CY7C1460KV25/CY7C1462KV25
CY7C1460KVE25/CY7C1462KVE25

36-Mbit (1M × 36/2M × 18) Pipelined SRAM with NoBL™ Architecture (With ECC)

Features

- Pin-compatible and functionally equivalent to ZBT™
- Supports 250 MHz bus operations with zero wait states
  - Available speed grades are 250 MHz, 200 MHz, and 167 MHz
- Internally self-timed output buffer control to eliminate the need to use asynchronous $\overline{OE}$
- Fully registered (inputs and outputs) for pipelined operation
- Byte Write capability
- 2.5 V core power supply
- 2.5 V I/O power supply
- Fast clock-to-output times
  - 2.5 ns (for 250 MHz device)
- Clock enable ($\overline{CEN}$) pin to suspend operation
- Synchronous self-timed writes
- CY7C1460KV25, CY7C1462KV25, CY7C1460KVE25 and CY7C1462KVE25 available in JEDEC-standard Pb-free 100-pin TQFP, and Pb-free and non Pb-free 165-ball FBGA packages.
- IEEE 1149.1 JTAG-Compatible Boundary Scan
- Burst capability — linear or interleaved burst order
- “ZZ” sleep mode option
- On-chip error correction code (ECC) to reduce soft error rate (SER)

Functional Description

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25 are 2.5 V, 1M × 36/2M × 18 synchronous pipelined burst SRAMs with No Bus Latency™ (NoBL™) logic, respectively. They are designed to support unlimited true back-to-back read/write operations with no wait states. The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25 are equipped with the advanced NoBL logic required to enable consecutive read/write operations with data being transferred on every clock cycle. This feature dramatically improves the throughput of data in systems that require frequent write/read transitions. The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25 are pin-compatible and functionally equivalent to ZBT devices.

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. The clock input is qualified by the clock enable ($\overline{CEN}$) signal, which when deasserted suspends operation and extends the previous clock cycle. Write operations are controlled by the byte write selects $\overline{BW_a}$–$\overline{BW_d}$ for CY7C1460KV25/CY7C1460KVE25 and $\overline{BW_a}$–$\overline{BW_b}$ for CY7C1462KV25/CY7C1462KVE25 and a write enable ($\overline{WE}$) input. All writes are conducted with on-chip synchronous self-timed write circuitry.

Three synchronous chip enables ($\overline{CE_1}$, CE_2, $\overline{CE_3}$) and an asynchronous output enable ($\overline{OE}$) provide for easy bank selection and output three-state control. In order to avoid bus contention, the output drivers are synchronously three-stated during the data portion of a write sequence.

Selection Guide

Description		250 MHz	200 MHz	167 MHz	Unit
Maximum access time		2.5	3.2	3.4	ns
Maximum operating current	× 18	220	190	170	mA
	× 36	240	210	190

Pin Definitions

Pin Name	I/O Type	Pin Description
A0, A1, A	Input-synchronous	**Address inputs used to select one of the address locations**. Sampled at the rising edge of the CLK.
$\overline{BW}_a$, $\overline{BW}_b$, $\overline{BW}_c$, $\overline{BW}_d$	Input-synchronous	**Byte write select inputs, active LOW**. Qualified with $\overline{WE}$ to conduct writes to the SRAM. Sampled on the rising edge of CLK. $\overline{BW}_a$ controls DQ_a and DQP_a, $\overline{BW}_b$ controls DQ_b and DQP_b, $\overline{BW}_c$ controls DQ_c and DQP_c, $\overline{BW}_d$ controls DQ_d and DQP_d
$\overline{WE}$	Input-synchronous	**Write enable input, active LOW**. Sampled on the rising edge of CLK if $\overline{CEN}$ is active LOW. This signal must be asserted LOW to initiate a write sequence.
ADV/$\overline{LD}$	Input-synchronous	**Advance/load input used to advance the on-chip address counter or load a new address**. When HIGH (and $\overline{CEN}$ is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, ADV/$\overline{LD}$ should be driven LOW in order to load a new address.
CLK	Input-clock	**Clock input**. Used to capture all synchronous inputs to the device. CLK is qualified with $\overline{CEN}$. CLK is only recognized if $\overline{CEN}$ is active LOW.
$\overline{CE}_1$	Input-synchronous	**Chip enable 1 input, active LOW**. Sampled on the rising edge of CLK. Used in conjunction with CE_2 and $\overline{CE}_3$ to select/deselect the device.
CE_2	Input-synchronous	**Chip enable 2 input, active HIGH**. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and $\overline{CE}_3$ to select/deselect the device.
$\overline{CE}_3$	Input-synchronous	**Chip enable 3 input, active LOW**. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and CE_2 to select/deselect the device.
$\overline{OE}$	Input-asynchronous	**Output enable, active LOW**. Combined with the synchronous logic block inside the device to control the direction of the I/O pins. When LOW, the I/O pins are allowed to behave as outputs. When deasserted HIGH, I/O pins are tristated, and act as input data pins. $\overline{OE}$ is masked during the data portion of a write sequence, during the first clock when emerging from a deselected state and when the device has been deselected.
$\overline{CEN}$	Input-synchronous	**Clock enable input, active LOW**. When asserted LOW the clock signal is recognized by the SRAM. When deasserted HIGH the clock signal is masked. Since deasserting $\overline{CEN}$ does not deselect the device, $\overline{CEN}$ can be used to extend the previous cycle when required.
DQ_a, DQ_b, DQ_c, DQ_d	I/O-synchronous	**Bidirectional data I/O lines**. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by A_X during the previous read cycle. The direction of the pins is controlled by $\overline{OE}$ and the internal control logic. When $\overline{OE}$ is asserted LOW, the pins can behave as outputs. When HIGH, DQ_a–DQ_d are placed in a tristate condition. The outputs are automatically tristated during the data portion of a write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of $\overline{OE}$.
DQP_a, DQP_b, DQP_c, DQP_d	I/O-synchronous	**Bidirectional data parity I/O lines**. Functionally, these signals are identical to $DQ_{[31:0]}$. During write sequences, DQP_a is controlled by $\overline{BW}_a$, DQP_b is controlled by $\overline{BW}_b$, DQP_c is controlled by $\overline{BW}_c$, and DQP_d is controlled by $\overline{BW}_d$, DQP_e is controlled by $\overline{BW}_e$, DQP_f is controlled by $\overline{BW}_f$, DQP_g is controlled by $\overline{BW}_g$, DQP_h is controlled by $\overline{BW}_h$.
MODE	Input strap pin	**Mode input**. Selects the burst order of the device. Tied HIGH selects the interleaved burst order. Pulled LOW selects the linear burst order. MODE should not change states during operation. When left floating MODE will default HIGH, to an interleaved burst order.
TDO	JTAG serial output synchronous	**Serial data-out to the JTAG circuit**. Delivers data on the negative edge of TCK.

