

High Side Current Sense Amplifier with Reference and Comparator

FEATURES

- Current Sense Amplifier
 - Fast Step Response: 500ns
 - Low Offset Voltage: 125 μ V Maximum
 - Low Gain Error: 0.2% Maximum
- Internal 400mV Precision Reference
- Internal Comparator
 - Fast Response Time: 500ns
 - Total Threshold Error: \pm 1.25% Maximum
 - Latching or Non-Latching Comparator Option
- Wide Supply Range: 2.7V to 60V
- Supply Current: 450 μ A
- Low Shutdown Current: 5 μ A Maximum
- Specified for -40° C to 125° C Temperature Range
- Available in 8-Lead MSOP and 8-Lead (2mm \times 3mm) DFN Packages

APPLICATIONS

- Overcurrent and Fault Detection
- Current Shunt Measurement
- Battery Monitoring
- Motor Control
- Automotive Monitoring and Control
- Remote Sensing
- Industrial Control

DESCRIPTION

The LT[®]6108 is a complete high side current sense device that incorporates a precision current sense amplifier, an integrated voltage reference and a comparator. Two versions of the LT6108 are available. The LT6108-1 has a latching comparator and the LT6108-2 has a non-latching comparator. In addition, the current sense amplifier and comparator inputs and outputs are directly accessible. The amplifier gain and comparator trip point are configured by external resistors. The open-drain comparator output allows for easy interface to other system components.

The overall propagation delay of the LT6108 is typically only 1.4 μ s, allowing for quick reaction to overcurrent conditions. The 1MHz bandwidth allows the LT6108 to be used for error detection in critical applications such as motor control. The high threshold accuracy of the comparator, combined with the ability to latch the comparator, ensures the LT6108 can capture high speed events.

The LT6108 is fully specified for operation from -40° C to 125° C, making it suitable for industrial and automotive applications. The LT6108 is available in the small 8-lead MSOP and 8-lead DFN packages.

LT, LT, LTC, LTM, TimerBlox, Linear Technology and the Linear logo are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

Circuit Fault Protection with Very Fast Latching Load Disconnect

Response to Overcurrent Event

LT6108-1/LT6108-2

ABSOLUTE MAXIMUM RATINGS (Note 1)

Total Supply Voltage (V^+ to V^-)	60V	Amplifier Output Short-Circuit Duration (to V^-)..	Indefinite
Maximum Voltage (SENSELO, SENSEHI, OUTA).....	$V^+ + 1V$	Operating Temperature Range (Note 3)	
Maximum $V^+ -$ (SENSELO or SENSEHI).....	33V	LT6108I.....	-40°C to 85°C
Maximum EN, EN/ \overline{RST} Voltage	60V	LT6108H	-40°C to 125°C
Maximum Comparator Input Voltage	60V	Specified Temperature Range (Note 3)	
Maximum Comparator Output Voltage.....	60V	LT6108I.....	-40°C to 85°C
Input Current (Note 2).....	-10mA	LT6108H	-40°C to 125°C

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: Input and output pins have ESD diodes connected to ground. The SENSEHI and SENSELO pins have additional current handling capability specified as SENSEHI, SENSELO Input Current.

Note 3: The LT6108I is guaranteed to meet specified performance from -40°C to 85°C . LT6108H is guaranteed to meet specified performance from -40°C to 125°C .

Note 4: Supply current is specified with the comparator output high. When the comparator output goes low the supply current will increase by $75\mu\text{A}$ typically.

Note 5: The full-scale input sense voltage and the maximum output current must be considered to achieve the specified performance.

Note 6: Supply voltage and input common mode voltage are varied while amplifier input offset voltage is monitored.

Note 7: The specified gain error does not include the effect of external resistors R_{IN} and R_{OUT} . Although gain error is only guaranteed between 12V and 60V, similar performance is expected for $V^+ < 12\text{V}$, as well.

Note 8: Refer to SENSELO, SENSEHI Range in the Applications Information section for more information.

Note 9: The input threshold voltage which causes the output voltage of the comparator to transition from high to low is specified. The input voltage which causes the comparator output to transition from low to high is the magnitude of the difference between the specified threshold and the hysteresis.

PIN FUNCTIONS

SENSELO (Pin 1): Sense Amplifier Input. This pin must be tied to the load end of the sense resistor.

EN/ $\overline{\text{RST}}$ (Pin 2, LT6108-1 Only): Enable and Latch Reset Input. When the EN/ $\overline{\text{RST}}$ pin is pulled high the LT6108-1 is enabled. When the EN/ $\overline{\text{RST}}$ pin is pulled low for longer than typically $40\mu\text{s}$, the LT6108-1 will enter the shutdown mode. Pulsing this pin low for between $2\mu\text{s}$ and $15\mu\text{s}$ will reset the comparator of the LT6108-1.

