GD55B02GE

FEATURES

- 2G-bit Serial Flash
 - 256M-Byte
 - 256 Bytes per programmable page
- ◆ Standard, Quad SPI, DTR,QPI
 - Standard SPI: SCLK, CS#, SI, SO, WP#, RESET#
 - Quad SPI: SCLK, CS#, IO0, IO1, IO2, IO3, RESET#
 - QPI: SCLK, CS#, IO0, IO1, IO2, IO3, RESET#
 - SPI DTR (Double Transfer Rate) Read
 - 3 or 4-Byte Address Mode
- High Speed Clock Frequency
 - 133MHz for fast read
 - Quad I/O Data transfer up to 532Mbits/s
 - QPI Mode Data transfer up to 532Mbits/s
 - DTR Quad I/O Data transfer up to 720Mbits/s
- ◆ Allows XIP (eXecute in Place) Operation
 - High speed Read reduce overall XiP instruction fetch time
 - Continuous Read with Wrap further reduce data latency to fill up SoC cache
- Software/Hardware Write Protection
 - Write protect all/portion of memory via software
 - Enable/Disable protection with WP# Pin
 - Individual Block Protection

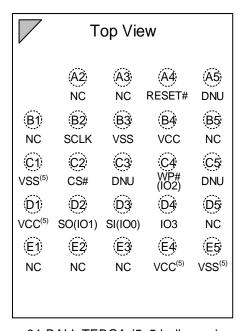

- Fast Program/Erase Speed
 - Page Program time: 0.15ms typical
- Sector Erase time: 30ms typical
- Block Erase time: 0.15/0.22s typical
- Chip Erase time: 300s typical
- Flexible Architecture
 - Sector of 4K-Byte
 - Block of 32/64K-Byte
 - Erase/Program Suspend/Resume
- ◆ Low Power Consumption
 - 64µA typical stand-by current
 - 8µA typical power-down current
- Advanced Security Features
 - 128-bit Unique ID
 - 4K-Byte Security Registers With OTP Lock
- ◆ Single Power Supply Voltage
 - Full voltage range: 2.7~3.6V
- Endurance and Data Retention
 - Minimum 100,000 Program/Erase Cycles
 - 20-year data retention typical
- Package Information
- TFBGA-24ball (5x5 Ball Array)

2 GENERAL DESCRIPTIONS

The GD55B02GE (2G-bit) Serial flash supports the standard Serial Peripheral Interface (SPI), and supports the Quad SPI and DTR mode: Serial Clock, Chip Select, Serial Data I/O0 (SI), I/O1 (SO), I/O2 (WP#), I/O3, and RESET#. The Quad I/O & Quad output data is transferred with speed of 532Mbits/s, and the DTR Quad I/O data is transferred with speed of 720Mbits/s.

CONNECTION DIAGRAM AND PIN DESCRIPTION

Figure 1 Connection Diagram for TFBGA24 5x5 ball array package

24-BALL TFBGA (5x5 ball array)

Table 1 Ball Description for TFBGA24 5x5 ball array package

| Pin No. | Pin Name | 1/0 | Description |
|----------|-----------|-----|---|
| A4 | RESET# | 1 | Reset Input |
| A5/C3/C5 | DNU | | Do Not Use (It may connect to internal signal inside) |
| B2 | SCLK | I | Serial Clock Input |
| B3/C1/E5 | VSS | | Ground |
| B4/D1/E4 | VCC | | Power Supply |
| C2 | CS# | I | Chip Select Input |
| C4 | WP# (IO2) | I/O | Write Protect Input (Data Input Output 2) |
| D2 | SO (IO1) | I/O | Data Output (Data Input Output 1) |
| D3 | SI (IO0) | I/O | Data Input (Data Input Output 0) |
| D4 | IO3 | I/O | Data Input Output 3 |

Note:

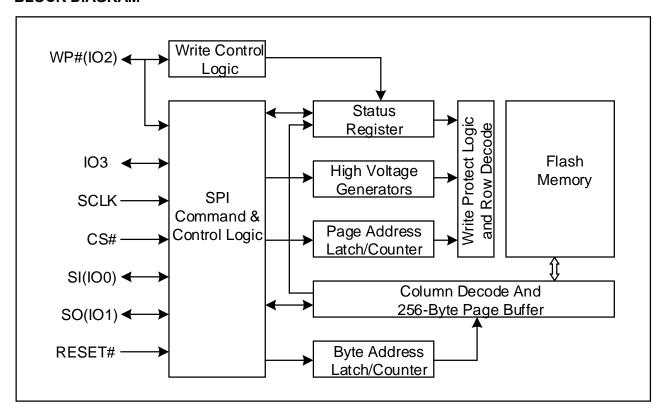

- 1. CS# must be driven high if chip is not selected. Please don't leave CS# floating any time after power is on.
- 2. The DNU ball must be floating. It may connect to internal signal inside.
- 3. The NC ball is not connected to any internal signal. It is OK to connect it to the system ground (GND) or leave it floating.

GD55B02GE

- 4. The RESET# pin is a dedicated hardware reset pin regardless of device settings or operation states. If the hardware reset function is not used, this pin must be connected to VCC in the system.
- 5. If WP# is unused, it must be driven high by the host, or an external pull-up resistor must be placed on the PCB in order to avoid allowing WP# input to float.
- 6. The device can work with only one group of VCC/VSS connected. Ball B4 must be connected to VCC and Ball B3 must be connected to VSS. The other two groups of VCC/VSS balls (Ball C1/D1/E4/E5) are optional. If Ball C1/D1/E4/E5 are not used, they must be left floating.

GD55B02GE

DEVICE OPERATIONS

SPI Mode 4.1

Standard SPI

The GD55B02GE features a serial peripheral interface on 4 signals bus: Serial Clock (SCLK), Chip Select (CS#), Serial Data Input (SI) and Serial Data Output (SO). Both SPI bus mode 0 and 3 are supported. Input data is latched on the rising edge of SCLK and data shifts out on the falling edge of SCLK.

Quad SPI

The GD55B02GE supports Quad SPI operation when using the "Quad Output Fast Read", "Quad I/O Fast Read", "Quad Page Program" (6BH/6CH, EBH/ECH, 32H/34H, C2H/3EH) commands. These commands allow data to be transferred to or from the device at four times the rate of the standard SPI. When using the Quad SPI command the SI and SO pins become bidirectional I/O pins: IO0 and IO1.

DTR Quad SPI

The GD55B02GE supports DTR Quad SPI operation when using the "DTR Quad I/O Fast Read" (EDH/EEH) command. These commands allow data to be transferred to or from the device at eight times the rate of the standard SPI, and data output will be latched on both rising and falling edges of the serial clock. When using the DTR Quad SPI command the SI and SO pins become bidirectional I/O pins: IO0 and IO1.

4.2 **QPI** Mode

The GD55B02GE supports Quad Peripheral Interface (QPI) operations only when the device is switched from Standard/Quad SPI mode to QPI mode using the "Enable the QPI (38H)" command. The QPI mode utilizes all four IO pins to input the command code. Standard/Quad SPI mode and QPI mode are exclusive. Only one mode can be active at any given times. "Enable the QPI (38H)" and "Disable the QPI (FFH)" commands are used to switch between these two modes. Upon power-up and after software reset using "Enable Reset (66H) and Reset (99H)" command, the default state of the device is Standard/Quad SPI mode.

4.3 **RESET Function**

The RESET# pin allows the device to be reset by the control.

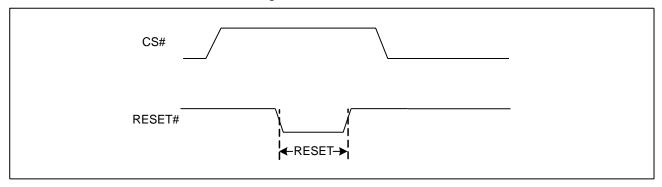

The RESET# pin goes low for a minimum period of tRLRH will reset the flash. After reset cycle, the flash is at the following states:

- Standby mode
- All the volatile bits will return to the default status as power on.

GD55B02GE

Figure 2 RESET Condition

GD55B02GE

5 DATA PROTECTION

The GD55B02GE provide the following data protection methods:

- Write Enable (WREN) command: The WREN command is set the Write Enable Latch bit (WEL). The WEL bit will return to reset by the following situation:
 - Power-Up/ Software reset (66H+99H)
 - Write Disable (WRDI)
 - Write Status Register (WRSR)
 - Write Extended Address Register (WEAR)
 - Write Nonvolatile Configuration Register (WNVCR)
 - Write Volatile Configuration Register (WVCR)
 - Page Program (PP)
 - Sector Erase (SE) / Block Erase (BE) / Chip Erase (CE)
 - Erase Security Registers / Program Security Registers
- Software Protection Mode:
 - -The Block Protect (BP4, BP3, BP2, BP1, and BP0) bits define the section of the memory array that can be read but cannot be changed.
 - Individual Block Protection bit provides the protection selection of each individual block.
- Hardware Protection Mode: WP# goes low to protect the BP0~BP4 bits and SRP0 bit.
- Deep Power-Down Mode: In Deep Power-Down Mode, all commands are ignored except the Release from Deep Power-Down Mode command and reset command (66H+99H).

Table 2. GD55B02GE Protected area size

| | Status I | Register | r Conter | nt | Memory Content | | | |
|-----|----------|----------|----------|-----|----------------|---------------------|---------|--------------|
| BP4 | BP3 | BP2 | BP1 | BP0 | Blocks | Addresses | Density | Portion |

| | | | | Global Block Lock: 7EH |
| | | | | Global Block Unlock: 98H |
| | | | | |
| 1 | 16~31 | 0001 0000h | 0001 FFFFh | |
| | 15 | 0000 F000h | 0000 FFFFh | |
| 0 | | | | |
| | 0 | 0000 0000h | 0000 0FFFh | |

Notes:

- 1. Protection configuration: This bit is used to select which Write Protect scheme should be used.
- 2. Individual Block Protection bits are volatile lock bits. Each volatile bit corresponds to and provides volatile protection for an individual memory sector, which is locked temporarily (protection is cleared when the device is reset or powered down).
- 3. The first and last sectors will have volatile protections at the 4KB sector level. Each 4KB sector in these sectors can be individually locked by volatile lock bits setting.

