# Dual 2-A High-Speed, Low-Side Gate Drivers

# **FAN3216 / FAN3217**

The FAN3216 and FAN3217 dual 2 A gate drivers are designed to drive N-channel enhancement-mode MOSFETs in low-side switching applications by providing high peak current pulses during the short sw itching intervals. They are both available with TTL input thresholds. Internal circuitry provides an under-voltage lockout function by holding the output LOW until the supply voltage is within the operating range. In addition, the drivers feature matched internal propagation delays between A and B channels for applications requiring dual gate drives with critical timing, such as synchronous rectifiers. This also enables connecting two drivers in parallel to effectively double the current capability driving a single MOSFET.

The FAN3216/17 drivers incorporate MillerDrive ™ architecture for the final output stage. This bipolar–MOSFET combination provides high current during the Miller plateau stage of the MOSFET turn–on / turn–off process to minimize switching loss, while providing rail–to–rail voltage swing and reverse current capability.

The FAN3216 offers two inverting drivers and the FAN3217 offers two non-inverting drivers. Both are offered in a standard 8-pin SOIC package.

#### **Features**

- Industry-Standard Pinouts
- 4.5 V to 18 V Operating Range
- 3 A Peak Sink/Source at V<sub>DD</sub> = 12 V
- 2.4 A Sink / 1.6 A Source at V<sub>OUT</sub> = 6 V
- Inverting Configuration (FAN3216) and Non–Inverting Configuration (FAN3217)
- Internal Resistors Turn Driver Off If No Inputs
- 12 ns / 9 ns Typical Rise/Fall Times (1 nF Load)
- 20 ns Typical Propagation Delay Matched within 1 ns to the Other Channel
- TTL Input Thresholds
- MillerDrive<sup>™</sup> Technology
- Double Current Capability by Paralleling Channels
- Standard SOIC-8 Package
- Rated from -40°C to +125°C Ambient
- Automotive Qualified to AEC-Q100
- These are Pb-Free Devices

#### **Applications**

- Switch-Mode Power Supplies
- High-Efficiency MOSFET Switching
- Synchronous Rectifier Circuits
- DC-to-DC Converters
- Motor Control
- Automotive Qualified Systems

#### THERMAL CHARACTERISTICS (Note 1)

Package	Θ <sub>JL</sub> (Note 2)	Θ <sub>JT</sub> (Note 3)	Θ <sub>JA</sub> (Note 4)	Ψ <sub>JB</sub> (Note 5)	Ψ <sub>JT</sub> (Note 6)	Unit
8-Pin Small Outline Integrated Circuit (SOIC)	40	31	89	43	3.0	°C/W

- 1. Estimates derived from thermal simulation; actual values depend on the application.
- Theta\_JL (Θ<sub>JL</sub>): Thermal resistance between the semiconductor junction and the bottom surface of all the leads (including any thermal pad)
  that are typically soldered to a PCB.
- Theta\_JT (Θ<sub>JT</sub>): Thermal resistance between the semiconductor junction and the top surface of the package, assuming it is held at a uniform temperature by a top−side heatsink.
- 4. Theta\_JA (ΘJA): Thermal resistance between junction and ambient, dependent on the PCB design, heat sinking, and airflow. The value given is for natural convection with no heatsink using a 2S2P board, as specified in JEDEC standards JESD51-2, JESD51-5, and JESD51-7, as appropriate.
- 5. Psi\_JB (Ψ<sub>JB</sub>): Thermal characterization parameter providing correlation between semiconductor junction temperature and an application circuit board reference point for the thermal environment defined in Note 4. For the SOIC–8 package, the board reference is defined as the PCB copper adjacent to pin 6.
- 6. Psi\_JT (Ψ<sub>JT</sub>): Thermal characterization parameter providing correlation between the semiconductor junction temperature and the center of the top of the package for the thermal environment defined in Note 4.

## **PIN DEFINITIONS**

Pin	Name	Pin Description
1	NC	No Connect. This pin can be grounded or left floating.
2	INA	Input to Channel A.
3	GND	Ground. Common ground reference for input and output circuits.
4	INB	Input to Channel B.
5 (FAN3216)	OUTB	Gate Drive Output B (inverted from the input): Held LOW unless required input is present and $V_{DD}$ is above UVLO threshold.
5 (FAN3217)	OUTB	Gate Drive Output B: Held LOW unless required input(s) are present and V <sub>DD</sub> is above UVLO threshold.
6	VDD	Supply Voltage. Provides power to the IC.
7 (FAN3216)	OUTA	Gate Drive Output A (inverted from the input): Held LOW unless required input is present and $V_{DD}$ is above UVLO threshold.
7 (FAN3217)	OUTA	Gate Drive Output A: Held LOW unless required input(s) are present and V <sub>DD</sub> is above UVLO threshold.
8	NC	No Connect. This pin can be grounded or left floating.