EN (Pin 2, LT6108-2 Only): Enable Input. When the enable pin is pulled high the LT6108-2 is enabled. When the enable pin is pulled low for longer than typically $40\mu\text{s}$, the LT6108-2 will enter the shutdown mode.

OUTC (Pin 3): Open-Drain Comparator Output. Off-state voltage may be as high as 60V above V^- , regardless of V^+ used.

V^- (Pin 4): Negative Supply Pin. This pin is normally connected to ground.

INC (Pin 5): This is the inverting input of the comparator. The other comparator input is internally connected to the 400mV reference.

OUTA (Pin 6): Current Output of the Sense Amplifier. This pin will source a current that is equal to the sense voltage divided by the external gain setting resistor, R_{IN} .

V^+ (Pin 7): Positive Supply Pin. The V^+ pin can be connected directly to either side of the sense resistor, R_{SENSE} . When V^+ is tied to the load end of the sense resistor, the SENSEHI pin can go up to 0.2V above V^+ . Supply current is drawn through this pin.

SENSEHI (Pin 8): Sense Amplifier Input. The internal sense amplifier will drive SENSEHI to the same potential as SENSELO. A resistor (typically R_{IN}) tied from supply to SENSEHI sets the output current, $I_{\text{OUT}} = V_{\text{SENSE}}/R_{\text{IN}}$, where V_{SENSE} is the voltage developed across R_{SENSE} .

Exposed Pad (Pin 9, DCB Package Only): V^- . The exposed pad may be left open or connected to device V^- . Connecting the exposed pad to a V^- plane will improve thermal management in high voltage applications. The exposed pad should not be used as the primary connection for V^- .

BLOCK DIAGRAMS

Figure 1. LT6108-1 Block Diagram (Latching Comparator)

Figure 2. LT6108-2 Block Diagram (Non-Latching Comparator)

APPLICATIONS INFORMATION

The LT6108 high side current sense amplifier provides accurate monitoring of currents through an external sense resistor. The input sense voltage is level-shifted from the sensed power supply to a ground referenced output and is amplified by a user-selected gain to the output. The output voltage is directly proportional to the current flowing through the sense resistor.

The LT6108 comparator has a threshold set with a built-in 400mV precision reference and has 10mV of hysteresis. The open-drain output can be easily used to level shift to digital supplies.

Amplifier Theory of Operation

An internal sense amplifier loop forces SENSEHI to have the same potential as SENSELO as shown in Figure 3. Connecting an external resistor, R_{IN} , between SENSEHI and V_{SUPPLY} forces a potential, V_{SENSE} , across R_{IN} . A corresponding current, I_{OUTA} , equal to V_{SENSE}/R_{IN} , will flow through R_{IN} . The high impedance inputs of the sense amplifier do not load this current, so it will flow through an internal MOSFET to the output pin, OUTA.

The output current can be transformed back into a voltage by adding a resistor from OUTA to V^- (typically ground). The output voltage is then:

$$V_{OUT} = V^- + I_{OUTA} \cdot R_{OUT}$$

where $R_{OUT} = R_1 + R_2$ as shown in Figure 3.

Table 1. Example Gain Configurations

GAIN	R_{IN}	R_{OUT}	V_{SENSE} FOR $V_{OUT} = 5V$	I_{OUTA} AT $V_{OUT} = 5V$
20	499 Ω	10k	250mV	500 μ A
50	200 Ω	10k	100mV	500 μ A
100	100 Ω	10k	50mV	500 μ A

Useful Equations

Input Voltage: $V_{SENSE} = I_{SENSE} \cdot R_{SENSE}$

Voltage Gain: $\frac{V_{OUT}}{V_{SENSE}} = \frac{R_{OUT}}{R_{IN}}$

Current Gain: $\frac{I_{OUTA}}{I_{SENSE}} = \frac{R_{SENSE}}{R_{IN}}$

Note that $V_{SENSE(MAX)}$ can be exceeded without damaging the amplifier, however, output accuracy will degrade as V_{SENSE} exceeds $V_{SENSE(MAX)}$, resulting in increased output current, I_{OUTA} .

Selection of External Current Sense Resistor

The external sense resistor, R_{SENSE} , has a significant effect on the function of a current sensing system and must be chosen with care.

First, the power dissipation in the resistor should be considered. The measured load current will cause power dissipation as well as a voltage drop in R_{SENSE} . As a result, the sense resistor should be as small as possible while still providing the input dynamic range required by the measurement. Note that the input dynamic range is the difference between the maximum input signal and the minimum accurately reproduced signal, and is limited primarily by input DC offset of the internal sense amplifier of the LT6108. To ensure the specified performance, R_{SENSE} should be small enough that V_{SENSE} does not exceed $V_{SENSE(MAX)}$ under peak load conditions. As an example, an application may require the maximum sense voltage be 100mV. If this application is expected to draw 2A at peak load, R_{SENSE} should be set to 50m Ω .

