LINEAR TECHNOLOGY

Precision, High Side Current Sense Amplifiers

FEATURES

- **Input Offset Voltage: 75μV (Max)**
- **60V Supply Operation (LT1787HV)**
- **12-Bit Dynamic Range**
- Operating Current: 60μA
- User-Selectable External Sense Resistor
- Bidirectional High Side Current Sensing
- Unidirectional or Bidirectional Output
- Input Noise Filtering
- −40°C to 125°C Operating Temperature Range
- Available in 8-Lead SO and MSOP Packages

APPLICATIONS

- Battery Monitoring
- Power Monitoring
- Portable Phones
- Cellular Phones
- Portable Test/Measurement Systems
- Battery-Operated Systems

DESCRIPTION

The LT®1787 is a complete micropower precision high side current sense amplifier. The LT1787 monitors bidirectional currents via the voltage across an external sense resistor. A current or voltage output indicates the direction and magnitude of the sense current. The LT1787 delivers greater than a 12-bit dynamic range with ultralow 40μV input offset voltage compared to a typical 250mV full-scale input voltage. A fixed gain of 8 is set by onboard precision resistors. Input signal filtering is easily implemented with a capacitor between the FIL⁻ and FIL⁺ pins. The LT1787HV operates from 2.5V to 60V total supply voltage and the LT1787 operates from 2.5V to 36V total supply voltage. Both versions have a PSRR in excess of 120dB. The LT1787/LT1787HV draw only 60μA and are available in 8-lead SO and MSOP packages.
LT, LT, LTC and LTM are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

12-Bit Dynamic Resolution Unidirectional Output into LTC®1286 ADC
$$V_{OUT} = V_{BIAS} + (8 \cdot I_{LOAD} \cdot R_{SENSE})$$

Input Offset Voltage vs Supply Voltage
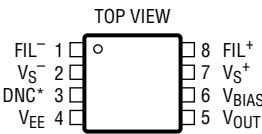

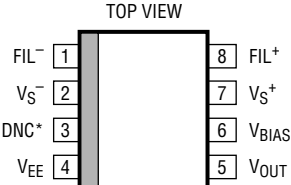

ABSOLUTE MAXIMUM RATINGS (Notes 1, 2)

Differential Sense Voltage .... ±10V
Total Supply Voltage (LT1787) 40V
Total Supply Voltage (LT1787HV) 65V
Output Voltage .... (V_{EE} − 0.3V) to (V_{EE} + 35V)
Output Bias Voltage .... (V_{EE} − 0.3V) to (V_{EE} + 35V)
Operating Temperature Range (Note 3)
   LT1787C .... −40°C to 85°C
   LT1787I .... −40°C to 85°C
   LT1787H .... −40°C to 125°C

Specified Temperature Range (Note 4)
   LT1787C .... −40°C to 85°C
   LT1787I .... −40°C to 85°C
   LT1787H .... −40°C to 125°C
Storage Temperature Range ....−65°C to 150°C
Lead Temperature (Soldering, 10 sec).................300°C

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: ESD (Electrostatic Discharge) sensitive devices. Extensive use of ESD protection devices are used internal to the LT1787/LT1787HV, however, high electrostatic discharge can damage or degrade the device. Use proper ESD handling precautions.

Note 3: The LT1787C/LT1787I are guaranteed functional over the operating temperature range of –40°C to 85°C. The LT1787H is
guaranteed functional over the operating temperature range of –40°C to 125°C.

Note 4: The LT1787C is guaranteed to meet specified performance from 0°C to 70°C. The LT1787C is designed, characterized and expected to meet specified performance from –40°C to 85°C but is not tested or QA sampled at these temperatures. The LT1787I is guaranteed to meet specified performance from –40°C to 85°C. The LT1787H is guaranteed to meet specified performance from –40°C to 125°C.
Note 5: Testing done at V_{BIAS} = 1.25V, V_{EE} = 0V unless otherwise specified.
Note 6: This parameter is not 100% tested.

PIN FUNCTIONS

FIL⁻, FIL⁺ (Pins 1, 8): Negative and Positive Filter Terminals. Differential mode noise can be filtered by connecting a capacitor across FIL⁻ and FIL⁺. Pole frequency $f_{-3dB} = 1/(2\pi RC)$, R = 1.25kΩ.

V$_S$⁻ (Pin 2): Negative Input Sense Terminal. Negative sense voltage will result in an output sinking current proportional to the sense current. V$_S$⁻ is connected to an internal gain-setting resistor R_{G1A} and supplies bias current to the internal amplifier.

DNC (Pin 3): Do Not Connect. Connected internally. Do not connect external circuitry to this pin.

V$_{EE}$ (Pin 4): Negative Supply or Ground for Single Supply Operation.

