DESCRIPTION

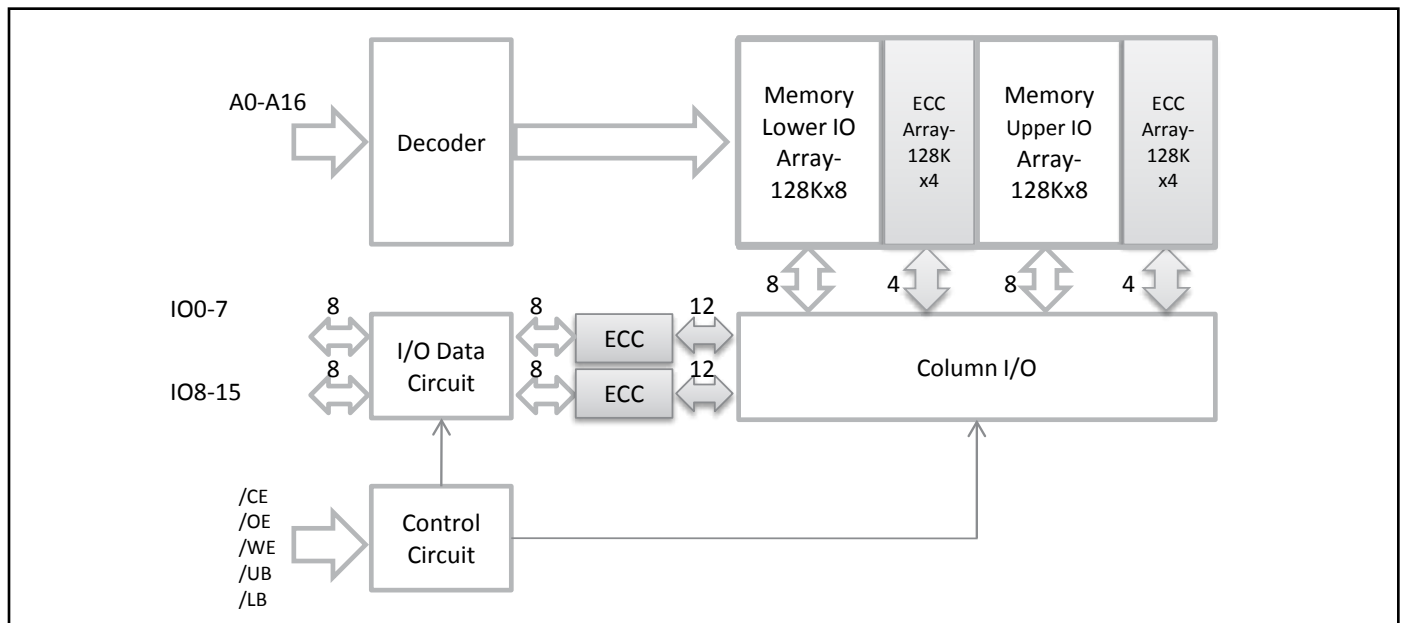

The *ISSI* IS61/64WV12816EDBLL is a high-speed, 2,097,152-bit static RAMs organized as 131,072 words by 16 bits. It is fabricated using *ISSI*'s high-performance CMOS technology. This highly reliable process coupled with innovative circuit design techniques, yields high-performance and low power consumption devices.

When \overline{CE} is HIGH (deselected), the device assumes a standby mode at which the power dissipation can be reduced down with CMOS input levels.

Easy memory expansion is provided by using Chip Enable and Output Enable inputs, \overline{CE} and \overline{OE} . The active LOW Write Enable (\overline{WE}) controls both writing and reading of the memory. A data byte allows Upper Byte (\overline{UB}) and Lower Byte (\overline{LB}) access.

The IS61/64WV12816EDBLL is packaged in the JEDEC standard 44-pin TSOP-II and 48-pin Mini BGA (6mm x 8mm).

V _{DD}	V _{DD} Relates to GND	-0.3 to 4.0	V
T _{STG}	Storage Temperature	-65 to +150	°C
P _T	Power Dissipation	1.0	W

Notes:

1. Stress greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

CAPACITANCE^(1,2)

Symbol	Parameter	Conditions	Max.	Unit
C _{IN}	Input Capacitance	V _{IN} = 0V	6	pF
C _{I/O}	Input/Output Capacitance	V _{OUT} = 0V	8	pF

Notes:

1. Tested initially and after any design or process changes that may affect these parameters.
2. Test conditions: T_A = 25°C, f = 1 MHz, V_{DD} = 3.3V.