Once the maximum R_{SENSE} value is determined, the minimum sense resistor value will be set by the resolution or dynamic range required. The minimum signal that can be accurately represented by this sense amplifier is limited by the input offset. As an example, the LT6108 has a maximum input offset of 125 μ V. If the minimum current is 20mA, a sense resistor of 6.25m Ω will set V_{SENSE} to 125 μ V. This is the same value as the input offset. A larger sense resistor will reduce the error due to offset by increasing the sense voltage for a given load current. Choosing a 50m Ω R_{SENSE} will maximize the dynamic range and provide a system that has 100mV across the sense resistor at peak load (2A), while input offset causes an error equivalent to only 2.5mA of load current.

In the previous example, the peak dissipation in R_{SENSE} is 200mW. If a 5m Ω sense resistor is employed, then the effective current error is 25mA, while the peak sense voltage is reduced to 10mV at 2A, dissipating only 20mW.

APPLICATIONS INFORMATION

The low offset and corresponding large dynamic range of the LT6108 make it more flexible than other solutions in this respect. The 125 μ V maximum offset gives 72dB of dynamic range for a sense voltage that is limited to 500mV max.

Sense Resistor Connection

Kelvin connection of the SENSEHI and SENSELO inputs to the sense resistor should be used in all but the lowest power applications. Solder connections and PC board interconnections that carry high currents can cause significant error in measurement due to their relatively large resistances. One 10mm \times 10mm square trace of 1oz copper is approximately 0.5m Ω . A 1mV error can be caused by as little as 2A flowing through this small interconnect. This will cause a 1% error for a full-scale V_{SENSE} of 100mV. A 10A load current in the same interconnect will cause a 5% error for the same 100mV signal. By isolating the sense traces from the high current paths, this error can be reduced by orders of magnitude. A sense resistor with integrated Kelvin sense terminals will give the best results. Figure 3 illustrates the recommended method for connecting the SENSEHI and SENSELO pins to the sense resistor.

Selection of External Input Gain Resistor, R_{IN}

R_{IN} should be chosen to allow the required speed and resolution while limiting the output current to 1mA. The maximum value for R_{IN} is 1k to maintain good loop stability. For a given V_{SENSE} , larger values of R_{IN} will lower power dissipation in the LT6108 due to the reduction in I_{OUT} while smaller values of R_{IN} will result in faster response time due to the increase in I_{OUT} . If low sense currents must be resolved accurately in a system that has a very wide dynamic range, a smaller R_{IN} may be used if the maximum I_{OUTA} current is limited in another way, such as with a Schottky diode across R_{SENSE} (Figure 4). This will reduce the high current measurement accuracy by limiting the result, while increasing the low current measurement resolution.

Figure 4. Shunt Diode Limits Maximum Input Voltage to Allow Better Low Input Resolution Without Overranging

Figure 3. LT6108-1 Typical Connection

APPLICATIONS INFORMATION

This approach can be helpful in cases where occasional bursts of high currents can be ignored.

Care should be taken when designing the board layout for R_{IN} , especially for small R_{IN} values. All trace and interconnect resistances will increase the effective R_{IN} value, causing a gain error.

The power dissipated in the sense resistor can create a thermal gradient across a printed circuit board and consequently a gain error if R_{IN} and R_{OUT} are placed such that they operate at different temperatures. If significant power is being dissipated in the sense resistor then care should be taken to place R_{IN} and R_{OUT} such that the gain error due to the thermal gradient is minimized.

Selection of External Output Gain Resistor, R_{OUT}

The output resistor, R_{OUT} , determines how the output current is converted to voltage. V_{OUT} is simply $I_{OUTA} \cdot R_{OUT}$. Typically, R_{OUT} is a combination of resistors configured as a resistor divider which has a voltage tap going to the comparator input to set the comparator threshold.

In choosing an output resistor, the maximum output voltage must first be considered. If the subsequent circuit is a buffer or ADC with limited input range, then R_{OUT} must be chosen so that $I_{OUTA(MAX)} \cdot R_{OUT}$ is less than the allowed maximum input range of this circuit.

In addition, the output impedance is determined by R_{OUT} . If another circuit is being driven, then the input impedance of that circuit must be considered. If the subsequent circuit has high enough input impedance, then almost any useful output impedance will be acceptable. However, if the subsequent circuit has relatively low input impedance, or draws spikes of current such as an ADC load, then a lower output impedance may be required to preserve the accuracy of the output. More information can be found in the Output Filtering section. As an example, if the input impedance of the driven circuit, $R_{IN(DRIVEN)}$, is 100 times R_{OUT} , then the accuracy of V_{OUT} will be reduced by 1% since:

$$\begin{aligned} V_{OUT} &= I_{OUTA} \cdot \frac{R_{OUT} \cdot R_{IN(DRIVEN)}}{R_{OUT} + R_{IN(DRIVEN)}} \\ &= I_{OUTA} \cdot R_{OUT} \cdot \frac{100}{101} = 0.99 \cdot I_{OUTA} \cdot R_{OUT} \end{aligned}$$

Amplifier Error Sources

The current sense system uses an amplifier and resistors to apply gain and level-shift the result. Consequently, the output is dependent on the characteristics of the amplifier, such as gain error and input offset, as well as the matching of the external resistors.