Pin Definitions *(continued)*

Pin Name	I/O Type	Pin Description
TDI	JTAG serial input synchronous	**Serial data-in to the JTAG circuit**. Sampled on the rising edge of TCK.
TMS	Test mode select synchronous	**This pin controls the Test Access Port state machine**. Sampled on the rising edge of TCK.
TCK	JTAG-clock	**Clock input to the JTAG circuitry**.
V_{DD}	Power supply	**Power supply inputs to the core of the device**.
V_{DDQ}	I/O power supply	**Power supply for the I/O circuitry**.
V_{SS}	Ground	**Ground for the device**. Should be connected to ground of the system.
NC	N/A	**No connects**. This pin is not connected to the die.
NC/72M	N/A	**Not connected to the die**. Can be tied to any voltage level.
NC/144M	N/A	**Not connected to the die**. Can be tied to any voltage level.
NC/288M	N/A	**Not connected to the die**. Can be tied to any voltage level.
NC/576M	N/A	**Not connected to the die**. Can be tied to any voltage level.
NC/1G	N/A	**Not connected to the die**. Can be tied to any voltage level.
ZZ	Input-asynchronous	**ZZ "sleep" Input**. This active HIGH input places the device in a non-time critical "sleep" condition with data integrity preserved. During normal operation, this pin has to be LOW or left floating. ZZ pin has an internal pull-down.

Functional Overview

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/ CY7C1462KVE25 are synchronous-pipelined burst NoBL SRAMs designed specifically to eliminate wait states during write/read transitions. All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock signal is qualified with the clock enable input signal (CEN). If CEN is HIGH, the clock signal is not recognized and all internal states are maintained. All synchronous operations are qualified with CEN. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise (t_{CO}) is 2.5 ns (250 MHz device).

Accesses can be initiated by asserting all three chip enables ($\overline{CE}_1$, CE_2, $\overline{CE}_3$) active at the rising edge of the clock. If clock enable (CEN) is active LOW and ADV/LD is asserted LOW, the address presented to the device will be latched. The access can either be a read or write operation, depending on the status of the write enable (WE). $BW_{[x]}$ can be used to conduct byte write operations.

Write operations are qualified by the write enable (WE). All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous chip enables ($\overline{CE}_1$, CE_2, $\overline{CE}_3$) and an asynchronous output enable (OE) simplify depth expansion. All operations (reads, writes, and deselects) are pipelined. ADV/LD should be driven LOW once the device has been deselected in order to load a new address for the next operation.

Single Read Accesses

A read access is initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2) $\overline{CE}_1$, CE_2, and $\overline{CE}_3$ are all asserted active, (3) the write enable input signal WE is deasserted HIGH, and (4) ADV/LD is asserted LOW. The address presented to the address inputs is latched into the address register and presented to the memory core and control logic. The control logic determines that a read access is in progress and allows the requested data to propagate to the input of the output register. At the rising edge of the next clock the requested data is allowed to propagate through the output register and onto the data bus within 2.5 ns (200-MHz device) provided OE is active LOW. After the first clock of the read access the output buffers are controlled by OE and the internal control logic. OE must be driven LOW in order for the device to drive out the requested data. During the second clock, a subsequent operation (read/write/deselect) can be initiated. Deselecting the device is also pipelined. Therefore, when the SRAM is deselected at clock rise by one of the chip enable signals, its output will tristate following the next clock rise.

Burst Read Accesses

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/ CY7C1462KVE25 have an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four reads without reasserting the address inputs. ADV/LD must be driven LOW in order to load a new address into the SRAM, as described in the Single Read Accesses section above. The sequence of the burst counter is determined by the MODE input signal. A LOW input on MODE selects a linear burst mode, a HIGH selects an interleaved burst sequence. Both burst counters use A0 and A1 in the burst sequence, and will wrap-around when incremented sufficiently. A HIGH input on ADV/LD will increment the internal burst counter regardless of the state of chip enables inputs or WE. WE is latched at the beginning of a burst cycle. Therefore, the type of access (Read or Write) is maintained throughout the burst sequence.

Single Write Accesses

Write access are initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2) CE_1, CE_2, and CE_3 are all asserted active, and (3) the write signal WE is asserted LOW. The address presented to the address inputs is loaded into the address register. The write signals are latched into the control logic block.

