### Low IQ Boost/SEPIC/ Inverting Converter with 1A, 60V Switch

### FEATURES DESCRIPTION

- 3V to 40V Input Voltage Range
- Ultralow Quiescent Current and Low Ripple Burst **Mode<sup>®</sup> Operation:**  $I_0 = 6\mu A$
- $\blacksquare$  **1A, 60V Power Switch**
- Positive or Negative Output Voltage Programming **with a Single Feedback Pin**
- Fixed 2MHz Switching Frequency
- Accurate 1.6V EN/UVLO Pin Threshold
- Internal Compensation and Soft-Start
- Low Profile (1mm) ThinSOT<sup>™</sup> Package
- Low Profile (0.75mm) 8-Lead (3mm  $\times$  2mm) DFN Package
- DFN Package is AEC-Q100 Qualified
- ThinSOT Package AEC-Q100 Qualification Is in Progress

### **APPLICATIONS**

- **n** Industrial and Automotive
- Telecom
- Medical Diagnostic Equipment
- Portable Electronics

### <span id="page-0-0"></span>TYPICAL APPLICATION

The [LT®8330](https://www.analog.com/LT8330?doc=LT8330.pdf) is a current mode DC/DC converter capable

of generating either positive or negative output voltages using a single feedback pin. It can be configured as a boost, SEPIC or inverting converter consuming as low as 6µA of quiescent current. Low ripple Burst Mode operation maintains high efficiency down to very low output currents while keeping the output ripple below 15mV in a typical application. The internally compensated current mode architecture results in stable operation over a wide range of input and output voltages. Integrated soft-start and frequency foldback functions are included to control inductor current during start-up. The LT8330 comes in small package options that, combined with a high switching frequency of 2MHz, help maintain a small foot print for an overall efficient, space-saving and cost effective solution.

All registered trademarks and trademarks are the property of their respective owners.

**Lead Free Finish**

TRM = 500 pieces. \*Temperature grades are identified by a label on the shipping container.

Contact the factory for parts specified with wider operating temperature ranges.

Contact the factory for information on lead based finish parts.

[Tape and reel specifications](https://www.analog.com/media/en/package-pcb-resources/package/tape-reel-rev-n.pdf). Some packages are available in 500 unit reels through designated sales channels with #TRMPBF suffix.

Rev. C **\*\***Versions of this part are available with controlled manufacturing to support the quality and reliability requirements of automotive applications. These models are designated with a #W suffix. Only the automotive grade products shown are available for use in automotive applications. Contact your local Analog Devices account representative for specific product ordering information and to obtain the specific Automotive Reliability reports for these models.

### <span id="page-2-0"></span>**ELECTRICAL CHARACTERISTICS** The  $\bullet$  denotes the specifications which apply over the full operating

temperature range, otherwise specifications are at T<sub>A</sub> = 25°C. V<sub>IN</sub> = 12V, EN/UVLO = 12V unless otherwise noted.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2: INTV<sub>CC</sub>** cannot be externally driven. No additional components or loading is allowed on this pin.

**Note 3:** The LT8330E is guaranteed to meet performance specifications from 0°C to 125°C junction temperature. Specifications over the –40°C to 125°C operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The

LT8330I is quaranteed over the full -40°C to 125°C operating junction temperature range. The LT8330J and LT8330H are guaranteed over the full –40°C to 150°C operating junction temperature range. High junction temperatures degrade operating lifetimes. Operating lifetime is derated at junction temperatures greater than 125°C.

**Note 4:** The IC includes overtemperature protection that is intended to protect the device during overload conditions. Junction temperature will exceed 150°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature will reduce lifetime.

### PIN FUNCTIONS

**EN/UVLO:** Shutdown and Undervoltage Detect Pin. The LT8330 is shut down when this pin is low and active when this pin is high. Below an accurate 1.6V threshold the part enters undervoltage lockout and stops switching. This allows an undervoltage lockout (UVLO) threshold to be programmed for system input voltage by resistively dividing down system input voltage to the EN/UVLO pin. An 80mV pin hysteresis ensures part switching resumes when the pin exceeds 1.68V. EN/UVLO pin voltage below 0.2V reduces  $V_{IN}$  current below 1µA. If shutdown and UVLO features are not required, the pin can be tied directly to system input.

**FBX:** Voltage Regulation Feedback Pin for Positive or Negative Outputs. Connect this pin to a resistor divider between the output and GND. FBX reduces the switching frequency during start-up and fault conditions when FBX is close to GND.

