

# Dual-Channel Hot Swap Controller/Power Sequencer

## FEATURES

- Allows Safe Board Insertion and Removal from a Live Backplane
- Programmable Power Supply Sequencing
- Programmable Electronic Circuit Breaker
- User-Programmable Supply Voltage Power-Up and Power-Down Rate
- High Side Drivers for External N-Channel FETs
- Controls Supply Voltages from 1.2V to 12V
- Ensures Proper Power-Up Behavior
- Undervoltage Lockout
- Glitch Filter Protects Against Spurious  $\overline{\text{RESET}}$  Signals
- 8- and 14-Pin SO Packages

## APPLICATIONS

- Hot Board Insertion
- Power Supply Sequencing
- Electronic Circuit Breaker

## DESCRIPTION

The LTC<sup>®</sup>1645 is a 2-channel Hot Swap<sup>™</sup> controller that allows a board to be safely inserted and removed from a live backplane. Using external N-channel pass transistors, the supply voltages can be ramped at a programmable rate. Two high side switch drivers control the N-channel gates for supply voltages ranging from 1.2V to 12V. The two channels can be set to ramp up and down separately, or they can be programmed to rise and fall simultaneously, ensuring power supply tracking at the two outputs.

Programmable electronic circuit breakers protect against shorts at either output. The  $\overline{\text{RESET}}$  output can be used to generate a system reset when a supply voltage falls below a user-programmed voltage. An additional spare comparator is available for monitoring a second supply voltage.

The LTC1645 is available in the 8- and 14-pin SO packages.

 LTC and LT are registered trademarks of Linear Technology Corporation. Hot Swap is a trademark of Linear Technology Corporation.

## TYPICAL APPLICATION

5V and 3.3V Hot Swap

5V and 3.3V Hot Swap Waveforms

**Note 1:** Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

**Note 2:** All currents into device pins are positive; all currents out of device pins are negative. All voltages are referenced to ground unless otherwise specified.

**Note 3:** An internal zener on the  $GATE_n$  pins clamps the charge pump voltage to a typical maximum operating voltage of 22V. External overdrive of a GATE pin (for example, from capacitive coupling of  $V_{CCn}$  glitches) beyond the internal zener voltage may damage the device. If a lower  $GATE_n$  pin clamp voltage is desired, use an external zener diode.

## PIN FUNCTIONS (14-Lead Package/8-Lead Package)

**V<sub>CC2</sub> (Pin 1/Pin 1):** Positive Supply Input. V<sub>CC2</sub> can range from 1.2V to 12V for normal operation. I<sub>CC2</sub> is typically 0.2mA. An undervoltage lockout circuit disables the LTC1645 whenever the voltage at V<sub>CC2</sub> is less than 1.12V.

**SENSE2 (Pin 2/Pin 2):** V<sub>CC2</sub> Circuit Breaker Set Pin. With a sense resistor placed in the supply path between V<sub>CC2</sub> and SENSE2, the circuit breaker trips when the voltage across the resistor exceeds 50mV for more than 1.5μs. If the circuit breaker trip current is set to twice the normal operating current, only 25mV is dropped across the sense resistor during normal operation. To disable the circuit breaker, short V<sub>CC2</sub> and SENSE2 together.

**GATE2 (Pin 3/Pin 3):** Channel 2 High Side Gate Drive. Connect to the gate of an external N-channel MOSFET. An internal charge pump guarantees at least 4.5V of gate drive. The charge pump is powered by the higher of V<sub>CC1</sub> and V<sub>CC2</sub>. When the ON pin exceeds 2V, GATE2 is turned on by connecting a 10μA current source from the charge pump output to the GATE2 pin and the voltage starts to ramp up with a slope  $dv/dt = 10\mu A/C_{GATE2}$ . While the ON pin is below 2V but above 0.4V, a 40μA current source pulls GATE2 toward ground. If the ON pin is below 0.4V, the circuit breaker trips or the undervoltage lockout circuit trips, the GATE2 pin is immediately pulled to ground with a 12mA (typ) current source.