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

6 REGISTERS

6.1 Status Register

Table 4. Status Register-SR No.1

| No. | Bit Name | Description | Note |
|-----|----------|--------------------------------|-----------------------|
| S7 | SRP0 | Status Register Protection Bit | Non-volatile writable |
| S6 | BP4 | Block Protect Bit | Non-volatile writable |
| S5 | BP3 | Block Protect Bit | Non-volatile writable |
| S4 | BP2 | Block Protect Bit | Non-volatile writable |
| S3 | BP1 | Block Protect Bit | Non-volatile writable |
| S2 | BP0 | Block Protect Bit | Non-volatile writable |
| S1 | WEL | Write Enable Latch | Volatile, read only |
| S0 | WIP | Erase/Write In Progress | Volatile, read only |

Table 5. Status Register-SR No.2

| No. | Bit Name | Description | Note |
|-----|----------|--------------------------------|-----------------------------|
| S15 | SUS1 | Erase Suspend Bit | Volatile, read only |
| S14 | SRP1 | Status Register Protection Bit | Non-volatile writable |
| S13 | EE | Erase Error Bit | Volatile, read only |
| S12 | PE | Program Error | Volatile, read only |
| S11 | LB | Security Register Lock Bit | Non-volatile writable (OTP) |
| S10 | SUS2 | Program Suspend Bit | Volatile, read only |
| S9 | Reserved | Reserved | Reserved |
| S8 | ADS | Current Address Mode | Volatile, read only |

The status and control bits of the Status Register are as follows:

WIP bit

The Write in Progress (WIP) bit indicates whether the memory is busy in program/erase/write status register or configuration register progress. When WIP bit sets to 1, means the device is busy in program/erase/write status register or configuration register progress, when WIP bit sets 0, means the device is not in program/erase/write status register or configuration register progress.

WEL bit

The Write Enable Latch (WEL) bit indicates the status of the internal Write Enable Latch. When set to 1 the internal Write Enable Latch is set, when set to 0 the internal Write Enable Latch is reset and no Write, Program or Erase command is accepted.

BP4, BP3, BP2, BP1, BP0 bits

The Block Protect (BP4, BP3, BP2, BP1, and BP0) bits are non-volatile. They define the size of the area to be software protected against Program and Erase commands. These bits are written with the Write Status Register (WRSR) command.

GD55B02GE

When the Block Protect (BP4, BP3, BP2, BP1, and BP0) bits are set to 1, the relevant memory area becomes protected against Page Program (PP), Sector Erase (SE) and Block Erase (BE) commands. The Block Protect (BP4, BP3, BP2, BP1, and BP0) bits can be written provided that the Hardware Protected mode has not been set. The Chip Erase (CE) command is executed only if none sector or block is protected.

SRP0, SRP1 bits

The Status Register Protect (SRP1 and SRP0) bits are non-volatile Read/Write bits in the status register. The SRP bits control the method of write protection: software protection, hardware protection, power supply lock-down or one time programmable protection.

| SRP1 | SRP0 | #WP | Status Register | Description |
|------|------|-----|---------------------------------|---|
| 0 | 0 | Х | Software Protected | The Status Register can be written to after a Write Enable |
| U | | ^ | Contware 1 Totected | command, WEL=1.(Default) |
| 0 | 1 | 0 | Hardware Protected | WP#=0, the Status Register locked and cannot be written to. |
| 0 | 4 | 1 | Hardwara Hanrata eta d | WP#=1, the Status Register is unlocked and can be written to |
| U | ' | ı | Hardware Unprotected | after a Write Enable command, WEL=1. |
| 1 | 0 | Х | Power Supply Lock- | Status Register is protected and cannot be written to again until |
| ' | | ^ | Down ⁽¹⁾⁽²⁾ | the next Power-Down, Power-Up cycle. |
| 1 | 1 | Х | One Time Program ⁽²⁾ | Status Register is permanently protected and cannot be written |
| | | ^ | One fille Program | to. |

NOTE:

- 1. When SRP1, SRP0= (1, 0), a Power-Down, Power-Up cycle will change SRP1, SRP0 to (0, 0) state.
- 2. This feature is available on special order. Please contact GigaDevice for details.

ADS bit

The Address Status (ADS) bit is a read only bit that indicates the current address mode the device is operating in. The device is in 3-Byte address mode when ADS=0 (default), and in 4-Byte address mode when ADS=1.

SUS1, SUS2 bits

The SUS1 and SUS2 bits are read only bits in the status register (S15 and S10) that are set to 1 after executing an Program/Erase Suspend (75H) command (The Erase Suspend will set the SUS1 bit to 1, and the Program Suspend will set the SUS2 bit to 1). The SUS1 and SUS2 bits are cleared to 0 by Erase/Program Resume (7AH) command, software reset (66H+99H) command as well as a power-down, power-up cycle.

LB bit

The LB bit is non-volatile One Time Program (OTP) bit in Status Register (S11) that provide the write protect control and status to the Security Registers. The default state of LB bit is 0, the security registers are unlocked. The LB bit can be set to 1 using the Write Register instruction. The LB bit is One Time Programmable, once they are set to 1, the Security Registers will become read-only permanently.

PE bit

The Program Error (PE) bit is a read only bit that indicates a program failure. It will also be set when the user attempts to

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

program a protected array sector or access the locked OTP space. PE is cleared to "0" after program operation resumes

EE bit

The Erase Error (EE) bit is a read only bit that indicates an erase failure. It will also be set when the user attempts to erase a protected array sector or access the locked OTP space. EE is cleared to "0" after erase operation resumes

6.2 Extended Address Register

Table 6 Extended Address Register

| No. | Name | Description | Note |
|-----|----------|-------------|-------------------|
| EA7 | Reserved | Reserved | Reserved |
| EA6 | Reserved | Reserved | Reserved |
| EA5 | Reserved | Reserved | Reserved |
| EA4 | Reserved | Reserved | Reserved |
| EA3 | A27 | Address bit | Volatile writable |
| EA2 | A26 | Address bit | Volatile writable |
| EA1 | A25 | Address bit | Volatile writable |
| EA0 | A24 | Address bit | Volatile writable |

The extended address register is only used when the address mode is 3-Byte mode, as to set the higher address. The default value of the address bit is "0".

For the read operation, the whole array can be continually read out with one command. Data output starts from the selected 128Mb, and it can cross the boundary. When the last Byte of the segment is reached, the next Byte (in a continuous reading) is the first Byte of the next segment. However, the EAR (Extended Address Register) value does not change. The random access reading can only be operated in the selected segment.

The Chip erase command will erase the whole chip and is not limited by EAR selected segment. However, the sector erase, block erase, program operation are limited in selected segment and will not cross the boundary.

A27, A26, A25, A24 bit

The Extended Address Bits are used only when the device is operating in the 3-Byte Address Mode (ADS=0), which is volatile writable by C5H command.

If Configuration Register Byte <5> set to FEH, or an "Enter 4-Byte Address Mode (B7H)" instruction is issued, the device will require 4-Byte address input for all address related instructions, and the Extended Address Bit setting will be ignored.

| A27, A26, A25, A24 | Address |
|--------------------|-----------------------|
| 0000 | 0000 0000h-00FF FFFFh |

7 INTERNAL CONFIGURATION REGISTER

The memory configuration is set by an internal configuration register that is not directly accessible to users. The user can change the default configuration at power up by using the WRITE NONVOLATILE CONFIGURATION REGISTER. Information from the nonvolatile configuration register overwrites the internal configuration register during power on or after a reset.

The user can change the configuration during device operation using the WRITE VOLATILE CONFIGURATION REGISTER command. Information from the volatile configuration registers overwrite the internal configuration register immediately after the WRITE command completes.

7.1 Nonvolatile Configuration Register

Nonvolatile Configuration Register bits set the device configuration after power-up or reset. All bits are erased (FFh) unless stated otherwise. This register is read from and written to using the READ NONVOLATILE CONFIGURATION REGISTER and the WRITE NONVOLATILE CONFIGURATION REGISTER commands, respectively. The commands use the main array address scheme, but only the LSB is used to access different register settings, thereby providing up to 256 Bytes of registers (See the table below for the details). A WRITE command to a reserved address will set the device to the default status of the corresponding Byte.

| | Table / Nonvolatile Configuration Register | | | | | | | | | |
|------|--|--------|------|------|------|------|------|------|----------|------------------------|
| Addr | Settings | bit7 | bit6 | bit5 | bit4 | bit3 | bit2 | bit1 | bit0 | Description |

| | configuration ⁽⁹⁾ | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 16-Byte Wrap |
| | Others | | | | | | | • | Reserved | |

Notes:

- 1. The number of cycles must be set to accord with the clock frequency, which varies by the type of FAST READ command (See Supported Clock Frequencies table). Insufficient dummy clock cycles for the operating frequency causes the memory to read incorrect data.
- 2. 03H/13H: SPI 0 dummy; QPI N/A
- 3. 05H/35H/9EH/9FH: SPI&QPI 0 dummy.
- 4. 3DH: SPI 0 dummy; QPI 8 dummy.
- 5. 4BH/5AH/B5H/85H: SPI&QPI 8 dummy.
- 6. 0BH/0CH/6BH/6CH/48H: SPI 8 dummy; QPI dummy follow CONFIGURATION REGISTER<1> (initiation = 6 dummy)
- 7. EBH/ECH/EDH/EEH: SPI&QPI dummy follow CONFIGURATION REGISTER<1> (initiation = 6 dummy)
- 8. When WPS protection is enabled, the entire memory array is being protected after Power-up or Reset.
- 9. Only Quad I/O (EBH and ECH) and DTR Quad I/O fast read (EDH and EEH) support wrap read and XIP operation.