**GND:** Ground Connection for the LT8330. The DFN package has the best thermal performance due to an exposed pad (Pin 9) on the bottom of the package. This exposed pad must be soldered to a ground plane. Pin 5 of the DFN package (and Pin 2 of the TSOT package) should also be connected to a ground plane. The ground plane should be connected to large copper layers to spread heat dissipated by the LT8330.

**INTV<sub>CC</sub>:** Regulated 3V Supply for Internal Loads. The  $INTV_{CC}$  pin must be bypassed with a minimum 1 $\mu$ F low ESR ceramic capacitor to ground. No additional components or loading is allowed on this pin.

**NC:** No Internal Connection. Tie directly to local ground.

**SW:** The Output of Internal Power Switch. Minimize the metal trace area connected to this pin to reduce EMI.

**VIN:** Input Supply. This pin must be locally bypassed. Be sure to place the positive terminal of the input capacitor as close as possible to the  $V_{IN}$  pin, and the negative terminal as close as possible to the GND pin.

### <span id="page-6-0"></span>BLOCK DIAGRAM

7

## **OPERATION**

The LT8330 uses a fixed frequency, current mode control scheme to provide excellent line and load regulation. Operation can be best understood by referring to the [Block](#page-6-0) [Diagram.](#page-6-0) An internal 2MHz oscillator turns on the internal power switch at the beginning of each clock cycle. Current in the inductor then increases until the current comparator trips and turns off the power switch. The peak inductor current at which the switch turns off is controlled by the voltage on the internal VC node. The error amplifier servos the VC node by comparing the voltage on the FBX pin with an internal reference voltage (1.60V or –0.80V, depending on the chosen topology). When the load current increases it causes a reduction in the FBX pin voltage relative to the internal reference. This causes the error amplifier to increase the VC voltage until the new load current is satisfied. In this manner, the error amplifier sets the correct peak switch current level to keep the output in regulation.

The LT8330 is capable of generating either a positive or negative output voltage with a single FBX pin. It can be configured as a boost or SEPIC converter to generate a positive output voltage, or as an inverting converter to generate a negative output voltage. When configured as a boost converter, as shown in the [Block Diagram](#page-6-0), the FBX pin is pulled up to the internal bias voltage of 1.60V by a voltage divider (R1 and R2) connected from  $V_{OUT}$ to GND. Amplifier A2 becomes inactive and amplifier A1 performs (inverting) amplification from FBX to VC. When the LT8330 is in an inverting configuration, the FBX pin is pulled down to  $-0.80V$  by a voltage divider from  $V_{OUT}$ to GND. Amplifier A1 becomes inactive and amplifier A2 performs (non-inverting) amplification from FBX to VC.

If the EN/UVLO pin voltage is below 1.6V, the LT8330 enters undervoltage lockout (UVLO), and stops switching. When the EN/UVLO pin voltage is above 1.68V (typical). the LT8330 resumes switching. If the EN/UVLO pin voltage is below 0.2V, the LT8330 only draws 1 $\mu$ A from V<sub>IN</sub>.

To optimize efficiency at light loads, the LT8330 operates in Burst Mode operation in light load situations. Between bursts, all circuitry associated with controlling the output switch is shut down, reducing the input supply current to 6µA.

### APPLICATIONS INFORMATION

#### **ACHIEVING ULTRALOW QUIESCENT CURRENT**

To enhance efficiency at light loads the LT8330 uses a low ripple Burst Mode architecture. This keeps the output capacitor charged to the desired output voltage while minimizing the input quiescent current and output ripple. In Burst Mode operation the LT8330 delivers single small pulses of current to the output capacitor followed by sleep periods where the output power is supplied by the output capacitor. While in sleep mode the LT8330 consumes only 6µA.

As the output load decreases, the frequency of single current pulses decreases (see [Figure 1\)](#page-7-0) and the percentage of time the LT8330 is in sleep mode increases, resulting in much higher light load efficiency than for typical converters. To optimize the quiescent current performance at light loads, the current in the feedback resistor divider must be minimized as it appears to the output as load current. In addition, all possible leakage currents from **Figure 1. Burst Frequency vs Load Current**

the output should also be minimized as they all add to the equivalent output load. The largest contributor to leakage current can be due to the reverse biased leakage of the Schottky diode (see [Diode Selection](#page-11-0) in the Applications Information section).