**FAULT (Pin 4/NA):** Circuit Breaker Fault. FAULT is an open-drain output that pulls low when the circuit breaker function trips. The circuit breaker is reset by pulling the ON pin below 0.4V. An external pull-up is required to generate a logic high at the FAULT pin. When the ON pin is low, FAULT will release.

The circuit breaker can be programmed to automatically reset by connecting the FAULT pin to the ON pin. In this circuit configuration, if a logic device is driving the ON pin, use a series resistor between the logic output and the ON pin to prevent large currents from flowing.

**RESET (Pin 5/NA):** Open-Drain RESET Output. The RESET pin is pulled low when the voltage at the FB pin goes below 1.238V or V<sub>CC1</sub> is below the undervoltage lockout threshold. The RESET pin goes high one timing cycle after the voltage at the FB pin goes above the FB pin threshold. The ON pin must remain above 0.8V during this timing cycle.

An external pull-up is required to generate a logic high at the RESET pin.

**FB (Pin 6/NA):** RESET Comparator Input. The FB pin is used to monitor the output supply voltage with an external resistive divider. When the voltage on the FB pin is lower than 1.238V, the RESET pin is pulled low. A glitch filter on the FB pin prevents fast transients from forcing RESET low. When the voltage on the FB pin rises above the trip point, the RESET pin goes high after one timing cycle.

**GND (Pin 7/Pin 4):** Ground. Connect to a ground plane for optimum performance.

**COMP+ (Pin 8/NA):** Spare Comparator Noninverting Input. When the voltage on COMP+ is lower than 1.238V, COMPOUT pulls low.

**COMPOUT (Pin 9/NA):** Open-Drain Spare Comparator Output. COMPOUT pulls low when the voltage on COMP+ is below 1.238V or V<sub>CC1</sub> is below the undervoltage lockout threshold. An external pull-up is required to generate a logic high at the COMPOUT pin.

**ON (Pin 10/Pin 5):** Analog Control Input. If the ON pin voltage is below 0.4V, both GATE1 and GATE2 are immediately pulled to ground. While the voltage is between 0.4V and 0.8V, both GATE1 and GATE2 are each pulled to ground with a 40μA current source. While the voltage is between 0.8V and 2V, the GATE1 pull-up is turned on after one timing cycle, but GATE2 continues to be pulled to ground with a 40μA current source. When the voltage exceeds 2V, both the GATE1 and GATE2 pull-ups are turned on one timing cycle after the voltage exceeds 0.8V.

The ON pin is also used to reset the electronic circuit breaker. If the ON pin is brought below and then above 0.4V following the trip of the circuit breaker, the circuit breaker resets, and a normal power-up sequence occurs.

**TIMER (Pin 11/NA):** System Timing Pin. The TIMER pin requires an external capacitor to ground to generate a timing delay. The pin is used to set the delay before the RESET pin goes high after the output supply voltage is good as sensed by the FB pin. It is also used to set the delay between the ON pin exceeding 0.8V and the GATE1 and GATE2 pins turning on (GATE2 turns on only if the ON pin exceeds 2V).

**PIN FUNCTIONS** (14-Lead Package/8-Lead Package)

Whenever the timer is inactive, an internal N-channel FET shorts the TIMER pin to ground. Activating the timer connects a  $2\mu\text{A}$  current source from  $V_{CC1}$  to the TIMER pin and the voltage starts to ramp up with a slope  $dv/dt = 2\mu\text{A}/C_{\text{TIMER}}$ . When the voltage reaches the trip point (1.23V), the timer is reset by pulling the TIMER pin back to ground. The timer period is  $(1.23\text{V} \cdot C_{\text{TIMER}})/2\mu\text{A}$ .

**GATE1 (Pin 12/Pin 6):** Channel 1 High Side Gate Drive. Connect to the gate of an external N-channel MOSFET. An internal charge pump guarantees at least 4.5V of gate drive. The charge pump is powered by the higher of  $V_{CC1}$  and  $V_{CC2}$ . When the ON pin exceeds 0.8V, GATE1 is turned on by connecting a  $10\mu\text{A}$  current source from the charge pump output to the GATE1 pin and the voltage starts to ramp up with a slope  $dv/dt = 10\mu\text{A}/C_{\text{GATE1}}$ . While the ON pin is below 0.8V but above 0.4V, a  $40\mu\text{A}$  current source pulls GATE1 toward ground. If the ON pin is below 0.4V,

the circuit breaker trips or the undervoltage lockout circuit trips, the GATE1 pin is immediately pulled to ground with a 12mA (typ) current source.

