

1nV/ $\sqrt{\text{Hz}}$ 420MHz GBW, 180V/ μs ,
Low Distortion Rail-to-Rail Output Op Amps

FEATURES

- Ultra Low Voltage Noise: 1nV/ $\sqrt{\text{Hz}}$
- Low Distortion: HD2/HD3 < -90dB_C at 4V_{P-P}, 1MHz into 1k Ω
- High Slew Rate: 180V/ μs
- GBW = 420MHz
- -3dB Frequency (A_V = +1): 330MHz
- Input Common Mode Range Includes Negative Rail
- Output Swings Rail-to-Rail
- Supply Current: 5.5mA/Channel Typ
- Operating Supply Range: 2.8V to 11.75V
- Input Offset Voltage: 95 μV Max
- Offset Drift :0.4 $\mu\text{V}/^\circ\text{C}$
- Low Power Shutdown
- Very High Open Loop Gain: 9V/ μV (139dB), R_L = 1k Ω
- Operating Temp Range: -40 $^\circ\text{C}$ to 125 $^\circ\text{C}$
- Single in 8-Lead SOIC, TSOT-23, 2mm x 2mm DFN.
Duals in 3mm x 3mm DFN, MS8E

APPLICATIONS

- Optical Electronics: Fast AC-Coupled Transimpedance Amplifiers
- Driving High Dynamic Range A/D Converters
- Active Filters
- Video Amplifiers
- Low Voltage Low Distortion Amplification

DESCRIPTION

The LTC[®]6226/LTC6227 are very fast, low noise rail-to-rail output, unity gain stable single/dual op amps, with a gain-bandwidth product of 420MHz and a slew rate of 180V/ μs . The low input referred voltage noise of only 1nV/ $\sqrt{\text{Hz}}$ and low distortion of less than -90dB_C for 4V_{P-P} signals at 1MHz makes them ideal for applications that require high dynamic range and deal with very fast signals, such as driving A/D converters.

The combination of low offset, low offset drift, high gain (139dB) and high CMRR (114dB) make these excellent devices for high dynamic range applications.

The LTC6226 family maintains excellent performance for supply voltages of 2.8V to 11.75V and the devices are fully specified at supplies of 3V, 5V and 10V ($\pm 5\text{V}$).

With an input range extending to the negative rail and rail-to-rail output stage, the operational amplifier can accommodate wide swinging signals, and true single supply operation.

For space constrained applications, the amplifiers come in 2mm x 2mm DFN (single) and 3mm x 3mm DFN (dual) packages. The devices are also available in 8-lead SOIC, TSOT-23 and MS8E.

These amplifiers can be used as replacements for many high speed op amps to improve speed, noise and dynamic range.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The inputs are protected by back-to-back diodes. If any of the input or shutdown pins goes 300mV beyond either supply or the differential input voltage exceeds 0.7V, the input current should be limited to less than 10mA.

Note 3: A heat sink may be required to keep the junction temperature below the absolute maximum rating when the output current is high.

Note 4: The LTC6226I/LTC6227I are guaranteed functional and specified over the temperature range of $-40^\circ C$ to $85^\circ C$. The LTC6226H/LTC6227H are guaranteed and specified functional over the temperature range of $-40^\circ C$ to $125^\circ C$.

Note 5: Matching parameters are the difference between amplifiers A and B on the LTC6227.

Note 6: The input bias current is the average of the average of the currents through the positive and negative input pins.

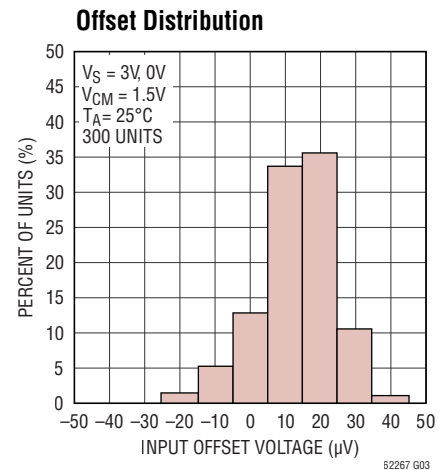

Note 7: Supply Voltage Range is guaranteed by Power Supply Rejection Ratio test.

