

# White LED Driver with Integrated Schottky in SC70 and 2mm × 2mm DFN

# **FEATURES**

- Drives Up to Six White LEDs from a 3V Supply
- High Side Sense Allows "One Wire Current Source"
- Internal Schottky Diode
- One Pin Dimming and Shutdown
- 27V Open LED Protection
- 2.3MHz Switching Frequency
- ±5% Reference Accuracy
- V<sub>IN</sub> Range: 2.5V to 12V
- Requires Only 1μF Output Capacitor
- Wide 300:1 True Color PWM<sup>™</sup> Dimming Range
- 8-Lead SC70 Package
- Low Profile 6-Lead DFN Package (2mm × 2mm × 0.75mm)

# **APPLICATIONS**

- Cellular Phones
- PDAs, Handheld Computers
- Digital Cameras
- MP3 Players
- GPS Receivers

# **DESCRIPTION**

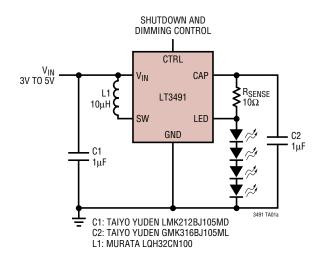

The LT®3491 is a fixed frequency step-up DC/DC converter specifically designed to drive up to six white LEDs in series from a Li-Ion cell. Series connection of the LEDs provides identical LED currents resulting in uniform brightness and eliminating the need for ballast resistors. The device features a unique high side LED current sense that enables the part to function as a "one wire current source;" one side of the LED string can be returned to ground anywhere, allowing a simpler one wire LED connection. Traditional LED drivers use a grounded resistor to sense LED current, requiring a 2-wire connection to the LED string.

The 2.3MHz switching frequency allows the use of tiny inductors and capacitors. A single pin performs both shutdown and accurate LED dimming control. Few external components are needed: open-LED protection and the Schottky diode are all contained inside the tiny SC70 and 2mm  $\times$  2mm DFN packages. With such a high level of integration, the LT3491 provides a high efficiency LED driver solution in the smallest of spaces.

# **ELECTRICAL CHARACTERISTICS**

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

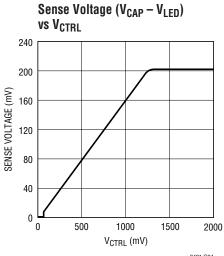

**Note 2:** The LT3491E is guaranteed to meet performance specifications from  $0^{\circ}$ C to  $85^{\circ}$ C. Specifications over the  $-40^{\circ}$ C to  $85^{\circ}$ C operating temperature range are assured by design, characterization and correlation with statistical process controls.