Ideally, the circuit output is:

$$V_{OUT} = V_{SENSE} \cdot \frac{R_{OUT}}{R_{IN}}; V_{SENSE} = R_{SENSE} \cdot I_{SENSE}$$

In this case, the only error is due to external resistor mismatch, which provides an error in gain only. However, offset voltage, input bias current and finite gain in the amplifier can cause additional errors:

Output Voltage Error, $\Delta V_{OUT(VOS)}$, Due to the Amplifier DC Offset Voltage, V_{OS}

$$\Delta V_{OUT(VOS)} = V_{OS} \cdot \frac{R_{OUT}}{R_{IN}}$$

The DC offset voltage of the amplifier adds directly to the value of the sense voltage, V_{SENSE} . As V_{SENSE} is increased, accuracy improves. This is the dominant error of the system and it limits the available dynamic range.

Output Voltage Error, $\Delta V_{OUT(IBIAS)}$, Due to the Bias Currents I_B^+ and I_B^-

The amplifier bias current I_B^+ flows into the SENSELO pin while I_B^- flows into the SENSEHI pin. The error due to I_B is the following:

$$\Delta V_{OUT(IBIAS)} = R_{OUT} \left(I_B^+ \cdot \frac{R_{SENSE}}{R_{IN}} - I_B^- \right)$$

Since $I_B^+ \approx I_B^- = I_{BIAS}$, if $R_{SENSE} \ll R_{IN}$ then,

$$\Delta V_{OUT(IBIAS)} = -R_{OUT} (I_{BIAS})$$

It is useful to refer the error to the input:

$$\Delta V_{VIN(IBIAS)} = -R_{IN} (I_{BIAS})$$

For instance, if I_{BIAS} is 100nA and R_{IN} is 1k, the input referred error is 100 μ V. This error becomes less significant as the value of R_{IN} decreases. The bias current error can

APPLICATIONS INFORMATION

be reduced if an external resistor, R_{IN}^+ , is connected as shown in Figure 5, the error is then reduced to:

$$V_{OUT(IBIAS)} = \pm R_{OUT} \cdot I_{OS}; I_{OS} = I_B^+ - I_B^-$$

Minimizing low current errors will maximize the dynamic range of the circuit.

Figure 5. R_{IN}^+ Reduces Error Due to I_B

Output Voltage Error, $\Delta V_{OUT(GAIN ERROR)}$, Due to External Resistors

The LT6108 exhibits a very low gain error. As a result, the gain error is only significant when low tolerance resistors are used to set the gain. Note the gain error is systematically negative. For instance, if 0.1% resistors are used for R_{IN} and R_{OUT} then the resulting worst-case gain error is -0.4% with $R_{IN} = 100\Omega$. Figure 6 is a graph of the maximum gain error which can be expected versus the external resistor tolerance.

Figure 6. Gain Error vs Resistor Tolerance

Output Current Limitations Due to Power Dissipation

The LT6108 can deliver a continuous current of 1mA to the OUTA pin. This current flows through R_{IN} and enters the current sense amplifier via the SENSEHI pin. The power dissipated in the LT6108 due to the output signal is:

$$P_{OUT} = (V_{SENSEHI} - V_{OUTA}) \cdot I_{OUTA}$$

$$\text{Since } V_{SENSEHI} \approx V^+, P_{OUTA} \approx (V^+ - V_{OUTA}) \cdot I_{OUTA}$$

There is also power dissipated due to the quiescent power supply current:

$$P_S = I_S \cdot V^+$$

The comparator output current flows into the comparator output pin and out of the V^- pin. The power dissipated in the LT6108 due to the comparator is often insignificant and can be calculated as follows:

$$P_{OUTC} = (V_{OUTC} - V^-) \cdot I_{OUTC}$$

The total power dissipated is the sum of these dissipations:

$$P_{TOTAL} = P_{OUTA} + P_{OUTC} + P_S$$

At maximum supply and maximum output currents, the total power dissipation can exceed 150mW. This will cause significant heating of the LT6108 die. In order to prevent damage to the LT6108, the maximum expected dissipation in each application should be calculated. This number can be multiplied by the θ_{JA} value, 163°C/W for the MS8 package or 64°C/W for the DFN, to find the maximum expected die temperature. Proper heat sinking and thermal relief should be used to ensure that the die temperature does not exceed the maximum rating.