On the subsequent clock rise the data lines are automatically three-stated regardless of the state of the OE input signal. This allows the external logic to present the data on DQ and DQP ($DQ_{a,b,c,d}$/$DQP_{a,b,c,d}$ for CY7C1460KV25/CY7C1460KVE25 and $DQ_{a,b}$/$DQP_{a,b}$ for CY7C1462KV25/CY7C1462KVE25). In addition, the address for the subsequent access (read/write/deselect) is latched into the address register (provided the appropriate control signals are asserted).

On the next clock rise the data presented to DQ and DQP ($DQ_{a,b,c,d}$/$DQP_{a,b,c,d}$ for CY7C1460KV25/CY7C1460KVE25 and $DQ_{a,b}$/$DQP_{a,b}$ for CY7C1462KV25/CY7C1462KVE25) (or a subset for byte write operations, see Write Cycle Description table for details) inputs is latched into the device and the write is complete.

The data written during the write operation is controlled by BW ($BW_{a,b,c,d}$ for CY7C1460KV25/CY7C1460KVE25 and $BW_{a,b}$ for CY7C1462KV25/CY7C1462KVE25) signals. The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/ CY7C1462KVE25 provides byte write capability that is described in the Write Cycle Description table. Asserting the write enable input (WE) with the selected byte write select (BW) input will selectively write to only the desired bytes. Bytes not selected during a byte write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the write operations. Byte write capability has been included in order to greatly simplify read/modify/write sequences, which can be reduced to simple byte write operations.

Because the CY7C1460KV25/CY7C1462KV25/ CY7C1460KVE25/CY7C1462KVE25 are common I/O devices, data should not be driven into the device while the outputs are active. The output enable (OE) can be deasserted HIGH before presenting data to the DQ and DQP ($DQ_{a,b,c,d}$/$DQP_{a,b,c,d}$ for CY7C1460KV25/CY7C1460KVE25 and $DQ_{a,b}$/$DQP_{a,b}$ for CY7C1462KV25/CY7C1462KVE25) inputs. Doing so will three-state the output drivers. As a safety precaution, DQ and DQP ($DQ_{a,b,c,d}$/$DQP_{a,b,c,d}$ for CY7C1460KV25/ CY7C1460KVE25 and $DQ_{a,b}$/$DQP_{a,b}$ for CY7C1462KV25/ CY7C1462KVE25) are automatically three-stated during the data portion of a write cycle, regardless of the state of OE.

Burst Write Accesses

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/ CY7C1462KVE25 have an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four WRITE operations without reasserting the address inputs. ADV/LD must be driven LOW in order to load the initial address, as described in the Single Write Accesses section above. When ADV/LD is driven HIGH on the subsequent clock rise, the chip enables (CE_1, CE_2, and CE_3) and WE inputs are ignored and the burst counter is incremented. The correct BW ($BW_{a,b,c,d}$ for CY7C1460KV25/CY7C1460KVE25 and $BW_{a,b}$ for CY7C1462KV25/CY7C1462KVE25) inputs must be driven in each cycle of the burst write in order to write the correct bytes of data.

Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. CE_1, CE_2, and CE_3, must remain inactive for the duration of t_{ZZREC} after the ZZ input returns LOW.

On-Chip ECC

CY7C1460KVE25/CY7C1462KVE25 SRAMs include an on-chip ECC algorithm that detects and corrects all single-bit memory errors, including Soft Error Upset (SEU) events induced by cosmic rays, alpha particles etc. The resulting Soft Error Rate (SER) of these devices is anticipated to be <0.01 FITs/Mb a 4-order-of-magnitude improvement over comparable SRAMs with no On-Chip ECC, which typically have an SER of 200 FITs/Mb or more. To protect the internal data, ECC parity bits (invisible to the user) are used.

The ECC algorithm does not correct multi-bit errors.However,Cypress SRAMs are architected in such a way that a single SER event has a very low probability of causing a multi-bit error across any data word. The extreme rarity of multi-bit errors results in a SER of <0.01 FITs/Mb.

Interleaved Burst Address Table

(MODE = Floating or V_{DD})

First Address A1, A0	Second Address A1, A0	Third Address A1, A0	Fourth Address A1, A0
00	01	10	11
01	00	11	10
10	11	00	01
11	10	01	00

Linear Burst Address Table

(MODE = GND)

IGNORE CLOCK EDGE (stall)	Current	X	L	X	X	X	X	H	L–H	–
Sleep MODE	None	X	H	X	X	X	X	X	X	Tristate

Notes
1. X = “Don't Care”, H = Logic HIGH, L = Logic LOW, $\overline{CE}$ stands for all chip enables active. $\overline{BWx}$ = L signifies at least one byte write select is active, $\overline{BWx}$ = valid signifies that the desired byte write selects are asserted, see Write Cycle Description table for details.
2. Write is defined by $\overline{WE}$ and $\overline{BW}_X$. See Write Cycle Description table for details.
3. When a write cycle is detected, all I/Os are tristated, even during byte writes.
4. The DQ and DQP pins are controlled by the current cycle and the $\overline{OE}$ signal.
5. $\overline{CEN}$ = H inserts wait states.
6. Device will power-up deselected and the I/Os in a tristate condition, regardless of $\overline{OE}$.
7. $\overline{OE}$ is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle DQ_s and DQP_X = Three-state when $\overline{OE}$ is inactive or when the device is deselected, and DQ_s=data when $\overline{OE}$ is active.

Partial Write Cycle Description

The Partial Write Cycle Description for CY7C1460KV25/CY7C1460KVE25 is as follows [8, 9, 10, 11].