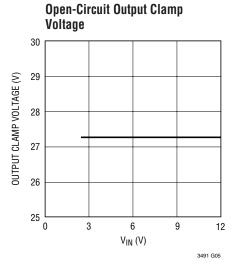

# TYPICAL PERFORMANCE CHARACTERISTICS (TA = 25°C unless otherwise specified)

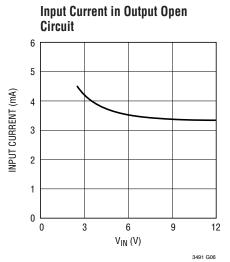

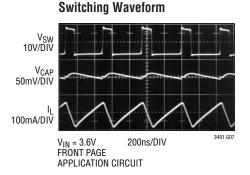

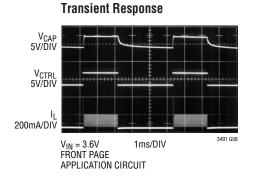

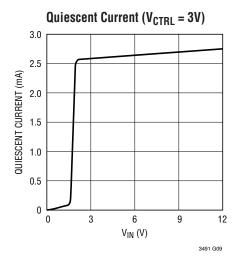

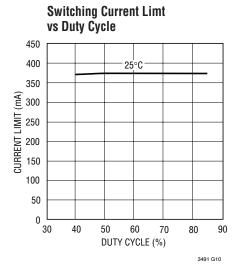

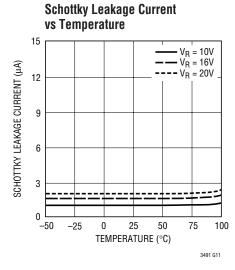

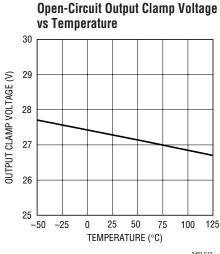

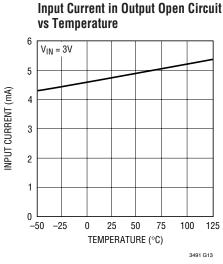

# TYPICAL PERFORMANCE CHARACTERISTICS ( $T_A = 25^{\circ}C$ unless otherwise specified)

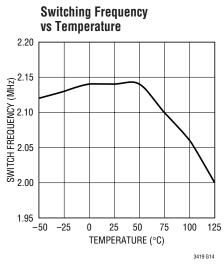

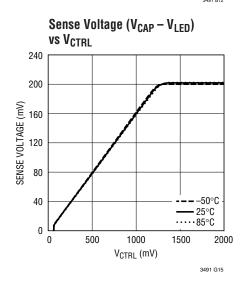

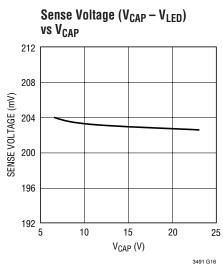

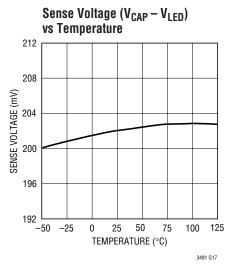

# PIN FUNCTIONS (SC70/DFN)

**SW** (Pin 1/Pin 3): Switch Pin. Minimize trace area at this pin to minimize EMI. Connect the inductor at this pin.

**GND** (Pins 2, 3, 4/Pin 2): Ground Pins. All three pins should be tied directly to local ground plane.

**V<sub>IN</sub>** (**Pin 5/Pin 1**): Input Supply Pin. Must be locally bypassed.

**CTRL** (**Pin 6/Pin 6**): Dimming and Shutdown Pin. Connect this pin below 50mV to disable the driver. As the pin voltage is ramped from 0V to 1.5V, the LED current ramps from 0 to  $I_{LED}$  (= 200mV/R<sub>SENSE</sub>). The CTRL pin must not be left floating.

**LED (Pin 7/Pin 5):** Connection Point for the Anode of the First LED and the Sense Resistor. The LED current can be programmed by :

$$I_{LED} = \frac{200mV}{R_{SENSE}}$$

**CAP** (**Pin 8/Pin 4**): Output of the Driver. This pin is connected to the cathode of internal Schottky. Connect the output capacitor to this pin and the sense resistor from this pin to the LED pin.

**EXPOSED PAD (NA/Pin 7):** The Exposed Pad should be soldered to the PCB ground to achieve the rated thermal performance.

# **BLOCK DIAGRAM**

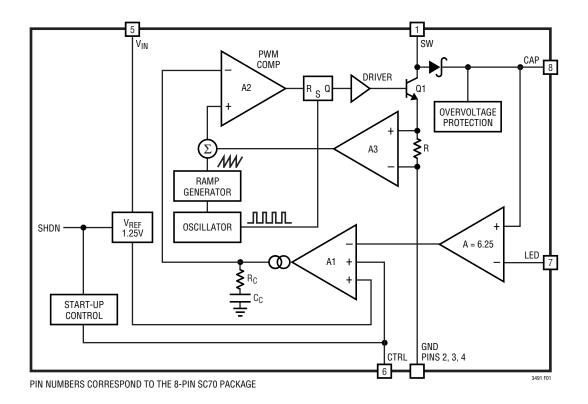

Figure 1. Block Diagram

# **OPERATION**

The LT3491 uses a constant frequency, current mode control scheme to provide excellent line and load regulation. Operation can be best understood by referring to the Block Diagram in Figure 1.