<span id="page-7-0"></span>

While in Burst Mode operation the current limit of the switch is approximately 240mA resulting in the output voltage ripple shown in [Figure 2.](#page-8-0) Increasing the output capacitance will decrease the output ripple proportionally. As the output load ramps upward from zero the switching frequency will increase but only up to the fixed 2MHz defined by the internal oscillator as shown in [Figure 1.](#page-7-0) The output load at which the LT8330 reaches the fixed 2MHz frequency varies based on input voltage, output voltage, and inductor choice.

**Figure 2. Burst Mode Operation**

#### **PROGRAMMING INPUT TURN-ON AND TURN-OFF THRESHOLDS WITH EN/UVLO PIN**

The EN/UVLO pin voltage controls whether the LT8330 is enabled or is in a shutdown state. A 1.6V reference and a comparator A6 with built-in hysteresis (typical 80mV) allow the user to accurately program the system input voltage at which the IC turns on and off (see the [Block Diagram](#page-6-0)). The typical input falling and rising threshold voltages can be calculated by the following equations:

 $V_{IN(FALLING, UVLO(-))} = 1.60 \cdot (R3 + R4)/R4$ 

 $V_{IN(RISING, UVLO(+))} = 1.68 \cdot (R3 + R4)/R4$ 

 $V_{IN}$  current is reduced below 1 $\mu$ A when the EN/UVLO pin voltage is less than 0.2V. The EN/UVLO pin can be connected directly to the input supply  $V_{IN}$  for always-enabled operation. A logic input can also control the EN/UVLO pin.

When operating in Burst Mode operation for light load currents, the current through the R3 and R4 network can easily be greater than the supply current consumed by the LT8330. Therefore, R3 and R4 should be large enough to minimize their effect on efficiency at light loads.

#### **INTV<sub>CC</sub> REGULATOR**

A low dropout (LDO) linear regulator, supplied from  $V_{IN}$ , produces a 3V supply at the INTV<sub>CC</sub> pin. A minimum  $1\mu$ F low ESR ceramic capacitor must be used to bypass the  $INTV_{CC}$  pin to ground to supply the high transient currents required by the internal power MOSFET gate driver.

No additional components or loading is allowed on this pin. The INTV<sub>CC</sub> rising threshold (to allow soft start and switching) is typically 2.6V. The INTV<sub>CC</sub> falling threshold (to stop switching and reset soft start) is typically 2.5V.

#### **DUTY CYCLE CONSIDERATION**

The LT8330 minimum on-time, minimum off-time and switching frequency ( $f<sub>OSC</sub>$ ) define the allowable minimum and maximum duty cycles of the converter (see Minimum On-Time, Minimum Off-Time, and Switching Frequency in the [Electrical Characteristics](#page-2-0) table).

Minimum Allowable Duty Cycle = Minimum On-Time $(MAX)$  •  $f_{OSC(MAX)}$ 

<span id="page-8-0"></span>Maximum Allowable Duty Cycle =

1 – Minimum Off-Time<sub>(MAX)</sub> •  $f_{\text{OSC}(MAX)}$ 

The required switch duty cycle range for a Boost converter operating in continuous conduction mode (CCM) can be calculated as:

 $D_{MIN}$  = 1–  $V_{IN(MAX)}/(V_{OUT} + V_D)$  $D_{MAX} = 1 - V_{IN(MIN)}/(V_{OUT} + V_D)$ 

where  $V_D$  is the diode forward voltage drop. If the above duty cycle calculations for a given application violate the minimum and/or maximum allowed duty cycles for the LT8330, operation in discontinuous conduction mode (DCM) might provide a solution. For the same  $V_{IN}$  and  $V_{\text{OUT}}$  levels, operation in DCM does not demand as low a duty cycle as in CCM. DCM also allows higher duty cycle operation than CCM. The additional advantage of DCM is the removal of the limitations to inductor value and duty cycle required to avoid sub-harmonic oscillations and the right half plane zero (RHPZ). While DCM provides these benefits, the trade-off is higher inductor peak current, lower available output power and reduced efficiency.