V$_{OUT}$ (Pin 5): Voltage Output or Current Output proportional to the magnitude of the sense current flowing through R$_{SENSE}$. For bidirectional current sensing operation, $V_{OUT} = A_V \bullet V_{SENSE} + V_{OUT(0)} + V_{BIAS}$,

where:

$$V_{OUT} > V_{BIAS} \text{ for } V_S^+ > V_S^-$$
$$V_{OUT} < V_{BIAS} \text{ for } V_S^+ < V_S^-$$

$V_{OUT(0)}$ is the no load output voltage at $V_{SENSE} = 0V$.

V$_{BIAS}$ (Pin 6): Output Bias Pin. For single supply, bidirectional current sensing operation, V$_{BIAS}$ is connected to an external bias voltage, so that at $V_{SENSE} = 0V$, $V_{OUT} = V_{OUT(0)} + V_{BIAS}$. For dual supply, bidirectional current sensing operation, V$_{BIAS}$ is connected to ground. Thus, $V_{OUT} = V_{OUT(0)}$ at $V_{SENSE} = 0V$.

V$_S$⁺ (Pin 7): Positive Input Sense Terminal. Positive sense voltage will result in an output sourcing current proportional to the sense current. V$_S$⁺ is connected to an internal gain-setting resistor R_{G2A}. Connecting a supply to V$_S$⁺ and a load to V$_S$⁻ will allow the LT1787 to measure its own supply current.

BLOCK DIAGRAM

Figure 1. LT1787 Functional Diagram

APPLICATIONS INFORMATION

The LT1787 high side current sense amplifier (Figure 1) provides accurate bidirectional monitoring of current through a user-selected sense resistor. The sense voltage is amplified by a fixed gain of 8 and level shifted from the positive power supply to the ground referenced outputs. The output signal may be used in a variety of ways to interface with subsequent signal processing circuitry. Input and output filtering are easily implemented to eliminate aliasing errors.

Theory of Operation

Inputs V_S^+ and V_S^- apply the sense voltage to matched resistors R_{G1} and R_{G2}. The opposite ends of resistors R_{G1} and R_{G2} are forced to be at equal potentials by the voltage gain of amplifier A1. The currents through R_{G1} and R_{G2} are forced to flow through transistors Q1 and Q2 and are summed at node V_{OUT} by the 1:1 current mirror. The net current from R_{G1} and R_{G2} flowing through resistor R_{OUT} gives a voltage gain of eight. Positive sense voltages result in V_{OUT} being positive with respect to pin V_{BIAS}.

Pins V_{EE}, V_{BIAS} and V_{OUT} may be connected in a variety of ways to interface with subsequent circuitry. Split supply and single supply output configurations are shown in the following sections.

Supply current for amplifier A1 is drawn from the V_S^- pin. The user may choose to include this current in the monitored current through R_{SENSE} by careful choice of connection polarity.

Selection of External Current Sense Resistor

External R_{SENSE} resistor selection is a delicate trade-off between power dissipation in the resistor and current measurement accuracy. The LT1787 makes this decision less difficult than with competitors' products. The maximum sense voltage may be as large as ±500mV to get maximum resolution, however, high current applications will not want to suffer this much power dissipation in the sense resistor. The LT1787's input offset voltage of 40μV gives high resolution for low sense voltages. This wide operating dynamic range gives the user wide latitude in tailoring the range and resolution of his supply monitoring function.

Kelvin connection of the LT1787's V_S^+ and V_S^- inputs to the sense resistor should be used in all but the lowest power applications. Solder connections and PC board interconnect resistance (approximately 0.5mΩ per square) can be a large error in high current systems. A 5-Amp application might choose a 20mΩ sense resistor to give a 100mV full-scale input to the LT1787. Input offset voltage will limit resolution to 2mA. Neglecting contact resistance at solder joints, even one square of PC board copper at each resistor end will cause an error of 5%. This error will grow proportionately higher as monitored current levels rise to tens or hundreds of amperes.

Input Noise Filtering

The LT1787 provides input signal filtering pins FIL$^+$ and FIL$^-$ that are internally connected to the midpoint taps of resistors R_{G1} and R_{G2}. These pins may be used to filter the input signal entering the LT1787's internal amplifier, and should be used when fast current ripple or transients may flow through the sense resistor. High frequency signals above the 300kHz bandwidth of the LT1787's internal amplifier will cause errors. A capacitor connected between FIL$^+$ and FIL$^-$ creates a single pole low pass filter with corner frequency:

$$f_{-3dB} = 1/(2\pi RC)$$

where R = 1.25k. A 0.01μF capacitor creates a pole at 12.7kHz, a good choice for many applications.

Common mode filtering from the FIL$^+$ and FIL$^-$ pins should not be attempted, as mismatch in the capacitors from FIL$^+$ and FIL$^-$ will create AC common mode errors. Common mode filtering must be done at the power supply output.