At power up, the capacitor at the CAP pin is charged up to V<sub>IN</sub> (input supply voltage) through the inductor and the internal Schottky diode. If CTRL is pulled higher than 100mV, the bandgap reference, the start-up bias and the oscillator are turned on. At the start of each oscillator cycle, the power switch Q1 is turned on. A voltage proportional to the switch current is added to a stabilizing ramp and the resulting sum is fed into the positive terminal of the PWM comparator, A2. When this voltage exceeds the level at the negative input of A2, the PWM logic turns off the power switch. The level at the negative input of A2 is set by the error amplifier A1, and is simply an amplified version of the difference between the V<sub>CAP</sub> and V<sub>LFD</sub> voltage and the bandgap reference. In this manner the error amplifier, A1, sets the correct peak current level in inductor L1 to keep the output in regulation. The CTRL pin is used to adjust the LED current. The LT3491 enters into shutdown when CTRL is pulled lower than 50mV.

### **Minimum Output Current**

The LT3491 can drive a 3-LED string at 2mA LED current without pulse skipping using the same external components shown in the application circuit on the front page of this data sheet. As current is further reduced, the device will begin skipping pulses. This will result in some low frequency ripple, although the average LED current remains regulated down to zero. The photo in Figure 2 details circuit operation driving three white LEDs at 2mA load. Peak inductor current is less than 60mA and the regulator operates in discontinuous mode, meaning the inductor current reaches zero during the discharge phase. After the inductor current reaches zero, the SW pin exhibits ringing due to the LC tank circuit formed by the inductor in combination with the switch and the diode capacitance. This ringing is not harmful; far less spectral energy is contained in the ringing than in the switch transitions.

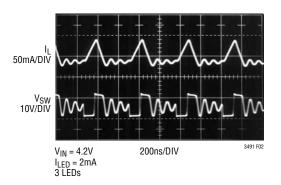

Figure 2. Switching Waveforms

### INDUCTOR SELECTION

A  $10\mu H$  inductor is recommended for most LT3491 applications. Although small size and high efficiency are major concerns, the inductor should have low core losses at 2.3MHz and low DCR (copper wire resistance). Some small inductors in this category are listed in Table 1. The efficiency comparison of different inductors is shown in Figure 3.

Table 1. Recommended Inductors

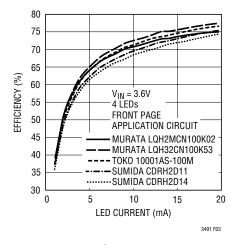

Figure 3. Efficiency Comparison of Different Inductors

#### CAPACITOR SELECTION

The small size of ceramic capacitors make them ideal for LT3491 applications. Use only X5R and X7R types because they retain their capacitance over wider temperature ranges than other types such as Y5V or Z5U. A 1 $\mu$ F input capacitor and a 1 $\mu$ F output capacitor are sufficient for most applications.

Table 2 shows a list of several ceramic capacitor manufacturers. Consult the manufacturers for detailed information on their entire selection of ceramic parts.

### **OVERVOLTAGE PROTECTION**

The LT3491 has an internal open-circuit protection circuit. In the cases of output open circuit, when the LEDs are disconnected from the circuit or the LEDs fail open circuit,  $V_{CAP}$  is clamped at 27V (typ). The LT3491 will then switch at a very low frequency to minimize input current. The  $V_{CAP}$  and input current during output open circuit are shown in the Typical Performance Characteristics. Figure 4 shows the transient response when the LEDs are disconnected.

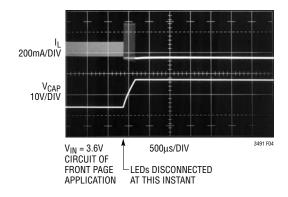

Figure 4. Output Open-Circuit Waveform

#### **INRUSH CURRENT**

The LT3491 has a built-in Schottky diode. When supply voltage is applied to the  $V_{\text{IN}}$  pin, an inrush current flows through the inductor and the Schottky diode and charges up the CAP voltage. The Schottky diode inside the LT3491 can sustain a maximum current of 1A.

For low DCR inductors, which is usually the case for this application, the peak inrush current can be simplified as follows:

$$I_{PK} = \frac{V_{IN} - 0.6}{L \cdot \omega} \cdot exp\left(-\frac{\alpha}{\omega} \cdot \frac{\pi}{2}\right)$$

$$\alpha = \frac{r}{2 \cdot L}$$

$$\omega = \sqrt{\frac{1}{L \cdot C} - \frac{r^2}{4 \cdot L^2}}$$

where L is the inductance, r is the DCR of the inductor and C is the output capacitance.