7.2 Volatile Configuration Register

Volatile Configuration Register bits temporarily set the device configuration after power-up or reset. All bits are erased (FFh) unless stated otherwise. This register is read from and written to using the READ VOLATILE CONFIGURATION REGISTER and the WRITE VOLATILE CONFIGURATION REGISTER commands, respectively. The commands use the main array address scheme; however, only the LSB is used to access different register settings to provide up to 256 Bytes of registers (See the table below for the details). A WRITE command to a reserved address will set the device to the default status of the corresponding Byte.

| | | Othe | s | | | | | | | Reserved |

Notes:

- 1. The number of cycles must be set to accord with the clock frequency, which varies by the type of FAST READ command (See Supported Clock Frequencies table). Insufficient dummy clock cycles for the operating frequency causes the memory to read incorrect data.
- 2. 03H/13H: SPI 0 dummy; QPI N/A
- 3. 05H/35H/9EH/9FH: SPI&QPI 0 dummy.
- 4. 3DH: SPI 0 dummy; QPI 8 dummy.
- 5. 4BH/5AH/B5H/85H: SPI&QPI 8 dummy.
- 6. 0BH/0CH/6BH/6CH/48H: SPI 8 dummy; QPI dummy follow CONFIGURATION REGISTER<1> (initiation = 6 dummy)
- 7. EBH/ECH/EDH/EEH: SPI&QPI dummy follow CONFIGURATION REGISTER<1> (initiation = 6 dummy)
- 8. When WPS protection is enabled, the entire memory array is being protected after Power-up or Reset.

9. Only Quad I/O (EBH and ECH) and DTR Quad I/O fast read (EDH and EEH) support wrap read and XIP operation.

DLP bit

The DLP bit is Data Learning Pattern Enable bit, which is writable by B1/81H command. For Quad output, Quad I/O and Quad I/O DTR Fast Read commands, a pre-defined "Data Learning Pattern" can be used by the flash memory controller to determine the flash data output timing on 4 I/O pins. When DLP=0, from the third dummy clock, the flash will output "00110100" Data Learning Pattern sequence on each of the I/O or 4 I/O pins until data output. If the dummy clock is not enough for the output of the whole Data Learning Pattern, the last several bit of the Data Learning Pattern would be cut-off. During this period, controller can fine tune the data latching timing for each I/O pins to achieve optimum system performance. DLP=1 will disable the Data Learning Pattern output.

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

8 COMMAND DESCRIPTIONS

All commands, addresses and data are shifted in and out of the device, beginning with the most significant bit on the first rising edge of SCLK after CS# is driven low. Then, the one-Byte command code must be shifted in to the device, with most significant bit first on SI, and each bit is latched on the rising edges of SCLK.

Every command sequence starts with a one-Byte command code. Depending on the command, this might be followed by address Bytes, or by data Bytes, or by both or none. CS# must be driven high after the last bit of the command sequence has been completed. For the command of Read, Fast Read, Read Status Register or Release from Deep Power-Down, and Read Device ID, the shifted-in command sequence is followed by a data-out sequence. All read instruction can be completed after any bit of the data-out sequence is being shifted out, and then CS# must be driven high to return to deselected status.

For the command of Page Program, Sector Erase, Block Erase, Chip Erase, Write Status Register, Write Enable, Write Disable or Deep Power-Down command, CS# must be driven high exactly at a Byte boundary, otherwise the command is rejected, and is not executed. That is CS# must be driven high when the number of clock pulses after CS# being driven low is an exact multiple of eight. For Page Program, if at any time the input Byte is not a full Byte, nothing will happen and WEL will not be reset.

8.1 Enable 4-Byte Mode (B7H)

The Enable 4-Byte Mode command enables accessing the address length of 32-bit for the memory area of the higher density (larger than 128Mb). After sending the Enable 4-Byte Mode command, the ADS bit (S8) will be set to 1 to indicate the 4-Byte address mode has been enabled. Once the 4-Byte address mode is enabled, the address length becomes 32-bit.

Figure 7 Enable 4-Byte Mode Sequence Diagram (SPI)

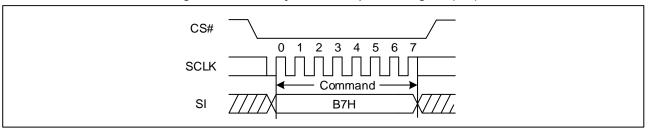

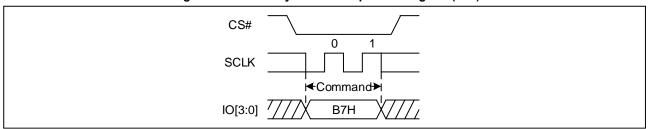

Figure 8 Enable 4-Byte Mode Sequence Diagram (QPI)

8.2 Disable 4-Byte Mode (E9H)

The Disable 4-Byte Mode command is executed to exit the 4-Byte address mode and enter the 3-Byte address mode. After sending the Disable 4-Byte Mode command, the ADS bit (S8) will be clear to be 0 to indicate the 4-Byte address mode has been disabled, and then the address length will return to 24-bit.

Figure 9 Disable 4-Byte Mode Sequence Diagram (SPI)

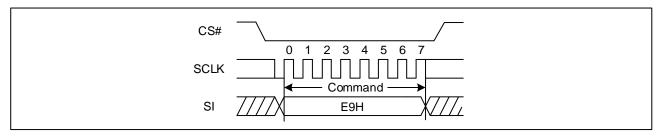

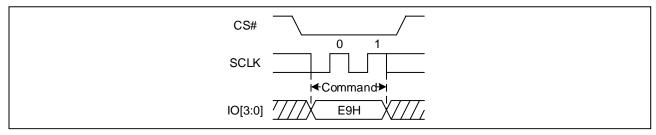

Figure 10 Disable 4-Byte Mode Sequence Diagram (QPI)

8.3 Write Enable (WREN) (06H)

The Write Enable (WREN) command is for setting the Write Enable Latch (WEL) bit. The Write Enable Latch (WEL) bit must be set prior to every Page Program (PP), Sector Erase (SE), Block Erase (BE), Chip Erase (CE), Write Status Register (WRSR), Write Extended Address Register (WEAR), Write Nonvolatile/Volatile configure register and Erase/Program Security Registers command. The Write Enable (WREN) command sequence: CS# goes low → sending the Write Enable command → CS# goes high.

Figure 11 Write Enable Sequence Diagram (SPI)

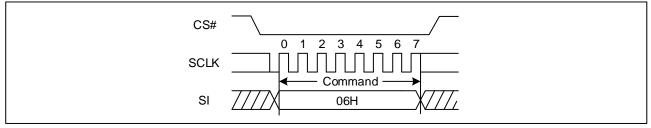

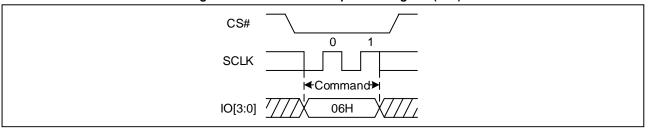

Figure 12 Write Enable Sequence Diagram (QPI)

8.4 Write Disable (WRDI) (04H)

The Write Disable command is for resetting the Write Enable Latch (WEL) bit. The Write Disable command sequence: CS# goes low →Sending the Write Disable command →CS# goes high. The WEL bit is reset by following condition: Power-up and upon completion of the Write Status Register, Write Extended Address Register (WEAR), Write Nonvolatile/Volatile configure register, Page Program, Sector Erase, Block Erase, Chip Erase, Erase/Program Security Registers and Reset commands.

Figure 13 Write Disable Sequence Diagram (SPI)

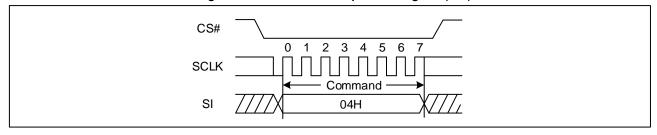

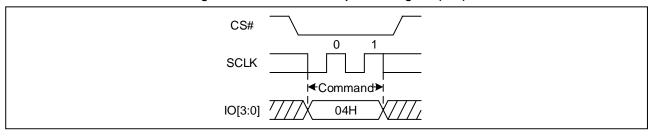

Figure 14 Write Disable Sequence Diagram (QPI)

8.5 Write Enable for Volatile Status Register (50H)

The non-volatile Status Register bits can also be written to as volatile bits. This gives more flexibility to change the system configuration and memory protection schemes quickly without waiting for the typical non-volatile bit write cycles or affecting the endurance of the Status Register non-volatile bits. The Write Enable for Volatile Status Register command must be issued prior to a Write Status Register command, and any other commands cannot be inserted between them. Otherwise, Write Enable for Volatile Status Register will be cleared. The Write Enable for Volatile Status Register command will not set the Write Enable Latch bit, it is only valid for the Write Status Register command to change the volatile Status Register bit values.

CS# 3 4 5

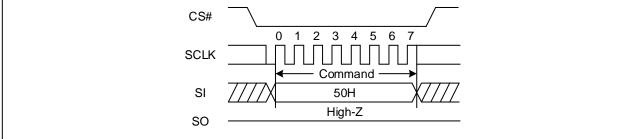

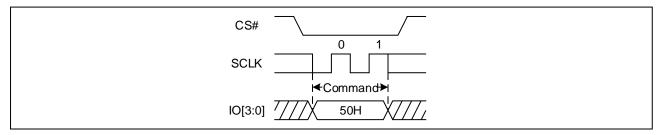

Figure 15 Write Enable for Volatile Status Register Sequence Diagram (SPI)

Figure 16 Write Enable for Volatile Status Register Sequence Diagram (QPI)

8.6 Write Status Register (WRSR) (01H/31H)

The Write Status Register (WRSR) command allows new values to be written to the Status Register. Before it can be accepted, a Write Enable (WREN) command must previously have been executed. After the Write Enable (WREN) command has been decoded and executed, the device sets the Write Enable Latch (WEL).

CS# must be driven high after the eighth of the data Byte has been latched in. Otherwise, the Write Status Register (WRSR) command is not executed. As soon as CS# is driven high, the self-timed Write Status Register cycle (whose duration is tW) is initiated. While the Write Status Register cycle is in progress, the Status Register may still be read to check the value of the Write In Progress (WIP) bit. The Write In Progress (WIP) bit is 1 during the self-timed Write Status Register cycle, and is 0 when it is completed. When the cycle is completed, the Write Enable Latch (WEL) is reset.

The Write Status Register (WRSR) command allows the user to change the values of the Block Protect (BP4, BP3, BP2, BP1, and BP0) bits, to define the size of the area that is to be treated as read-only. The Write Status Register (WRSR) command also allows the user to set or reset the Status Register Protect (SRP0) bit in accordance with the Write Protect (WP#) signal. The Status Register Protect (SRP1 and SRP0) bits and Write Protect (WP#) signal allow the device to be put in the Hardware Protected Mode. The Write Status Register (WRSR) command is not executed once the Hardware Protected Mode is entered.

