# Type-C CC and SBU Protection IC

## **PRODUCT SUMMARY**

## **General Description**

The FUSB251 is an I2C controlled switch with over voltage protection on CC and SBU pins in Type–C interface port. The device has SPST switches on CC1/2 and SBU1/2 which enable automatically with valid VDD so that Type–C/PD controller can use the over voltage protected CC path. The FUSB251 has dead battery mode, CC pulled down with Rd, where Source device can provide Vbus for battery charging. Another feature in FUSB251 is moisture detection on both CC and SBU paths with ADC detection. Once moisture is detected, and Interrupt is generated and the corresponding register is updated to notify host. The device has on–chip IEC protection with surge protection on both CC and SBU. Both CC and SBU ports are 24 V DC tolerant. Package type is WLCSP with 15 ball 3x5 array.

#### **Features**

- Low Ron SPST Switches on both CC1/2 and SBU1/2 Path for Type-C
- Dead Battery Mode Provides Default Rd Presenting on CC1/2
- 24 V DC Tolerant on CC and SBU
- ±35 V Surge Protection on CC and SBU
- Over Voltage Protection on CC and SBU
- I2C Interface with Processor with Interrupt for event Notification
- Moisture Detection on CC and SBU Pins
- On-chip IEC ESD Protection with External Capacitor on CAP Pin
- CC Ron 0.3 Ω Typical
- SBU Ron 3 Ω Typical
- 50 MHz Bandwidth on SBU Switch
- 15 ball WLCSP

#### **Applications**

- Smart Phones
- Tablets, Netbooks, Ultra-Mobile PCs
- Gaming Devices and E-books
- Portable Devices with Li-ion Battery
- Car Cigarette Jack
- External USB Storage

## **PIN DESCRIPTIONS**

| Pin# | Name   | Туре              | Description  |
|------|--------|-------------------|--|
| C1   | GND    | Ground            | GND  |
| A2   | VDD    | Power             | Power  |
| A3   | CC1    | I/O               | Type-C CC interface. Connect to USB Type-C connector CC1 pin   |
| B3   | CC2    | I/O               | Type-C CC interface. Connect to USB Type-C connector CC2 pin   |
| A1   | CC1_H  | I/O               | Type-C CC Host interface, Connect to USB Type-C controller CC1 pin   |
| B1   | CC2_H  | I/O               | Type-C CC Host interface, Connect to USB Type-C controller CC2 pin   |
| D3   | SBU1   | I/O               | Type-C SBU interface, Connect to USB Type-C connector SBU1 pin   |
| E3   | SBU2   | I/O               | Type-C SBU interface, Connect to USB Type-C connector SBU2 pin   |
| D1   | SBU1_H | I/O               | Type-C SBU Host Interface, Connect to Host side SBU1 application pin   |
| E1   | SBU2_H | I/O               | Type-C SBU Host Interface, Connect to Host side SBU2 application pin.  |
| E2   | FM     | I/O               | Factory test mode pin, Connect to ADC input of host processor. If not used, connect to GND. FM can be switched over to one of SBU. |
| СЗ   | CAP    | 0                 | Capacitor pin, Connect to 0.1 μF capacitor to GND  |
| B2   | SCL    | Open Drain Input  | I <sup>2</sup> C interface, Pull up to Vdd is required, Connect to SCL pin of Processor  |
| C2   | SDA    | Open Drain I/O    | I <sup>2</sup> C interface, Pull up to Vdd is required, Connect to SDA pin of Processor  |
| D2   | INTB   | Open Drain Output | Interrupt for Host alert, Pull-up to VDD required, Connect to processor Interrupt input  |