Function (CY7C1460KV25/CY7C1460KVE25)	$\overline{WE}$	$\overline{BW}_d$	$\overline{BW}_c$	$\overline{BW}_b$	$\overline{BW}_a$
Read	H	X	X	X	X
Write – no bytes written	L	H	H	H	H
Write byte a – (DQ_a and DQP_a)	L	H	H	H	L
Write byte b – (DQ_b and DQP_b)	L	H	H	L	H
Write bytes b, a	L	H	H	L	L
Write byte c – (DQ_c and DQP_c)	L	H	L	H	H
Write bytes c, a	L	H	L	H	L
Write bytes c, b	L	H	LL	L	H
Write bytes c, b, a	L	H	L	L	L
Write byte d – (DQ_d and DQP_d)	L	L	H	H	H
Write bytes d, a	L	L	H	H	L
Write bytes d, b	L	L	H	L	H
Write bytes d, b, a	L	L	H	L	L
Write bytes d, c	L	L	L	H	H
Write bytes d, c, a	L	L	L	H	L
Write bytes d, c, b	L	L	L	L	H
Write all bytes	L	L	L	L	L

Partial Write Cycle Description

The Partial Write Cycle Description for CY7C1462KV25/CY7C1462KVE25 is as follows[8, 9, 10, 11].

Function (CY7C1462KV25/CY7C1462KVE25)	$\overline{WE}$	$\overline{BW}_b$	$\overline{BW}_a$
Read	H	X	X
Write – no bytes written	L	H	H
Write byte a – (DQ_a and DQP_a)	L	H	L
Write byte b – (DQ_b and DQP_b)	L	L	H
Write both bytes	L	L	L

Notes
8. X = "Don't Care", H = Logic HIGH, L = Logic LOW, $\overline{CE}$ stands for all chip enables active. $\overline{BWx}$ = L signifies at least one byte write select is active, $\overline{BWx}$ = valid signifies that the desired byte write selects are asserted, see Write Cycle Description table for details.
9. Write is defined by $\overline{WE}$ and $\overline{BW}_X$. See Write Cycle Description table for details.
10. When a write cycle is detected, all I/Os are tristated, even during byte writes.
11. Table only lists a partial listing of the byte write combinations. Any combination of $\overline{BW}_X$ is valid. Appropriate write will be done based on which byte write is active.

IEEE 1149.1 Serial Boundary Scan (JTAG)

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25 incorporates a serial boundary scan test access port (TAP). This part is fully compliant with 1149.1. The TAP operates using JEDEC-standard 2.5 V I/O logic level.

The CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25 contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW(VSS) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to VDD through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

Test Access Port (TAP)

Test Clock (TCK)

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

Test Mode Select (TMS)

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this ball unconnected if the TAP is not used. The ball is pulled up internally, resulting in a logic HIGH level.

Test Data-In (TDI)

The TDI ball is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) of any register (see TAP Controller Block Diagram on page 16).

Test Data-Out (TDO)

The TDO output ball is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine. The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register (see TAP Controller State Diagram on page 16).

Performing a TAP Reset

A RESET is performed by forcing TMS HIGH (V_{DD}) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating.

At power-up, the TAP is reset internally to ensure that TDO comes up in a high Z state.

TAP Registers

Registers are connected between the TDI and TDO balls and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction register. Data is serially loaded into the TDI ball on the rising edge of TCK. Data is output on the TDO ball on the falling edge of TCK.

Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO balls as shown in the TAP Controller Block Diagram on page 16. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture-IR state, the two least significant bits are loaded with a binary “01” pattern to allow for fault isolation of the board-level serial test data path.

Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between the TDI and TDO balls. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW (V_{SS}) when the BYPASS instruction is executed.

Boundary Scan Register

The boundary scan register is connected to all the input and bidirectional balls on the SRAM. The length of the Boundary Scan Register for the SRAM in different packages is listed in the Scan Register Sizes on page 19.

The boundary scan register is loaded with the contents of the RAM I/O ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO balls when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the I/O ring.

The Boundary Scan Order on page 20 show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions on page 19.

TAP Instruction Set

Overview

Eight different instructions are possible with the three bit instruction register. All combinations are listed in the Instruction Codes table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO balls. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO balls and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state.

The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO pins when the TAP controller is in a Shift-DR state. The SAMPLE Z command puts the output bus into a high Z state until the next command is given during the “Update IR” state.

SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1-mandatory instruction. When the SAMPLE/PRELOAD instructions are loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the inputs and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 20 MHz, while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller’s capture set-up plus hold times (t_{CS} and t_{CH}). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the clock captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

PRELOAD allows an initial data pattern to be placed at the latched parallel outputs of the boundary scan register cells prior to the selection of another boundary scan test operation.

The shifting of data for the SAMPLE and PRELOAD phases can occur concurrently when required – that is, while data captured is shifted out, the preloaded data can be shifted in.

BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO pins. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

EXTEST

The EXTEST instruction enables the preloaded data to be driven out through the system output pins. This instruction also selects the boundary scan register to be connected for serial access between the TDI and TDO in the shift-DR controller state.

EXTEST Output Bus Tristate

IEEE Standard 1149.1 mandates that the TAP controller be able to put the output bus into a tristate mode.