Note 8: Thermal resistance varies with the amount of PC board metal connected to the package. The specified values are with short traces connected to the leads.

Note 9: Middle 2/3 of the output waveform is observed for Slew Rate. $R_L = 1k$ to half supply.

Note 10: Input Common Mode Range is guaranteed by Common Mode Rejection Ratio Test.

TYPICAL PERFORMANCE CHARACTERISTICS $V_S = \pm 5V, V_{CM} = 0V, R_L = 1k\Omega$ to Half Supply, $T_A = 25^\circ C$, unless otherwise noted.

TYPICAL PERFORMANCE CHARACTERISTICS $V_S = \pm 5V$, $V_{CM} = 0V$, $R_L = 1k\Omega$ to Half Supply, $T_A = 25^\circ C$, unless otherwise noted.

PIN FUNCTIONS

FB (SOIC-8 Only): Feedback Pin. Internally connected to OUT.

+IN: Non-Inverting Input of Amplifier. Valid input range is from V^- to $V^+ - 1.2V$

-IN: Inverting Input of Amplifier. Valid input range is from V^- to $V^+ - 1.2V$

OUT: Output of the Amplifier. Swings rail to rail and can typically source/sink 60mA of current.

SHDN: Shutdown Pin (Active Low). Referenced to V^+ . When taken 2.75V below V^+ , the amplifier shuts down and enters low power mode, with the outputs in a high impedance state. When left floating, the amplifier is on.

V^+ : Positive Supply to Amplifier. Valid range is from 2.8V to 11.75V when V^- is 0V.

V^- : Negative Supply to Amplifier. Typically 0V. This can be made a negative voltage as long as $2.8V \leq (V^+ - V^-) \leq 11.75V$

APPLICATIONS INFORMATION

Circuit Description

The LTC6226/LTC6227 have an input signal range that extends from the negative power supply to 1.2V below the positive power supply. Figure 1 depicts a simplified schematic of the amplifier. The input stage consists of PNP transistors Q1 and Q2. Bootstrap transistor Q13 improves DC accuracy by reducing the offset contribution of the base currents of Q11 and Q12 since it has twice their collector current thus Q11/Q12 current matching becomes

independent of transistor β . The bootstrap arrangement also enhances gain by improving output impedance. A pair of complementary common emitter stages, Q15 and Q14, enables the output to swing to either rail. The SHDN Interface block translates the SHDN signal into pwr_dn for powering down the device (by deactivating current sources I1 - I4) and putting the output in a high impedance state (by shorting the bases of Q15/Q14 to the supplies via M2 and M1).

Figure 1. LTC6226/LTC6227 Simplified Schematic Diagram

APPLICATIONS INFORMATION

Output

The LTC6226 family has excellent output drive capability. The amplifiers can typically deliver more than 50mA of output drive current at a total supply of 10V, and can typically swing to within 600mV of the rail for load currents as high as 25mA. As the supply voltage to the amplifier decreases, the output current capability also decreases. Attention must be paid to keep the junction temperature of the IC below 150°C (refer to power dissipation section) when the output is in continuous short-circuit. The output of the amplifier has reverse-biased diodes connected to each supply. If the output is forced beyond either supply, extremely high currents will flow through those diodes which can result in damage to the device. Forcing the output to even 1V beyond either supply could result in several hundred milliamps of current through either diode. Thus forcing the output beyond the supplies should be avoided.

