earlier before the Read and enabled later after the Read than shown in this example.

**Figure 22. ODT must be disabled externally during Reads by driving ODT low**  
(CL=6; AL=CL-1=5; RL=AL+CL=11; CWL=5; ODTLon=CWL+AL-2=8; ODTLoff=CWL+AL-2=8)

## Dynamic ODT

In certain application cases and to further enhance signal integrity on the data bus, it is desirable that the termination strength of the DDR3 SDRAM can be changed without issuing an MRS command. This requirement is supported by the “Dynamic ODT” feature as described as follows:

### Functional Description

The Dynamic ODT Mode is enabled if bit (A9) or (A10) of MR2 is set to ‘1’. The function is described as follows:

Two RTT values are available: RTT\_Nom and RTT\_WR.

- The value for RTT\_Nom is preselected via bits A[9,6,2] in MR1.
- The value for RTT\_WR is preselected via bits A[10,9] in MR2.

During operation without write commands, the termination is controlled as follows:

- Nominal termination strength RTT\_Nom is selected.
- Termination on/off timing is controlled via ODT pin and latencies ODTLon and ODTLoff.

When a Write command (WR, WRA, WRS4, WRS8, WRAS4, WRAS8) is registered, and if Dynamic ODT is enabled, the termination is controlled as follows:

- A latency ODTLcnw after the write command, termination strength RTT\_WR is selected.
- A latency ODTLcwn8 (for BL8, fixed by MRS or selected OTF) or ODTLcwn4 (for BC4, fixed by MRS or selected OTF) after the write command, termination strength RTT\_Nom is selected.
- Termination on/off timing is controlled via ODT pin and ODTLon, ODTLoff.

The following table shows latencies and timing parameters which are relevant for the on-die termination control in Dynamic ODT mode.

The dynamic ODT feature is not supported at DLL-off mode. User must use MRS command to set RTT\_WR, MR2 [A10,A9 = [0,0], to disable Dynamic ODT externally.

When ODT is asserted, it must remain high until ODTL4 is satisfied. If a Write command is registered by the SDRAM with ODT high, then ODT must remain high until ODTL4 (BL=4) or ODTL8 (BL=8) after the Write command. ODTL4 and ODTL8 are measured from ODT registered high to ODT registered low or from the registration of Write command until ODT is register low.

**Table 27. Latencies and timing parameters relevant for Dynamic ODT**

Name and Description	Abbr.	Defined from	Defined to	Definition for all DDR3 speed pin	Unit
ODT turn-on Latency	ODTLon	registering external ODT signal high	turning termination on	ODTLon=WL-2	tCK
ODT turn-off Latency	ODTLoFF	registering external ODT signal low	turning termination off	ODTLoFF=WL-2	tCK
ODT Latency for changing from RTT_Nom to RTT_WR	ODTLcnw	registering external write command	change RTT strength from RTT_Nom to RTT_WR	ODTLcnw=WL-2	tCK
ODT Latency for change from RTT_WR to RTT_Nom (BL=4)	ODTLcnw4	registering external write command	change RTT strength from RTT_WR to RTT_Nom	ODTLcnw4=4+ODTLoFF	tCK
ODT Latency for change from RTT_WR to RTT_Nom (BL=8)	ODTLcnw8	registering external write command	change RTT strength from RTT_WR to RTT_Nom	ODTLcnw8=6+ODTLoFF	tCK (avg)
Minimum ODT high time after ODT assertion	ODTH4	registering ODT high	ODT registered low	ODTH4=4	tCK (avg)
Minimum ODT high time after Write (BL=4)	ODTH4	registering write with ODT high	ODT registered low	ODTH4=4	tCK (avg)
Minimum ODT high time after Write (BL=8)	ODTH8	registering write with ODT high	ODT register low	ODTH8=6	tCK (avg)
RTT change skew	tADC	ODTLcnw ODTLcwn	RTT valid	tADC(min)=0.3tCK(avg) tADC(max)=0.7tCK(avg)	tCK (avg)

**Note 1:** tAOF, nom and tADC, nom are 0.5tCK (effectively adding half a clock cycle to ODTLoFF, ODTcnw, and ODTLcwn)

### Asynchronous ODT Mode

Asynchronous ODT mode is selected when DRAM runs in DLLon mode, but DLL is temporarily disabled (i.e. frozen) in precharge power-down (by MR0 bit A12). Based on the power down mode definitions, this is currently Precharge power down mode if DLL is disabled during precharge power down by MR0 bit A12.