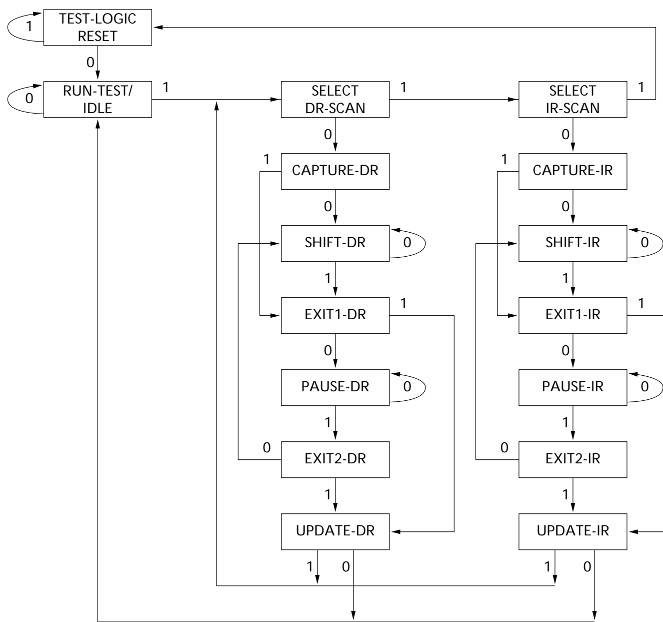
The boundary scan register has a special bit located at bit #89 (for 165-ball FBGA package). When this scan cell, called the “extest output bus tristate,” is latched into the preload register during the “Update-DR” state in the TAP controller, it will directly control the state of the output (Q-bus) pins, when the EXTEST is entered as the current instruction. When HIGH, it will enable the output buffers to drive the output bus. When LOW, this bit will place the output bus into a high Z condition.

This bit can be set by entering the SAMPLE/PRELOAD or EXTEST command, and then shifting the desired bit into that cell, during the “Shift-DR” state. During “Update-DR,” the value loaded into that shift-register cell will latch into the preload register. When the EXTEST instruction is entered, this bit will directly control the output Q-bus pins. Note that this bit is preset HIGH to enable the output when the device is powered-up, and also when the TAP controller is in the “Test-Logic-Reset” state.

Reserved

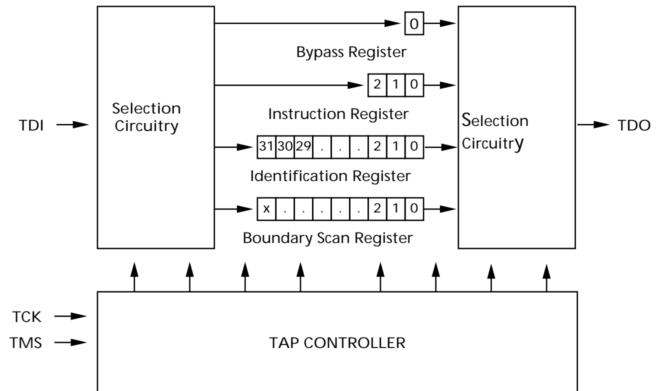
These instructions are not implemented but are reserved for future use. Do not use these instructions.

TAP Controller State Diagram

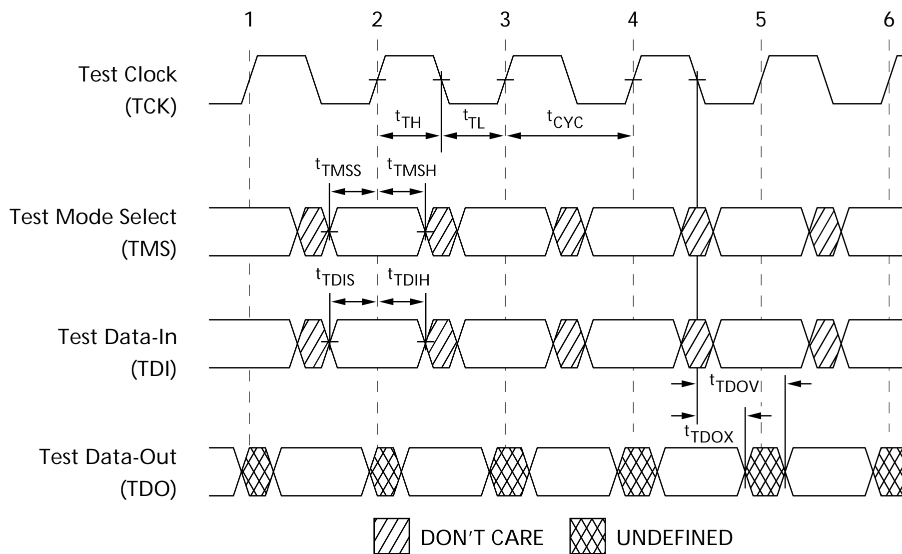


The 0/1 next to each state represents the value of TMS at the rising edge of TCK.

TAP Controller Block Diagram



TAP Timing



TAP AC Switching Characteristics

Over the Operating Range

Parameter [12, 13]	Description	Min	Max	Unit
Clock				
t_{TCYC}	TCK clock cycle time	50	–	ns
t_{TF}	TCK clock frequency	–	20	MHz
t_{TH}	TCK clock HIGH time	20	–	ns
t_{TL}	TCK clock LOW time	20	–	ns
Output Times				
t_{TDOV}	TCK clock LOW to TDO valid	–	10	ns
t_{TDOX}	TCK clock LOW to TDO invalid	0	–	ns
Set-up Times				
t_{TMSS}	TMS set-up to TCK clock rise	5	–	ns
t_{TDIS}	TDI set-up to TCK clock rise	5	–	ns
t_{CS}	Capture set-up to TCK rise	5	–	ns
Hold Times				
t_{TMSH}	TMS hold after TCK clock rise	5	–	ns
t_{TDIH}	TDI hold after clock rise	5	–	ns
t_{CH}	Capture hold after clock rise	5	–	ns

Notes

12. t_{CS} and t_{CH} refer to the set-up and hold time requirements of latching data from the boundary scan register.
13. Test conditions are specified using the load in TAP AC test Conditions. t_R/t_F = 2 V/ns (Slew Rate).

