

## FEATURES

- Allows Safe Board Insertion into a Live Backplane
- Small Footprint
- 33mΩ MOSFET with R<sub>SENSE</sub>
- Wide Operating Voltage Range: 2.9V to 15V
- Adjustable, 10% Accurate Current Limit
- Current and Temperature Monitor Outputs
- Overtemperature Protection
- Adjustable Current Limit Timer Before Fault
- Power Good and Fault Outputs
- Adjustable Inrush Current Control
- 2% Accurate Undervoltage and Overvoltage Protection
- Pin Compatible with LTC4217 (DFN Package Only)
- Available in 16-Lead 5mm × 3mm DFN Package

## APPLICATIONS

- RAID Systems, Solid State Drives
- Server I/O Cards
- Industrial

## DESCRIPTION

The LTC<sup>®</sup>4232 is an integrated solution for Hot Swap applications that allows a board to be safely inserted and removed from a live backplane. The part integrates a Hot Swap controller, power MOSFET and current sense resistor in a single package for small form factor applications.

The LTC4232 provides separate inrush current control and a 10% accurate 5A current limit with foldback current limiting. The current limit threshold can be adjusted dynamically using an external pin. Additional features include a current monitor output that amplifies the sense resistor voltage for ground referenced current sensing and a MOSFET temperature monitor output. Thermal limit, overvoltage, undervoltage and power good monitoring are also provided. For a 2A pin compatible version, see LTC4217.

The LTC4232-1 (separate data sheet) allows faster turn-on than the LTC4232 by providing 16ms debounce delay and external control of the GATE ramp rate.

**Note 1:** Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

**Note 2:** All currents into pins are positive, all voltages are referenced to GND unless otherwise specified.

**Note 3:** An internal clamp limits the GATE pin to a maximum of 6.5V above OUT. Driving this pin to voltages beyond the clamp may damage the device.

**Note 4:** This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed  $125^\circ\text{C}$  when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

**Note 5:**  $T_J$  is calculated from the ambient temperature,  $T_A$ , and power dissipation,  $P_D$ , according to the formula:

$$T_J = T_A + (P_D \cdot 46^\circ\text{C}/\text{W})$$

## TYPICAL PERFORMANCE CHARACTERISTICS $T_A = 25^\circ\text{C}$ , $V_{DD} = 12\text{V}$ unless otherwise noted.

**TYPICAL PERFORMANCE CHARACTERISTICS**  $T_A = 25^\circ\text{C}$ ,  $V_{DD} = 12\text{V}$  unless otherwise noted.

## PIN FUNCTIONS

**FB:** Foldback and Power Good Input. Connect this pin to an external resistive divider from OUT. If the voltage falls below 0.6V, the current limit is reduced using a foldback profile (see the Typical Performance Characteristics section). If the voltage falls below 1.21V, the PG pin will pull low to indicate the power is bad.

**FLT:** Overcurrent Fault Indicator. Open-drain output pulls low when an overcurrent fault has occurred and the circuit breaker trips. For overcurrent auto-retry tie to UV pin (see the Applications Information section for details).

**GATE:** Gate Drive for Internal N-channel MOSFET. An internal 24 $\mu$ A current source charges the gate of the N-channel MOSFET. At start-up the GATE pin ramps up at a 0.3V/ms rate determined by internal circuitry. During an undervoltage or overvoltage condition a 250 $\mu$ A pull-down current turns the MOSFET off. During a short-circuit or undervoltage lockout condition, a 140mA pull-down current source between GATE and OUT is activated.

**GND:** Device Ground.

**I<sub>MON</sub>:** Current Monitor Output. The current in the internal MOSFET switch is divided by 50,000 and sourced from this pin. Placing a 20k resistor from this pin to GND creates a 0V to 2V voltage swing when current ranges from 0A to 5A.

**INTV<sub>CC</sub>:** Internal 3.1V Supply Decoupling Output. This pin must have a 1 $\mu$ F or larger bypass capacitor. Overloading this pin can disrupt internal operation.