Output Filtering

The AC output voltage, V_{OUT} , is simply $I_{OUTA} \cdot Z_{OUT}$. This makes filtering straightforward. Any circuit may be used which generates the required Z_{OUT} to get the desired filter response. For example, a capacitor in parallel with R_{OUT} will give a lowpass response. This will reduce noise at the output, and may also be useful as a charge reservoir to keep the output steady while driving a switching circuit

APPLICATIONS INFORMATION

such as a MUX or ADC. This output capacitor in parallel with R_{OUT} will create an output pole at:

$$f_{-3dB} = \frac{1}{2 \cdot \pi \cdot R_{OUT} \cdot C_L}$$

SENSELO, SENSEHI Range

The difference between V_{BATT} (see Figure 7) and V^+ , as well as the maximum value of V_{SENSE} , must be considered to ensure that the SENSELO pin doesn't exceed the range listed in the Electrical Characteristics table. The SENSELO and SENSEHI pins of the LT6108 can function from 0.2V above the positive supply to 33V below it. These operating voltages are limited by internal diode clamps shown in Figures 1 and 2. On supplies less than 35.5V, the lower range is limited by $V^- + 2.5V$. This allows the monitored supply, V_{BATT} , to be separate from the LT6108 positive supply as shown in Figure 7. Figure 8 shows the range of operating voltages for the SENSELO and SENSEHI inputs, for different supply voltage inputs (V^+). The SENSELO and SENSEHI range has been designed to allow the LT6108 to monitor its own supply current (in addition to the load), as long as V_{SENSE} is less than 200mV. This is shown in Figure 9.

Minimum Output Voltage

The output of the LT6108 current sense amplifier can produce a non-zero output voltage when the sense voltage is zero. This is a result of the sense amplifier V_{OS} being forced across R_{IN} as discussed in the Output Voltage Error, $\Delta V_{OUT(V_{OS})}$ section. Figure 10 shows the effect of the input offset voltage on the transfer function for parts at the V_{OS} limits. With a negative offset voltage, zero input

Figure 8. Allowable SENSELO, SENSEHI Voltage Range

Figure 9. LT6108 Supply Current Monitored with Load

Figure 7. V^+ Powered Separately from Load Supply (V_{BATT})

Figure 10. Amplifier Output Voltage vs Input Sense Voltage

APPLICATIONS INFORMATION

sense voltage produces an output voltage. With a positive offset voltage, the output voltage is zero until the input sense voltage exceeds the input offset voltage. Neglecting V_{OS} , the output circuit is not limited by saturation of pull-down circuitry and can reach 0V.

Response Time

The LT6108 amplifier is designed to exhibit fast response to inputs for the purpose of circuit protection or current monitoring. This response time will be affected by the external components in two ways, delay and speed.

If the output current is very low and an input transient occurs, there may be an increased delay before the output voltage begins to change. The Typical Performance Characteristics show that this delay is short and it can be improved by increasing the minimum output current, either by increasing R_{SENSE} or decreasing R_{IN} . Note that the Typical Performance Characteristics are labeled with respect to the initial sense voltage.

The speed is also affected by the external components. Using a larger R_{OUT} will decrease the response time, since $V_{OUT} = I_{OUTA} \cdot Z_{OUT}$ where Z_{OUT} is the parallel combination of R_{OUT} and any parasitic and/or load capacitance. Note that reducing R_{IN} or increasing R_{OUT} will both have the effect of increasing the voltage gain of the circuit. If the output capacitance is limiting the speed of the system, R_{IN} and R_{OUT} can be decreased together in order to maintain the desired gain and provide more current to charge the output capacitance.

The response time of the comparator is the sum of the propagation delay and the fall time. The propagation delay is a function of the overdrive voltage on the input of the comparator. A larger overdrive will result in a lower propagation delay. This helps achieve a fast system response time to fault events. The fall time is affected by the load on the output of the comparator as well as the pull-up voltage.

The LT6108 amplifier has a typical response time of 500ns and the comparators have a typical response time of 500ns. When configured as a system, the amplifier output drives the comparator input causing a total system response time which is typically greater than that implied by the individually specified response times. This is due to the

overdrive on the comparator input being determined by the speed of the amplifier output.

Internal Reference and Comparator

The integrated precision reference and comparator combined with the high precision current sense allow for rapid and easy detection of abnormal load currents. This is often critical in systems that require high levels of safety and reliability. The LT6108-1 comparator is optimized for fault detection and is designed with a latching output. The latching output prevents faults from clearing themselves and requires a separate system or user to reset the output. In applications where the comparator output can intervene and disconnect loads from the supply, a latched output is required to avoid oscillation. The latching output is also useful for detecting problems that are intermittent. The comparator output on the LT6108-2 is non-latching and can be used in applications where a latching output is not desired.

The comparator has one input available externally. The other comparator input is connected internally to the 400mV precision reference. The input threshold (the voltage which causes the output to transition from high to low) is designed to be equal to that of the reference. The reference voltage is established with respect to the device V^- connection.

Comparator Input

The comparator input can swing from V^- to 60V regardless of the supply voltage used. The input current for inputs well above the threshold is just a few pAs. With decreasing input voltage, a small bias current begins to be drawn out of the input near the threshold, reaching 50nA max when at ground potential. Note that this change in input bias current can cause a small nonlinearity in the OUTA transfer function if the comparator input is coupled to the amplifier output with a voltage divider. For example, if the maximum comparator input current is 50nA, and the resistance seen looking out of the comparator input is 1k, then a change in output voltage of 50 μ V will be seen on the analog output when the comparator input voltage passes through its threshold.