**SENSE1 (Pin 13/Pin 7):**  $V_{CC1}$  Circuit Breaker Set Pin. With a sense resistor placed in the supply path between  $V_{CC1}$  and SENSE1, the circuit breaker trips when the voltage across the resistor exceeds 50mV for more than  $1.5\mu\text{s}$ . If the circuit breaker trip current is set to twice the normal operating current, only 25mV is dropped across the sense resistor during normal operation. To disable the circuit breaker, short  $V_{CC1}$  and SENSE1 together.

**$V_{CC1}$  (Pin 14/Pin 8):** Positive Supply Input.  $V_{CC1}$  can range from 2.375V to 12V for normal operation.  $I_{CC1}$  is typically 1mA. An undervoltage lockout circuit disables the chip whenever the voltage at  $V_{CC1}$  is less than 2.23V. All internal logic is powered by  $V_{CC1}$ .

**BLOCK DIAGRAM**

## APPLICATIONS INFORMATION

### Hot Circuit Insertion

When a circuit board is inserted into a live backplane, the supply bypass capacitors on the board can draw huge transient currents from the backplane power bus as they charge. These transient currents can cause permanent damage to the connector pins and produce glitches on the system supply, resetting other boards in the system.

The LTC1645 is designed to turn a board's supply voltages on and off in a controlled manner, allowing the board to be safely inserted or removed from a live backplane. The chip provides a system reset signal and a spare comparator to indicate when board supply voltages drop below user-programmable voltages, and a fault signal to indicate if an overcurrent condition has occurred.

The LTC1645 can be located before or after the connector as shown in Figure 1. A staggered PCB connector can sequence pin connections when plugging and unplugging circuit boards. Alternatively, the control signal can be generated by processor control.

### Power Supply Tracking and Sequencing

Some applications require that the potential difference between two power supplies not exceed a certain voltage. This requirement applies during power-up and power-down as well as during steady state operation, often to prevent latch-up in a dual supply ASIC. Other systems require one supply to come up after another, for example, if a system clock needs to start before a block of logic. Typical dual supplies or backplane connections may come up at arbitrary rates depending on load current, capacitor size, soft-start rates, etc. Traditional solutions are cumbersome and require complex circuitry to meet the power supply requirements.

The LTC1645 provides a simple solution to power supply tracking and sequencing needs. The LTC1645 guarantees supply tracking by ramping the supplies up and down together (see Figure 15). The sequencing capabilities of the LTC1645 allow nearly any combination of supply ramping (e.g., see Figure 17) to satisfy various sequencing specifications. See the Power Supply Tracking and Sequencing Applications section for more information.

(b) Hot Swap Controller on Daughterboard

Figure 1. Staggered Pins Connection

## APPLICATIONS INFORMATION

### Power Supply Ramping

The power supplies on a board are controlled by placing external N-channel pass transistors in the power paths as shown in Figure 2. Consult Table 1 for a selection of N-channel FETs suitable for use with the LTC1645.  $R_{SENSE1}$  and  $R_{SENSE2}$  provide current fault detection and R1 and R2 prevent high frequency oscillation. By ramping the gates of the pass transistors up and down at a controlled rate, the transient surge current ( $I = C \cdot dv/dt$ ) drawn from the main backplane supply is limited to a safe value when the board makes connection.

When power is first applied to the chip, the gates of the N-channels (GATE1 and GATE2 pins) are pulled low. After the ON pin is held above 0.8V for at least one timing cycle, the voltage at GATE1 begins to rise with a slope equal to  $dv/dt = 10\mu A/C1$  (Figure 3), where C1 is the external capacitor connected between the GATE1 pin and GND. If the ON pin is brought above 2V (and the ON pin has been held above 0.8V for at least one timing cycle), the voltage at GATE2 begins to rise with a slope equal to  $dv/dt = 10\mu A/C2$ .