In asynchronous ODT timing mode, internal ODT command is NOT delayed by Additive Latency (AL) relative to the external ODT command.

In asynchronous ODT mode, the following timing parameters apply: tAONPD min/max, tAOFPD min/max.

Minimum RTT turn-on time (tAONPD min) is the point in time when the device termination circuit leaves high impedance state and ODT resistance begins to turn on. Maximum RTT turn on time (tAONPD max) is the point in time when the ODT resistance is fully on.

tAONPDmin and tAONPDmax are measured from ODT being sampled high.

Minimum RTT turn-off time (tAOFPDmin) is the point in time when the devices termination circuit starts to turn off the ODT resistance. Maximum ODT turn off time (tAOFPDmax) is the point in time when the on-die termination has reached high impedance. tAOFPDmin and tAOFPDmax are measured from ODT being sample low.

**Table 28. ODT timing parameters for Power Down (with DLL frozen) entry and exit**

Description	Min	Max
ODT to RTT turn-on delay	min{ ODTLon * tCK + tAONmin; tAONPDmin } min{ (WL - 2) * tCK + tAONmin; tAONPDmin }	max{ ODTLon * tCK + tAONmax; tAONPDmax } max{ (WL - 2) * tCK + tAONmax; tAONPFmax }
ODT to RTT turn-off delay	min{ ODTLoFF * tCK + tAOFmin; tAOFPDmin } min{ (WL - 2) * tCK + tAOFmin; tAOFPDmin }	max{ ODTLoFF * tCK + tAOFmax; tAOFPDmax } max{ (WL - 2) * tCK + tAOFmax; tAOFPDmax }
tANPD	WL - 1	

### **Synchronous to Asynchronous ODT Mode Transition during Power-Down Entry**

If DLL is selected to be frozen in Precharge Power Down Mode by the setting of bit A12 in MR0 to "0", there is a transition period around power down entry, where the DDR3 SDRAM may show either synchronous or asynchronous ODT behavior.

The transition period is defined by the parameters  $t_{ANPD}$  and  $t_{CPDED(min)}$ .  $t_{ANPD}$  is equal to  $(WL-1)$  and is counted backwards in time from the clock cycle where CKE is first registered low.  $t_{CPDED(min)}$  starts with the clock cycle where CKE is first registered low. The transition period begins with the starting point of  $t_{ANPD}$  and terminates at the end point of  $t_{CPDED(min)}$ . If there is a Refresh command in progress while CKE goes low, then the transition period ends at the later one of  $t_{RFC(min)}$  after the Refresh command and the end point of  $t_{CPDED(min)}$ . Please note that the actual starting point at  $t_{ANPD}$  is excluded from the transition period, and the actual end point at  $t_{CPDED(min)}$  and  $t_{RFC(min)}$ , respectively, are included in the transition period.

ODT assertion during the transition period may result in an RTT changes as early as the smaller of  $t_{AONPDmin}$  and  $(ODTLon * t_{CK} + t_{AONmin})$  and as late as the larger of  $t_{AONPDmax}$  and  $(ODTLon * t_{CK} + t_{AONmax})$ . ODT de-assertion during the transition period may result in an RTT change as early as the smaller of  $t_{AOFPDmin}$  and  $(ODTloff * t_{CK} + t_{AOFmin})$  and as late as the larger of  $t_{AOFPDmax}$  and  $(ODTloff * t_{CK} + t_{AOFmax})$ . Note that, if AL has a large value, the range where RTT is uncertain becomes quite large. The following figure shows the three different cases: ODT\_A, synchronous behavior before  $t_{ANPD}$ ; ODT\_B has a state change during the transition period; ODT\_C shows a state change after the transition period.

### **Asynchronous to Synchronous ODT Mode transition during Power-Down Exit**

If DLL is selected to be frozen in Precharge Power Down Mode by the setting of bit A12 in MR0 to "0", there is also a transition period around power down exit, where either synchronous or asynchronous response to a change in ODT must be expected from the DDR3 SDRAM.