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

Figure 17 Write Status Register Sequence Diagram (SPI)

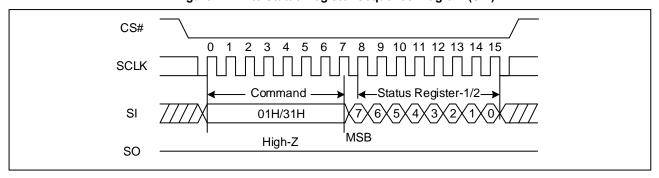

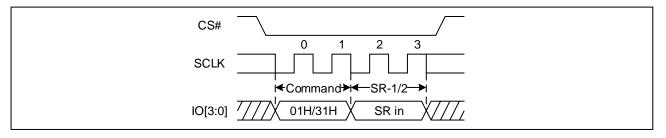

Figure 18 Write Status Register Sequence Diagram (QPI)

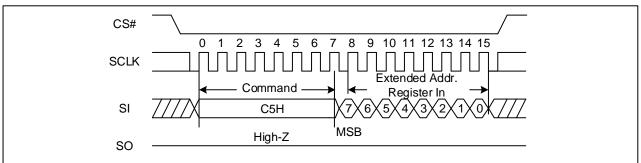

8.7 Write Extended Address Register (C5H)

The Extended Address Register is a volatile register that stores the 4th Byte address (A31-A24) when the device is operating in the 3-Byte Address Mode (ADS=0). To write the Extended Address Register bits, a Write Enable (06h) instruction must previously have been executed for the device to accept the Write Extended Address Register instruction (Status Register bit WEL must equal 1). Once write enabled, the instruction is entered by driving CS# low, sending the instruction code "C5H", and then writing the Extended Address Register data Byte.

Upon power up or the execution of a Software/Hardware Reset, the Extended Address Register bit values will be cleared to 0.

The Extended Address Bit is only effective when the device is in the 3-Byte Address Mode. When the device operates in the 4-Byte Address Mode (ADS=1), any command with address input of A31-A24 will replace the Extended Address Register values. It is recommended to check and update the Extended Address Register if necessary when the device is switched from 4-Byte to 3-Byte Address Mode.

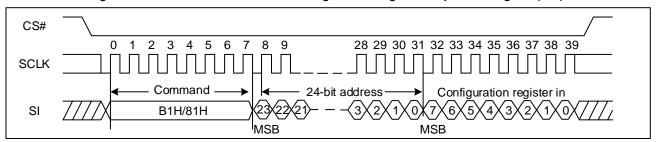

Figure 20 Write Extended Address Register Sequence Diagram (QPI)

8.8 Write Nonvolatile/Volatile Configuration Register (B1H/81H)

IO[3:0] /

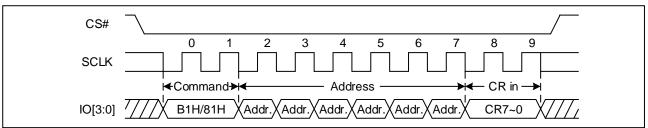

The Write Nonvolatile/Volatile Configuration Register command allows new values to be written to the Nonvolatile/Volatile Configuration Register. Before it can be accepted, a Write Enable (WREN) command must previously have been executed. After the Write Enable (WREN) command has been decoded and executed, the device sets the Write Enable Latch (WEL). CS# must be driven high after the data Byte has been latched in. If not, the Write Configuration Register command is not executed. As soon as CS# is driven high, the self-timed Write Configuration Register cycle (whose duration is tW for B1H) is initiated. The Write In Progress (WIP) bit is 1 during the self-timed Write Configuration Register cycle, and is 0 when it is completed. When the cycle is completed, the Write Enable Latch (WEL) is reset.

Figure 21 Write Nonvolatile/Volatile Configuration Register Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Figure 22 Write Nonvolatile/Volatile Configuration Register Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.9 Read Status Register (05H/35H)

The Read Status Register command is for reading the Status Register. The Status Register may be read at any time, even while a Program, Erase or Write Status Register cycle is in progress. When one of these cycles is in progress, it is recommended to check the Write in Progress (WIP) bit before sending a new command to the device. It is also possible to read the Status Register continuously. For command code "05H"/"35H", the SO will output Status Register bits S7~S0/S15~S8.

8.10 Read Nonvolatile/Volatile Configuration Register (B5H/85H)

The Read Nonvolatile/Volatile Configuration Register command is for reading the Nonvolatile/Volatile Configuration Registers. It is followed by a 3-Byte address (A23-A0) or a 4-Byte address (A31-A0) and a dummy Byte, and each bit is latched-in on the rising edge of SCLK. Then the Configuration Register, at that address, is shifted out on SO, and each bit is shifted out, at a Max frequency fc, on the falling edge of SCLK. Read Nonvolatile/Volatile Configuration Register command, while an Erase, Program or Write cycle is in progress, is rejected without having any effects on the cycle that is in progress.

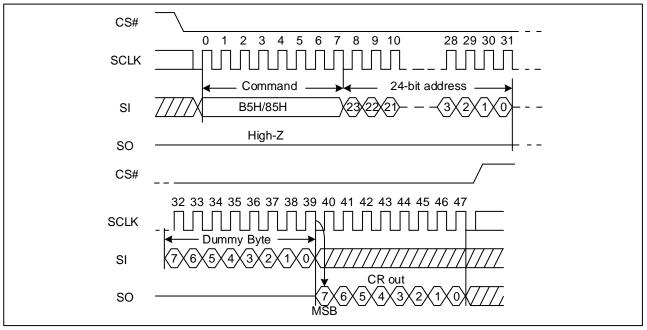

Figure 25 Read Configuration Registers Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Figure 26 Read Configuration Registers Sequence (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.11 Read Extended Address Register (C8H)

The Read Extended Address Register instruction is entered by driving CS# low and shifting the instruction code "C8H" into the SI pin on the rising edge of SCLK. The Extended Address Register bits are then shifted out on the SO pin at the falling edge of SCLK with most significant bit (MSB) first.

When the device is in the 4-Byte Address Mode, the value of the address bits is ignored.

Figure 27 Read Extended Address Register Sequence Diagram (SPI)

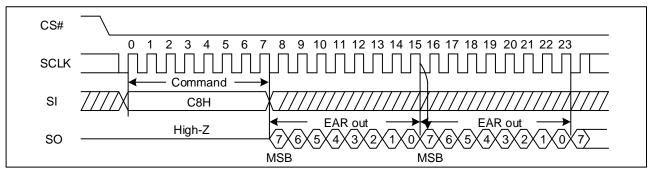

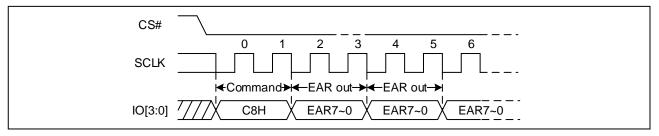

Figure 28 Read Extended Address Register Sequence Diagram (QPI)

8.12 Read Data Bytes (03H/13H)

The Read Data Bytes (READ) command is followed by a 3-Byte address (A23-A0) or a 4-Byte address (A31-A0), and each bit is latched-in on the rising edge of SCLK. Then the memory content, at that address, is shifted out on SO, and each bit is shifted out, at a Max frequency fR, on the falling edge of SCLK. The first Byte addressed can be at any location. The address is automatically incremented to the next higher address after each Byte of data is shifted out. The whole memory can, therefore, be read with a single Read Data Bytes (READ) command. Any Read Data Bytes (READ) command, while an Erase, Program or Write cycle is in progress, is rejected without having any effects on the cycle that is in progress.

8.13 Read Data Bytes at Higher Speed (0BH/0CH)

The Read Data Bytes at Higher Speed (Fast Read) command is for quickly reading data out. It is followed by a 3-Byte address (A23-A0) or a 4-Byte address (A31-A0) and dummy clocks, and each bit is latched-in on the rising edge of SCLK. Then the memory content, at that address, is shifted out on SO, and each bit is shifted out, at a Max frequency f_C , on the falling edge of SCLK. The first Byte addressed can be at any location. The address is automatically incremented to the next higher address after each Byte of data is shifted out.

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.14 Quad Output Fast Read (6BH/6CH)

The Quad Output Fast Read command is followed by 3-Byte address (A23-A0) or a 4-Byte address (A31-A0) and dummy clocks, and each bit is latched in on the rising edge of SCLK, then the memory contents are shifted out 4-bit per clock cycle from IO3, IO2, IO1 and IO0. The first Byte addressed can be at any location. The address is automatically incremented to the next higher address after each Byte of data is shifted out.

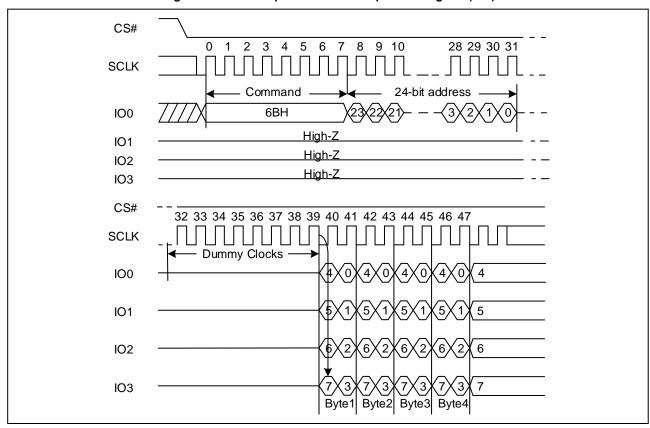

Figure 32 Quad Output Fast Read Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

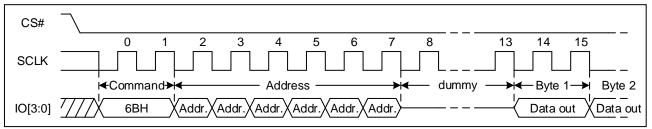

Figure 33 Quad Output Fast Read Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.15 Quad I/O Fast Read (EBH/ECH)

The Quad I/O Fast Read command is similar to the Quad Output Fast Read command but with the capability to input the 3-Byte address (A23-0) or a 4-Byte address (A31-A0) and a "Continuous Read Mode" Byte and dummy clocks. 4-bit per clock is transferred by IO0, IO1, IO2, IO3, and each bit is latched in on the rising edge of SCLK, then the memory contents are shifted out 4-bit per clock cycle from IO0, IO1, IO2, IO3. The first Byte addressed can be at any location. The address is automatically incremented to the next higher address after each Byte of data is shifted out.