Figure 2. Typical Hot Swap Connection

The ramp time for each supply is  $t = (V_{CCn} \cdot Cn)/10\mu A$ . If the ON pin is pulled below 2V for GATE2 or 0.8V for GATE1 (but above 0.4V), a  $40\mu A$  current source is connected from GATE $n$  to GND, and the voltage at the GATE $n$  pin will ramp down, as shown in Figure 4.

### Ringing

Good engineering practice calls for bypassing the supply rail of any circuit. Bypass capacitors are often placed at the supply connection of every active device, in addition to one or more large value bulk bypass capacitors per supply rail. If power is connected abruptly, the bypass capacitors slow the rate of rise of voltage and heavily damp any parasitic resonance of lead or trace inductance working against the supply bypass capacitors.

The opposite is true for LTC1645 Hot Swap circuits on a daughterboard. In most cases, on the powered side of the N-channel FET switches ( $V_{CCn}$ ) there is no supply bypass capacitor present. An abrupt connection, produced by plugging a board into a backplane connector, results in a fast rising edge applied to the  $V_{CCn}$  line of the LTC1645.

Figure 3. Supply Turning On

Figure 4. Supply Turning Off

## APPLICATIONS INFORMATION

No bulk capacitance is present to slow the rate of rise and heavily damp the parasitic resonance. Instead, the fast edge shock excites a resonant circuit formed by a combination of wiring harness, backplane and circuit board parasitic inductances and FET capacitance. In theory, the peak voltage should rise to 2X the input supply, but in practice the peak can reach 2.5X, owing to the effects of voltage dependent FET capacitance.

The absolute maximum  $V_{CCn}$  potential for the LTC1645 is 13.2V; any circuit with an input of 5V or greater should be scrutinized for ringing. A well-bypassed backplane should not escape suspicion: circuit board trace inductances of as little as 10nH can produce sufficient ringing to overvoltage  $V_{CC}$ .

Check ringing with a fast storage oscilloscope (such as a LECROY 9314AL DSO) by attaching coax or a probe to  $V_{CC}$

and GND, then repeatedly inserting the circuit board into the backplane. Figures 5a and 5b show typical results in a 12V application with different  $V_{CC}$  lead lengths. The peak amplitude reaches 22V, breaking down the ESD protection diode in the process.

There are two methods for eliminating ringing: clipping and snubbing. A transient voltage suppressor is an effective means of limiting peak voltage to a safe level. Figure 6 shows the effect of adding an ON Semiconductor, 1SMA12CAT3, on the waveform of Figure 5.

Figures 7a and 7b show the effects of snubbing with different RC networks. The capacitor value is chosen as 10X to 100X the FET  $C_{OSS}$  under bias and R is selected for best damping—1 $\Omega$  to 50 $\Omega$  depending on the value of parasitic inductance.

## APPLICATIONS INFORMATION

### Supply Glitching

LTC1645 Hot Swap circuits on the backplane are generally used to provide power-up/down sequence at insertion/removal as well as overload/short-circuit protection. If a short-circuit occurs at supply ramp-up, the circuit breaker

trips. The partially enhanced FET is easily disconnected without any supply glitch.

If a dead short occurs after a supply connection is made (Figure 8), the sense resistor R1 and the  $R_{DS(ON)}$  of the fully enhanced FET provide a low impedance path for

(a)  $V_{CC}$  Short-Circuit Supply Current Glitch Without Any Limiting

(d)  $V_{CC}$  Supply Glitch with  $2\mu\text{H}$  Series Inductor

Figure 8. Supply Glitch

## APPLICATIONS INFORMATION

nearly unlimited current flow. The LTC1645 discharges the GATE pin in a few microseconds, but during this discharge time current on the order of 150 amperes flows from the  $V_{CC}$  power supply. This current spike glitches the power supply, causing  $V_{CC}$  to dip (Figure 8a and 8b).