This transition period starts  $t_{ANPD}$  before CKE is first registered high, and ends  $t_{XPDLL}$  after CKE is first registered high.  $t_{ANPD}$  is equal to  $(WL - 1)$  and is counted (backwards) from the clock cycle where CKE is first registered high. ODT assertion during the transition period may result in an RTT change as early as the smaller of  $t_{AONPDmin}$  and  $(ODTLon * t_{CK} + t_{AONmin})$  and as late as the larger of  $t_{AONPDmax}$  and  $(ODTLon * t_{CK} + t_{AONmax})$ . ODT de-assertion during the transition period may result in an RTT change as early as the smaller of  $t_{AOFPDmin}$  and  $(ODTloff * t_{CK} + t_{AOFmin})$  and as late as the larger of  $t_{AOFPDmax}$  and  $(ODTloff * t_{CK} + t_{AOFmax})$ . Note that if AL has a large value, the range where RTT is uncertain becomes quite large. The following figure shows the three different cases: ODT\_C, asynchronous response before  $t_{ANPD}$ ; ODT\_B has a state change of ODT during the transition period; ODT\_A shows a state change of ODT after the transition period with synchronous response.

### **Asynchronous to Synchronous ODT Mode during short CKE high and short CKE low periods**

If the total time in Precharge Power Down state or Idle state is very short, the transition periods for PD entry and PD exit may overlap. In this case, the response of the DDR3 SDRAMs RTT to a change in ODT state at the input may be synchronous or asynchronous from the state of the PD entry transition period to the end of the PD exit transition period (even if the entry ends later than the exit period).

If the total time in Idle state is very short, the transition periods for PD exit and PD entry may overlap. In this case, the response of the DDR3 SDRAMs RTT to a change in ODT state at the input may be synchronous or asynchronous from the state of the PD exit transition period to the end of the PD entry transition period. Note that in the following figure, it is assumed that there was no Refresh command in progress when Idle state was entered.

## ZQ Calibration Commands

### ZQ Calibration Description

ZQ Calibration command is used to calibrate DRAM Ron and ODT values. DDR3 SDRAM needs longer time to calibrate output driver and on-die termination circuits at initialization and relatively smaller time to perform periodic calibrations.

ZQCL command is used to perform the initial calibration during power-up initialization sequence. This command may be issued at any time by the controller depending on the system environment. ZQCL command triggers the calibration engine inside the DRAM and once calibration is achieved the calibrated values are transferred from calibration engine to DRAM IO which gets reflected as updated output driver and on-die termination values.

The first ZQCL command issued after reset is allowed a timing period of  $t_{zQinit}$  to perform the full calibration and the transfer of values. All other ZQCL commands except the first ZQCL command issued after RESET is allowed a timing period of  $t_{zQoper}$ .

ZQCS command is used to perform periodic calibrations to account for voltage and temperature variations. A shorter timing window is provided to perform the calibration and transfer of values as defined by timing parameter  $t_{zQCS}$ .

No other activities should be performed on the DRAM channel by the controller for the duration of  $t_{zQinit}$ ,  $t_{zQoper}$ , or  $t_{zQCS}$ . The quiet time on the DRAM channel allows calibration of output driver and on-die termination values. Once DRAM calibration is achieved, the DRAM should disable ZQ current consumption path to reduce power.

All banks must be precharged and  $t_{RP}$  met before ZQCL or ZQCS commands are issued by the controller.

ZQ calibration commands can also be issued in parallel to DLL lock time when coming out of self refresh. Upon self-refresh exit, DDR3 SDRAM will not perform an IO calibration without an explicit ZQ calibration command. The earliest possible time for ZQ Calibration command (short or long) after self refresh exit is  $t_{XS}$ .

In systems that share the ZQ resistor between devices, the controller must not allow any overlap of  $t_{zQoper}$ ,  $t_{zQinit}$ , or  $t_{zQCS}$  between ranks.

**Figure 23. ZQ Calibration Timing**

**NOTES:**

1. CKE must be continuously registered high during the calibration procedure.
2. On-die termination must be disabled via the ODT signal or MRS during the calibration procedure.
3. All devices connected to the DQ bus should be high impedance during the calibration procedure.

