

FEATURES

- **Smallest Pin-Compatible Single DACs:**
LTC2601: 16 Bits
LTC2611: 14 Bits
LTC2621: 12 Bits
- **Guaranteed Monotonic Over Temperature**
- Wide 2.5V to 5.5V Supply Range
- Low Power Operation: 300 μ A at 3V
- Power Down to 1 μ A, Max
- High Rail-to-Rail Output Drive (\pm 15mA, Min)
- Double-Buffered Data Latches
- Asynchronous DAC Update Pin
- LTC2601-1/LTC2611-1/LTC2621-1: Power-On Reset to Midscale
- Tiny (3mm \times 3mm) 10-Lead DFN Package

APPLICATIONS

- Mobile Communications
- Process Control and Industrial Automation
- Instrumentation
- Automatic Test Equipment

DESCRIPTION

The LTC[®]2601/LTC2611/LTC2621 are single 16-, 14- and 12-bit, 2.5V-to-5.5V rail-to-rail voltage output DACs in a 10-lead DFN package. They have built-in high performance output buffers and are guaranteed monotonic.

These parts establish new board-density benchmarks for 16- and 14-bit DACs and advance performance standards for output drive and load regulation in single-supply, voltage-output DACs.

The parts use a simple SPI/MICROWIRE compatible 3-wire serial interface which can be operated at clock rates up to 50MHz. Daisy-chain capability, hardware $\overline{\text{CLR}}$ and asynchronous DAC update ($\overline{\text{LDAC}}$) pins are included.

The LTC2601/LTC2611/LTC2621 incorporate a power-on reset circuit. During power-up, the voltage outputs rise less than 10mV above zero scale until a valid write and update take place. The power-on reset circuit resets the LTC2601-1/LTC2611-1/LTC2621-1 to midscale. The voltage outputs stay at midscale until a valid write and update take place.

TIMING CHARACTERISTICS

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: Linearity and monotonicity are defined from code K_L to code $2^N - 1$, where N is the resolution and K_L is given by $K_L = 0.016(2^N/V_{REF})$, rounded to the nearest whole code. For $V_{REF} = 4.096V$ and $N = 16$, $K_L = 256$ and linearity is defined from code 256 to code 65,535.

Note 3: Digital inputs at 0V or V_{CC} .

Note 4: Guaranteed by design and not production tested.

Note 5: Inferred from measurement at code $K_L = 0.016(2^N/V_{REF})$ and at full scale.

Note 6: $V_{CC} = 5V$, $V_{REF} = 4.096V$. DAC is stepped 1/4 scale to 3/4 scale and 3/4 scale to 1/4 scale. Load is 2k in parallel with 200pF to GND.

Note 7: $V_{CC} = 5V$, $V_{REF} = 4.096V$. DAC is stepped $\pm 1LSB$ between half scale and half scale - 1. Load is 2k in parallel with 200pF to GND.

Note 8: These specifications apply to LTC2601/LTC2601-1, LTC2611/LTC2611-1, LTC2621/LTC2621-1

PIN FUNCTIONS

SDO (Pin 1): Serial Interface Data Output. This pin is used for daisy-chain operation. The serial output of the shift register appears at the SDO pin. The data transferred to the device via the SDI pin is delayed 32 SCK rising edges before being output at the next falling edge. SDO is an active output and does not go high impedance even when \overline{CS}/LD is taken to a logic high level.

SDI (Pin 2): Serial Interface Data Input. Data is applied to SDI for transfer to the device at the rising edge of SCK (Pin 3). The LTC2601 accepts input word lengths of either 24 or 32 bits.

SCK (Pin 3): Serial Interface Clock Input. CMOS and TTL compatible.

\overline{CLR} (Pin 4): Asynchronous Clear Input. A logic low at this level-triggered input clears all registers and causes the DAC voltage outputs to drop to 0V for LTC2601/LTC2611/LTC2621. A logic low at this input sets all registers to midscale code and causes the DAC voltage outputs to go to midscale for LTC2601-1/LTC2611-1/LTC2621-1. CMOS and TTL compatible.