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

1. Guaranteed by Design, Characterization, not Production tester.

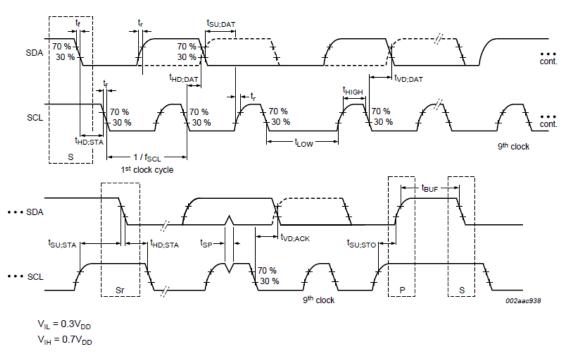

Figure 4. Definition of Timing for Full-Speed Mode Devices on the I2C Bus

## **FUNCTIONAL SPECIFICATIONS**

#### **POR and Reset**

The FUSB251 closes both CC and SBU switches with a valid VDD supply after Power On reset. Until valid VDD is supplied, FUSB251 presents Rd on both CC1 and CC2 so that a source device can provide Vbus and Type–C controller can present Rd continuously after POR so VBUS will be consistent. At UVLO condition which is 2.4 volt (falling), CC and SBU switches get open again and Rd will be presented on both CC.

There is device reset register, bit0 in 0x0B register. If the register bit is set, all registers in the device are set to default, so momentarily both switches will be open and closed back.

#### **CC and SBU Switch Characteristics**

The FUSB251 has 2x SPST switches on both CCx and SBUx with OVP feature. Both CC and SBU switch paths are closed automatically with valid Vdd supply. CC switch is used for Type-C/PD communication channel. Also Vconn can be provided through the switch from CCx\_H to CCx. Up to 1A Vconn current can be provided over the low Ron(0.3  $\Omega$ ) path. Both CCx and SBUx pins are 24 volt DC-tolerant. SBU switch can be used for DisplayPort Aux channels following USB PD Alternative mode or UART.

## **Dead Battery Mode**

Upon dead battery condition, the both CC1/2 ports present  $Rd(5.1~k\Omega)$  pull down to allow a Type-C source device to attach and provide Vbus to the sink which is under dead battery mode. Once system power comes back and valid VDD supplied to FUSB251, the dead battery Rd is removed and both CC switches are closed. Then, Type-C / PD controller can detect the attached Type-C source device.

## **Over Voltage Protection**

When an over-voltage event is detected on either CCx or SBUx, the FUSB251 will activate OVP circuit to open the switch within tOVP. The OVP event is independent between CC and SBU. Any CC channel OVP opens the CC1 and CC2 switch path only, and SBU switch is keep closed. OVP on SBU opens the SBU switch only. Upon the detection of an over-voltage event, the INTB pin is asserted low to notify processor with register update.

When OVP condition is removed from the port, the switch path is closed automatically and OVP recovery interrupt is generated to notify processor. Getting interrupt service is not required to close the switch back. OVP function is only working on the connector face ports, CCx and SBUx.

#### **FM Pin**

FM pin is for Factory test Mode (FM) purpose. When Factory test mode is used over Type–C connector and if host device needs to detect Factory Test fixtures by using ID with ADC function, the FM can be used by connecting FM to ADC input port in the processor. Without any external pull down on FM PIN, FM can be switched to one of SBU pins, default is SBU1 and it can be manually switched over to SBU2 if needed. The other SBU2 or SBU1 pin will be open.

If Factory test mode is not needed, pull down(less than  $10 \text{ k}\Omega$ ) or direct connecting to GND makes switch close between SBUx H and SBUx after POR or reset.

#### **Manual Mode Control**

For switch, there is manual mode switch control for CC and SBU switches. Processor can manually open or close the switch paths in the FUSB251 even though both switches are closed in default with valid VDD. Manual mode switch configuration overrides the auto switch control. However, there are exceptions, such as during moisture detection process and OVP event because switch has to be open in these cases. The switch configuration has to be set in the switch control register and then, bit 0 of control register has to be set.