On recovery from overload, some supplies may overshoot. Other devices attached to this supply may reset or malfunction and the overshoot may also damage some components. An inductor ( $1\mu\text{H}$  to  $10\mu\text{H}$ ) in series with the FET's source limits the short-circuit  $di/dt$ , thereby limiting the peak current and the supply glitch (Figure 8c and 8d). Additional power supply bypass capacitance also reduces the magnitude of the  $V_{CC}$  glitch.

### Reset

The LTC1645 uses an internal 1.238V bandgap reference, a precision voltage comparator, and a resistive divider to monitor the output supply voltage (Figure 9).

Whenever the voltage at the FB pin rises above its reset threshold (1.238V), the comparator output goes high, and a timing cycle starts (see Figure 10, time points 1 and 4). After a complete timing cycle,  $\overline{\text{RESET}}$  is released. An external pull-up is required for the  $\overline{\text{RESET}}$  pin to rise to a logic high.

When the voltage at the FB pin drops below its reset threshold, the comparator output goes low. After passing through a glitch filter,  $\overline{\text{RESET}}$  is pulled low (time point 2). If the FB pin rises above the reset threshold for less than a timing cycle, the  $\overline{\text{RESET}}$  output remains low (time point 3).

Figure 9. Supply Monitor Block Diagram

### Glitch Filter

The LTC1645 has a glitch filter to prevent  $\overline{\text{RESET}}$  from generating a spurious system reset in the presence of transients on the FB pin. The filter is  $20\mu\text{s}$  for large transients (greater than 150mV) and up to  $80\mu\text{s}$  for smaller transients. The relationship between glitch filter time and the transient voltage is shown in Typical Performance Characteristics: Glitch Filter Time vs Feedback Transient.

### Timer

The system timing for the LTC1645 is generated by the circuitry shown in Figure 11. The timer is used to set the turn-on delay after the ON pin goes high. It also sets the delay before the  $\overline{\text{RESET}}$  pin goes high after the FB pin exceeds 1.238V.

Whenever the timer is off, the internal N-channel shorts the TIMER pin to ground (Figure 11). Activating the timer connects a  $2\mu\text{A}$  current from  $V_{CC1}$  to the TIMER pin and the

Figure 10. Supply Monitor Waveforms

Figure 11. System Timing Block Diagram

## APPLICATIONS INFORMATION

voltage on the external capacitor  $C_{TIMER}$  starts to ramp up with a slope  $dv/dt = 2\mu A/C_{TIMER}$ . When the voltage reaches the trip point (1.23V), the timer is reset by pulling the TIMER pin back to ground. The timer period is  $t = (1.23V \cdot C_{TIMER})/2\mu A$ . For a 200ms delay, use a  $0.33\mu F$  capacitor.

### Electronic Circuit Breaker

The LTC1645 features an electronic circuit breaker function that protects against short circuits or excessive output currents. By placing sense resistors between the supply inputs and sense pins of the supplies, the circuit breaker trips whenever the voltage across either sense resistor is greater than 50mV for more than  $1.5\mu s$ . If the circuit breaker trips, both GATE pins are immediately pulled to ground and the external N-channels FETs are quickly turned off (time point 6 in Figure 12). The circuit breaker resets and another timing cycle starts by taking

the ON pin below 0.4V and then high as shown at time point 7.

At the end of the timer cycle (time point 8), the charge pump turns on again. If the circuit breaker feature is not required, short the SENSE $_n$  pin to  $V_{CCn}$ .

If the  $1.5\mu s$  response time is too fast to reject supply noise, add external resistors and capacitors  $R_F$  and  $C_F$  to the sense circuit as shown in Figure 13.

### The ON Pin

The ON pin is used to control system operation as shown in Figure 14. At time point 1, the board makes connection and the supplies power up the chip. At time point 2, the ON pin goes high and a timer cycle starts as long as both  $V_{CC}$  pins are higher than the undervoltage lockout trip point (2.23V for  $V_{CC1}$  and 1.12V for  $V_{CC2}$ ) and an overcurrent fault is not detected. At the end of the timer cycle (time point 3), the charge pump is turned on and the GATE $_n$  pin voltages start to ramp up with the output supply voltages,  $V_{OUTn}$ , following one gate-to-source voltage drop lower. At time point 4,  $V_{OUT2}$  reaches its power-good trip level (this example assumes the FB pin resistive divider is connected to  $V_{OUT2}$ ) and a timing cycle starts. At the end of the timing cycle (time point 5), RESET goes high and the power-up process is complete.