#### **OUTPUT LOGIC**

FAN3216 (x = A or B)			FAN3217 (2	x = A or B)
INx	INx OUTx		INx	OUTx
0	1		0 (Note 7)	0
1 (Note 7)	0		1	1

7. Default input signal if no external connection is made.

## **BLOCK DIAGRAMS**

#### **ABSOLUTE MAXIMUM RATINGS**

Symbol	Parameter	Min.	Max.	Unit
$V_{DD}$	VDD to PGND	-0.3	20.0	V
V <sub>IN</sub>	INA and INB to GND	GND - 0.3	V <sub>DD</sub> + 0.3	V
V <sub>OUT</sub>	OUTA and OUTB to GND	GND - 0.3	V <sub>DD</sub> + 0.3	V
T <sub>L</sub>	Lead Soldering Temperature (10 Seconds)		260	°C
$T_J$	Junction Temperature	-55	150	°C
T <sub>STG</sub>	Storage Temperature	-65	150	°C

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

#### RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	Min.	Max.	Unit
$V_{DD}$	Supply Voltage Range	4.5	18.0	V
$V_{IN}$	Input Voltage INA and INB	0	$V_{DD}$	V
$T_A$	Operating Ambient Temperature	-40	125	°C

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

 $\textbf{ELECTRICAL CHARACTERISTICS} \ (Unless otherwise noted, \ V_{DD} = 12 \ V, \ T_{J} = -40 ^{\circ}C \ to \ +125 ^{\circ}C. \ Currents \ are \ defined \ as \ positive \ into \ (Unless otherwise noted) \ (Unless otherw$ the device and negative out of the device.)

#### APPLICATIONS INFORMATION

#### **Input Thresholds**

The FAN3216 and the FAN3217 drivers consist of two identical channels that may be used independently at rated current or connected in parallel to double the individual current capacity.

The input thresholds meet industry–standard TTL–logic thresholds independent of the  $V_{DD}$  voltage, and there is a hysteresis voltage of approximately 0.4 V. These levels permit the inputs to be driven from a range of input logic signal levels for which a voltage over 2 V is considered logic HIGH. The driving signal for the TTL inputs should have fast rising and falling edges with a slew rate of 6 V/ $\mu$ s or faster, so a rise time from 0 to 3.3 V should be 550 ns or less. With reduced slew rate, circuit noise could cause the driver input voltage to exceed the hysteresis voltage and retrigger the driver input, causing erratic operation.

#### **Static Supply Current**

In the  $I_{DD}$  (static) typical performance characteristics shown in Figure 8 and Figure 9, each curve is produced with both inputs floating and both outputs LOW to indicate the lowest static  $I_{DD}$  current. For other states, additional current flows through the  $100~\text{k}\Omega$  resistors on the inputs and outputs shown in the block diagram of each part (see Figure 6 and Figure 7). In these cases, the actual static  $I_{DD}$  current is the value obtained from the curves plus this additional current.

#### MillerDrive Gate Drive Technology

FAN3216 and FAN3217 gate drivers incorporate the MillerDrive architecture shown in Figure 29. For the output stage, a combination of bipolar and MOS devices provide large currents over a wide range of supply voltage and temperature variations. The bipolar devices carry the bulk of

the current as OUT swings between 1/3 to 2/3 V<sub>DD</sub> and the MOS devices pull the output to the HIGH or LOW rail.

The purpose of the MillerDrive<sup>™</sup> architecture is to speed up switching by providing high current during the Miller plateau region when the gate-drain capacitance of the MOSFET is being charged or discharged as part of the turn-on/turn-off process.

For applications with zero voltage switching during the MOSFET turn-on or turn-off interval, the driver supplies high peak current for fast switching even though the Miller plateau is not present. This situation often occurs in synchronous rectifier applications because the body diode is generally conducting before the MOSFET is switched ON.

The output pin slew rate is determined by  $V_{DD}$  voltage and the load on the output. It is not user adjustable, but a series resistor can be added if a slower rise or fall time at the MOSFET gate is needed.

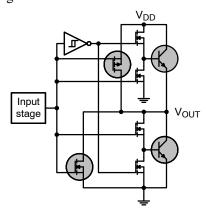

Figure 29. MillerDrive Output Architecture

#### **Under-Voltage Lockout**

The FAN321x startup logic is optimized to drive ground–referenced N–channel MOSFETs with an under–voltage lockout (UVLO) function to ensure that the IC starts up in an orderly fashion. When  $V_{DD}$  is rising, yet below the 3.9 V operational level, this circuit holds the output LOW, regardless of the status of the input pins. After the part is active, the supply voltage must drop 0.2 V before the part shuts down. This hysteresis helps prevent chatter when low  $V_{DD}$  supply voltages have noise from the power switching. This configuration is not suitable for driving high–side P–channel MOSFETs because the low output voltage of the driver would turn the P–channel MOSFET on with  $V_{DD}$  below 3.9 V.

#### **V<sub>DD</sub>** Bypass Capacitor Guidelines

To enable this IC to turn a device ON quickly, a local high-frequency bypass capacitor,  $C_{BYP}$  with low ESR and ESL should be connected between the VDD and GND pins with minimal trace length. This capacitor is in addition to the bulk electrolytic capacitance of  $10~\mu F$  to  $47~\mu F$  commonly found on driver and controller bias circuits.

A typical criterion for choosing the value of  $C_{BYP}$  is to keep the ripple voltage on the  $V_{DD}$  supply to  $\leq$ 5%. This is often achieved with a value  $\geq$ 20 times the equivalent load capacitance  $C_{EQV}$ , defined here as  $Q_{GATE}/V_{DD}$ . Ceramic capacitors of 0.1  $\mu F$  to 1  $\mu F$  or larger are common choices, as are dielectrics, such as X5R and X7R with good temperature characteristics and high pulse current capability.

If circuit noise affects normal operation, the value of  $C_{BYP}$  may be increased to 50–100 times the  $C_{EQV}$ , or  $C_{BYP}$  may be split into two capacitors. One should be a larger value, based on equivalent load capacitance, and the other a smaller value, such as 1–10 nF mounted closest to the VDD and GND pins to carry the higher frequency components of the current pulses. The bypass capacitor must provide the pulsed current from both of the driver channels and, if the drivers are switching simultaneously, the combined peak current sourced from the  $C_{BYP}$  would be twice as large as when a single channel is switching.

#### **Layout and Connection Guidelines**

The FAN3216 and FAN3217 gate drivers incorporates fast-reacting input circuits, short propagation delays, and powerful output stages capable of delivering current peaks over 2 A to facilitate voltage transition times from under 10 ns to over 150 ns. The following layout and connection guidelines are strongly recommended:

 Keep high-current output and power ground paths separate from logic input signals and signal ground paths. This is especially critical for TTL-level logic thresholds at driver input pins

- Keep the driver as close to the load as possible to minimize the length of high-current traces. This reduces the series inductance to improve high-speed switching, while reducing the loop area that can radiate EMI to the driver inputs and surrounding circuitry.
- If the inputs to a channel are not externally connected, the internal 100 kΩ resistors indicated on block diagrams command a low output. In noisy environments, it may be necessary to tie inputs of an unused channel to VDD or GND using short traces to prevent noise from causing spurious output switching.
- Many high-speed power circuits can be susceptible to noise injected from their own output or other external sources, possibly causing output re-triggering. These effects can be obvious if the circuit is tested in breadboard or non-optimal circuit layouts with long input or output leads. For best results, make connections to all pins as short and direct as possible.
- FAN3216 and FAN3217 are pin-compatible with many other industry-standard drivers.
- The turn-on and turn-off current paths should be minimized, as discussed in the following section.

Figure 30 shows the pulsed gate drive current path when the gate driver is supplying gate charge to turn the MOSFET on. The current is supplied from the local bypass capacitor,  $C_{BYP}$  and flows through the driver to the MOSFET gate and to ground. To reach the high peak currents possible, the resistance and inductance in the path should be minimized. The localized  $C_{BYP}$  acts to contain the high peak current pulses within this driver–MOSFET circuit, preventing them from disturbing the sensitive analog circuitry in the PWM controller.

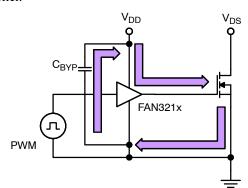

Figure 30. Current Path for MOSFET Turn-On

Figure 31 shows the current path when the gate driver turns the MOSFET OFF. Ideally, the driver shunts the current directly to the source of the MOSFET in a small circuit loop. For fast turn-off times, the resistance and inductance in this path should be minimized.

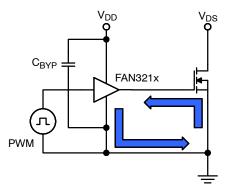

Figure 31. Current Path for MOSFET Turn-Off

#### **Operational Waveforms**

At power-up, the driver output remains LOW until the  $V_{DD}$  voltage reaches the turn-on threshold. The magnitude of the OUT pulses rises with  $V_{DD}$  until steady-state  $V_{DD}$  is reached. The non-inverting operation illustrated in Figure 32 shows that the output remains LOW until the UVLO threshold is reached, then the output is in-phase with the input.