⌘ TIME BREAK █ Don't Care

### ZQ External Resistor Value, Tolerance, and Capacitive loading

In order to use the ZQ calibration function, a 240 ohm  $\pm 1\%$  tolerance external resistor connected between the ZQ pin and ground. The single resistor can be used for each SDRAM or one resistor can be shared between two SDRAMs if the ZQ calibration timings for each SDRAM do not overlap. The total capacitive loading on the ZQ pin must be limited.

### - Single-ended requirements for differential signals

Each individual component of a differential signal (CK, CK#, DQS, DQS#) has also to comply with certain requirements for single-ended signals.

CK and CK# have to approximately reach VSEHmin / VSELmax (approximately equal to the ac-levels (VIH(ac) / VIL(ac)) for ADD/CMD signals) in every half-cycle. DQS, DQS# have to reach VSEHmin / VSELmax (approximately the ac-levels (VIH(ac) / VIL(ac)) for DQ signals) in every half-cycle proceeding and following a valid transition.

Note that the applicable ac-levels for ADD/CMD and DQ's might be different per speed-bin etc. E.g., if VIH150(ac) / VIL150(ac) is used for ADD/CMD signals, then these ac-levels apply also for the single-ended signals CK and CK#.

**Table 29. Single-ended levels for CK, DQS, CK#, DQS#**

Symbol	Parameter	Min.	Max.	Unit	Note
VSEH	Single-ended high level for strobes	$(V_{DD} / 2) + 0.175$	Note 3	V	1,2
	Single-ended high level for CK, CK#	$(V_{DD} / 2) + 0.175$	Note 3	V	1,2
VSEL	Single-ended low level for strobes	Note 3	$(V_{DD} / 2) - 0.175$	V	1,2
	Single-ended low level for CK, CK#	Note 3	$(V_{DD} / 2) - 0.175$	V	1,2

Note 1. For CK, CK# use VIH/VIL(ac) of ADD/CMD; for strobes (DQS, DQS#) use VIH/VIL(ac) of DQs.

Note 2. VIH(ac)/VIL(ac) for DQs is based on VREFDQ; VIH(ac)/VIL(ac) for ADD/CMD is based on VREFCA; if a reduced ac-high or ac-low level is used for a signal group, then the reduced level applies also here.

Note 3. These values are not defined, however the single-ended signals CK, CK#, DQS, DQS# need to be within the respective limits (VIH(dc) max, VIL(dc)min) for single-ended signals as well as the limitations for overshoot and undershoot.

### - Differential Input Cross Point Voltage

To guarantee tight setup and hold times as well as output skew parameters with respect to clock and strobe, each cross point voltage of differential input signals (CK, CK# and DQS, DQS#) must meet the requirements in the following table. The differential input cross point voltage Vix is measured from the actual cross point of true and complete signal to the midlevel between of VDD and VSS.

**Table 30. Cross point voltage for differential input signals (CK, DQS)**

Symbol	Parameter	Min.	Max.	Unit	Note
VIX(CK)	Differential Input Cross Point Voltage relative to VDD/2 for CK, CK#	- 150	150	mV	2
		- 175	175	mV	1
VIX(DQS)	Differential Input Cross Point Voltage relative to VDD/2 for DQS, DQS#	- 150	150	mV	2

Note 1. Extended range for Vix is only allowed for clock and if single-ended clock input signals CK and CK# are monotonic with a single-ended swing VSEL / VSEH of at least VDD/2 +/-250 mV, and when the differential slew rate of CK - CK# is larger than 3 V/ns.

Note 2. The relation between Vix Min/Max and VSEL/VSEH should satisfy following.

$$(V_{DD}/2) + V_{ix}(\text{Min}) - V_{SEL} \geq 25\text{mV}$$

$$V_{SEH} - ((V_{DD}/2) + V_{ix}(\text{Max})) \geq 25\text{mV}$$

### - Slew Rate Definition for Differential Input Signals

Input slew rate for differential signals (CK, CK# and DQS, DQS#) are defined and measured as shown below.