\overline{CS}/LD (Pin 5): Serial Interface Chip Select/Load Input. When \overline{CS}/LD is low, SCK is enabled for shifting data on SDI into the register. When \overline{CS}/LD is taken high, SCK is disabled and the specified command (see Table 1) is executed.

REF (Pin 6): Reference Voltage Input. $0V \leq V_{REF} \leq V_{CC}$.

V_{OUT} (Pin 7): DAC Analog Voltage Output. The output range is 0V to V_{REF} .

GND (Pin 8): Analog Ground.

V_{CC} (Pin 9): Supply Voltage Input. $2.5V \leq V_{CC} \leq 5.5V$.

\overline{LDAC} (Pin 10): Asynchronous DAC Update Pin. If \overline{CS}/LD is high, a falling edge on \overline{LDAC} immediately updates the DAC register with the contents of the input register (similar to a software update). If \overline{CS}/LD is low when \overline{LDAC} goes low, the DAC register is updated after \overline{CS}/LD returns high. A low on the \overline{LDAC} pin powers up the DAC. A software power down command is ignored if \overline{LDAC} is low.

Exposed Pad (Pin 11): Ground. Must be soldered to PCB ground.

OPERATION

Power-On Reset

The LTC2601/LTC2611/LTC2621 clear the outputs to zero scale when power is first applied, making system initialization consistent and repeatable. The LTC2601-1/LTC2611-1/LTC2621-1 set the voltage outputs to midscale when power is first applied.

For some applications, downstream circuits are active during DAC power-up, and may be sensitive to nonzero outputs from the DAC during this time. The LTC2601/LTC2611/LTC2621 contain circuitry to reduce the power-on glitch; furthermore, the glitch amplitude can be made arbitrarily small by reducing the ramp rate of the power supply. For example, if the power supply is ramped to 5V in 1ms, the analog outputs rise less than 10mV above ground (typ) during power-on. See Power-On Reset Glitch in the Typical Performance Characteristics section.

Power Supply Sequencing

The voltage at REF (Pin 6) should be kept within the range $-0.3V \leq V_{REF} \leq V_{CC} + 0.3V$ (see Absolute Maximum Ratings). Particular care should be taken to observe these limits during power supply turn-on and turn-off sequences, when the voltage at V_{CC} (Pin 16) is in transition.

Transfer Function

The digital-to-analog transfer function is:

$$V_{OUT(IDEAL)} = \left(\frac{k}{2^N} \right) V_{REF}$$

where k is the decimal equivalent of the binary DAC input code, N is the resolution and V_{REF} is the voltage at REF (Pin 6).

Serial Interface

The \overline{CS}/LD input is level triggered. When this input is taken low, it acts as a chip-select signal, powering-on the SDI and SCK buffers and enabling the input shift register. Data (SDI input) is transferred at the next 24 rising SCK edges. The 4-bit command, C3-C0, is loaded first; then 4 don't care bits; and finally the 16-bit data word. The data word comprises the 16-, 14- or 12-bit input code, ordered MSB-to-LSB, followed by 0, 2 or 4 don't care bits (LTC2601, LTC2611 and LTC2621 respectively). Data can

only be transferred to the device when the \overline{CS}/LD signal is low. The rising edge of \overline{CS}/LD ends the data transfer and causes the device to execute the command specified in the 24-bit input word. The complete sequence is shown in Figure 2a.

The command (C3-C0) assignments are shown in Table 1. The first four commands in the table consist of write and update operations. A write operation loads a 16-bit data word from the 32-bit shift register into the input register of the DAC. In an update operation, the data word is copied from the input register to the DAC register and converted to an analog voltage at the DAC output. The update operation also powers up the DAC if it had been in power-down mode. The data path and registers are shown in the Block Diagram.