APPLICATIONS INFORMATION

Setting Comparator Threshold

The comparator has an internal 400mV precision reference. In order to set the trip point of the LT6108 comparator as configured in Figure 11, the input sense voltage at which the comparator will trip, $V_{SENSE(TRIP)}$ must be calculated:

$$V_{SENSE(TRIP)} = I_{SENSE(TRIP)} \cdot R_{SENSE}$$

The selection of R_{IN} is discussed in the Selection of External Input Gain Resistor R_{IN} section. Once R_{IN} is selected, R_{OUT} can be calculated:

$$R_{OUT} = R_{IN} \frac{400mV}{V_{SENSE(TRIP)}}$$

Since the amplifier output is connected directly to the comparator input, the gain from V_{SENSE} to V_{OUT} is:

$$A_V = \frac{400mV}{V_{SENSE(TRIP)}}$$

As shown in Figure 12, R_2 can be used to increase the gain from V_{SENSE} to V_{OUT} without changing $V_{SENSE(TRIP)}$. As before, R_1 can be easily calculated:

$$R_1 = R_{IN} \frac{400mV}{V_{SENSE(TRIP)}}$$

The gain is now:

$$A_V = \frac{R_1 + R_2}{R_{IN}}$$

This gain equation can be easily solved for R_2 :

$$R_2 = A_V \cdot R_{IN} - R_1$$

If the configuration of Figure 11 gives too much gain, R_2 can be used to reduce the gain without changing $V_{SENSE(TRIP)}$ as shown in Figure 13. A_V can be easily calculated:

$$A_V = \frac{R_1}{R_{IN}}$$

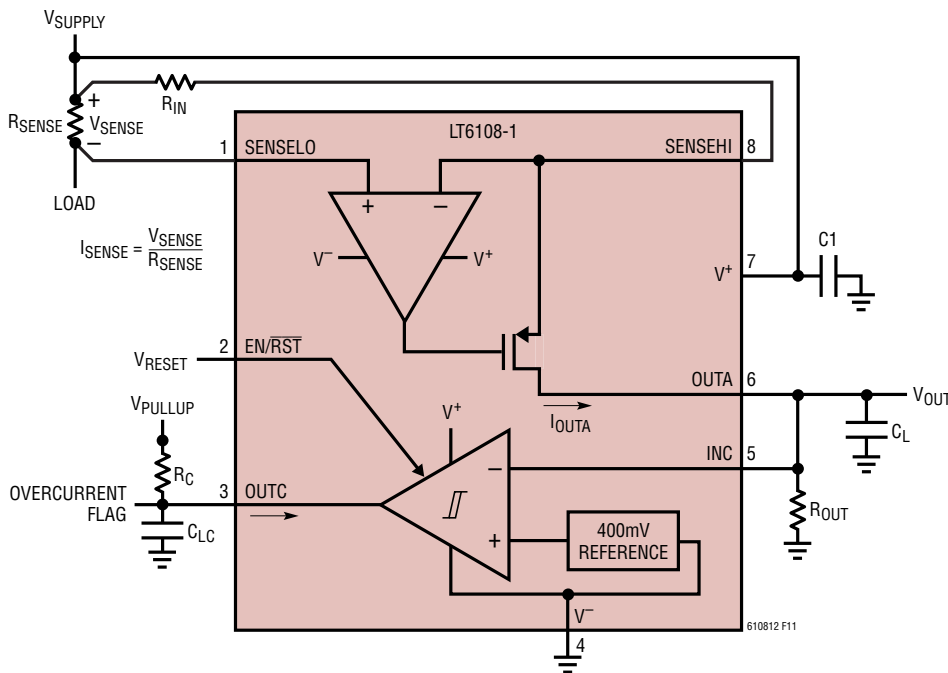

Figure 11. Basic Comparator Configuration

APPLICATIONS INFORMATION

This gain equation can be easily solved for R1:

$$R1 = A_V \cdot R_{IN}$$

The value of R2 can be calculated:

$$R2 = \frac{400\text{mV} \cdot R_{IN} - V_{\text{SENSE(TRIP)}} \cdot R1}{V_{\text{SENSE(TRIP)}}$$

Hysteresis

The comparator has a typical built-in hysteresis of 10mV to simplify design, ensure stable operation in the presence of noise at the input, and to reject supply noise that might be induced by state change load transients. The hysteresis is designed such that the threshold voltage is altered when the output is transitioning from low to high as is shown in Figure 14.

External positive feedback circuitry can be employed to increase the effective hysteresis if desired, but such

Figure 14. Comparator Output Transfer Characteristics

circuitry will have an effect on both the rising and falling input thresholds, V_{TH} (the actual internal threshold remains unaffected).