Table 3 gives inrush peak currents for some component selections.

**Table 3. Inrush Peak Currents** 

V <sub>IN</sub> (V)	r (Ω)	<b>L</b> (μ <b>H</b> )	<b>C</b> <sub>0UT</sub> (μ <b>F</b> )	I <sub>P</sub> (A)
4.2	0.3	10	1.0	1.06
4.2	1.2	10	1.0	0.86
4.2	0.58	15	1.0	0.83
4.2	1.6	15	1.0	0.68

#### PROGRAMMING LED CURRENT

The feedback resistor ( $R_{SENSE}$ ) and the sense voltage ( $V_{CAP}-V_{LED}$ ) control the LED current.

The CTRL pin controls the sense reference voltage as shown in the Typical Performance Characteristics. For CTRL higher than 1.5V, the sense reference is 200mV, which results in full LED current. In order to have accurate LED current, precision resistors are preferred (1% is recommended). The formula and table for  $R_{\text{SENSE}}$  selection are shown below.

$$R_{SENSE} = \frac{200mV}{I_{LED}}$$

Table 4. R<sub>SENSE</sub> Value Selection for 200mV Sense

I <sub>LED</sub> (mA)	$R_{SENSE}$ ( $\Omega$ )
5	40
10	20
15	13.3
20	10

#### DIMMING CONTROL

There are three different types of dimming control circuits. The LED current can be set by modulating the CTRL pin with a DC voltage, a filtered PWM signal or directly with a PWM signal.

### Using a DC Voltage

For some applications, the preferred method of brightness control is a variable DC voltage to adjust the LED current. The CTRL pin voltage can be modulated to set the dimming of the LED string. As the voltage on the CTRL pin increases from 0V to 1.5V, the LED current increases from 0 to  $I_{LED}$ . As the CTRL pin voltage increases beyond 1.5V, it has no effect on the LED current.

The LED current can be set by:

$$I_{LED} \approx \frac{200mV}{R_{SENSE}}$$
, when  $V_{CTRL} > 1.5V$ 

$$I_{LED} \approx \frac{V_{CTRL}}{6.25 \bullet R_{SENSE}}$$
, when  $V_{CTRL} < 1.25 V_{CTRL}$ 

Feedback voltage variation versus control voltage is given in the Typical Performance Characteristics.

# **Using a Filtered PWM Signal**

A filtered PWM signal can be used to control the brightness of the LED string. The PWM signal is filtered (Figure 5) by a RC network and fed to the CTRL pin.

The corner frequency of R1, C1 should be much lower than the frequency of the PWM signal. R1 needs to be much smaller than the internal impedance of the CTRL pin which is  $10M\Omega$  (typ).

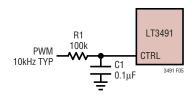

Figure 5. Dimming Control Using a Filtered PWM Signal

## **Direct PWM Dimming**

Changing the forward current flowing in the LEDs not only changes the intensity of the LEDs, it also changes the color. The chromaticity of the LEDs changes with the change in forward current. Many applications cannot tolerate any shift in the color of the LEDs. Controlling the intensity of the LEDs with a direct PWM signal allows dimming of the LEDs without changing the color. In addition, direct PWM dimming offers a wider dimming range to the user.

Dimming the LEDs via a PWM signal essentially involves turning the LEDs on and off at the PWM frequency. The typical human eye has a limit of ~60 frames per second. By increasing the PWM frequency to ~80Hz or higher, the eye will interpret that the pulsed light source is continuously on. Additionally, by modulating the duty cycle (amount of "ontime"), the intensity of the LEDs can be controlled. The color of the LEDs remains unchanged in this scheme since the LED current value is either zero or a constant value.

Figure 6 shows a Li-Ion powered driver for four white LEDs. Direct PWM dimming method requires an external NMOS tied between the cathode of the lowest LED in the string and ground as shown in Figure 6. A simple logic

level Si2302 MOSFET can be used since its source is connected to ground. The PWM signal is applied to the CTRL pin of the LT3491 and the gate of the MOSFET. The PWM signal should traverse between 0V to 2.5V, to ensure proper turn on and off of the driver and the NMOS transistor Q1. When the PWM signal goes high, the LEDs are connected to ground and a current of  $I_{LED} = 200 \text{mV/R}_{SENSE}$  flows through the LEDs. When the PWM signal goes low, the LEDs are disconnected and turn off. The MOSFET ensures that the LEDs quickly turn off without discharging the output capacitor which in turn allows the LEDs to turn on faster. Figure 7 shows the PWM dimming waveforms for the circuit in Figure 6.