While the minimum input word is 24 bits, it may optionally be extended to 32 bits. To use the 32-bit word width, 8 don't-care bits are transferred to the device first, followed by the 24-bit word as just described. Figure 2b shows the 32-bit sequence. The 32-bit word is required for daisy-chain operation, and is also available to accommodate microprocessors which have a minimum word width of 16 bits (2 bytes).

Daisy-Chain Operation

The serial output of the shift register appears at the SDO pin. Data transferred to the device from the SDI input is delayed 32 SCK rising edges before being output at the next SCK falling edge.

The SDO output can be used to facilitate control of multiple serial devices from a single 3-wire serial port (i.e., SCK, SDI and \overline{CS}/LD). Such a "daisy chain" series is configured by connecting SDO of each upstream device to SDI of the

Table 1.

| COMMAND* | | | | |
|----------|----|----|----|--------------------------------|
| C3 | C2 | C1 | C0 | |
| 0 | 0 | 0 | 0 | Write to Input Register |
| 0 | 0 | 0 | 1 | Update (Power Up) DAC Register |
| 0 | 0 | 1 | 1 | Write to and Update (Power Up) |
| 0 | 1 | 0 | 0 | Power Down |
| 1 | 1 | 1 | 1 | No Operation |

*Command codes not shown are reserved and should not be used.

OPERATION

INPUT WORD (LTC2601)

INPUT WORD (LTC2611)

INPUT WORD (LTC2621)

next device in the chain. The shift registers of the devices are thus connected in series, effectively forming a single input shift register which extends through the entire chain. Because of this, the devices can be addressed and controlled individually by simply concatenating their input words; the first instruction addresses the last device in the chain and so forth. The SCK and \overline{CS}/LD signals are common to all devices in the series.

In use, \overline{CS}/LD is first taken low. Then the concatenated input data is transferred to the chain, using SDI of the first device as the data input. When the data transfer is complete, \overline{CS}/LD is taken high, which executes the commands specified for each of the devices simultaneously. A single device can be controlled by using the no-operation command (1111) for the other devices in the chain.

Power-Down Mode

For power-constrained applications, power-down mode can be used to reduce the supply current whenever the DAC output is not needed. When in power-down, the buffer amplifier, bias circuit and reference input is disabled and draws essentially zero current. The DAC output is put into a high impedance state, and the output pin is passively pulled to ground through 90k resistors. Input- and DAC-register contents are not disturbed during power-down.

The DAC can be put into power-down mode by using

command 0100_b. The 16-bit data word is ignored. The supply and reference currents are reduced to almost zero when the DAC is powered down; the effective resistance at REF rises accordingly becoming a high impedance input (typically > 1GΩ).

Normal operation can be resumed by executing any command which includes a DAC update, as shown in Table 1 or performing an asynchronous update (\overline{LDAC}) as described in the next section. The DAC is powered up as its voltage output is updated. When the DAC in powered-down state is powered up and updated, normal settling is delayed. The main bias generation circuit block has been automatically shut down in addition to the DAC amplifier and reference input and so the power up delay time is 12μs (for $V_{CC} = 5V$) or 30μs (for $V_{CC} = 3V$).

Asynchronous DAC Update Using \overline{LDAC}

In addition to the update commands shown in Table 1, the \overline{LDAC} pin asynchronously updates the DAC register with the contents of the input register.

If \overline{CS}/LD is high, a low on the \overline{LDAC} pin causes the DAC register to be updated with the contents of the input register.

If \overline{CS}/LD is low, a low going pulse on the \overline{LDAC} pin before the rising edge of \overline{CS}/LD powers up the DAC but does not cause the output to be updated. If \overline{LDAC} remains low after

OPERATION

the rising edge of $\overline{CS/LD}$, then \overline{LDAC} is recognized, the command specified in the 24-bit word just transferred is executed and the DAC output is updated.