Quad I/O Fast Read with "Continuous Read Mode"

The Quad I/O Fast Read command can further reduce command overhead through setting the "Continuous Read Mode" bits (M7-0) after the input 3-Byte address (A23-A0) or 4-Byte address (A31-A0). If the "Continuous Read Mode" bits (M5-4) = (1, 0), then the next Quad I/O Fast Read command (after CS# is raised and then lowered) does not require the EBH/ECH command code. If the "Continuous Read Mode" bits (M5-4) do not equal to (1, 0), the next command requires the command code, thus returning to normal operation. The only way to quit the Quad I/O Continuous Read Mode" is to set the "Continuous Read Mode" bits (M5-4) not equal to (1, 0).

CS# 8 10 11 12 13 14 15 19 20 21 22 23 **SCLK** 100 **EBH** 101 102 **IO3**

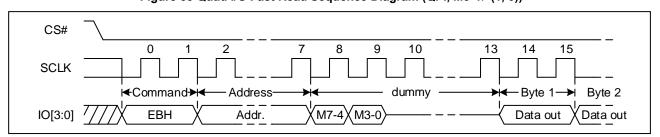

Figure 35 Quad I/O Fast Read Sequence Diagram (QPI, M5-4≠ (1, 0))

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

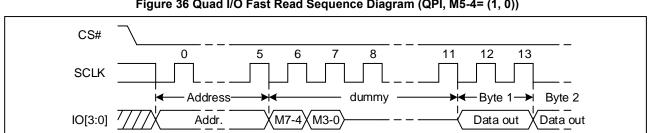

Figure 36 Quad I/O Fast Read Sequence Diagram (QPI, M5-4= (1, 0))

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Quad I/O Fast Read with "16/32/64-Byte Wrap Around"

The Quad I/O Fast Read command can be used to access a specific portion within a page by issuing Wrap configuration register Byte prior to EBH/ECH. The data being accessed can be limited to either a 16/32/64-Byte section of a 256-Byte page. The output data starts at the initial address specified in the command, once it reaches the ending boundary of the

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

16/32/64-Byte section, the output will wrap around the beginning boundary automatically until CS# is pulled high to terminate the command.

The Burst with Wrap feature allows applications that use cache to quickly fetch a critical address and then fill the cache afterwards within a fixed length (16/32/64-Byte) of data without issuing multiple read commands.

8.16 Quad I/O DTR Read (EDH/EEH)

The Quad I/O DTR Read instruction enables Double Transfer Rate throughput on quad I/O of Serial Flash in read mode. The address (interleave on 4 I/O pins) is latched on both rising and falling edge of SCLK, and data (interleave on 4 I/O pins) shift out on both rising and falling edge of SCLK. The 8-bit address can be latched-in at one clock, and 8-bit data can be read out at one clock, which means four bits at rising edge of clock, the other four bits at falling edge of clock. The first address Byte can be at any location. The address is automatically increased to the next higher address after each Byte data is shifted out, so the whole memory can be read out at a single Quad I/O DTR Read command. The address counter rolls over to 0 when the highest address has been reached.

While Program/Erase/Write Status Register cycle is in progress, Quad I/O DTR Read command is rejected without any impact on the Program/Erase/Write Status Register current cycle.

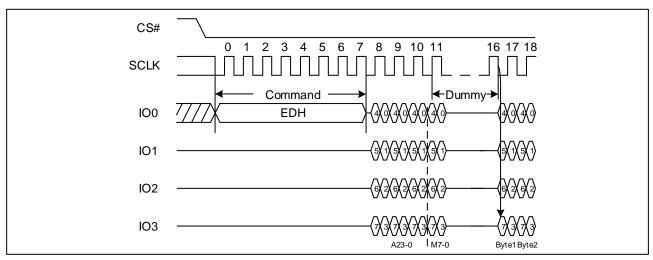

Figure 37. DTR Quad I/O Fast Read Sequence Diagram (SPI, M5-4 ≠ (1, 0))

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

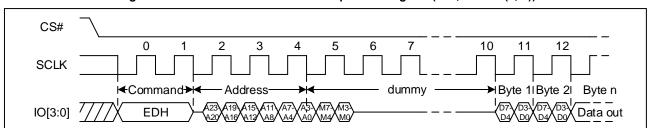

Figure 38. DTR Quad I/O Fast Read Sequence Diagram (QPI, M5-4 ≠ (1, 0))

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Quad I/O DTR Read with "Continuous Read Mode"

The Quad I/O DTR Read command can further reduce command overhead through setting the "Continuous Read Mode" bits (M7-0) after the input address. If the "Continuous Read Mode" bits (M5-4) = (1, 0), then the next Quad I/O DTR Read command (after CS# is raised and then lowered) does not require the EDH/EEH command code. If the "Continuous Read

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

Mode" bits (M5-4) do not equal to (1, 0), the next command requires the first EDH/EEH command code, thus returning to normal operation. The only way to quit the Quad I/O DTR Continuous Read Mode" is to set the "Continuous Read Mode" bits (M5-4) not equal to (1, 0).

Figure 39. DTR Quad I/O Fast Read Sequence Diagram (M5-4 = (1, 0))

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Quad I/O DTR Fast Read with "16/32/64-Byte Wrap Around"

The Quad I/O DTR Fast Read command can be used to access a specific portion within a page by issuing Wrap configuration register Byte prior to EDH/EEH. The data being accessed can be limited to either a 16/32/64-Byte section of a 256-Byte page. The output data starts at the initial address specified in the command, once it reaches the ending boundary of the 16/32/64-Byte section, the output will wrap around the beginning boundary automatically until CS# is pulled high to terminate the command.

The Burst with Wrap feature allows applications that use cache to quickly fetch a critical address and then fill the cache afterwards within a fixed length (16/32/64-Byte) of data without issuing multiple read commands.

8.17 Page Program (PP) (02H/12H)

The Page Program (PP) command is for programming the memory. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit before sending the Page Program command.

The Page Program (PP) command is entered by driving CS# Low, followed by the command code, three or four address Bytes and at least one data Byte on SI. If the 8 least significant address bits (A7-A0) are not all zero, all transmitted data that goes beyond the end of the current page are programmed from the start address of the same page (from the address whose 8 least significant bits (A7-A0) are all zero). CS# must be driven low for the entire duration of the sequence. The Page Program command sequence: CS# goes low → sending Page Program command → 3-Byte address or 4-Byte address on SI → at least 1 Byte data on SI → CS# goes high. If more than 256 Bytes are sent to the device, previously latched data are discarded and the last 256 data Bytes are guaranteed to be programmed correctly within the same page. If less than 256 data Bytes are sent to device, they are correctly programmed at the requested addresses without having any effects on the other Bytes of the same page. CS# must be driven high after the eighth bit of the last data Byte has been latched in; otherwise the Page Program (PP) command is not executed.

As soon as CS# is driven high, the self-timed Page Program cycle (whose duration is tpp) is initiated. While the Page Program cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Page Program cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset.

A Page Program (PP) command applied to a page which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) is not executed.

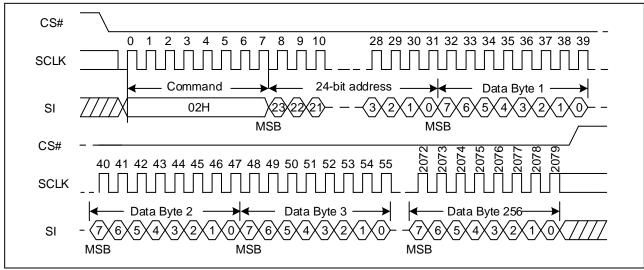

Figure 40 Page Program Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

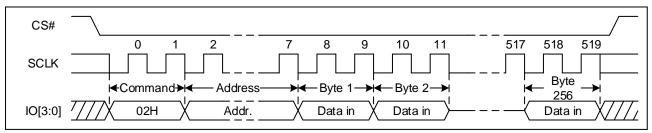

Figure 41 Page Program Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.18 Quad Page Program (32H/34H)

The Quad Page Program command is for programming the memory using four pins: IO0, IO1, IO2, and IO3. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit before sending the Page Program command. The quad Page Program command is entered by driving CS# Low, followed by the command code (32H/34H), three or four address Bytes and at least one data Byte on IO pins.

If more than 256 Bytes are sent to the device, previously latched data are discarded and the last 256 data Bytes are guaranteed to be programmed correctly within the same page. If less than 256 data Bytes are sent to device, they are correctly programmed at the requested addresses without having any effects on the other Bytes of the same page. CS# must be driven high after the eighth bit of the last data Byte has been latched in; otherwise the Quad Page Program (PP) command is not executed.

As soon as CS# is driven high, the self-timed Quad Page Program cycle (whose duration is tpp) is initiated. While the Quad Page Program cycle is in progress, the Status Register may be read to check the value of the Write In Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Quad Page Program cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset.

A Quad Page Program command applied to a page which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) is not executed.

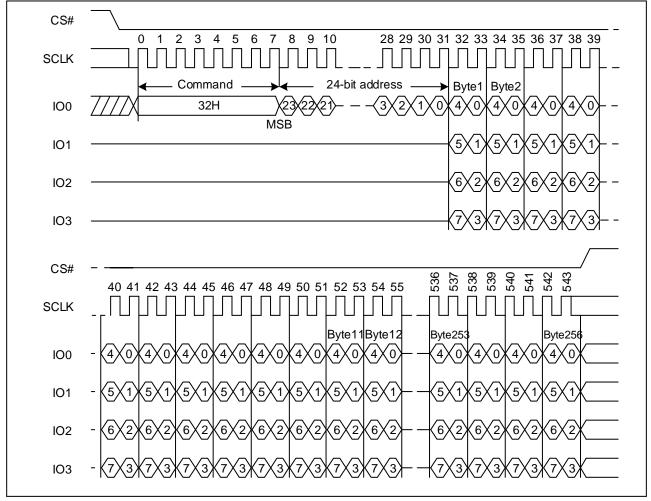

Figure 42 Quad Page Program Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.19 Extend Quad Page Program (C2H/3EH)

The Extend Quad Page Program command is for programming the memory using four pins: IO0, IO1, IO2, and IO3. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit before sending the Page Program command. The extend quad Page Program command is entered by driving CS# Low, followed by the command code (C2H/3EH), three or four address Bytes and at least one data Byte on IO pins.