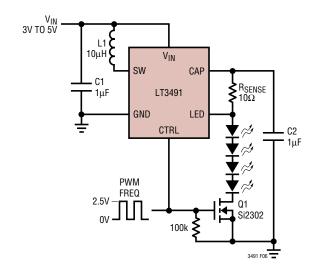

Figure 6. Li-Ion to Four White LEDs with Direct PWM Dimming

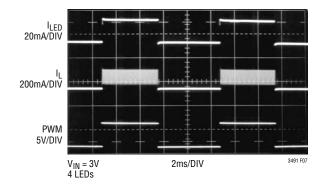

Figure 7. Direct PWM Dimming Waveforms

The time it takes for the LED current to reach its programmed value sets the achievable dimming range for a given PWM frequency. For example, the settling time of the LED current in Figure 7 is approximately 30µs for a 3V input voltage. The achievable dimming range for this application and 100Hz PWM frequency can be determined using the following method.

Example:

$$f = 100$$
Hz,  $t_{SFTTLF} = 30 \mu s$ 

$$t_{PERIOD} = \frac{1}{f} = \frac{1}{100} = 0.01s$$

Dim Range = 
$$\frac{t_{PERIOD}}{t_{SETTLE}} = \frac{0.01s}{30\mu s} = 300:1$$

Min Duty Cycle = 
$$\frac{t_{SETTLE}}{t_{PERIOD}} \cdot 100 = \frac{30\mu s}{0.01s} \cdot 100 = 0.3\%$$

Duty Cycle Range =  $100\% \rightarrow 0.3\%$  at 100Hz

The calculations show that for a 100Hz signal the dimming range is 300 to 1. In addition, the minimum PWM duty cycle of 0.3% ensures that the LED current has enough time to settle to its final value. Figure 8 shows the dimming range achievable for three different frequencies with a settling time of  $30\mu s$ .

The dimming range can be further extended by changing the amplitude of the PWM signal. The height of the PWM signal sets the commanded sense voltage across the sense resistor through the CTRL pin. In this manner both analog dimming and direct PWM dimming extend the dimming range for a given application. The color of the LEDs no longer remains constant because the forward current of the LED changes with the height of the CTRL signal. For the four LED application described above, the LEDs can be dimmed first, modulating the duty cycle of the PWM signal. Once the minimum duty cycle is reached, the height of the PWM signal can be decreased below 1.5V

down to 100mV. The use of both techniques together allows the average LED current for the four LED application to be varied from 20mA down to less than  $20\mu A$ . Figure 9 shows the application for dimming using both analog dimming and PWM dimming. A potentiometer must be added to ensure that the gate of the NMOS receives a logic-level signal, while the CTRL signal can be adjusted to lower amplitudes.

LINEAR

### LOW INPUT VOLTAGE APPLICATIONS

The LT3491 can be used in low input voltage applications. The input supply voltage to the LT3491 must be 2.5V or higher. However, the inductor can be run off a lower battery voltage. This technique allows the LEDs to be powered off two alkaline cells. Most portable devices have a 3.3V logic supply voltage which can be used to power the LT3491. The LEDs can be driven straight from the battery, resulting in higher efficiency.

Figure 10 shows three LEDs powered by two AA cells. The battery is connected to the inductor and the chip is powered off a 3.3V logic supply voltage.

#### **BOARD LAYOUT CONSIDERATIONS**

As with all switching regulators, careful attention must be paid to the PCB board layout and component placement. To prevent electromagnetic interference (EMI) problems, proper layout of high frequency switching paths is essential. Minimize the length and area of all traces connected to the switching node pin (SW). Keep the sense voltage pins (CAP and LED) away from the switching node. Place  $C_{OUT}$  next to the CAP pin. Always use a ground plane under the switching regulator to minimize interplane coupling. Recommended component placement is shown in Figure 11.