#### **Surge and ESD Protection**

The FUSB251 connector facing ports, CCx and SBUx, are designed to endure up to ±35volt surge protection. The voltage can occur when 20 volt DC voltage from VBUS touches the CC and SBU pins with the inductance inside cable. Also, system ESD protection, IEC61000-4-2, is supported with the external capacitor on CAP pin.

## **Capacitor Recommendation**

The CAP pin needs an external capacitor ranges  $0.1~\mu F$  to  $1.0~\mu F$ . Recommended capacitor type is X7R which has low capacitance variation with temperature change and 0603~or larger size. Also the capacitor rated voltage is important because the voltage on the CAP could be greater than 35 volt with Surge or hot plug in the Type–C cable so 50 volt or larger rated capacitor is recommended.

#### **Interrupt Service**

FUSB251 has INTB pin to notify processor the status change in the device. Any change in the Interrupt register will trigger the INTB pin which is open drain output. INTB is ready after POR or reset without any register set. Once INTB pin is triggered to low, the pin stays low until the interrupt register is read by processor. The interrupt mask registers are default disabled. If any interrupt mask bit is set, the corresponding interrupt register bit won't set, so INTB pin won't be triggered.

#### **I2C Interface**

The FUSB251 includes a full I2C slave controller. The I2C slave fully complies with the I2C specification version

6 requirements. This block is designed for fast mode signals. Examples of an I<sup>2</sup>C write and read sequence are shown in below figures respectively.

NOTE: Single Byte read is initiated by Master with P immediately following first data byte

Figure 5. I<sup>2</sup>C Write Example

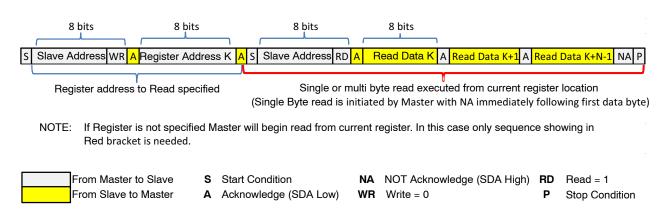

Figure 6. I<sup>2</sup>C Read Example

#### **SLAVE ADDRESS**

| Part Number | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0     |
|-------------|-------|-------|-------|-------|-------|-------|-------|-----------|
| FUSB251UCX  | 0     | 1     | 0     | 1     | 0     | 0     | 0     | R(1)/W(0) |

### **Moisture Detection**

#### **CC Moisture Detection**

Moisture detection is default disabled. Once CC moisture detection is enabled, voltage of both CC1\_H and CC2\_H are monitored to see if both CCs rise above 170 mV. If they rise above the voltage, moisture detection started on one of the CC first, and moisture detection on the other CC is occurred at the next both CC rising. If only one of CCs rises up above the threshold, in case of source device attach, CC moisture detection does not start.

If both CCs cross the threshold, both CC switches are open momentarily, and FUSB251 supplies 1volt source onto one of CCs with 320 k $\Omega$  pull up. And ADC detection is enabled to measure the voltage of the CC channel. Since moisture in connector can make leakage path between the CC pin and other pins including GND, there will be resistance between CC and GND and it can be detected by ADC. Once moisture detection is finished on one CC, the other CC channel is also tried at the next both CC rise. If there is no both CC rise on either CC within 120 ms from the last detection, it will go to timer expire. If source or sink device is attached, the timer will expire. Timer expire is interrupted to host and CC moisture detection stops and moisture detection is continued on SBU float voltage detection instead. To be determined as moisture presence, both CC channels have to be tried and

moisture has to be detected on either of channel with no timer expire. If moisture is detected, the result is updated in the register and interrupt is triggered to processor. Regardless of moisture presence on CC, once detection is finished, both CC switches are closed again for Type–C controller to use the CC channel. Moisture detection range can be changed by I2C register, Threshold1 in 0x08. Once the measured resistance is less than the threshold, it will be detected as moisture.