If more than 256 Bytes are sent to the device, previously latched data are discarded and the last 256 data Bytes are guaranteed to be programmed correctly within the same page. If less than 256 data Bytes are sent to device, they are

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

correctly programmed at the requested addresses without having any effects on the other Bytes of the same page. CS# must be driven high after the eighth bit of the last data Byte has been latched in; otherwise the Extend Quad Page Program (EPP) command is not executed.

As soon as CS# is driven high, the self-timed Extend Quad Page Program cycle (whose duration is tPP) is initiated. While the Extend Quad Page Program cycle is in progress, the Status Register may be read to check the value of the Write In Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Extend Quad Page Program cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. An Extend Quad Page Program command applied to a page which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) is not executed.

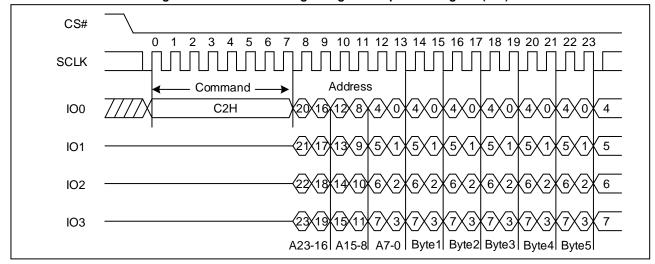

Figure 44 Extend Quad Page Program Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

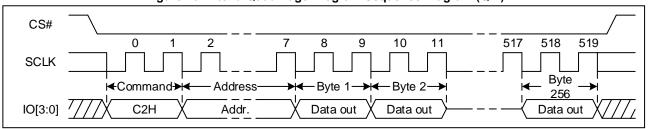

Figure 45 Extend Quad Page Program Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.20 Sector Erase (SE) (20H/21H)

The Sector Erase (SE) command is erased the all data of the chosen sector. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit. The Sector Erase (SE) command is entered by driving CS# low, followed by the command code, and 3- Byte address or 4-Byte address on SI. Any address inside the sector is a valid address for the Sector Erase (SE) command. CS# must be driven low for the entire duration of the sequence. The Sector Erase command sequence: CS# goes low \rightarrow sending Sector Erase command \rightarrow 3-Byte address or 4-Byte address on SI \rightarrow CS# goes high. CS# must be driven high after the eighth bit of the last address Byte has been latched in; otherwise the Sector Erase (SE) command is not executed. As soon as CS# is driven high, the self-timed Sector Erase cycle (whose duration is t_{SE}) is initiated. While the Sector Erase cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Sector Erase

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. A Sector Erase (SE) command applied to a sector which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) bits is not executed.

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.21 32KB Block Erase (BE32) (52H/5CH)

The 32KB Block Erase command is erased the all data of the chosen block. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit. The 32KB Block Erase (BE) command is entered by driving CS# low, followed by the command code, and 3-Byte address or 4-Byte address on SI. Any address inside the block is a valid address for the 32KB Block Erase command. CS# must be driven low for the entire duration of the sequence. The 32KB Block Erase command sequence: CS# goes low → sending 32KB Block Erase command → 3-Byte address or 4-Byte address on SI → CS# goes high. CS# must be driven high after the eighth bit of the last address Byte has been latched in; otherwise the 32KB Block Erase command is not executed. As soon as CS# is driven high, the self-timed Block Erase cycle (whose duration is t_{BE1}) is initiated. While the Block Erase cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Block Erase cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. A 32KB Block Erase command applied to a block which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) bits is not executed.

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.22 64KB Block Erase (BE64) (D8H/DCH)

The 64KB Block Erase command is erased the all data of the chosen block. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit. The 64KB Block Erase command is entered by driving CS# low, followed by the command code, and 3-Byte address or 4-Byte address on SI. Any address inside the block is a valid address for the 64KB Block Erase command. CS# must be driven low for the entire duration of the sequence.

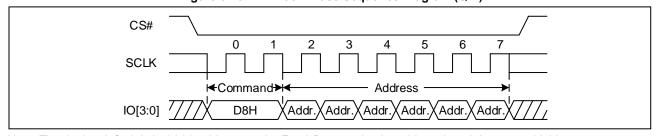

The 64KB Block Erase command sequence: CS# goes low \rightarrow sending 64KB Block Erase command \rightarrow 3-Byte address or 4-Byte address on SI \rightarrow CS# goes high. CS# must be driven high after the eighth bit of the last address Byte has been latched in; otherwise the 64KB Block Erase command is not executed. As soon as CS# is driven high, the self-timed Block Erase cycle (whose duration is t_{BE2}) is initiated. While the Block Erase cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Block Erase cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. A 64KB Block Erase command applied to a block which is protected by the Block Protect (BP4, BP3, BP2, BP1, and BP0) bits is not executed.

Figure 50 64KB Block Erase Sequence Diagram (SPI)

Figure 51 64KB Block Erase Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.23 Chip Erase (CE) (60H/C7H)

The Chip Erase (CE) command is erased the all data of the chip. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit .The Chip Erase (CE) command is entered by driving CS# Low, followed by the command code on Serial Data Input (SI). CS# must be driven Low for the entire duration of the sequence.

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

The Chip Erase command sequence: CS# goes low \rightarrow sending Chip Erase command \rightarrow CS# goes high. CS# must be driven high after the eighth bit of the command code has been latched in; otherwise the Chip Erase command is not executed. As soon as CS# is driven high, the self-timed Chip Erase cycle (whose duration is t_{CE}) is initiated. While the Chip Erase cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Chip Erase cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. The Chip Erase (CE) command is executed if the Block Protect (BP2, BP1, and BP0) bits are 0 The Chip Erase (CE) command is ignored if one or more sectors are protected.

Figure 52 Chip Erase Seguence Diagram (SPI)

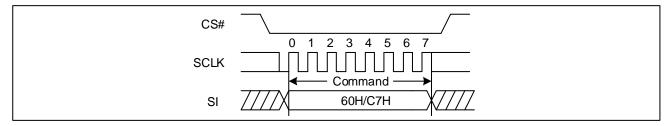

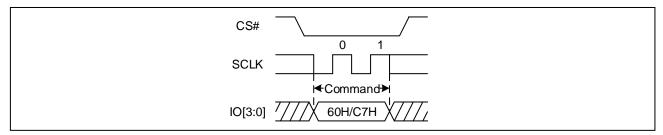

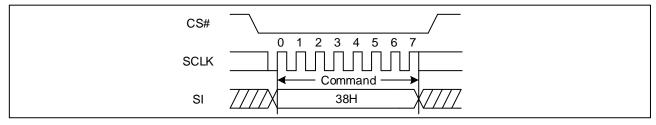

Figure 53 Chip Erase Sequence Diagram (QPI)

8.24 Enable QPI (38H)

The device support both Standard/Quad SPI and QPI mode. The "Enable QPI (38H)" command can switch the device from SPI mode to QPI mode. In order to switch the device to QPI mode, "Enable QPI (38H)" command must be issued. When the device is switched from SPI mode to QPI mode, the existing Write Enable Latch and Program/Erase Suspend status, and the Wrap Length setting will remain unchanged.

Figure 54 Enable QPI mode command Sequence Diagram

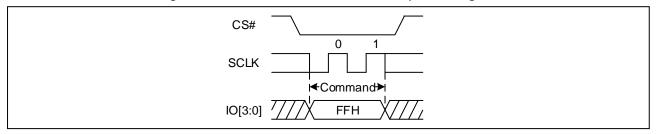

8.25 Disable QPI (FFH)

To exit the QPI mode and return to Standard/Quad SPI mode, the "Disable QPI (FFH)" command must be issued. When the device is switched from QPI mode to SPI mode, the existing Write Enable Latch and Program/Erase Suspend status, and the Wrap Length setting will remain unchanged.

GD55B02GE

Figure 55 Disable QPI mode command Sequence Diagram

8.26 Deep Power-Down (DP) (B9H)

Executing the Deep Power-Down (DP) command is the only way to put the device in the lowest consumption mode (the Deep Power-Down Mode). It can also be used as an extra software protection mechanism, while the device is not in active use, since in this mode, the device ignores all Write, Program and Erase commands. Driving CS# high deselects the device, and puts the device in the Standby Mode (if there is no internal cycle currently in progress). But this mode is not the Deep Power-Down Mode. The Deep Power-Down Mode can only be entered by executing the Deep Power-Down (DP) command. Once the device has entered the Deep Power-Down Mode, all commands are ignored except the Release from Deep Power-Down (ABH) or Enable Reset (66H) and Reset (99H) commands. These commands can release the device from this mode. The Release from Deep Power-Down command releases the device from deep power down mode.

The Deep Power-Down Mode automatically stops at Power-Down, and the device is in the Standby Mode after Power-Up. The Deep Power-Down command sequence: CS# goes low \rightarrow sending Deep Power-Down command \rightarrow CS# goes high. CS# must be driven high after the eighth bit of the command code has been latched in; otherwise the Deep Power-Down (DP) command is not executed. As soon as CS# is driven high, it requires a delay of t_{DP} before the supply current is reduced to l_{CC2} and the Deep Power-Down Mode is entered. Any Deep Power-Down (DP) command, while an Erase, Program or Write cycle is in progress, is rejected without having any effects on the cycle that is in progress.

Figure 56 Deep Power-Down Sequence Diagram (SPI)

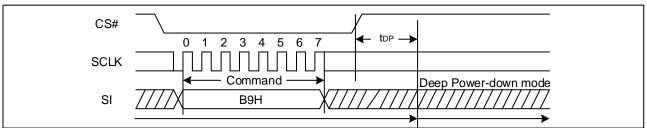

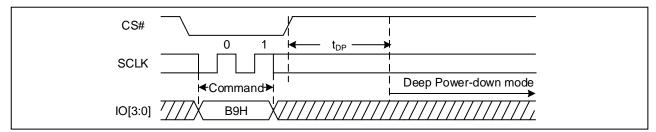

Figure 57 Deep Power-Down Sequence Diagram (QPI)

8.27 Release from Deep Power-Down (ABH)

To release the device from the Power-Down state, the command is issued by driving the CS# pin low, shifting the instruction code "ABH" and driving CS# high. Release from Power-Down will take the time duration of tress (See AC Characteristics) before the device will resume normal operation and other command are accepted. The CS# pin must

remain high during the tRES1 time duration.