### **SETTING THE OUTPUT VOLTAGE**

The output voltage is programmed with a resistor divider from the output to the FBX pin. Choose the resistor values for a positive output voltage according to:

 $R1 = R2 \cdot (V_{OIII}/1.60V - 1)$ 

Choose the resistor values for a negative output voltage according to:

 $R1 = R2 \cdot (|V_{OUT}|/0.80V - 1)$ 

The locations of R1 and R2 are shown in the [Block Dia](#page-6-0)[gram](#page-6-0). 1% resistors are recommended to maintain output voltage accuracy.

Higher-value FBX divider resistors result in the lowest input quiescent current and highest light-load efficiency. FBX divider resistors R1 and R2 are usually in the range from 25k to 1M. Most applications use a phase-lead capacitor from  $V_{OUT}$  to FBX in combination with high-value FBX divider resistors (see Compensation in the Applications Information section).

#### **SOFT-START**

The LT8330 contains several features to limit peak switch currents and output voltage  $(V_{OUT})$  overshoot during start-up or recovery from a fault condition. The primary purpose of these features is to prevent damage to external components or the load.

High peak switch currents during start-up may occur in switching regulators. Since  $V_{\text{OUT}}$  is far from its final value, the feedback loop is saturated and the regulator tries to charge the output capacitor as quickly as possible, resulting in large peak currents. A large surge current may cause inductor saturation or power switch failure.

The LT8330 addresses this mechanism with an internal soft-start function. As shown in the [Block Diagram,](#page-6-0) the soft-start function controls the ramp of the power switch current by controlling the ramp of VC through M2. This allows the output capacitor to be charged gradually toward its final value while limiting the start-up peak currents. [Figure 3](#page-9-0) shows the output voltage and supply current for the first page [Typical Application.](#page-0-0) It can be seen that both the output voltage and supply current come up gradually.

<span id="page-9-0"></span>**Figure 3. Soft-Start Waveforms**

 $INTV_{CC}$  undervoltage (INTV<sub>CC</sub> < 2.5V) and/or thermal lockout ( $T_{\rm J}$  > 170°C) will immediately prevent switching, will reset the internal soft-start function and will pull down VC. Once all faults are removed, the LT8330 will soft-start VC and hence inductor peak current.

#### **FREQUENCY FOLDBACK**

During start-up or fault conditions in which  $V_{OUI}$  is very low, extremely small duty cycles may be required to maintain control of inductor peak current. The minimum on-time limitation of the power switch might prevent these low duty cycles from being achievable. In this scenario inductor current rise will exceed inductor current fall during each cycle, causing inductor current to 'walk up' beyond the switch current limit. The LT8330 provides protection from this by folding back switching frequency whenever FBX pin is close to GND (low  $V_{\text{OUT}}$  levels). This frequency foldback provides a larger switch-off time, allowing inductor current to fall enough each cycle (see [Normalized Switch](#page-3-0)[ing Frequency vs FBX Voltage](#page-3-0) in the Typical Performance Characteristics section).

#### **THERMAL LOCKOUT**

If the LT8330 die temperature reaches 170°C (typical), the part will stop switching and go into thermal lockout. When the die temperature has dropped by 5°C (nominal), the part will resume switching with a soft-started inductor peak current.

#### **SWITCHING FREQUENCY AND INDUCTOR SELECTION**

The LT8330 switches at 2MHz, allowing small value inductors to be used. 0.68µH to 10µH will usually suffice. Choose an inductor that can handle at least 1.4A without saturating, and ensure that the inductor has a low DCR (copper-wire resistance) to minimize  $1^2R$  power losses. Note that in some applications, the current handling requirements of the inductor can be lower, such as in the SEPIC topology where each inductor only carries one-half of the total switch current. For better efficiency, use similar valued inductors with a larger volume. Many different sizes and shapes are available from various manufacturers. Choose a core material that has low losses at 2MHz, such as a ferrite core. The final value chosen for the inductor should not allow peak inductor currents to exceed 1A in steady state at maximum load. Due to tolerances, be sure to account for minimum possible inductance value, switching frequency and converter efficiency.

**Table 1. Inductor Manufacturers**

#### **INPUT CAPACITOR**

Bypass the input of the LT8330 circuit with a ceramic capacitor of X7R or X5R type placed as close as possible to the  $V_{IN}$  and GND pins. Y5V types have poor performance over temperature and applied voltage, and should not be used. A 4.7µF to 10µF ceramic capacitor is adequate to bypass the LT8330 and will easily handle the ripple current. If the input power source has high impedance, or there is significant inductance due to long wires or cables, additional bulk capacitance may be necessary. This can be provided with a low performance electrolytic capacitor.