Output Signal Range

The LT1787's output signal is developed by summing the net currents through R_{G1} and R_{G2} into output resistor R_{OUT}. The pins V_{OUT} and V_{BIAS} may be connected in numerous configurations to interface with following circuitry in either single supply or split supply applications. Care must be used in connecting the output pins to preserve signal accuracy. Limitations on the signal swing at V_{OUT} are imposed by the negative supply, V_{EE}, and the input voltage V_S^+. In the negative direction, internal circuit saturation with loss of accuracy occurs for $V_{OUT} < 70mV$

1787fc

APPLICATIONS INFORMATION

with absolute minimum swing at 30mV above V_{EE}. V_{OUT} may swing positive to within 0.75V of V_S^+ or a maximum of 35V, a limit set by internal junction breakdown. Within these contraints, an amplified, level shifted representation of the R_{SENSE} voltage is developed across R_{OUT}.

Split Supply Bipolar Output Swing

Figure 2 shows the LT1787 used with split power supplies. The V_{BIAS} pin is connected to ground, and the output signal appears at the V_{OUT} pin. Bidirectional input currents can be monitored with the output swinging positive for current flow from V_S^+ and V_S^-. Input currents in the opposite direction cause V_{OUT} to swing below ground. Figure 2 shows an optional output capacitor connected from V_{OUT} to ground. This capacitor may be used to filter the output signal before it is processed by other circuitry.Figure 3 shows the voltage transfer function of the LT1787 used in this configuration.

Single Supply with Shifted V_{BIAS}

Figure 4 shows the LT1787 used in a single supply mode with the V_{BIAS} pin shifted positive using an external LT1634 voltage reference. The V_{OUT} output signal can swing above and below V_{BIAS} to allow monitoring of positive or negative currents through the sense resistor, as shown in Figure 5. The choice of reference voltage is not critical except for the precaution that adequate headroom must be provided for V_{OUT} to swing without saturating the internal circuitry. The component values shown in Figure 4 allow operation with V_S supplies as low as 3.1V.

Figure 3. Split Supply Output Voltage

Figure 4. Charge/Discharge Current Monitor on Single Supply with V_{BIAS} = 1.25V

Figure 5. Single Supply Output Voltage with V_{BIAS} = 1.25V

Figure 2. Split Supply Operation

APPLICATIONS INFORMATION

Operation with A/D Converter

Figure 6 shows the LT1787 operating with the LTC1286 A/D converter. This low cost circuit is capable of 12-bit resolution of unipolar currents. The –IN pin of the A/D converter is biased at 1V by the resistor divider R1 and R2. This voltage increases as sense current increases, with the amplified sense voltage appearing between the A/D converters –IN and +IN terminals. The front page of the data sheet shows a similar circuit which uses a voltage reference for improved accuracy and signal range. The LTC1286 converter uses sequential sampling of its –IN and +IN inputs. Accuracy is degraded if the inputs move between sampling intervals. A filter capacitor from FIL$^+$ to FIL$^-$ as well as a filter capacitor from V$_{BIAS}$ to V$_{OUT}$ may be necessary if the sensed current changes more than 1LSB within a conversion cycle.

Buffered Output Operation

Figure 7 shows the LT1787's outputs buffered by an operational amplifier configured as an I/V converter. This configuration is ideal for monitoring very low voltage supplies. The LT1787's V$_{OUT}$ pin is held equal to the reference voltage appearing at the op amp's noninverting input. This allows monitoring V$_S$ supplies as low as 2.5V. The op amp's output may swing from ground to its positive supply voltage. The low impedance output of the op amp may drive following circuitry more effectively than the high output impedance of the LT1787. The I/V converter configuration also works well with split supply voltages.

Single Supply Unidirectional Operation

Figure 8 shows the simplest connection in which the LT1787 may be used. The V$_{BIAS}$ pin is connected to ground, and the V$_{OUT}$ pin swings positive with increasing sense current. The LT1787's outputs can swing as low as 30mV as shown in Figure 9. Accuracy is sacrificed at small output levels, but this is not a limitation in protection circuit applications or where sensed currents do not vary greatly. Increased low level accuracy can be obtained by level shifting V$_{BIAS}$ above ground. The level shifting may be done with resistor dividers, voltage references or a simple diode. Accuracy is ensured if the output signal is sensed differentially between V$_{BIAS}$ and V$_{OUT}$.

APPLICATIONS INFORMATION

Figure 9. Expanded Scale of Unidirectional Output

Adjusting Gain Setting

The LT1787 may be used in all operating modes with an external resistor used in place of the internal 20k R_{OUT} resistor. When an external resistor is used, leave the V_{BIAS} pin floating or connected to the V_{OUT} pin. This will remove the internal R_{OUT} from the circuit.

The voltage gain will be gm • R_{OUT} where gm is the LT1787's transconductance, 400µA/V typical. A nominal gain of 40 may be obtained with an external 100k resistor used in place of the internal 20k R_{OUT}:

A_V = gm • R_{OUT} = 400µA/V • 100k = 40

The transconductance gm is set by on-chip resistors on the LT1787. These resistors match well but have loose absolute tolerance. This will normally require that the external gain setting resistor be trimmed for initial accuracy. After trimming, the temperature stability of the gm and therefore gain will be –200ppm/°C.

The only limitations placed upon the resistor choice is care must be taken not to saturate the internal circuitry by violating the V_{OMAX} specification of V_S + –0.75V.