When used to release the device from the Power-Down state, the command is the same as previously described, After this time duration the device will resume normal operation and other command will be accepted. If the Release from Power-Down command is issued while an Erase, Program or Write cycle is in process (when WIP equal 1) the command is ignored and will not have any effects on the current cycle.

8.28 Read Unique ID (4BH)

The Read Unique ID command accesses a factory-set read-only 128bit number that is unique to each device. The Unique ID can be used in conjunction with user software methods to help prevent copying or cloning of a system.

The Read Unique ID command sequence: CS# goes low \rightarrow sending Read Unique ID command \rightarrow 3-Byte (000000H) or 4-Byte (0000000H) Address \rightarrow 1 Byte Dummy \rightarrow 128bit Unique ID Out \rightarrow CS# goes high.

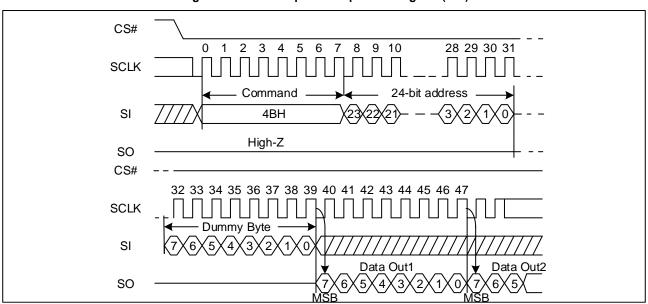

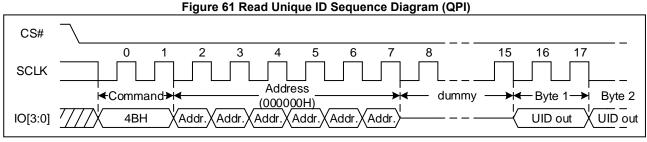

Figure 60 Read Unique ID Sequence Diagram (SPI)

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.29 Read Identification (RDID) (9FH/9EH)

The Read Identification (RDID) command allows the 8-bit manufacturer identification to be read, followed by three Bytes of device identification. The device identification indicates the memory type in the first Byte, and the memory capacity of the device in the second Byte. The Read Identification (RDID) command while an Erase or Program cycle is in progress, is not decoded, and has no effect on the cycle that is in progress. The Read Identification (RDID) command should not be issued while the device is in Deep Power-Down Mode.

The device is first selected by driving CS# low. Then, the 8-bit command code for the command is shifted in. This is followed by the 32-bit device identification, stored in the memory. Each bit is shifted out on the falling edge of Serial Clock. The Read Identification (RDID) command is terminated by driving CS# high at any time during data output. When CS# is driven high, the device is in the Standby Mode. Once in the Standby Mode, the device waits to be selected, so that it can receive, decode and execute commands.

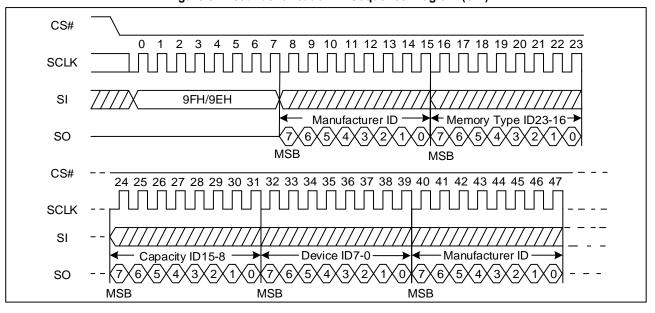

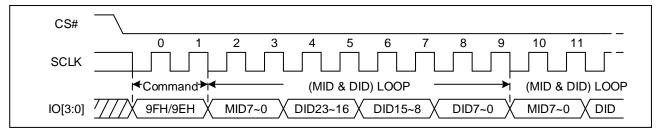

Figure 62 Read Identification ID Sequence Diagram (SPI)

Figure 63 Read Identification ID Sequence Diagram (QPI)

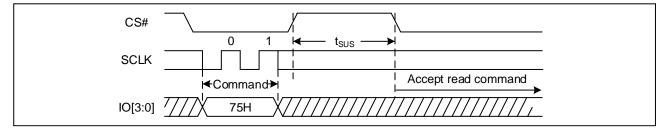

8.30 Program/Erase Suspend (PES) (75H)

The Program/Erase Suspend command "75H", allows the system to interrupt a page program or sector/block erase operation and then read data from any other sector or block. The Write Register command (01H, B1H) and Erase/Program Security Registers command (44H, 42H) and Erase commands (20H/21H, 52H/5CH, D8H/DCH, C7H, 60H) and Page Program command (02H/12H, 32H/34H, C2H/3EH) are not allowed during Program suspend. The Write Register command (01H, B1H) and Erase Security Registers command (44H) and Erase commands (20H/21H, 52H/5CH, D8H/DCH, C7H, 60H) are not allowed during Erase suspend. Program/Erase Suspend is valid only during the page program or sector/block erase operation. A maximum of time of "tsus" (See AC Characteristics) is required to suspend the program/erase operation. The Program/Erase Suspend command will be accepted by the device only if the SUS2/SUS1 bit in the Status Register equal to 0 and WIP bit equal to 1 while a Page Program or a Sector or Block Erase operation is on-going. If the SUS2/SUS1 bit equal to 0 or WIP bit equal to 0, the Suspend command will be ignored by the device. The WIP bit will be cleared from 1 to 0 within "tsus" and the SUS2/SUS1 bit will be set from 0 to 1 immediately after Program/Erase Suspend. A power-off during the suspend period will reset the device and release the suspend state.

Figure 64 Program/Erase Suspend Sequence Diagram (SPI)

8.31 Program/Erase Resume (PER) (7AH)

The Program/Erase Resume command must be written to resume the program or sector/block erase operation after a Program/Erase Suspend command. The Program/Erase Resume command will be accepted by the device only if the SUS2/SUS1 bit equal to 1 and the WIP bit equal to 0. After issued the SUS2/SUS1 bit in the status register will be cleared from 1 to 0 immediately, the WIP bit will be set from 0 to 1 within 200ns and the Sector or Block will complete the erase operation or the page will complete the program operation. The Program/Erase Resume command will be ignored unless a Program/Erase Suspend is active.

GD55B02GE

Figure 66 Program/Erase Resume Sequence Diagram

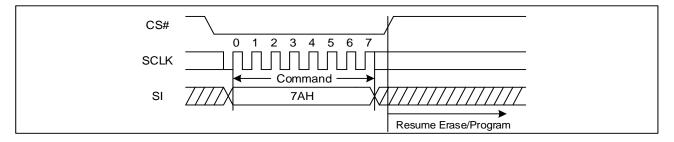

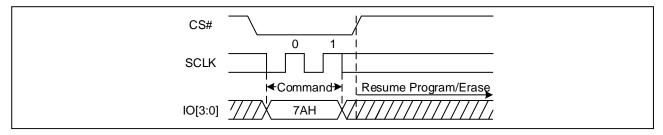

Figure 67 Program/Erase Resume Sequence Diagram (QPI)

8.32 Erase Security Registers (44H)

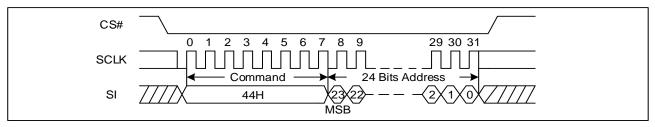

The GD55B02GE provides 4K-Byte Security Registers which can be erased and programmed individually. These registers may be used by the system manufacturers to store security and other important information separately from the main memory array.

The Erase Security Registers command is similar to Sector/Block Erase command. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit.

The Erase Security Registers command sequence: CS# goes low \rightarrow sending Erase Security Registers command \rightarrow CS# goes high. CS# must be driven high after the eighth bit of the last address Byte has been latched in; otherwise the Erase Security Registers command is not executed. As soon as CS# is driven high, the self-timed Erase Security Registers cycle (whose duration is t_{SE}) is initiated. While the Erase Security Registers cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Erase Security Registers cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset. The Security Registers Lock Bit in the Status Register can be used to OTP protect the security registers. Once the bit is set to 1, the Security Registers will be permanently locked; the Erase Security Registers command will be ignored.

| Address A23-16 | | A15-12 | A11-0 |
|-------------------|-----|--------|------------|
| Security Register | 00H | 0000 | Don't care |

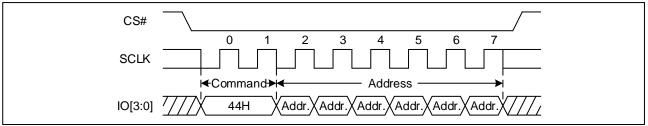

Figure 68 Erase Security Registers command Sequence Diagram (SPI)

Uniform Sector Standard and Quad Serial Flash

GD55B02GE

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.33 Program Security Registers (42H)

The Program Security Registers command is similar to the Page Program command. The security register contains 16 pages content. A Write Enable (WREN) command must previously have been executed to set the Write Enable Latch (WEL) bit before sending the Program Security Registers command. The Program Security Registers command is entered by driving CS# Low, followed by the command code (42H), three address Bytes and at least one data Byte on SI. As soon as CS# is driven high, the self-timed Program Security Registers cycle (whose duration is tPP) is initiated. While the Program Security Registers cycle is in progress, the Status Register may be read to check the value of the Write in Progress (WIP) bit. The Write in Progress (WIP) bit is 1 during the self-timed Program Security Registers cycle, and is 0 when it is completed. At some unspecified time before the cycle is completed, the Write Enable Latch (WEL) bit is reset.