**Table 31. Differential Input Slew Rate Definition**

Description	Measured		Defined by
	From	To	
Differential input slew rate for rising edge (CK, CK# and DQS, DQS#)	VILdiffmax	VIHdiffmin	$[VIHdiffmin - VILdiffmax] / \Delta TRdiff$
Differential input slew rate for falling edge (CK, CK# and DQS, DQS#)	VIHdiffmin	VILdiffmax	$[VIHdiffmin - VILdiffmax] / \Delta TFdiff$

**NOTE:** The differential signal (i.e., CK, CK# and DQS, DQS#) must be linear between these thresholds.

**Table 32. Single-ended AC and DC Output Levels**

Symbol	Parameter	Values	Unit	Note
V <sub>OH</sub> (DC)	DC output high measurement level (for IV curve linearity)	$0.8 \times V_{DDQ}$	V	
V <sub>OM</sub> (DC)	DC output mid measurement level (for IV curve linearity)	$0.5 \times V_{DDQ}$	V	
V <sub>OL</sub> (DC)	DC output low measurement level (for IV curve linearity)	$0.2 \times V_{DDQ}$	V	
V <sub>OH</sub> (AC)	AC output high measurement level (for output SR)	$V_{TT} + 0.1 \times V_{DDQ}$	V	1
V <sub>OL</sub> (AC)	AC output low measurement level (for output SR)	$V_{TT} - 0.1 \times V_{DDQ}$	V	1

**NOTE 1:** The swing of  $\pm 0.1 \times V_{DDQ}$  is based on approximately 50% of the static single-ended output high or low swing with a driver impedance of 40  $\Omega$  and an effective test load of 25  $\Omega$  to  $V_{TT} = V_{DDQ}/2$ .

**Table 33. Differential AC and DC Output Levels**

Symbol	Parameter	Values	Unit	Note
V <sub>OHdiff</sub> (AC)	AC differential output high measurement level (for output SR)	$+ 0.2 \times V_{DDQ}$	V	1
V <sub>OLdiff</sub> (AC)	AC differential output low measurement level (for output SR)	$- 0.2 \times V_{DDQ}$	V	1

**NOTE 1:** The swing of  $\pm 0.2 \times V_{DDQ}$  is based on approximately 50% of the static single-ended output high or low swing with a driver impedance of 40  $\Omega$  and an effective test load of 25  $\Omega$  to  $V_{TT} = V_{DDQ}/2$  at each of the differential outputs.

### - Single Ended Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between VOL(AC) and VOH(AC) for single ended signals as shown in Table.

**Table 34. Output Slew Rate Definition (Single-ended)**

Description	Measured		Defined by
	From	To	
Single-ended output slew rate for rising edge	VOL(AC)	VOH(AC)	$[VOH(AC) - VOL(AC)] / \Delta TR_{se}$
Single-ended output slew rate for falling edge	VOH(AC)	VOL(AC)	$[VOH(AC) - VOL(AC)] / \Delta TF_{se}$

**NOTE:** Output slew rate is verified by design and characterization, and may not be subject to production test.

**Table 35. Output Slew Rate (Single-ended)**

Symbol	Parameter	DDR3-1600		Unit
		Min.	Max.	
SRQse	Single-ended Output Slew Rate	2.5	5	V/ns

**Description:**

SR: Slew Rate

Q: Query Output (like in DQ, which stands for Data-in, Query-Output)

se: Single-ended Signals

For Ron = RZQ/7 setting

**NOTE1:** In two cases, a maximum slew rate of 6V/ns applies for a single DQ signal within a byte lane.

**Case 1** is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are static (i.e. they stay at either high or low).

**Case 2** is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are switching into the opposite direction (i.e. from low to high or high to low respectively). For the remaining DQ signal switching into the opposite direction, the regular maximum limit of 5 V/ns applies.

### - Differential Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between VOLdiff(AC) and VOHdiff(AC) for differential signals as shown in Table.