Electrical Characteristics

Over the Operating Range

Parameter [16, 17]	Description	Test Conditions	Min	Max	Unit
V_{DD}	Power supply voltage	–	2.375	2.625	V
V_{DDQ}	I/O supply voltage	for 2.5 V I/O	2.375	V_{DD}	V
V_{OH}	Output HIGH voltage	for 2.5 V I/O, I_{OH} = –1.0 mA	2.0	–	V
V_{OL}	Output LOW voltage	for 2.5 V I/O, I_{OL} = 1.0 mA	–	0.4	V
V_{IH}	Input HIGH voltage [16]	for 2.5 V I/O	1.7	V_{DD} + 0.3 V	V
V_{IL}	Input LOW voltage [16]	for 2.5 V I/O	–0.3	0.7	V
I_X	Input leakage current except ZZ and MODE	GND ≤ V_I ≤ V_{DDQ}	–5	5	µA
	Input current of MODE	Input = V_{SS}	–30	–	µA
		Input = V_{DD}	–	5	µA
	Input current of ZZ	Input = V_{SS}	–5	–	µA
		Input = V_{DD}	–	30	µA
I_{OZ}	Output leakage current	GND ≤ V_I ≤ $V_{DDQ,}$ output disabled	-5	5	µA

Notes
16. Overshoot: $V_{IH}(AC) < V_{DD}$ +1.5 V (Pulse width less than $t_{CYC}/2$), undershoot: $V_{IL}(AC) > –2$ V (Pulse width less than $t_{CYC}/2$).
17. $T_{Power-up}$: Assumes a linear ramp from 0 V to V_{DD} (min) within 200 ms. During this time $V_{IH} < V_{DD}$ and $V_{DDQ} \leq V_{DD}$.

Clock								
t_{CYC}	Clock cycle time	4.0	–	5.0	–	6.0	–	ns
F_{MAX}	Maximum operating frequency	–	250	–	200	–	167	MHz
t_{CH}	Clock HIGH	1.5	–	2.0	–	2.4	–	ns
t_{CL}	Clock LOW	1.5	–	2.0	–	2.4	–	ns
Output Times								
t_{CO}	Data output valid after CLK rise	–	2.5	–	3.2	–	3.4	ns
t_{EOV}	$\overline{OE}$ LOW to output valid	–	2.6	–	3.0	–	3.4	ns
t_{DOH}	Data output hold after CLK rise	1.0	–	1.5	–	1.5	–	ns
t_{CHZ}	Clock to high Z [22, 23, 24]	–	2.6	–	3.0	–	3.4	ns
t_{CLZ}	Clock to low Z [22, 23, 24]	1.0	–	1.3	–	1.5	–	ns
t_{EOHZ}	$\overline{OE}$ HIGH to output high Z [22, 23, 24]	–	2.6	–	3.0	–	3.4	ns
t_{EOLZ}	$\overline{OE}$ LOW to output low Z [22, 23, 24]	0	–	0	–	0	–	ns
Set-up Times								
t_{AS}	Address set-up before CLK rise	1.2	–	1.4	–	1.5	–	ns
t_{DS}	Data input set-up before CLK rise	1.2	–	1.4	–	1.5	–	ns
t_{CENS}	$\overline{CEN}$ set-up before CLK rise	1.2	–	1.4	–	1.5	–	ns
t_{WES}	$\overline{WE}$, $\overline{BW}_x$ set-up before CLK rise	1.2	–	1.4	–	1.5	–	ns
t_{ALS}	ADV/$\overline{LD}$ set-up before CLK rise	1.2	–	1.4	–	1.5	–	ns
t_{CES}	Chip select set-up	1.2	–	1.4	–	1.5	–	ns
Hold Times								
t_{AH}	Address hold after CLK rise	0.3	–	0.4	–	0.5	–	ns
t_{DH}	Data input hold after CLK rise	0.3	–	0.4	–	0.5	–	ns
t_{CENH}	$\overline{CEN}$ hold after CLK rise	0.3	–	0.4	–	0.5	–	ns
t_{WEH}	$\overline{WE}$, $\overline{BW}_x$ hold after CLK rise	0.3	–	0.4	–	0.5	–	ns
t_{ALH}	ADV/$\overline{LD}$ hold after CLK rise	0.3	–	0.4	–	0.5	–	ns
t_{CEH}	Chip select hold after CLK rise	0.3	–	0.4	–	0.5	–	ns

Notes
19. Timing reference is 1.25 V when V_{DDQ} = 2.5 V.
20. Test conditions shown in (a) of AC Test Loads unless otherwise noted.
21. This part has a voltage regulator internally; t_{power} is the time power needs to be supplied above V_{DD} minimum initially, before a read or write operation can be initiated.
22. t_{CHZ}, t_{CLZ}, t_{EOLZ}, and t_{EOHZ} are specified with AC test conditions shown in (b) of Figure 3 on page 23. Transition is measured ± 200 mV from steady-state voltage.
23. At any given voltage and temperature, t_{EOHZ} is less than t_{EOLZ} and t_{CHZ} is less than t_{CLZ} to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve high Z prior to low Z under the same system conditions.
24. This parameter is sampled and not 100% tested.