Figure 15 shows how to add additional hysteresis to the comparator.

R5 can be calculated from the amplifier output current which is required to cause the comparator output to trip, I_{OVER} .

$$R5 = \frac{400\text{mV}}{I_{OVER}}, \text{ Assuming } (R1+R2) \gg R5$$

To ensure $(R1 + R2) \gg R5$, R1 should be chosen such that $R1 \gg R5$ so that V_{OUTA} does not change significantly when the comparator trips.

R3 should be chosen to allow sufficient V_{OL} and comparator output rise time due to capacitive loading.

R2 can be calculated:

$$R2 = R1 \cdot \left(\frac{V_{DD} - 390\text{mV}}{V_{\text{HYS(EXTRA)}}} \right)$$

Note that the hysteresis being added, $V_{\text{HYS(EXTRA)}}$, is in addition to the typical 10mV of built-in hysteresis. For very large values of R2 PCB related leakage may become an issue. A tee network can be implemented to reduce the required resistor values.

Figure 15. Inverting Comparator with Added Hysteresis

APPLICATIONS INFORMATION

The approximate total hysteresis is:

$$V_{\text{HYS}} = 10\text{mV} + R1 \cdot \left(\frac{V_{\text{DD}} - 390\text{mV}}{R2} \right)$$

For example, to achieve $I_{\text{OVER}} = 900\mu\text{A}$ with 50mV of total hysteresis, $R5 = 442\Omega$. Choosing $R1 = 4.42\text{k}$, $R3 = 10\text{k}$ and $V_{\text{DD}} = 5\text{V}$ results in $R2 = 513\text{k}$.

The analog output voltage will also be affected when the comparator trips due to the current injected into $R5$ by the positive feedback. Because of this, it is desirable to have $(R1 + R2) \gg R5$. The maximum V_{OUTA} error caused by this can be calculated as:

$$\Delta V_{\text{OUTA}} = V_{\text{DD}} \cdot \left(\frac{R5}{R1 + R2 + R5} \right)$$

In the previous example, this is an error of 4.3mV at the output of the amplifier or $43\mu\text{V}$ at the input of the amplifier assuming a gain of 100.

When using the comparator with its input decoupled from the output of the amplifier it may be driven directly by a voltage source. It is useful to know the threshold voltage equations with additional hysteresis. The input rising edge threshold which causes the output to transition from high to low is:

$$V_{\text{TH(R)}} = 400\text{mV} \cdot \left(1 + \frac{R1}{R2} \right)$$

The input falling edge threshold which causes the output to transition from low to high is:

$$V_{\text{TH(F)}} = 390\text{mV} \left(1 + \frac{R1}{R2} \right) - V_{\text{DD}} \left(\frac{R1}{R2} \right)$$

Comparator Output

The comparator output can maintain a logic-low level of 150mV while sinking $500\mu\text{A}$. The output can sink higher currents at elevated V_{OL} levels as shown in the Typical Performance Characteristics. Load currents are conducted to the V^- pin. The output off-state voltage may range between 0V and 60V with respect to V^- , regardless of the supply voltage used.

EN/ $\overline{\text{RST}}$ Pin (LT6108-1 Only)

The EN/ $\overline{\text{RST}}$ pin performs the two functions of resetting the latch on the comparator as well as shutting down the LT6108-1. When this pin is pulled high the LT6108-1 is enabled. After powering on the LT6108-1, the comparator must be reset in order to guarantee a valid state at its output.

Applying a pulse to the EN/ $\overline{\text{RST}}$ pin will reset the comparator from its tripped low state as long as the input on the comparator is below the threshold and hysteresis. For example, if V_{INC} is pulled higher than 400mV and latches the comparator, a reset pulse will not reset that comparator unless its input is held below the threshold by a voltage greater than the 10mV typical hysteresis. The comparator output typically unlatches in $0.5\mu\text{s}$ with 2pF of capacitive load. Increased capacitive loading on the comparator output will cause an increased unlatch time.

Figure 16 shows the reset functionality of the EN/ $\overline{\text{RST}}$ pin. The width of the pulse applied to reset the comparator must be greater than $t_{\text{RPW(MIN)}}$ ($2\mu\text{s}$) but less than $t_{\text{RPW(MAX)}}$ ($15\mu\text{s}$). Applying a pulse that is longer than $40\mu\text{s}$ typically (or tying the pin low) will cause the part to enter shutdown. Once the part has entered shutdown, the supply current will be reduced to $3\mu\text{A}$ typically and the amplifier, comparator and reference will cease to function until the EN/ $\overline{\text{RST}}$ pin is transitioned high. When the part is disabled, both the amplifier and comparator outputs are high impedance.