A precaution regarding the ceramic input capacitor concerns the maximum input voltage rating of the LT8330. A ceramic input capacitor combined with trace or cable inductance forms a high quality (under damped) tank circuit. If the LT8330 circuit is plugged into a live supply, the input voltage can ring to twice its nominal value, possibly exceeding the LT8330's voltage rating. This situation is easily avoided (see Application Note 88).

#### **OUTPUT CAPACITOR AND OUTPUT RIPPLE**

Low ESR (equivalent series resistance) capacitors should be used at the output to minimize the output ripple voltage. Multilayer ceramic capacitors are an excellent choice, as they are small and have extremely low ESR. Use X5R or X7R types. This choice will provide low output ripple and good transient response. A 4.7µF to 15µF output capacitor is sufficient for most applications, but systems with very low output currents may need only a 1µF or 2.2µF output capacitor. Solid tantalum or OS-CON capacitor can be used, but they will occupy more board area than a ceramic and will have a higher ESR. Always use a capacitor with a sufficient voltage rating.

#### **COMPENSATION**

The LT8330 is internally compensated. The decision to use either low ESR (ceramic) capacitors or the higher ESR (tantalum or OS-CON) capacitors, for the output capacitor, can affect the stability of the overall system. The ESR of any capacitor, along with the capacitance itself, contributes a zero to the system. For the tantalum and OS-CON capacitors, this zero is located at a lower frequency due to the higher value of the ESR, while the zero of a ceramic capacitor is at a much higher frequency and can generally be ignored.

A phase lead zero can be intentionally introduced by placing a capacitor in parallel with the resistor between  $V_{OIIT}$  and FBX. By choosing the appropriate values for the resistor and capacitor, the zero frequency can be designed to improve the phase margin of the overall converter. The typical target value for the zero frequency is between 30kHz to 60kHz.

A practical approach to compensation is to start with one of the circuits in this data sheet that is similar to your application. Optimize performance by adjusting the output capacitor and/or the feed forward capacitor (connected across the feedback resistor from output to FBX pin).

#### **CERAMIC CAPACITORS**

Ceramic capacitors are small, robust and have very low ESR. However, ceramic capacitors can cause problems when used with the LT8330 due to their piezoelectric nature. When in Burst Mode operation, the LT8330's switching frequency depends on the load current, and at very light loads the LT8330 can excite the ceramic capacitor at audio frequencies, generating audible noise. Since the LT8330 operates at a lower current limit during Burst Mode operation, the noise is typically very quiet to a casual ear. If this is unacceptable, use a high performance tantalum or electrolytic capacitor at the output. Low noise ceramic capacitors are also available.

#### **Table 2. Ceramic Capacitor Manufacturers**

#### <span id="page-11-0"></span>**DIODE SELECTION**

A Schottky diode is recommended for use with the LT8330. Low leakage Schottky diodes are necessary when low quiescent current is desired at low loads. The diode leakage appears as an equivalent load at the output and should be minimized. Choose Schottky diodes with sufficient reverse voltage ratings for the target applications.

#### **Table 3. Recommended Schottky Diodes**

#### **LAYOUT HINTS**

The high speed operation of the LT8330 demands careful attention to board layout. Careless layout will result in performance degradation. [Figure 4](#page-11-1)a shows the recommended component placement for the ThinSOT package. [Figure 4b](#page-11-1) shows the recommended component placement for the DFN package. Note the vias under the exposed pad. These should connect to a local ground plane for better thermal performance.

<span id="page-11-1"></span>**Figure 4. Suggested Layout – (a) ThinSOT, (b) DFN**

#### **THERMAL CONSIDERATIONS**

Care should be taken in the layout of the PCB to ensure good heat sinking of the LT8330. The DFN package has the best thermal performance due to an exposed pad (Pin 9) on the bottom of the package. This exposed pad must be soldered to a ground plane. Pin 5 of the DFN package (and Pin 2 of the TSOT package) should also be connected to a ground plane. The ground plane should be connected to large copper layers to spread heat dissipated by the LT8330 and to further reduce the thermal resistance  $(\theta_{IA})$  values listed in the [Pin Configuration](#page-1-0) section. Power dissipation within the LT8330 ( $P_{DISS+TS330}$ ) can be estimated by subtracting the inductor and Schottky diode power losses from the total power losses calculated in an efficiency measurement. The junction temperature of LT8330 can then be estimated by,

T<sub>J</sub> (LT8330) = T<sub>A</sub> +  $\theta$ <sub>JA</sub> • P<sub>DISS</sub> LT8330

#### **ADDITIONAL TOPOLOGIES : SEPIC AND INVERTING**

In addition to the Boost topology, the LT8330 can be configured in a SEPIC or Inverting topology. SEPIC and Inverting converters are analyzed below.