**Table 36. Output Slew Rate Definition (Differential)**

Description	Measured		Defined by
	From	To	
Differential output slew rate for rising edge	VOLdiff(AC)	VOHdiff(AC)	$[VOHdiff(AC) - VOLdiff(AC)] / \Delta TR_{diff}$
Differential output slew rate for falling edge	VOHdiff(AC)	VOLdiff(AC)	$[VOHdiff(AC) - VOLdiff(AC)] / \Delta TF_{diff}$

**NOTE:** Output slew rate is verified by design and characterization, and may not be subject to production test.

**Table 37. Output Slew Rate (Differential)**

Symbol	Parameter	DDR3-1600		Unit
		Min.	Max.	
SRQdiff	Differential Output Slew Rate	5	10	V/ns

**Description:**

SR: Slew Rate

Q: Query Output (like in DQ, which stands for Data-in, Query-Output)

diff: Differential Signals

For Ron = RZQ/7 setting

### Reference Load for AC Timing and Output Slew Rate

The following figure represents the effective reference load of 25 ohms used in defining the relevant AC timing parameters of the device as well as output slew rate measurements.

It is not intended as a precise representation of any particular system environment or a depiction of the actual load presented by a production tester. System designers should use IBIS or other simulation tools to correlate the timing reference load to a system environment. Manufacturers correlate to their production test conditions, generally one or more coaxial transmission lines terminated at the tester electronics.

**Figure 24. Reference Load for AC Timing and Output Slew Rate**

**Table 38. AC Overshoot/Undershoot Specification for Address and Control Pins**

Parameter	-12	Unit
Maximum peak amplitude allowed for overshoot area.	0.4	V
Maximum peak amplitude allowed for undershoot area.	0.4	V
Maximum overshoot area above VDD	0.33	V-ns
Maximum undershoot area below VSS	0.33	V-ns

**Table 39. AC Overshoot/Undershoot Specification for Clock, Data, Strobe and Mask**

Parameter	-12	Unit
Maximum peak amplitude allowed for overshoot area.	0.4	V
Maximum peak amplitude allowed for undershoot area.	0.4	V
Maximum overshoot area above VDD	0.13	V-ns
Maximum undershoot area below VSS	0.13	V-ns

### - Address / Command Setup, Hold and Derating

For all input signals the total tIS (setup time) and tIH (hold time) required is calculated by adding the data sheet tIS(base) and tIH(base) and tIH(base) value to the delta tIS and delta tIH derating value respectively.

Example: tIS (total setup time) = tIS(base) + delta tIS.

Setup (tIS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of Vref(dc) and the first crossing of VIH(ac)min. Setup (tIS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of Vref(dc) and the first crossing of VIL(ac)max. If the actual signal is always earlier than the nominal slew rate line between shaded 'Vref(dc) to ac region', use nominal slew rate for derating value. If the actual signal is later than the nominal slew rate line anywhere between shaded 'Vref(dc) to ac region', the slew rate of the tangent line to the actual signal from the ac level to dc level is used for derating value.

Hold (tIH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(dc)max and the first crossing of Vref(dc). Hold (tIH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(dc)min and the first crossing of Vref(dc). If the actual signal is always later than the nominal slew rate line between shaded 'dc to Vref(dc) region', use nominal slew rate for derating value. If the actual signal is earlier than the nominal slew rate line anywhere between shaded 'dc to Vref(dc) region', the slew rate of a tangent line to the actual signal from the dc level to Vref(dc) level is used for derating value.

For a valid transition the input signal has to remain above/below VIH/IL(ac) for some time tVAC.

Although for slow slew rates the total setup time might be negative (i.e. a valid input signal will not have reached VIH/IL(ac) at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach VIH/IL(ac).

For slow rates in between the values listed in the following tables, the derating values may be obtained by linear interpolation.

These values are typically not subject to production test. They are verified by design and characterization

**Table 40. ADD/CMD Setup and Hold Base**

Symbol	Reference	-12	Unit
t <sub>IS</sub> (base) AC175	V <sub>IH/L</sub> (ac)	45	ps
t <sub>IS</sub> (base) AC150	V <sub>IH/L</sub> (ac)	170	ps
t <sub>IS</sub> (base) AC135	V <sub>IH/L</sub> (ac)	-	ps
t <sub>IS</sub> (base) AC125	V <sub>IH/L</sub> (ac)	-	ps
t <sub>IH</sub> (base) DC100	V <sub>IH/L</sub> (dc)	120	ps

**NOTE 1:** (ac/dc referenced for 1V/ns Address/Command slew rate and 2 V/ns differential CK-CK# slew rate)

**NOTE 2:** The tIS(base) AC150 specifications are adjusted from the tIS(base) AC175 specification by adding an additional 100ps of derating to accommodate for the lower alternate threshold of 150 mV and another 25 ps to account for the earlier reference point [(175 mv - 150 mV) / 1 V/ns].