**I<sub>SET</sub>:** Current Limit Adjustment Pin. For a 5.6A current limit value open this pin. This pin is driven by a 20k resistor in series with a voltage source. The pin voltage is used to generate the current limit threshold. The internal 20k resistor ( $R_{ISET}$ ) and an external resistor ( $R_{SET}$ ) between I<sub>SET</sub> and ground create an attenuator that lowers the current limit value. Due to circuit tolerance,  $R_{SET}$  should not be less than 2k. In order to match the temperature variation of the sense resistor, the voltage on this pin increases at the same rate as the sense resistance increases. Therefore the voltage at I<sub>SET</sub> pin is made proportional to temperature of the MOSFET switch.

**OUT:** Output of Internal MOSFET Switch. Connect this pin directly to the load.

**OV:** Overvoltage Comparator Input. Connect this pin to an external resistive divider from V<sub>DD</sub>. If the voltage at this pin rises above 1.235V, an overvoltage is detected and the switch turns off. Tie to GND if unused.

**PG:** Power Good Indicator. Open-drain output pulls low when the FB pin drops below 1.21V indicating the power is bad. If the FB pin rises above 1.23V and the GATE to OUT voltage exceeds 4.2V, the open-drain pull-down releases the PG pin to go high.

**SENSE:** Current Sense Node and MOSFET Drain. The current limit circuit controls the GATE pin to limit the sense voltage between the V<sub>DD</sub> and SENSE pins to 42mV (5.6A) or less depending on the voltage at the FB pin. The exposed pad on DHC packages are connected to SENSE and must be soldered to an electrically isolated printed circuit board trace to properly transfer the heat out of the package.

**TIMER:** Timer Input. Connect a capacitor between this pin and ground to set a 12ms/ $\mu$ F duration for current limit before the switch is turned off. If the UV pin is toggled low while the MOSFET switch is off, the switch will turn on again following a cooldown time of 518ms/ $\mu$ F duration. Tie this pin to INTV<sub>CC</sub> for a fixed 2ms overcurrent delay and 100ms auto-retry time.

**UV:** Undervoltage Comparator Input. Tie high if unused. Connect this pin to an external resistive divider from V<sub>DD</sub>. If the UV pin voltage falls below 1.15V, an undervoltage is detected and the switch turns off. Pulling this pin below 0.62V resets the overcurrent fault and allows the switch to turn back on (see the Applications Information section for details). If overcurrent auto-retry is desired then tie this pin to the FLT pin.

**V<sub>DD</sub>:** Supply Voltage and Current Sense Input. This pin has an undervoltage lockout threshold of 2.73V.

# FUNCTIONAL DIAGRAM

## OPERATION

The Functional Diagram displays the main circuits of the device. The LTC4232 is designed to turn a board's supply voltage on and off in a controlled manner allowing the board to be safely inserted and removed from a live backplane. The LTC4232 includes a 25m $\Omega$  MOSFET and a 7.5m $\Omega$  current sense resistor. During normal operation, the charge pump and gate driver turn on the pass MOSFET's gate to provide power to the load. The inrush current control is accomplished by the INRUSH circuit. This circuit limits the GATE ramp rate to 0.3V/ms and hence controls the voltage ramp rate of the output capacitor.

The current sense (CS) amplifier monitors the load current using the voltage sensed across the current sense resistor. The CS amplifier limits the current in the load by reducing the GATE-to-OUT voltage in an active control loop. It is simple to adjust the current limit threshold using the current limit adjustment ( $I_{SET}$ ) pin. This allows a different threshold during other times such as start-up.

A short circuit on the output to ground causes significant power dissipation during active current limiting. To limit this power, the foldback amplifier reduces the current limit value from 5.6A to 1.5A in a linear manner as the FB pin drops below 0.6V (see the Typical Performance Characteristics section).