#### **SEPIC CONVERTER APPLICATIONS**

The LT8330 can be configured as a SEPIC (single-ended primary inductance converter), as shown in [Figure 5](#page-12-0). This topology allows for the input to be higher, equal, or lower than the desired output voltage. The conversion ratio as a function of duty cycle is:

$$
\frac{V_{OUT} + V_D}{V_{IN}} = \frac{D}{1 - D}
$$

in continuous conduction mode (CCM).

In a SEPIC converter, no DC path exists between the input and output. This is an advantage over the boost converter for applications requiring the output to be disconnected from the input source when the circuit is in shutdown.

#### **SEPIC Converter: Switch Duty Cycle and Frequency**

For a SEPIC converter operating in CCM, the duty cycle of the main switch can be calculated based on the output voltage ( $V_{\text{OUT}}$ ), the input voltage ( $V_{\text{IN}}$ ) and the diode forward voltage  $(V_D)$ .

The maximum duty cycle  $(D_{MAX})$  occurs when the converter operates at the minimum input voltage:

$$
D_{MAX} = \frac{V_{OUT} + V_D}{V_{IN(MIN)} + V_{OUT} + V_D}
$$

Conversely, the minimum duty cycle  $(D_{MIN})$  occurs when the converter operates at the maximum input voltage:

$$
D_{MIN} = \frac{V_{OUT} + V_D}{V_{IN(MAX)} + V_{OUT} + V_D}
$$

Be sure to check that  $D_{MAX}$  and  $D_{MIN}$  obey:

 $D_{MAX}$  < 1-Minimum Off-Time<sub>(MAX)</sub> •  $f_{OSC(MAX)}$ 

and

 $D_{MIN}$  > Minimum On-Time<sub>(MAX)</sub> •  $f_{OSC(MAX)}$ 

where Minimum Off-Time, Minimum On-Time and  $f_{\text{OSC}}$ are specified in the Electrical Characteristics table.

#### **SEPIC Converter: The Maximum Output Current Capability and Inductor Selection**

As shown in [Figure 5](#page-12-0), the SEPIC converter contains two inductors: L1 and L2. L1 and L2 can be independent, but can

<span id="page-12-0"></span>**Figure 5. LT8330 Configured in a SEPIC Topology**

also be wound on the same core, since identical voltages are applied to L1 and L2 throughout the switching cycle.

For the SEPIC topology, the current through L1 is the converter input current. Based on the fact that, ideally, the output power is equal to the input power, the maximum average inductor currents of L1 and L2 are:

$$
I_{L1(MAX)(AVE)} = I_{IN(MAX)(AVE)} = I_{O(MAX)} \cdot \frac{D_{MAX}}{1 - D_{MAX}}
$$

$$
I_{L2(MAX)(AVE)} = I_{O(MAX)}
$$

In a SEPIC converter, the switch current is equal to  $I_{11}$  +  $I_{L2}$  when the power switch is on, therefore, the maximum average switch current is defined as:

$$
I_{SW(MAX)(AVE)} = I_{L1(MAX)(AVE)} + I_{L2(MAX)(AVE)}
$$
  
=  $I_{O(MAX)} \cdot \frac{1}{1 - D_{MAX}}$ 

and the peak switch current is:

$$
I_{SW(PEAK)} = \left(1 + \frac{\chi}{2}\right) \cdot I_{O(MAX)} \cdot \frac{1}{1 - D_{MAX}}
$$

The constant  $x$  in the preceding equations represents the percentage peak-to-peak ripple current in the switch, relative to  $I_{SW(MAX)(AVE)}$ , as shown in [Figure 6.](#page-13-0) Then, the switch ripple current ∆I<sub>SW</sub> can be calculated by:

<span id="page-13-0"></span>**Figure 6. The Switch Current Waveform of the SEPIC Converter**

The inductor ripple currents  $\Delta I_{L1}$  and  $\Delta I_{L2}$  are identical:

$$
\Delta I_{L1} = \Delta I_{L2} = 0.5 \cdot \Delta I_{SW}
$$

The inductor ripple current has a direct effect on the choice of the inductor value. Choosing smaller values of ∆I<sub>L</sub> requires large inductances and reduces the current loop gain (the converter will approach voltage mode). Accepting larger values of  $\Delta I_1$  allows the use of low inductances, but results in higher input current ripple and greater core losses. It is recommended that  $\chi$  falls in the range of 0.2 to 0.6.