Figure 16. Comparator Reset Functionality

When the EN/ $\overline{\text{RST}}$ pin is transitioned from low to high to enable the part, the amplifier output PMOS can turn on momentarily causing typically 1mA of current to flow into the SENSEHI pin and out of the OUTA pin. Once the amplifier is fully on, the output will go to the correct

610812fa

APPLICATIONS INFORMATION

current. Figure 17 shows this behavior and the impact it has on V_{OUTA} . Circuitry connected to $OUTA$ can be protected from these transients by using an external diode to clamp V_{OUTA} , or a capacitor to filter V_{OUTA} .

Figure 17. Amplifier Enable Response

EN Pin (LT6108-2)

When this pin is pulled high, the LT6108-2 is enabled. When the enable pin is pulled low for longer than 40µs typically, the LT6108-2 will enter the shutdown mode.

Power Up

After powering on the LT6108-1, the comparator must be reset in order to guarantee a valid state at its output. Fast supply ramps may cause a supply current transient during start-up as shown in the Typical Performance Characteristics. This current can be lowered by reducing the edge speed of the supply.

Reverse-Supply Protection

The LT6108 is not protected internally from external reversal of supply polarity. To prevent damage that may occur during this condition, a Schottky diode should be added in series with V^- (Figure 18). This will limit the reverse current through the LT6108. Note that this diode will limit the low voltage operation of the LT6108 by effectively reducing the supply voltage to the part by V_D .

Also note that the comparator reference, comparator output and EN/RST input are referenced to the V^- pin. In order to preserve the precision of the reference and to avoid driving the comparator inputs below V^- , $R2$ must connect to the V^- pin. This will shift the amplifier output voltage up by V_D . V_{OUTA} can be accurately measured

Figure 18. Schottky Prevents Damage During Supply Reversal

APPLICATIONS INFORMATION

differentially across R1 and R2. The comparator output low voltage will also be shifted up by V_D . The EN/RST pin threshold is referenced to the V^- pin. In order to provide

valid input levels to the LT6108 and avoid driving EN/RST below V^- the negative supply of the driving circuit should be tied to V^- of the LT6108.

TYPICAL APPLICATIONS

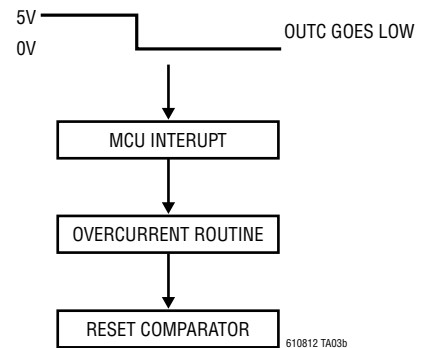

Overcurrent Battery Fault Protection

MCU Interfacing with Hardware Interrupts

Example:

The comparator is set to have a 300mA overcurrent threshold. The MCU will receive the comparator output as

a hardware interrupt and immediately run an appropriate fault routine.

TYPICAL APPLICATIONS

Simplified DC Motor Torque Control

The figure above shows a simplified DC motor control circuit. The circuit controls motor current, which is proportional to motor torque; the LT6108 is used to provide current feedback to an integrator that servos the motor

current to the current set point. The LTC[®]6992 is used to convert the output of the difference amp to the motors PWM control signal.

Power-On Reset or Disconnect Using TimerBlox[®] Circuit

The LTC6993-3 provides a 10μs reset pulse to the LT6108-1. The reset pulse is delayed by R4 and C1 whose time constant must be greater than 10ms and longer than the supply turn-on time. Optional components R6 and Q1 discharge capacitor C1 when the supply and/or ground are disconnected. This ensures that when the power supply and/or

ground are restored, capacitor C1 can fully recharge and trigger the LTC6993-3 to produce another comparator reset pulse. These optional components are particularly useful if the power and/or ground connections are intermittent, as can occur when PCB are plugged into a connector.

TYPICAL APPLICATIONS

LT6108-2 with External Latch and Power-On Reset or Disconnect

An external latch is implemented with positive feedback. R6 and C1 provide a reset pulse on power-up. The time constant formed by R6 and C1 should be set slower than that of the supply. Optional components R9 and Q1 discharge capacitor C1 when the supply and/or ground are disconnected. This ensures that when the power supply and/or ground are restored, capacitor C1 can fully recharge. While C1 is charging, the NOR gate output is low, ensuring that the comparator powers up in the correct state. These optional components are particularly useful if the power and/or ground connections are intermittent, as can occur when PCB are plugged into a connector. R4 and R5 are optional and minimize the movement of the rising input threshold voltage.

The input rising edge threshold which causes the output to transition from high to low is:

$$V_{TH(R)} = 400\text{mV if } R4 = R5 \cdot \left(\frac{400\text{mV}}{V_{DD} - 400\text{mV}} \right)$$

The input falling edge which causes the output to transition from low to high is:

$$V_{TH(F)} = 390\text{mV} \cdot R1 \cdot \left(\frac{1}{R1} + \frac{1}{R2 + R4 || R5} \right) - \left(\frac{V_{DD} \cdot R1}{R2 + R4 || R5} \right)$$