If an overcurrent condition persists, the TIMER pin ramps up with a 100 $\mu$ A current source until the pin voltage exceeds 1.235V (comparator TM2). This indicates to the logic that it is time to turn off the pass MOSFET to prevent overheating. At this point the TIMER pin ramps down using the

2 $\mu$ A current source until the voltage drops below 0.21V (Comparator TM1) which tells the logic to start an internal 100ms timer. At this point, the pass transistor has cooled and it is safe to turn it on again. It is suitable for many applications to use an internal 2ms overcurrent timer with a 100ms cooldown period. Tying the TIMER pin to INTV<sub>CC</sub> sets this default timing. Latchoff is the normal operating condition following overcurrent turnoff. Retry is initiated by pulling the UV pin low for a minimum of 1 $\mu$ s then high. Auto retry is implemented by tying the  $\overline{FLT}$  to the UV pin.

The output voltage is monitored using the FB pin and the PG comparator to determine if the power is available for the load. The power good condition is signaled by the PG pin using an open-drain pull-down transistor.

The Functional Diagram also shows the monitoring blocks of the LTC4232. The two comparators on the left side include the UV and OV comparators. These comparators determine if the external conditions are valid prior to turning on the MOSFET. But first the undervoltage lockout circuits UVLO1 and UVLO2 must validate the input supply and the internally generated 3.1V supply (INTV<sub>CC</sub>) and generate the power up initialization to the logic circuits. If the external conditions remain valid for 100ms the MOSFET is allowed to turn on.

Other features include MOSFET current and temperature monitoring. The current monitor (CM) outputs a current proportional to the sense resistor current. This current can drive an external resistor or other circuits for monitoring purposes. A voltage proportional to the MOSFET temperature is output to the  $I_{SET}$  pin. The MOSFET is protected by a thermal shutdown circuit.

## APPLICATIONS INFORMATION

The typical LTC4232 application is in a high availability system that uses a positive voltage supply to distribute power to individual cards. A complete application circuit is shown in Figure 1. External component selection is discussed in detail in the following sections.

\*TVS Z1: DIODES INC. SMAJ17A

Figure 1. 2A, 12V Card Resident Application

### Turn-On Sequence

Several conditions must be present before the internal pass MOSFET can be turned on. First the supply  $V_{DD}$  must exceed its undervoltage lockout level. Next the internally generated supply  $INTV_{CC}$  must cross its 2.65V undervoltage threshold. This generates a 25µs power-on-reset pulse which clears the fault register and initializes internal latches.

After the power-on-reset pulse, the UV and OV pins must indicate that the input voltage is within the acceptable range. All of these conditions must be satisfied for the duration of 100ms to ensure that any contact bounce during the insertion has ended.

The MOSFET is turned on by charging up the GATE with a charge pump generated 24µA current source whose value is adjusted by shunting a portion of the pull-up current to ground. The charging current is controlled by the INRUSH circuit that maintains a constant slope of GATE voltage versus time (Figure 2). The voltage at the GATE pin rises with a slope of 0.3[V/ms] and the supply inrush current is set at:

$$I_{INRUSH} = C_L \cdot 0.3[V/ms]$$

Figure 2. Supply Turn-On

This gate slope is designed to charge up a 1000µF capacitor to 12V in 40ms, with an inrush current of 300mA. This allows the inrush current to stay under the current limit threshold (1.5A) for capacitors less than 1000µF. Included in the Typical Performance Characteristics section is a graph of the Safe Operating Area for the MOSFET. It is evident from this graph that the power dissipation at 12V, 300mA for 40ms is in the safe region.

Adding the  $R_{GATE}$ ,  $C_{GATE}$  and  $C_{COMP}$  network on the GATE pin will lower the inrush current below the default value set by the INRUSH circuit. The GATE is charged with an 24µA current source (when INRUSH circuit is not driving the GATE). The voltage at the GATE pin rises with a slope equal to  $24\mu A/C_{GATE}$  and the supply inrush current is set at:

$$I_{INRUSH} = \frac{C_L}{C_{GATE}} \cdot 24\mu A$$

When the GATE voltage reaches the MOSFET threshold voltage, the switch begins to turn on and the OUT voltage follows the GATE voltage as it increases. Once OUT reaches  $V_{DD}$ , the GATE will ramp up until clamped by the 6.15V Zener between GATE and OUT.