Due to the current limit of its internal power switch, the LT8330 should be used in a SEPIC converter whose maximum output current ( $I_{O(MAX)}$ ) is less than the output current capability by a sufficient margin (10% or higher is recommended):

$$
I_{O(MAX)} < (1 - D_{MAX}) \cdot (1A - 0.5 \cdot \Delta I_{SW}) \cdot (0.9)
$$

Given an operating input voltage range, and having chosen ripple current in the inductor, the inductor value (L1 and L2 are independent) of the SEPIC converter can be determined using the following equation:

$$
L1 = L2 = \frac{V_{IN(M1N)}}{0.5 \cdot \Delta I_{SW} \cdot f_{OSC}} \cdot D_{MAX}
$$

For most SEPIC applications, the equal inductor values will fall in the range of 1µH to 47µH.

By making  $L1 = L2$ , and winding them on the same core, the value of inductance in the preceding equation is replaced by 2L, due to mutual inductance:

$$
L = \frac{V_{IN(MIN)}}{\Delta I_{SW} \cdot f_{OSC}} \cdot D_{MAX}
$$

This maintains the same ripple current and energy storage in the inductors. The peak inductor currents are:

$$
I_{L1(PEAK)} = I_{L1(MAX)} + 0.5 \cdot \Delta I_{L1}
$$

$$
I_{L2(PEAK)} = I_{L2(MAX)} + 0.5 \cdot \Delta I_{L2}
$$

The maximum RMS inductor currents are approximately equal to the maximum average inductor currents.

Based on the preceding equations, the user should choose the inductors having sufficient saturation and RMS current ratings.

#### **SEPIC Converter: Output Diode Selection**

To maximize efficiency, a fast switching diode with a low forward drop and low reverse leakage is desirable. The average forward current in normal operation is equal to the output current.

It is recommended that the peak repetitive reverse voltage rating V<sub>RRM</sub> is higher than V<sub>OUT</sub> + V<sub>IN(MAX)</sub> by a safety margin (a 10V safety margin is usually sufficient).

The power dissipated by the diode is:

 $P_D = I_{O(MAX)} \cdot V_D$ 

where  $V_D$  is diode's forward voltage drop, and the diode junction temperature is:

 $T_J = T_A + P_D \bullet R_{\theta JA}$ 

The  $R_{\theta,IA}$  used in this equation normally includes the  $R_{\theta,IC}$ for the device, plus the thermal resistance from the board, to the ambient temperature in the enclosure.  $T_{\text{J}}$  must not exceed the diode maximum junction temperature rating.

#### **SEPIC Converter: Output and Input Capacitor Selection**

The selections of the output and input capacitors of the SEPIC converter are similar to those of the boost converter.

#### **SEPIC Converter: Selecting the DC Coupling Capacitor**

The DC voltage rating of the DC coupling capacitor  $(C_{DC}$ , as shown in [Figure 5](#page-12-0)) should be larger than the maximum input voltage:

 $V_{CDC}$  >  $V_{IN(MAX)}$ 

 $C_{DC}$  has nearly a rectangular current waveform. During the switch off-time, the current through  $C_{DC}$  is  $I_{IN}$ , while approximately  $-I_0$  flows during the on-time. The RMS rating of the coupling capacitor is determined by the following equation:

$$
I_{RMS(CDC)} > I_{O(MAX)} \bullet \sqrt{\frac{V_{OUT} + V_D}{V_{IN(MIN)}}}
$$

A low ESR and ESL, X5R or X7R ceramic capacitor works well for  $C_{\text{DC}}$ .

#### **INVERTING CONVERTER APPLICATIONS**

The LT8330 can be configured as a dual-inductor inverting topology, as shown in [Figure 7](#page-14-0). The  $V_{\text{OUT}}$  to  $V_{\text{IN}}$  ratio is:

$$
\frac{V_{OUT} - V_D}{V_{IN}} = -\frac{D}{1 - D}
$$

in continuous conduction mode (CCM).