If the Security Registers Lock Bit is set to 1, the Security Registers will be permanently locked. Program Security Registers command will be ignored.

| Address | A23-16 | A15-12 | A11-8 | A7-0 |
|-------------------|--------|--------|--------------|--------------|
| Security Register | 00H | 0000 | Page Address | Byte Address |

Figure 70 Program Security Registers command Sequence Diagram (SPI)

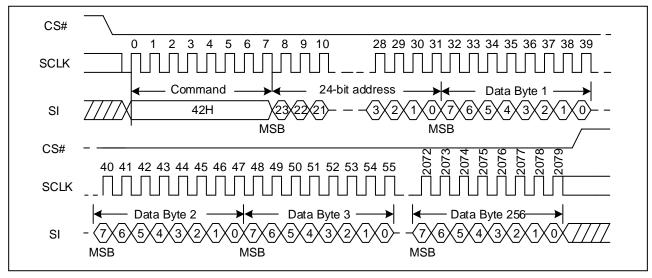

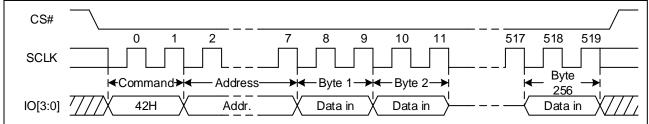

Figure 71 Program Security Registers command Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.34 Read Security Registers (48H)

The Read Security Registers command is similar to Fast Read command. The command is followed by a 3-Byte or 4-Byte address (A23-A0 or A31-A0) and a dummy Byte, and each bit is latched-in on the rising edge of SCLK. Then the memory content, at that address, is shifted out on SO, and each bit is shifted out, at a Max frequency fc, on the falling edge of SCLK. The first Byte addressed can be at any location. The address is automatically incremented to the next higher address after each Byte of data is shifted out. Once the A11-A0 address reaches the last Byte of the register (Byte FFFH), it will reset to 000H, the command is completed by driving CS# high.

| Address | A23-16 | A15-12 | A11-8 | A7-0 |
|-------------------|--------|--------|--------------|--------------|
| Security Register | 00H | 0000 | Page Address | Byte Address |

CS# 28 29 30 31 8 9 0 SCLK SI 48H High-Z SO CS# 35 36 37 38 39 40 **SCLK** Dummy Byte SI Data Out1 Data Out2 SO

Figure 72 Read Security Registers command Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

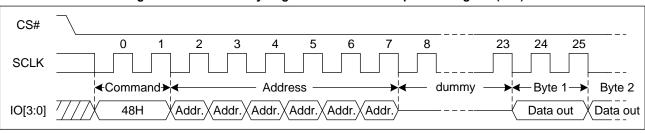

Figure 73 Read Security Registers command Sequence Diagram (QPI)

8.35 Individual Block/Sector Lock (36H)/Unlock (39H)/Read (3DH)

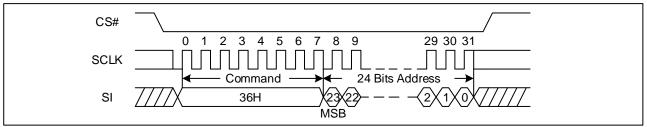

The individual block/sector lock provides an alternative way to protect the memory array from adverse Erase/Program. In order to use the Individual Block/Sector Locks, the WPS bit in Configuration Register bit 2 at address 04h must be set to 0. If WPS=1, the write protection will be determined by the combination of BP (4:0) bits in the Status Register.

The individual Block/Sector Lock command (36H) sequence: CS# goes low →SI: Sending individual Block/Sector Lock command → SI: Sending 3-Byte or 4-Byte individual Block/Sector Lock Address → CS# goes high.

The individual Block/Sector Unlock command (39H) sequence: CS# goes low →SI: Sending individual Block/Sector Unlock command → SI: Sending 3-Byte or 4-Byte individual Block/Sector Lock Address → CS# goes high.

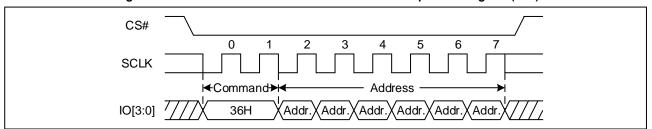

The Read individual Block/Sector lock command (3DH) sequence: CS# goes low \rightarrow SI: Sending Read individual Block/Sector Lock command \rightarrow SI: Sending 3-Byte or 4-Byte individual Block/Sector Lock Address \rightarrow SO: The Block/Sector Lock Bit will out \rightarrow CS# goes high. If the least significant bit (LSB) is1, the corresponding block/sector is locked, if the LSB is 0, the corresponding block/sector is unlocked, Erase/Program operation can be performed.

Figure 74 Individual Block/Sector Lock command Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Figure 75 Individual Block/Sector Lock command Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Figure 78 Read Individual Block/Sector lock command Sequence Diagram (SPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

Figure 79 Read Individual Block/Sector lock command Sequence Diagram (QPI)

Note: The device default is in 24-bit address mode. For 4-Byte mode, the address length becomes 32-bit.

8.36 Global Block/Sector Lock (7EH) or Unlock (98H)

All Block/Sector Lock bits can be set to 1 by the Global Block/Sector Lock command, or can set to 0 by the Global Block/Sector Unlock command.

The Global Block/Sector Lock command (7EH) sequence: CS# goes low →SI: Sending Global Block/Sector Lock command → CS# goes high.

The Global Block/Sector Unlock command (98H) sequence: CS# goes low →SI: Sending Global Block/Sector Unlock command → CS# goes high.

Figure 80 Global Block/Sector Lock Sequence Diagram (SPI)

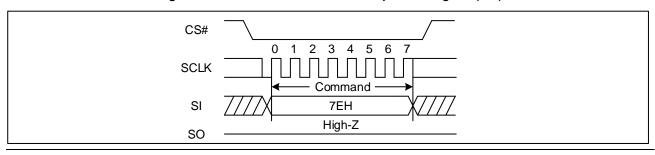

Figure 81 Global Block/Sector Lock Sequence Diagram (QPI)

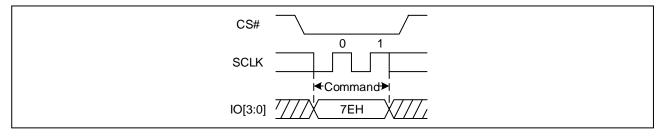

Figure 82 Global Block/Sector Unlock Sequence Diagram (SPI)

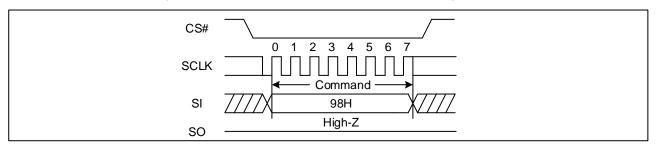

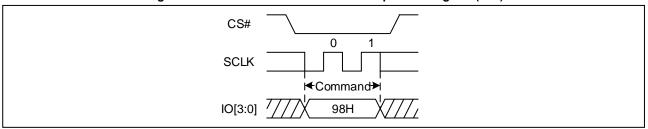

Figure 83 Global Block/Sector Unlock Sequence Diagram (QPI)

8.37 Enable Reset (66H) and Reset (99H)

If the Reset command is accepted, any on-going internal operation (except in Continuous Read Mode) will be terminated and the device will return to its default power-on state and lose all the current volatile settings, such as Volatile Status Register bits, Write Enable Latch status (WEL), Program/Erase Suspend status, Read Parameter setting (P7-P0), Deep Power Down Mode, Continuous Read Mode bit setting (M7-M0).

When Flash is in QPI Mode or Continuous Read Mode (XIP), 66H&99H cannot reset Flash to power-on state. Therefore, it is recommended to send the following sequence to reset Flash in these modes:

- 1. 8CLK with IO<3:0>= all "H" or all "L": ensure Flash guit XIP mode
- 2. QPI format 66H/99H: ensure Flash in QPI mode can be reset
- 3. SPI format 66H/99H: ensure Flash in SPI mode can be reset

The "Enable Reset (66H)" and the "Reset (99H)" commands can be issued in either SPI or QPI mode. The "Reset (99H)" command sequence as follow: CS# goes low → Sending Enable Reset command → CS# goes high → CS# goes low → Sending Reset command → CS# goes high. Once the Reset command is accepted by the device, the device will take approximately tRST / tRST_E to reset. During this period, no command will be accepted. Data corruption may happen if there is an on-going or suspended internal Erase or Program operation when Reset command sequence is accepted by the device. It is recommended to check the WIP bit and the SUS2/SUS1 bits in Status Register before issuing the Reset command sequence.

GD55B02GE

Figure 84 Enable Reset and Reset command Sequence Diagram (SPI)

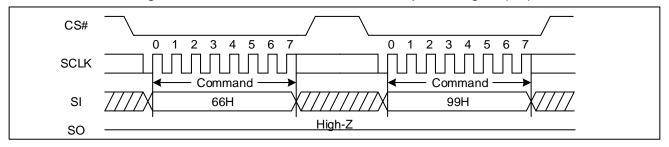

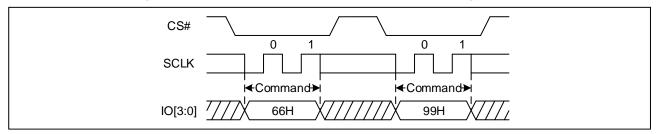

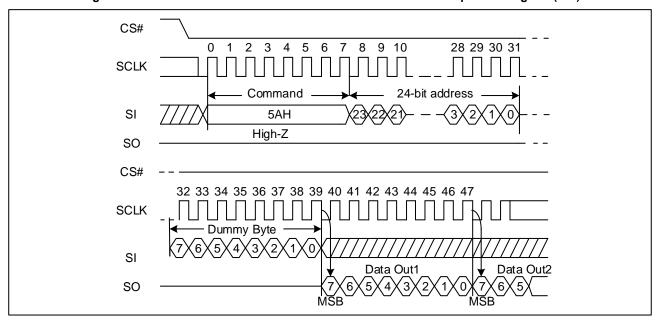

Figure 85 Enable Reset and Reset command Sequence Diagram (QPI)

8.38 Read Serial Flash Discoverable Parameter (5AH)

The Serial Flash Discoverable Parameter (SFDP) standard provides a consistent method of describing the functional and feature capabilities of serial flash devices in a standard set of internal parameter tables. These parameter tables can be interrogated by host system software to enable adjustments needed to accommodate divergent features from multiple vendors. The concept is similar to the one found in the Introduction of JEDEC Standard, JESD68 on CFI. SFDP is a standard of JEDEC Standard No.216B.

Figure 86 Read Serial Flash Discoverable Parameter command Sequence Diagram (SPI)