As the OUT voltage rises, so will the FB pin which is monitoring it. Once the FB pin crosses its 1.235V threshold and the GATE to OUT voltage exceeds 4.2V, the PG pin will cease to pull low and indicate that the power is good.

### Parasitic MOSFET Oscillation

When the N-channel MOSFET ramps up the output during power-up it operates as a source follower. The source follower configuration may self-oscillate in the range of 25kHz to 300kHz when the load capacitance is less than

## APPLICATIONS INFORMATION

10 $\mu$ F, especially if the wiring inductance from the supply to the V<sub>DD</sub> pin is greater than 3 $\mu$ H. The possibility of oscillation will increase as the load current (during power-up) increases. There are two ways to prevent this type of oscillation. The simplest way is to avoid load capacitances below 10 $\mu$ F. For wiring inductance larger than 20 $\mu$ H, the minimum load capacitance may extend to 100 $\mu$ F. A second choice is to connect an external gate capacitor C<sub>P</sub> > 1.5nF as shown in Figure 3.

Figure 3. Compensation for Small C<sub>LOAD</sub>

### Turn-Off Sequence

The switch can be turned off by a variety of conditions. A normal turn-off is initiated by the UV pin going below its 1.235V threshold. Additionally, several fault conditions will turn off the switch. These include an input overvoltage (OV pin), overcurrent circuit breaker (SENSE pin) or overtemperature. Normally the switch is turned off with a 250 $\mu$ A current pulling down the GATE pin to ground. With the switch turned off, the OUT voltage drops which pulls the FB pin below its threshold. PG then pulls low to indicate output power is no longer good.

If V<sub>DD</sub> drops below 2.65V for greater than 5 $\mu$ s or INTV<sub>CC</sub> drops below 2.5V for greater than 1 $\mu$ s, a fast shutdown of the switch is initiated. The GATE is pulled down with a 140mA current to the OUT pin.

### Overcurrent Fault

The LTC4232 features an adjustable current limit with foldback that protects against short-circuits and excessive load current. To prevent excessive power dissipation in the switch during active current limit, the available current is reduced as a function of the output voltage sensed by the FB pin. A graph in the Typical Performance Characteristics curves shows the Current Limit Threshold Foldback.

An overcurrent fault occurs when the current limit circuitry has been engaged for longer than the timeout delay set by the TIMER. Current limiting begins when the MOSFET current reaches 1.5A to 5.6A (depending on the foldback). The GATE pin is then brought down with a 140mA GATE-to-OUT current. The voltage on the GATE is regulated in order to limit the current to less than 5.6A. At this point, a circuit breaker time delay starts by charging the external timing capacitor with a 100 $\mu$ A pull-up current from the TIMER pin. If the TIMER pin reaches its 1.235V threshold, the internal switch turns off (with a 250 $\mu$ A current from GATE to ground). Included in the Typical Performance Characteristics curves is a graph of the Safe Operating Area for the MOSFET. From this graph one can determine the MOSFET's maximum time in current limit for a given output power.

Tying the TIMER pin to INTV<sub>CC</sub> will force the part to use the internally generated (circuit breaker) delay of 2ms. In either case the FLT pin is pulled low to indicate an overcurrent fault has turned off the pass MOSFET. For a given circuit breaker time delay, the equation for setting the timing capacitor's value is as follows:

$$C_T = t_{CB} \cdot 0.083[\mu\text{F}/\text{ms}]$$

After the switch is turned off, the TIMER pin begins discharging the timing capacitor with a 2 $\mu$ A pull-down current. When the TIMER pin reaches its 0.21V threshold, an internal 100ms timer is started. After the 100ms delay, the switch is allowed to turn on again if the overcurrent fault latch has been cleared. Bringing the UV pin below 0.6V for a minimum of 1 $\mu$ s and then high will clear the fault latch. If the TIMER pin is tied to INTV<sub>CC</sub> then the switch is allowed to turn on again (after an internal 100ms delay), if the overcurrent fault latch is cleared.

Tying the FLT pin to the UV pin allows the part to self-clear the fault and turn the MOSFET on as soon as TIMER pin has ramped below 0.21V. In this auto-retry mode the LTC4232 repeatedly tries to turn on after an overcurrent at a period determined by the capacitor on the TIMER pin. The auto-retry mode also functions when the TIMER pin is tied to INTV<sub>CC</sub>.

The waveform in Figure 4 shows how the output latches off following a short-circuit. The current in the MOSFET is 1.4A as the timer ramps up.

4232fc

## APPLICATIONS INFORMATION

Figure 4. Short-Circuit Waveform

### Current Limit Adjustment

The default value of the active current limit is 5.6A. The current limit threshold can be adjusted lower by placing a resistor between the  $I_{SET}$  pin and ground. As shown in the Functional Block Diagram the voltage at the  $I_{SET}$  pin (via the clamp circuit) sets the CS amplifier's built-in offset voltage. This offset voltage directly determines the active current limit value. With the  $I_{SET}$  pin open, the voltage at the  $I_{SET}$  pin is determined by a positive temperature coefficient reference. This voltage is set to 0.618V at room temperature which corresponds to a 5.6A current limit at room temperature.

An external resistor  $R_{SET}$  placed between the  $I_{SET}$  pin and ground forms a resistive divider with the internal 20k  $R_{ISET}$  sourcing resistor. The divider acts to lower the voltage at the  $I_{SET}$  pin and therefore lower the current limit threshold. The overall current limit threshold precision is reduced to  $\pm 12\%$  when using a 20k resistor to halve the threshold.

Using a switch (connected to ground) in series with  $R_{SET}$  allows the active current limit to change only when the switch is closed. This feature can be used to program a reduced running current while the maximum available current limit is used at startup.

### Monitor MOSFET Temperature

The voltage at the  $I_{SET}$  pin increases linearly with increasing temperature. The temperature profile of the  $I_{SET}$  pin is shown in the Typical Performance Characteristics section. Using a comparator or ADC to measure the  $I_{SET}$  voltage provides an indicator of the MOSFET temperature.

The  $I_{SET}$  voltage follows the formula:

$$V_{ISET} = \frac{R_{SET}}{R_{SET} + R_{ISET}} \cdot (T + 273^{\circ}\text{C}) \cdot 2.093[\text{mV}/^{\circ}\text{C}]$$

The MOSFET temperature is calculated using  $R_{ISET}$  of 20k.

$$T = \frac{(R_{SET} + 20\text{k}) \cdot V_{ISET}}{R_{SET} \cdot 2.093[\text{mV}/^{\circ}\text{C}]} - 273^{\circ}\text{C}$$

When  $R_{SET}$  is not present, T becomes:

$$T = \frac{V_{ISET}}{2.093[\text{mV}/^{\circ}\text{C}]} - 273^{\circ}\text{C}$$

There is an overtemperature circuit in the LTC4232 that monitors an internal voltage similar to the  $I_{SET}$  pin voltage. When the die temperature exceeds  $145^{\circ}\text{C}$  the circuit turns off the MOSFET until the temperature drops to  $125^{\circ}\text{C}$ .

### Monitor MOSFET Current

The current in the MOSFET passes through an internal  $7.5\text{m}\Omega$  sense resistor. The voltage on the sense resistor is converted to a current that is sourced out of the  $I_{MON}$  pin. The gain of  $I_{SENSE}$  amplifier is  $20\mu\text{A}/\text{A}$  referenced from the MOSFET current. This output current can be converted to a voltage using an external resistor to drive a comparator or ADC. The voltage compliance for the  $I_{MON}$  pin is from 0V to  $\text{INT}V_{CC} - 0.7\text{V}$ .

A microcontroller with a built-in comparator can build a simple integrating single-slope ADC by resetting a capacitor that is charged with this current. When the capacitor voltage trips the comparator and the capacitor is reset, a timer is started. The time between resets will indicate the MOSFET current.

### Monitor OV and UV Faults

Protecting the load from an overvoltage condition is the main function of the OV pin. In Figure 1 an external resistive divider (driving the OV pin) connects to a comparator to turn off the MOSFET when the  $V_{DD}$  voltage exceeds 15.2V. If the  $V_{DD}$  pin subsequently falls back below 14.9V, the switch will be allowed to turn on immediately. In the LTC4232 the OV pin threshold is 1.235V when rising, and 1.215V when falling out of overvoltage.

## APPLICATIONS INFORMATION

The UV pin functions as an undervoltage protection pin or as an “ON” pin. In the Figure 1 application the MOSFET turns off when  $V_{DD}$  falls below 9.23V. If the  $V_{DD}$  pin subsequently rises above 9.88V for 100ms, the switch will be allowed to turn on again. The LTC4232 UV turn-on/off thresholds are 1.235V (rising) and 1.155V (falling).

In the cases of an undervoltage or overvoltage the MOSFET turns off and there is indication on the PG status pin. When the overvoltage is removed the MOSFET’s gate ramps up immediately at the rate determined by the INRUSH block.

### Power Good Indication

In addition to setting the foldback current limit threshold, the FB pin is used to determine a power good condition. The Figure 1 application uses an external resistive divider on the OUT pin to drive the FB pin. The PG comparator indicates logic high when OUT pin rises above 10.5V. If the OUT pin subsequently falls below 10.3V the comparator toggles low. On the LTC4232 the PG comparator drives high when the FB pin rises above 1.235V and low when it falls below 1.215V.

Once the PG comparator is high the GATE pin voltage is monitored with respect to the OUT pin. Once the GATE minus OUT voltage exceeds 4.2V the PG pin goes high. This indicates to the system that it is safe to load the OUT pin while the MOSFET is completely turned “on”. The PG pin goes low when the GATE is commanded off (using the UV, OV or SENSE pins) or when the PG comparator drives low.

### Design Example

Consider the following design example (Figure 5):  $V_{IN} = 12V$ ,  $I_{MAX} = 5A$ ,  $I_{INRUSH} = 100mA$ ,  $C_L = 330\mu F$ ,  $V_{UVON} = 9.88V$ ,  $V_{OVOFF} = 15.2V$ ,  $V_{PGTHRESHOLD} = 10.5V$ . A current limit fault triggers an automatic restart of the power-up sequence.

The inrush current is defined by the current required to charge the output capacitor using the fixed 0.3V/ms GATE charge-up rate. The inrush current is defined as:

$$I_{INRUSH} = C_L \cdot 0.3[V/ms] = 330\mu F \cdot 0.3[V/ms] = 100mA$$

\*TVS Z1: DIODES INC. SMAJ17A

Figure 5. 5A, 12V Card Resident Application

As mentioned previously the charge-up time is the output voltage (12V) divided by the output rate of 0.3V/ms resulting in 40ms. The peak power dissipation of 12V at 100mA (or 1.2W) is within the SOA of the pass MOSFET for 40ms (see MOSFET SOA curve in the Typical Performance Characteristics section).

Next the power dissipated in the MOSFET during overcurrent must be limited. The active current limit uses a timer to prevent excessive energy dissipation in the MOSFET. The worst-case power dissipation occurs when the voltage versus current profile of the foldback current limit is at the maximum. This occurs when the current is 6.1A and the voltage is one half of the  $V_{IN}$  or 6V. See the Current Limit Threshold Foldback in the Typical Performance Characteristics section to view this profile. In order to survive 36W, the MOSFET SOA dictates a maximum time of 10ms (see SOA graph). Use the internal 2ms timer invoked by tying the TIMER pin to  $INTV_{CC}$ . After the 2ms timeout the  $\overline{FLT}$  pin needs to pull-down on the UV pin to restart the power-up sequence.

The values for overvoltage, undervoltage and power good thresholds using the resistive dividers on the UV, OV and FB pins match the requirements of turn-on at 9.88V and turn-off at 15.2V.

The final schematic in Figure 5 results in very few external components. The pull-up resistor, R7, connects to the PG pin while the 20k ( $R_{MON}$ ) converts the  $I_{MON}$  current to a voltage at a ratio:

$$V_{IMON} = 20[\mu A/A] \cdot 20k \cdot I_{OUT} = 0.4[V/A] \cdot I_{OUT}$$

In addition there is a 1µF bypass (C1) on the  $INTV_{CC}$  pin.

## APPLICATIONS INFORMATION

### Layout Considerations

In Hot Swap applications where load currents can be 5A, narrow PCB tracks exhibit more resistance than wider tracks and operate at elevated temperatures. The minimum trace width for 1oz copper foil is 0.02" per amp to make sure the trace stays at a reasonable temperature. Using 0.03" per amp or wider is recommended. Note that 1oz copper exhibits a sheet resistance of about 0.5m $\Omega$ /square. Small resistances add up quickly in high current applications.

There are two  $V_{DD}$  pins on opposite sides of the package that connect to the sense resistor and MOSFET. The PCB layout should be balanced and symmetrical to each  $V_{DD}$  pin to balance current in the MOSFET bond wires. Figure 6 shows a recommended layout for the LTC4232.

Although the MOSFET is self protected from overtemperature, it is recommended to solder the backside of the package to a copper trace to provide a good heat sink. Note that the backside is connected to the SENSE pin and cannot be soldered to the ground plane. During normal loads the power dissipated in the MOSFET is as high as 1.9W. A 10mm  $\times$  10mm area of 1oz copper should be sufficient. This area of copper can be divided in many layers.

It is also important to put C1, the bypass capacitor for the INTV<sub>CC</sub> pin as close as possible between the INTV<sub>CC</sub> and GND.

### Additional Applications

The LTC4232 has a wide operating range from 2.9V to 15V. The UV, OV and PG thresholds are set with few resistors. All other functions are independent of supply voltage.

In addition to Hot Swap applications, the LTC4232 also functions as a backplane resident switch for removable load cards (see Figure 7).

The last page shows a 3.3V application with a UV threshold of 2.87V, an OV threshold of 3.77V and a PG threshold of 3.05V.

## REVISION HISTORY

REV	DATE	DESCRIPTION	PAGE NUMBER
A	12/12	Modifications to application drawings	1, 9, 12, 13, 16
		Updated conditions on $I_{LIM(TH)}$ , $I_{IN}$ , $V_{TH}$ , $V_{OL}$ , $I_{OH}$	2, 3
		Switched MIN / MAX values for $I_{TIMER(UP)}$ and $I_{GATE(UP)}$	3
		Changed formula in Note 5 to use $\theta_{JA}$ 46°C/W	3
		Added test condition to Current Limit Threshold Foldback graph, G07	4
		Updated title and axes on G12	5
		Updated $INTV_{CC}$ voltage to 3.1V	6
B	04/15	Typical Application, Figure 5 and Figure 7: Added SMAJ22A (Z1); updated C1 value	1, 12, 13, 16
		Raised $I_{GATE(DN)}$ maximum from 340 $\mu$ A to 400 $\mu$ A	3
		Updated TPCs G08, G11	4, 5
		$INTV_{CC}$ Pin Function: Raised bypass capacitor value from 0.1 $\mu$ F to 1 $\mu$ F	6
		$I_{SET}$ Pin Function: Recommended minimum resistor value to be 2k	6
		Figure 1: Added Z1, $C_{COMP}$ ; updated C1, $R_{GATE}$	9
C	01/16	Changed TVS to SMAJ17A in application circuit	1, 9, 12, 13, 16
		Clarified that operating temperature range refers to ambient	2
		Added $BW_{IMON}$ and $t_{D(FAULT)}$ specifications	3
		Updated $INTV_{CC}$ and $I_{SET}$ pin functions	6
		Added equations to calculate MOSFET temperature from $V_{ISET}$	11