<span id="page-14-0"></span>**Figure 7. A Simplified Inverting Converter**

#### **Inverting Converter: Switch Duty Cycle and Frequency**

For an inverting converter operating in CCM, the duty cycle of the main switch can be calculated based on the negative output voltage ( $V_{\text{OUT}}$ ) and the input voltage ( $V_{\text{IN}}$ ).

The maximum duty cycle  $(D_{MAX})$  occurs when the converter has the minimum input voltage:

$$
D_{MAX} = \frac{|V_{OUT}| + V_D}{|V_{OUT}| + V_D + V_{IN(MIN)}}
$$

Conversely, the minimum duty cycle  $(D_{MIN})$  occurs when the converter operates at the maximum input voltage :

$$
D_{\text{MIN}} = \frac{|V_{\text{OUT}}| + V_{\text{D}}}{|V_{\text{OUT}}| + V_{\text{D}} + V_{\text{IN}(\text{MAX})}}
$$

Be sure to check that  $D_{MAX}$  and  $D_{MIN}$  obey :

 $D_{MAX}$  < 1-Minimum Off-Time<sub>(MAX)</sub> •  $f_{OSC(MAX)}$ 

and

 $D_{MIN}$  > Minimum On-Time<sub>(MAX)</sub> • f<sub>OSC(MAX)</sub>

where Minimum Off-Time, Minimum On-Time and  $f_{\text{OSC}}$ are specified in the [Electrical Characteristics](#page-2-0) table.

#### **Inverting Converter: Inductor, Output Diode and Input Capacitor Selections**

The selections of the inductor, output diode and input capacitor of an inverting converter are similar to those of the SEPIC converter. Please refer to the corresponding SEPIC converter sections.

#### **Inverting Converter: Output Capacitor Selection**

The inverting converter requires much smaller output capacitors than those of the boost, flyback and SEPIC converters for similar output ripples. This is due to the fact that, in the inverting converter, the inductor L2 is in series with the output, and the ripple current flowing through the output capacitors are continuous. The output ripple voltage is produced by the ripple current of L2 flowing through the ESR and bulk capacitance of the output capacitor:

$$
\Delta V_{\text{OUT}}(P-P)} = \Delta I_{L2} \cdot \left( ESR_{\text{COUT}} + \frac{1}{8 \cdot f \cdot C_{\text{OUT}}} \right)
$$

After specifying the maximum output ripple, the user can select the output capacitors according to the preceding equation.

The ESR can be minimized by using high quality X5R or X7R dielectric ceramic capacitors. In many applications, ceramic capacitors are sufficient to limit the output voltage ripple.

The RMS ripple current rating of the output capacitor needs to be greater than:

 $I_{RMS(COUT)} > 0.3$  •  $\Delta I_{L2}$ 

#### **Inverting Converter: Selecting the DC Coupling Capacitor**

The DC voltage rating of the DC coupling capacitor  $(C_{DC}$ , as shown in [Figure 7](#page-14-0)) should be larger than the maximum input voltage minus the output voltage (negative voltage):

 $V_{CDC} > V_{IN(MAX)} - V_{OUT}$ 

 $C_{DC}$  has nearly a rectangular current waveform. During the switch off-time, the current through  $C_{DC}$  is  $I_{IN}$ , while approximately  $-I_0$  flows during the on-time. The RMS rating of the coupling capacitor is determined by the following equation:

$$
I_{RMS(CDC)} > I_{O(MAX)} \cdot \sqrt{\frac{D_{MAX}}{1 - D_{MAX}}}
$$

A low ESR and ESL, X5R or X7R ceramic capacitor works well for  $C_{\text{DC}}$ .

### PACKAGE DESCRIPTION

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS

2. DRAWING NOT TO SCALE

3. ALL DIMENSIONS ARE IN MILLIMETERS

4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE

5. EXPOSED PAD SHALL BE SOLDER PLATED

6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

### PACKAGE DESCRIPTION

**S6 Package 6-Lead Plastic TSOT-23** (Reference LTC DWG # 05-08-1636)

3. DIMENSIONS ARE INCLUSIVE OF PLATING

- 4. DIMENSIONS ARE EXCLUSIVE OF MOLD FLASH AND METAL BURR
- 5. MOLD FLASH SHALL NOT EXCEED 0.254mm

6. JEDEC PACKAGE REFERENCE IS MO-193

### REVISION HISTORY