ERROR DETECTION AND ERROR CORRECTION

- Independent ECC with hamming code for each byte
- Detect and correct one bit error per byte
- Better reliability than parity code schemes which can only detect an error but not correct an error
- Backward Compatible: Drop in replacement to current in industry standard devices (without ECC)

1. Test conditions and output loading conditions are specified in the AC Test Conditions and AC Test Loads (Figure 1).
2. Tested with the load in Figure 2. Transition is measured ± 500 mV from steady-state voltage. Not 100% tested.
3. The internal write time is defined by the overlap of CE LOW and UB or LB, and WE LOW. All signals must be in valid states to initiate a Write, but any one can go inactive to terminate the Write. The Data Input Setup and Hold timing are referenced to the rising or falling edge of the signal that terminates the write. Shaded area product in development

AC WAVEFORMS

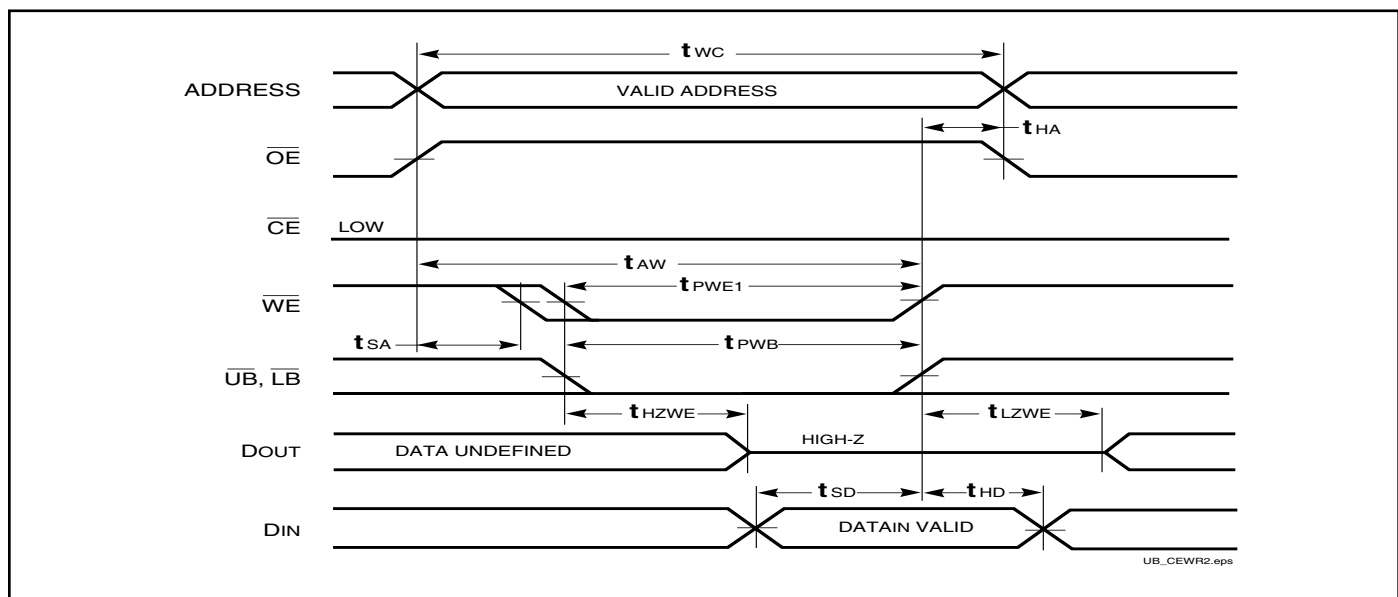

WRITE CYCLE NO. 1 (\overline{CE} Controlled, \overline{OE} is HIGH or LOW) ⁽¹⁾

Notes:

1. WRITE is an internally generated signal asserted during an overlap of the LOW states on the \overline{CE} and \overline{WE} inputs and at least one of the \overline{LB} and \overline{UB} inputs being in the LOW state.
2. WRITE = (\overline{CE}) [(\overline{LB}) = (\overline{UB})] (\overline{WE}).

WRITE CYCLE NO. 2 (\overline{WE} Controlled. \overline{OE} is HIGH During Write Cycle) ^(1,2)

AC WAVEFORMS

WRITE CYCLE NO. 3 (\overline{WE} Controlled, \overline{OE} is LOW During Write Cycle) ⁽¹⁾

WRITE CYCLE NO. 4 (\overline{LB} , \overline{UB} Controlled, Back-to-Back Write) ^(1,3)

Notes:

1. The internal Write time is defined by the overlap of $\overline{CE} = \text{LOW}$, \overline{UB} and/or $\overline{LB} = \text{LOW}$, and $\overline{WE} = \text{LOW}$. All signals must be in valid states to initiate a Write, but any can be deasserted to terminate the Write. The t_{SA} , t_{HA} , t_{SD} , and t_{HD} timing is referenced to the rising or falling edge of the signal that terminates the Write.
2. Tested with \overline{OE} HIGH for a minimum of 4 ns before $\overline{WE} = \text{LOW}$ to place the I/O in a HIGH-Z state.
3. \overline{WE} may be held LOW across many address cycles and the \overline{LB} , \overline{UB} pins can be used to control the Write function.