Switching Waveforms

Figure 4. Read/Write/Timing [25, 26, 27]

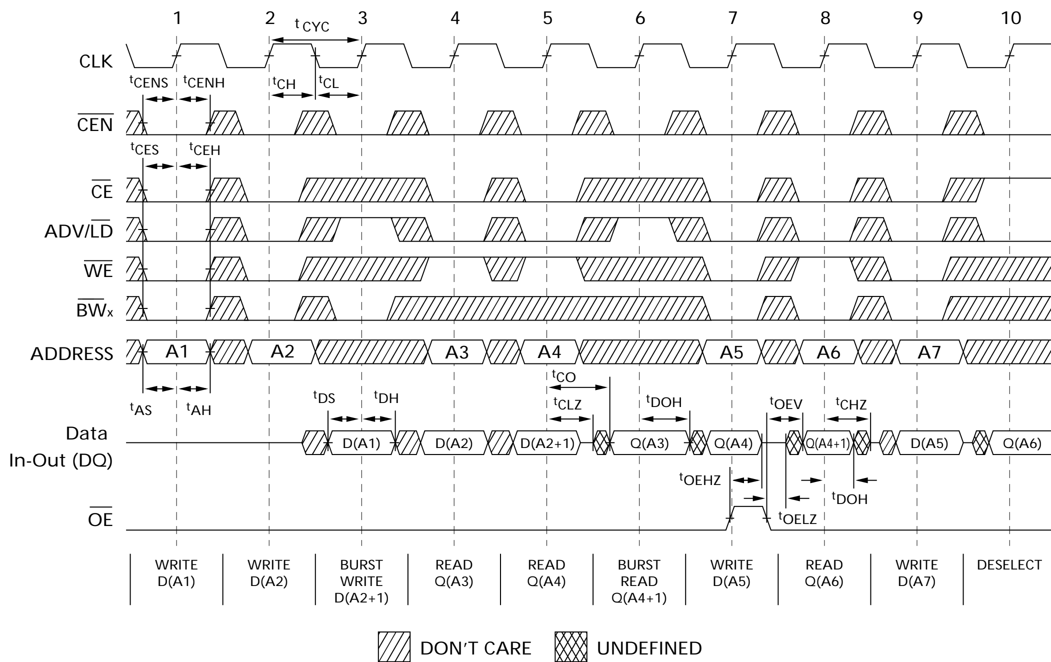

Figure 5. NOP, STALL and DESELECT Cycles [25, 26, 28]

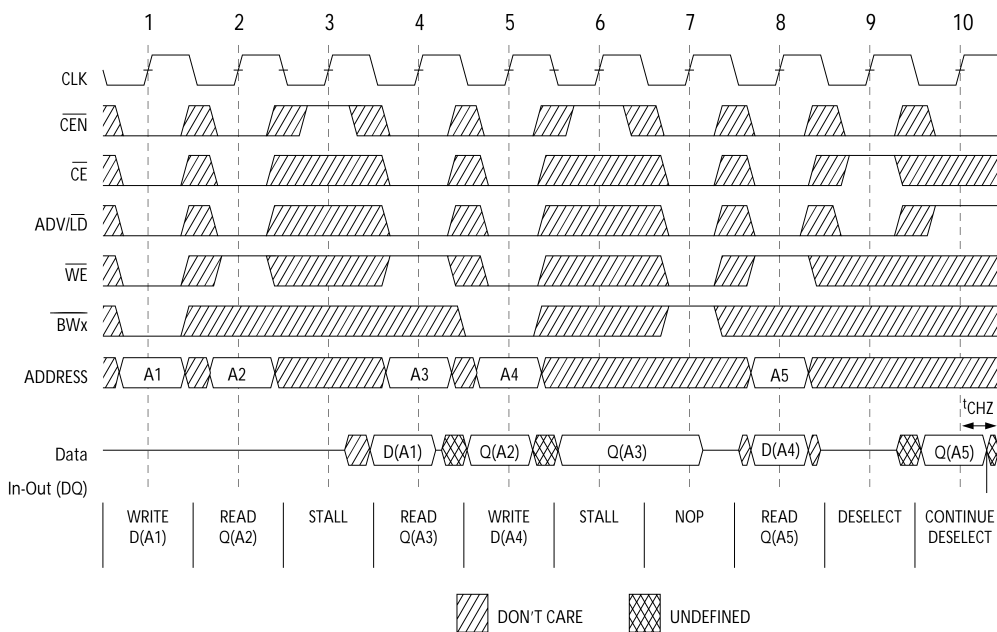
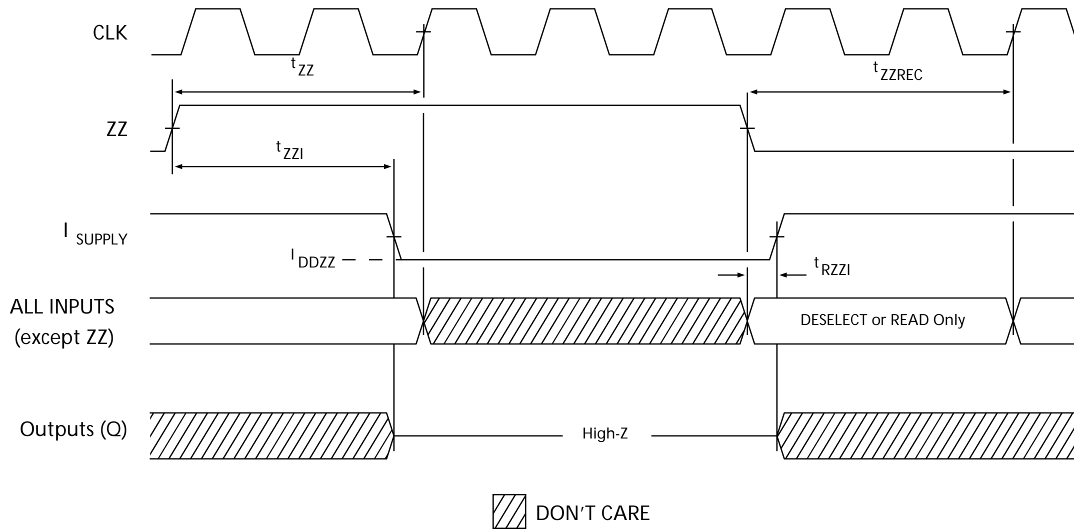