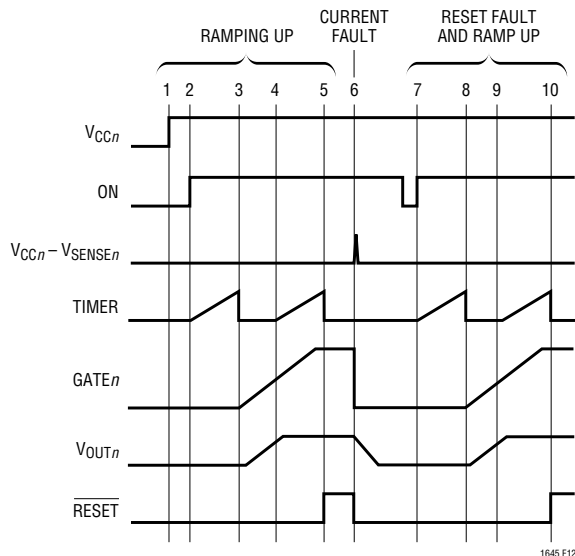

Figure 12. Current Fault Timing

Figure 13. Extending the Short-Circuit Protection Delay

Figure 14. ON Pin Waveforms

## APPLICATIONS INFORMATION

An external hard reset is initiated at time point 6. The ON pin is forced below 0.8V but above 0.4V, and the GATE<sub>n</sub> pin voltages start to ramp down. V<sub>OUT<sub>n</sub></sub> also starts to ramp down, and RESET goes low when V<sub>OUT2</sub> drops below the power-good trip level at time point 7.

Time points 8 to 15 are similar to time points 1 to 7, except the ON pin's different voltage thresholds are used to ramp V<sub>OUT1</sub> and V<sub>OUT2</sub> separately. At time point 8, the ON pin goes above 0.8V but below 2V, and one timing cycle later (time point 9) GATE1 begins to ramp up with V<sub>OUT1</sub> following one gate-to-source voltage drop lower. At time point 10, the ON pin goes above 2V and GATE2 immediately begins ramping up with V<sub>OUT2</sub> following one gate-to-source voltage drop lower. As soon as V<sub>OUT2</sub> reaches its power-good trip level at time point 11, a timing cycle starts. At the end of the timing cycle (time point 12), RESET goes high and the power-up process is complete.

The ON pin is forced below 2V but above 0.8V at time point 13 and the GATE2 pin voltage starts to ramp down. V<sub>OUT2</sub> also starts to ramp down and RESET goes low when V<sub>OUT2</sub> drops below the power-good trip level at time point 14. When the ON pin goes below 0.8V but above 0.4V at time point 15, GATE1 and V<sub>OUT1</sub> ramp down.

Time points 16 to 19 show the same power-up sequence as time points 2 to 5, while time point 20 demonstrates the GATE<sub>n</sub> pins being pulled immediately to ground (instead of ramping down) by the ON pin going below 0.4V.

### Power Supply Tracking and Sequencing Applications

The LTC1645 is able to sequence V<sub>OUT<sub>n</sub></sub> in a number of ways, including ramping V<sub>OUT1</sub> up first and down last; ramping V<sub>OUT1</sub> up first and down first; ramping V<sub>OUT1</sub> up first and V<sub>OUT1</sub> and V<sub>OUT2</sub> down together; and ramping V<sub>OUT1</sub> and V<sub>OUT2</sub> up and down together.

Figure 15 shows an application ramping V<sub>OUT1</sub> and V<sub>OUT2</sub> up and down together. The ON pin must reach 0.8V to ramp up V<sub>OUT1</sub> and V<sub>OUT2</sub>. The spare comparator pulls the ON pin low until V<sub>CC2</sub> is above 2.3V, and the ON pin cannot reach 0.8V before V<sub>CC1</sub> is above 3V. Thus, both input supplies must be within regulation before a timing cycle can start. At the end of the timing cycle, the output voltages ramp up together. If either input supply falls out of regulation, the gates of Q1 and Q2 are pulled low together. Figure 16 shows an oscilloscope photo of the circuit in Figure 15.