**NOTE 3:** The tIS(base) AC125 specifications are adjusted from the tIS(base) AC135 specification by adding an additional 75ps of derating to accommodate for the lower alternate threshold of 125 mV and another 10 ps to account for the earlier reference point [(135 mv - 125 mV) / 1 V/ns].

### - Data Setup, Hold, and Slew Rate De-rating

For all input signals the total tDS (setup time) and tDH (hold time) required is calculated by adding the data sheet tDS(base) and tDH(base) value to the  $\Delta$  tDS and  $\Delta$  tDH derating value respectively.

Example: tDS (total setup time) = tDS(base) +  $\Delta$  tDS.

Setup (tDS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of Vref(dc) and the first crossing of VIH(ac)min. Setup (tDS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of Vref(dc) and the first crossing of VIL(ac)max. If the actual signal is always earlier than the nominal slew rate line between shaded 'Vref(dc) to ac region', use nominal slew rate for derating value. If the actual signal is later than the nominal slew rate line anywhere between shaded 'Vref(dc) to ac region', the slew rate of the tangent line to the actual signal from the ac level to dc level is used for derating value.

Hold (tDH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(dc)max and the first crossing of Vref(dc). Hold (tDH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(dc)min and the first crossing of Vref(dc). If the actual signal is always later than the nominal slew rate line between shaded 'dc level to Vref(dc) region', use nominal slew rate for derating value. If the actual signal is earlier than the nominal slew rate line anywhere between shaded 'dc to Vref(dc) region', the slew rate of a tangent line to the actual signal from the dc level to Vref(dc) level is used for derating value.

For a valid transition the input signal has to remain above/below VIH/IL(ac) for some time tVAC.

Although for slow slew rates the total setup time might be negative (i.e. a valid input signal will not have reached VIH/IL(ac) at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach VIH/IL(ac).

For slew rates in between the values listed in the following tables, the derating values may be obtained by linear interpolation.

These values are typically not subject to production test. They are verified by design and characterization.

 Example for BC4 (via MRS or OTF), AL = 0, CWL = 5. ODT<sub>H4</sub> applies to first registering ODT high and to the registration of the Write command.  
 In this example, ODT<sub>H4</sub> would be satisfied if ODT went low at T8 (4 clocks after the Write command).

**Figure 68. Dynamic ODT: Behavior without write command, AL = 0, CWL = 5**

**NOTES:**

1.  $ODTH4$  is defined from ODT registered high to ODT registered low, so in this example,  $ODTH4$  is satisfied.
2. ODT registered low at T5 would also be legal.

□ TRANSITIONING DATA    ■ Don't Care

**Figure 69. Dynamic ODT: Behavior with ODT pin being asserted together with write command for a duration of 6 clock cycles**

**NOTES:**

Example for BL8 (via MRS or OTF), AL = 0, CWL = 5. In this example,  $ODTH8 = 6$  is exactly satisfied.

□ TRANSITIONING DATA    ■ Don't Care

**Figure 70. Dynamic ODT: Behavior with ODT pin being asserted together with write command for a duration of 6 clock cycles, example for BC4 (via MRS or OTF), AL = 0, CWL = 5.**

**Figure 71. Dynamic ODT: Behavior with ODT pin being asserted together with write command for a duration of 4 clock cycles**

**Figure 72. Asynchronous ODT Timings on DDR3 SDRAM with fast ODT transition**

**Figure 73. Synchronous to asynchronous transition during Precharge Power Down (with DLL frozen) entry (AL = 0; CWL = 5;  $t_{ANPD} = WL - 1 = 4$ )**

**Figure 74. Synchronous to asynchronous transition after Refresh command**  
(AL = 0; CWL = 5; tANPD = WL - 1 = 4)

**Figure 75. Asynchronous to synchronous transition during Precharge Power Down**  
(with DLL frozen) exit (CL = 6; AL = CL - 1; CWL = 5; tANPD = WL - 1 = 9)