Notes

25. For this waveform ZZ is tied low.
26. When CE is LOW, $\overline{CE_1}$ is LOW, CE_2 is HIGH and $\overline{CE_3}$ is LOW. When CE is HIGH, $\overline{CE_1}$ is HIGH or CE_2 is LOW or $\overline{CE_3}$ is HIGH.
27. Order of the burst sequence is determined by the status of the MODE (0=Linear, 1=Interleaved). Burst operations are optional.
28. The IGNORE CLOCK EDGE or STALL cycle (Clock 3) illustrated CEN being used to create a pause. A write is not performed during this cycle.

Switching Waveforms *(continued)*

Figure 6. ZZ Mode Timing [29, 30]



Notes
29. Device must be deselected when entering ZZ mode. See cycle description table for all possible signal conditions to deselect the device.
30. I/Os are in high Z when exiting ZZ sleep mode.

Ordering Information

Table 1 lists the ordering codes. The table contains only the parts that are currently available. If you do not see what you are looking for, contact your local sales representative. For more information, visit the Cypress website at www.cypress.com and refer to the product summary page at http://www.cypress.com/products.

Table 1. Ordering Information

Speed (MHz)	Ordering Code	Package Diagram	Part and Package Type	Operating Range
250	CY7C1460KV25-250AXC	51-85050	100-pin TQFP (14 × 20 × 1.4 mm) Pb-free	Commercial
	CY7C1462KV25-250BZXC	51-85195	165-ball FBGA (15 × 17 × 1.4 mm) Pb-free	
	CY7C1460KV25-250BZC		165-ball FBGA (15 × 17 × 1.4 mm)	
	CY7C1460KVE25-250AXC	51-85050	100-pin TQFP (14 × 20 × 1.4 mm) Pb-free	
200	CY7C1460KV25-200BZXI	51-85195	165-ball FBGA (15 × 17 × 1.4 mm) Pb-free	Industrial
	CY7C1460KV25-200BZI		165-ball FBGA (15 × 17 × 1.4 mm)	
	CY7C1460KVE25-200BZXI		165-ball FBGA (15 × 17 × 1.4 mm) Pb-free	
	CY7C1462KV25-200AXC	51-85050	100-pin TQFP (14 × 20 × 1.4 mm) Pb-free	Commercial
167	CY7C1460KV25-167AXC		100-pin TQFP (14 × 20 × 1.4 mm) Pb-free	
	CY7C1460KVE25-167AXC		100-pin TQFP (14 × 20 × 1.4 mm) Pb-free	
	CY7C1460KV25-167BZXI	51-85195	165-ball FBGA (15 × 17 × 1.4 mm) Pb-free	Industrial
	CY7C1460KV25-167BZC		165-ball FBGA (15 × 17 × 1.4 mm)	Commercial
	CY7C1462KV25-167BZI		165-ball FBGA (15 × 17 × 1.4 mm)	Industrial
	CY7C1462KVE25-167BZI		165-ball FBGA (15 × 17 × 1.4 mm)

Acronyms

Table 2. Acronyms Used in this Document

Acronym	Description
$\overline{CE}$	Chip Enable
$\overline{CEN}$	Clock Enable
CMOS	Complementary Metal Oxide Semiconductor
FBGA	Fine-Pitch Ball Grid Array
I/O	Input/Output
JTAG	Joint Test Action Group
NoBL	No Bus Latency
$\overline{OE}$	Output Enable
SRAM	Static Random Access Memory
TCK	Test Clock
TDI	Test Data-In
TDO	Test Data-Out
TMS	Test Mode Select
TQFP	Thin Quad Flat Pack
$\overline{WE}$	Write Enable
ECC	Error Correcting Code

Units of Measure

Table 3. Units of Measure

Symbol	Unit of Measure
°C	degree Celsius
MHz	megahertz
µA	microampere
mA	milliampere
mm	millimeter
ms	millisecond
ns	nanosecond
%	percent
pF	picofarad
V	volt
W	watt

Document History Page

Document Title: CY7C1460KV25/CY7C1462KV25/CY7C1460KVE25/CY7C1462KVE25, 36-Mbit (1M × 36/2M × 18) Pipelined SRAM with NoBL™ Architecture (With ECC) Document Number: 001-66679				
Revision	**ECN**	**Orig. of Change**	**Submission Date**	**Description of Change**
*E	4680535	PRIT	04/10/2015	Changed status from Preliminary to Final.
*F	4757974	DEVM	05/07/2015	Updated Functional Overview: Updated ZZ Mode Electrical Characteristics: Changed maximum value of I_{DDZZ} parameter from 89 mA to 75 mA.
*G	5028596	PRIT	11/26/2015	Added Errata.
*H	5210861	DEVM	04/07/2016	Removed Errata. Updated to new template. Completing Sunset Review.
*I	5337537	PRIT	07/05/2016	Updated Neutron Soft Error Immunity: Updated values in “Typ” and “Max” columns corresponding to LSBU (Device without ECC) parameter.
*J	6062214	CNX	02/07/2018	Updated Package Diagrams: spec 51-85050 – Changed revision from *E to *G. Updated to new template.