Figure 15. Ramping 3.3V and 2.5V Up and Down Together

## APPLICATIONS INFORMATION

Figure 16. Ramping 3.3V and 2.5V Up and Down Together

This circuit guarantees that: (1)  $V_{OUT1}$  never exceeds  $V_{OUT2}$  by more than 1.2V, and (2)  $V_{OUT2}$  is never greater than  $V_{OUT1}$  by more than 0.4V. On power-up,  $V_{OUT1}$  and  $V_{OUT2}$  ramp up together. On power-down, the LTC1645 turns off Q1 and Q2 simultaneously. Charge remains stored on  $C_{LOAD1}$  and  $C_{LOAD2}$  and the output voltages will vary depending on the loads. D1 and D2 turn on at  $\approx 1V$  ( $\approx 0.5V$  each), ensuring condition 1 is satisfied, while D3 prevents violations of condition 2. Different diodes may be necessary for different output voltage configurations. Barring an overvoltage condition at the input(s), the only time these diodes might conduct current is during a power-down event, and then only to discharge  $C_{LOAD1}$  or  $C_{LOAD2}$ . In the case of an input overvoltage condition that causes excess current to flow, the circuit breaker will trip if the current limit level is set appropriately.

Figure 17 shows an application circuit where  $V_{OUT1}$  ramps up before  $V_{OUT2}$ .  $V_{OUT1}$  is initially discharged and D1 is reverse-biased, thus the voltage at the ON pin is determined only by  $V_{CC1}$  through the resistor divider R1 and R2. The voltage at the ON pin exceeds 0.8V if  $V_{CC1}$  is above 4.6V and  $V_{OUT1}$  begins to ramp up after a timing cycle. As  $V_{OUT1}$  ramps up, D1 becomes forward-biased and pulls the ON pin above 2V when  $V_{OUT1} \approx 4.5V$ . This turns on GATE2 and  $V_{OUT2}$  ramps up. The FB comparator monitors  $V_{OUT2}$ , and the spare comparator monitors  $V_{OUT1}$  with  $R_{HYST}$  creating  $\approx 50mV$  of hysteresis.

## Power Supply Multiplexer

Using back-to-back FETs, the LTC1645 can Hot Swap two supplies to the same output, automatically selecting the primary supply if present or the secondary supply if the primary supply is not available. Referring to Figure 18, a diode-or circuit provides power to the LTC1645 if either supply is up. Schottky diodes are used to prevent the voltage at  $V_{CC1}$  from approaching the undervoltage lock-out threshold. This application assumes that if a supply is not present, the supply input is floating.

If only the 3.3V supply is present, the voltage at the COMP<sup>+</sup> pin is below the trip point and COMP<sub>OUT</sub> pulls the base of Q3 low, allowing the GATE1 pin to ramp up normally. The voltage at the ON pin exceeds 0.8V if the 3.3V supply is greater than 3V, ramping up GATE1 and turning on Q1A and Q1B. The ON pin does not exceed 2V (unless the 3.3V supply exceeds 7.5V!), keeping GATE2 low and Q2A and Q2B off.

If only the 5V supply is present or if both supplies are present, the COMP<sup>+</sup> pin is above 1.238V and COMP<sub>OUT</sub> allows the base of Q3 to be pulled high by R2. This turns Q3 on, keeping GATE1 low and Q1A and Q1B off. The voltage at the ON pin is pulled above 2V by R1 and GATE2 turns Q2A and Q2B on.