The DAC is powered up when \overline{LDAC} is taken low, independent of the state of $\overline{CS/LD}$.

If \overline{LDAC} is low at the time $\overline{CS/LD}$ goes high, it inhibits any software power-down command that was specified in the input word.

Voltage Outputs

The rail-to-rail amplifier contained in these parts has guaranteed load regulation when sourcing or sinking up to 15mA at 5V (7.5mA at 3V).

Load regulation is a measure of the amplifier's ability to maintain the rated voltage accuracy over a wide range of load conditions. The measured change in output voltage per milliampere of forced load current change is expressed in LSB/mA.

DC output impedance is equivalent to load regulation, and may be derived from it by simply calculating a change in units from LSB/mA to Ohms. The amplifier's DC output impedance is 0.05Ω when driving a load well away from the rails.

When drawing a load current from either rail, the output voltage headroom with respect to that rail is limited by the 25Ω typical channel resistance of the output devices; e.g., when sinking 1mA, the minimum output voltage = $25\Omega \cdot 1\text{mA} = 25\text{mV}$. See the graph Headroom at Rails vs Output Current in the Typical Performance Characteristics section.

The amplifier is stable driving capacitive loads of up to 1000pF.

Board Layout

The excellent load regulation of these devices is achieved in part by keeping "signal" and "power" grounds separated internally and by reducing shared internal resistance.

The GND pin functions both as the node to which the reference and output voltages are referred and as a return path

for power currents in the device. Because of this, careful thought should be given to the grounding scheme and board layout in order to ensure rated performance.

The PC board should have separate areas for the analog and digital sections of the circuit. This keeps digital signals away from sensitive analog signals and facilitates the use of separate digital and analog ground planes which have minimal capacitive and resistive interaction with each other.

Digital and analog ground planes should be joined at only one point, establishing a system star ground as close to the device's ground pin as possible. Ideally, the analog ground plane should be located on the component side of the board, and should be allowed to run under the part to shield it from noise. Analog ground should be a continuous and uninterrupted plane, except for necessary lead pads and vias, with signal traces on another layer.

The GND pin of the part should be connected to analog ground. Resistance from the GND pin to system star ground should be as low as possible. Resistance here will add directly to the effective DC output impedance of the device (typically 0.05Ω). Note that the LTC2601/LTC2611/LTC2621 are no more susceptible to these effects than other parts of their type; on the contrary, they allow layout-based performance improvements to shine rather than limiting attainable performance with excessive internal resistance.

Rail-to-Rail Output Considerations

In any rail-to-rail voltage output device, the output is limited to voltages within the supply range.

Since the analog output of the device cannot go below ground, it may limit for the lowest codes as shown in Figure 3b. Similarly, limiting can occur near full scale when the REF pin is tied to V_{CC} . If $V_{REF} = V_{CC}$ and the DAC full-scale error (FSE) is positive, the output for the highest codes limits at V_{CC} as shown in Figure 3c. No full-scale limiting can occur if V_{REF} is less than $V_{CC} - \text{FSE}$.

Offset and linearity are defined and tested over the region of the DAC transfer function where no output limiting can occur.

PACKAGE DESCRIPTION

DD Package
10-Lead Plastic DFN (3mm × 3mm)
 (Reference LTC DWG # 05-08-1699)

RECOMMENDED SOLDER PAD PITCH AND DIMENSIONS

- NOTE:
1. DRAWING TO BE MADE A JEDEC PACKAGE OUTLINE M0-229 VARIATION OF (WEED-2). CHECK THE LTC WEBSITE DATA SHEET FOR CURRENT STATUS OF VARIATION ASSIGNMENT
 2. DRAWING NOT TO SCALE
 3. ALL DIMENSIONS ARE IN MILLIMETERS
 4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.15mm ON ANY SIDE
 5. EXPOSED PAD SHALL BE SOLDER PLATED
 6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE