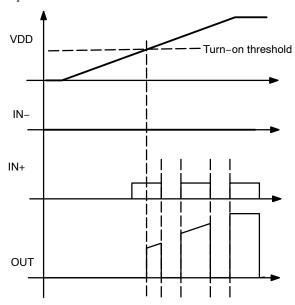

Figure 32. Non-Inverting Startup Waveforms

The inverting configuration of startup waveforms are shown in Figure 33. With IN+ tied to VDD and the input signal applied to IN-, the OUT pulses are inverted with respect to the input. At power-up, the inverted output remains LOW until the  $V_{DD}$  voltage reaches the turn-on threshold, then it follows the input with inverted phase.

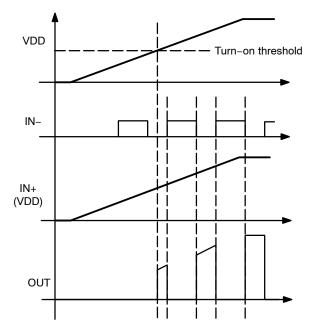

Figure 33. Inverting Startup Waveforms

#### **Thermal Guidelines**

Gate drivers used to switch MOSFETs and IGBTs at high frequencies can dissipate significant amounts of power. It is important to determine the driver power dissipation and the resulting junction temperature in the application to ensure that the part is operating within acceptable temperature limits.

The total power dissipation in a gate driver is the sum of two components,  $P_{GATE}$  and  $P_{DYNAMIC}$ :

$$P_{TOTAL} = P_{GATE} + P_{DYNAMIC}$$
 (eq. 1)

 $P_{GATE}$  (Gate Driving Loss): The most significant power loss results from supplying gate current (charge per unit time) to switch the load MOSFET on and off at the switching frequency. The power dissipation that results from driving a MOSFET at a specified gate–source voltage,  $V_{GS}$ , with gate charge,  $Q_{G}$ , at switching frequency,  $f_{SW}$ , is determined by:

$$P_{GATE} = Q_G \times V_{GS} \times f_{SW} \times n$$
 (eq. 2)

where n is the number of driver channels in use (1 or 2).

 $P_{DYNAMIC}$  (Dynamic Pre–Drive / Shoot–through Current): A power loss resulting from internal current consumption under dynamic operating conditions, including pin pull–up / pull–down resistors, can be obtained using the graphs in the Typical Performance Characteristics to determine the current  $I_{DYNAMIC}$  drawn from  $V_{DD}$  under actual operating conditions:

$$P_{DYNAMIC} = I_{DYNAMIC} \times V_{DD} \times n$$
 (eq. 3)

Once the power dissipated in the driver is determined, the driver junction rise with respect to circuit board can be evaluated using the following thermal equation, assuming  $\Psi_{JB}$  was determined for a similar thermal design (heat sinking and air flow):

$$T_{J} = P_{TOTAL} \times \psi_{JB} + T_{B}$$
 (eq. 4)

where:

 $T_J$  = driver junction temperature;

 $\Psi_{JB}$  = (psi) thermal characterization parameter relating temperature rise to total power dissipation; and

 $T_B$  = board temperature in location as defined in the Thermal Characteristics table.

In the forward converter with synchronous rectifier shown in the typical application diagrams, the FDMS8660S is a reasonable MOSFET selection. The gate charge for each SR MOSFET would be 60 nC with  $V_{GS} = V_{DD} = 7$  V. At a

switching frequency of 500 kHz, the total power dissipation is:

$$P_{GATE} = 60nC \times 7 \text{ V} \times 500 \text{ kHz} \times 2 = 0.42 \text{ W} \qquad \text{(eq. 5)}$$

$$P_{DYNAMIC} = 3 \text{ mA} \times 7 \text{ V} \times 2 = 0.042 \text{ W}$$
 (eq. 6)

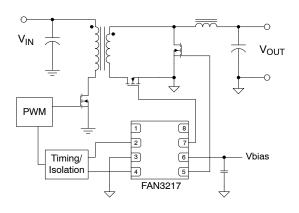

$$P_{TOTAL} = 0.46 W$$
 (eq. 7)

The SOIC–8 has a junction–to–board thermal characterization parameter of  $\Psi_{JB} = 43$  °C/W. In a system application, the localized temperature around the device is a function of the layout and construction of the PCB along with airflow across the surfaces. To ensure reliable operation, the maximum junction temperature of the device must be prevented from exceeding the maximum rating of 150 °C; with 80% derating,  $T_J$  would be limited to 120 °C. Rearranging Equation 4 determines the board temperature required to maintain the junction temperature below 120 °C:

$$T_B = T_J - P_{TOTAL} \times \psi_{JB} \tag{eq. 8} \label{eq:total_prop_state}$$

$$T_B = 120^{\circ}C - 0.46 \text{ W} \times 43^{\circ}C/W = 100^{\circ}C$$
 (eq. 9)