If sink device is attached while host with FUSB251 is on DRP toggle, both CC will rise together, So, CC moisture detection will happen. And, FUSB251 can find the Rd in sink device because the Rd,  $5.1~\mathrm{k}\Omega$ , is in moisture detection range. But the other CC channel detection will end up as timer expire because there will be no both CC rise after attach. So, the final result will be timer expire and moisture detection will continue on SBU pins.

To support audio and debug accessories which have two terminations on both CC, there is a register bit in the control register, bit7 in 0x02. The register bit makes moisture detection occur on every other both CC rising so moisture detection skips for Type–C detection can happen during the time.

Detection time on CC moisture is dependent on the settling time and number of ADC read, default is 1 time ADC and 400  $\mu$ s settle time. They can be programmed in Timer2 register, 0x0C.

#### **SBU Moisture Detection**

If CC port is on DRP or Source mode, moisture inside connector can make leakage path from CC to SBU, which makes SBU can have float voltage similar to the shape of CC. So the SBU float voltage can be detected if moisture is present while CC is on toggle or SRC mode. SBU float voltage detection can be started with the EN\_SBUFT register set. If the bit is set, FUSB251 starts monitoring voltage on both SBU1 and SUB2, and if the voltage on either port is the same or above the threshold, the moisture\_status register (0x06, bit 4 and/or 5) is set with an interrupt. With the interrupt, processor can turn off the CC and SBU switch path to protect from corrosion, or processor could further moisture check using force SBU detection.

SBU float voltage detection also can be enabled when CC moisture detection result is timer expire, which can happen where there is no DRP toggle on CC. For example, if CC moisture detection is enabled where Type-C accessory is already plugged-in, the moisture detection will end up timer expire and so SBU float voltage detection will be started instead.

Once SBU float voltage detection is enabled, it keeps monitoring until moisture found. If device is reset or both EN\_CC and EN\_SBUFT are disabled, the floating detection stops and goes back to disable mode which is idle mode.

Force SBU detection is initiated by EN\_SBU or Auto\_EN\_SBU bit. Auto\_EN\_SBU bit is for pre-set before

moisture is detected, EN\_SBU can be set at anytime when SBU moisture detection is needed. After either CC or SBU float voltage detection detected moisture, if Auto\_EN\_SBU bit is set, FUSB251 goes to moisture detection on SBU with the same way of CC moisture detection, using 1volt source with 320 k $\Omega$  pull up, which is secondary moisture detection using SBU. So, Host processor can use force SBU detection in case CC moisture or SBU float voltage detection result is not enough and additional moisture detection is needed.

Force SBU detection makes open the both CC and SBU switches and detects moisture on SBU. Opening CC switch will disconnect the Type-C device and will remove Vbus from Type-C source. The detection time of SBU force detection is 1msec. Device reset or moisture reset bit can be used to close the CC and SBU switch again.

If moisture is present in connector and if source device provides VBUS, there could be OVP interrupt on SBU by leakage path between Vbus and SBU.

### **Dry Check**

Dry check routine can be started after moisture is detected by force SBU detection. After moisture detected on SBU, if EN\_DRY bit is enabled, dry check routine is started which is keep checking moisture on SBU every second or up to 10second. The Dry check timer can be set in the register, 0x0A, timer register. Also, the moisture threshold can be set in the Threshold2 register, 0x09. If Dry condition is reached, Interrupt is generated to let host know the change, then processor has to disable all the moisture detection or moisture reset to go to idle mode. If moisture reset bit is set after Dry condition reached, the moisture detection state machine will restart based on control register bits.

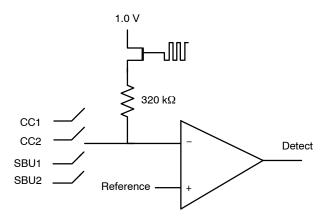

Figure 7. Moisture Detection with ADC

# ADC TABLE FOR MOISTURE DETECTION

|    | Bit  | Pull up (kΩ) to 1 V | Moisture resistance (kΩ) | Voltage (V) |
|----|------|---------------------|--------------------------|-------------|