## APPLICATIONS INFORMATION

### Using the LTC1645 as a Linear Regulator

This application uses the LTC1645 to Hot Swap one primary supply and generate a secondary low dropout regulated supply. Figure 19 shows how to switch a 5V supply and create a 3.3V supply using the spare comparator and one additional transistor. The COMP<sup>+</sup> pin is used to monitor the 3.3V output. As the voltage on the gate of Q2 increases, the 3.3V output increases. At the 3.3V threshold the spare comparator trips. The COMPOUT pin

goes high which turns on Q3. This lowers the voltage on the gate of Q2. This feedback loop is compensated by capacitors C1 and C2 and resistor R1. When power is first applied, the FB pin is low and RESET holds one side of C2 low, slowing the ramp-up of V<sub>OUT2</sub>. As V<sub>OUT2</sub> exceeds 2.75V, RESET releases to allow improved loop transient response. Figure 20 shows the load transient response and voltage ripple of the generated supply.

## APPLICATIONS INFORMATION

### Switching Regulator Supply Sequencing

Figure 21 shows the LTC1645 sequencing two power supplies, the lower of which is generated by the LTC1430A switching regulator. Connecting the regulator's FB pin resistor divider (R1 and R2) to the other side of the pass FET (Q1) allows the LTC1430A to compensate for the voltage drop across  $R_{SENSE1}$  and Q1, assuring an accurate voltage output. The spare comparator holds the LTC1645's ON pin low until the LTC1430A's output is at least 3V, and shuts both channels off if it drops below 3V. When the ON/OFF signal is taken high to 5V (turn-on), the voltage at the ON pin rises with an RC exponential characteristic, reaching 0.8V first. This starts a timing cycle, and GATE1 begins to rise. GATE2 starts to ramp up after the ON pin reaches 2V. As long as the timing cycle is shorter than the time for the ON pin to rise from 0.8V to 2V,  $V_{OUT2}$  ramps up after  $V_{OUT1}$ . RESET goes high one timing cycle after  $V_{OUT1}$  exceeds 3V. When the ON/OFF signal is brought low, the voltage at the ON pin exponentially decays and GATE2 ramps down before GATE1. RESET goes low as soon as  $V_{OUT1}$  falls below 3V. Figure 22 shows the power-up and power-down sequences of the circuit in Figure 21.

Figure 22. Switching Regulator Supply Sequencing

### Switching Regulator Hot Swapping

High current switching regulators usually require large bypass capacitors on both input and output for proper operation. The application in Figure 23 controls the inrush current to the LTC1649's input bypass capacitors and ramps the two output voltages up and down together. As with the previous application, connecting the regulator's FB pin resistor divider to the other side of the output pass FET (Q2) allows the LTC1649 to compensate for the voltage drop across Q2, assuring an accurate voltage output. The voltage at the LTC1645's ON pin reaches 0.8V when  $V_{IN}$  exceeds 3V, and GATE1 begins to ramp up one timing cycle later. As the regulator's output rises, D2 pulls the ON pin above 2V and GATE2 begins to rise, ramping  $V_{OUT1}$  and  $V_{OUT2}$  up together. RESET goes high one timing cycle after  $V_{OUT1}$  exceeds 3V and  $V_{OUT2}$  exceeds 2.35V. Figure 24 shows the circuit in Figure 23 powering up.

Care should be taken connecting a switching regulator's FB or SENSE pins to a node other than its output. Depending on the regulator's internal architecture, unusual behavior may occur as it tries in vain to raise the voltage at

its FB or SENSE pin. In the case of the LTC1649, large peak currents result if the FB pin is at ground and not connected directly to the output inductor and capacitors. To keep the peak currents under control, R1, R2 and D1 hold the FB pin above ground but below its normal regulated value until  $V_{OUT2}$  ramps up and D1 reverse-biases.

### Power N-Channel Selection

The  $R_{DS(ON)}$  of the external pass transistors must be low enough so that the voltage drop across them is 100mV or less at full current. If the  $R_{DS(ON)}$  is too high, the voltage drop across the transistor can cause the output voltage to trip the reset circuit. The transistors listed in Table 1 or other similar transistors are recommended for use with the LTC1645.

Low voltage applications may require the use of logic-level FETs; ensure their maximum  $V_{GS}$  rating is sufficient for the application. GATE voltage as a function of  $V_{CC}$  is illustrated in the Typical Performance curves. If lower GATE drive is desired, connect a diode in series with a zener between GATE and  $V_{CC}$  or between GATE and  $V_{OUT}$  as shown in Figure 25.