Input Protection

The LTC6226/LTC6227 has a pair of back to back diodes (D5 and D7) to prevent the emitter base breakdown of the input transistors and limit the differential input to $\pm 700\text{mV}$. Unlike many other high performance amplifiers, the bases of the input pair transistors Q1 and Q2 are not connected to the pins using internal resistors to limit input current, since that would cause the noise to increase. For instance, a 100Ω resistor in series with each input would generate $1.8\text{nV}/\sqrt{\text{Hz}}$ of noise, and the total amplifier noise voltage would rise from $1\text{nV}/\sqrt{\text{Hz}}$ to $2.06\text{nV}/\sqrt{\text{Hz}}$. Once the input differential voltage exceeds $\pm 0.7\text{V}$, current conducted through the protection diodes should be limited to $\pm 10\text{mA}$. This implies 25Ω of protection resistance per quarter volt (250mV) of overdrive beyond $\pm 0.7\text{V}$. In addition, the input and shutdown pins have reverse biased diodes connected to the supplies. The current in these diodes must be limited to less than 10mA. The amplifiers should not be used as comparators or in other open loop applications.

ESD

The LTC6226 family has reverse biased ESD protection diodes on all inputs as shown in Figure 1. There is an additional clamp between the positive and negative supplies that further protects the device during ESD strikes.

Hot plugging of the device into a powered socket must be avoided since this can trigger the clamp resulting in larger currents flowing between the supply pins.

Capacitive Loads

The LTC6226/LTC6227 are optimized for high bandwidth applications, and have not been designed to directly drive capacitive loads. Hence any trace capacitance at the output should be made as small as possible. Increased capacitance at the output creates an additional pole in the open loop frequency response, worsening the phase margin. When driving capacitive loads, a resistor of 10Ω to 100Ω should be connected between the amplifier output and the capacitive load to avoid ringing or oscillation. The feedback should be taken directly from the amplifier output. Higher voltage gain configurations tend to have better capacitive drive capability than lower gain configurations due to lower closed loop bandwidth and hence higher phase margin. The graphs titled Overshoot vs Capacitive Load demonstrate the transient response of the amplifier when driving capacitive loads with various series resistors.

APPLICATIONS INFORMATION

Feedback Components

When feedback resistors are used to set up gain, care must be taken to ensure that the pole formed by the feedback resistors and the parasitic capacitance at the inverting input does not degrade stability. For example if the amplifier is set up in a gain of +2 configuration with gain and feedback resistors of 1k, a parasitic capacitance of 7pF (device + PC board) at the amplifier's inverting input will cause the part to oscillate, due to a pole formed at 45MHz. An additional capacitor of 7pF across the feedback resistor as shown in Figure 2 will eliminate any ringing or oscillation. In general, if the resistive feedback network results in a pole whose frequency lies within the closed loop bandwidth of the amplifier, a capacitor can be added in parallel with the feedback resistor to introduce a zero whose frequency is close to the frequency of the pole, improving stability. For high speed designs, minimizing parasitic inductance is important. The use of capacitors where the electrodes are terminated on the long side instead of the short side (for example the use of 0306 instead of 0603 components) can help in this regard.

Figure 2. 7pF Feedback Cancels Parasitic Pole

Shutdown

The LTC6226 and LTC6227DD have $\overline{\text{SHDN}}$ pins that can shut down the amplifier to 350 μ A typical supply current. The $\overline{\text{SHDN}}$ pin needs to be taken 2.75V below the positive supply to shut down. When left floating, the $\overline{\text{SHDN}}$ pin is internally pulled up to 1.2V below the positive supply and the amplifier remains on. During shutdown, the output transistors Q15 and Q14 in Figure 1 are in a high impedance state.

Power Dissipation

Care must be taken to ensure that the junction temperature of the die does not exceed 150°C.

The junction temperature, T_J , is calculated from the ambient temperature, T_A , power dissipation, P_D , and thermal resistance, θ_{JA} :

$$T_J = T_A + (P_D \cdot \theta_{JA}).$$

The power dissipation in the IC is a function of the supply voltage, output voltage and load resistance. For symmetric supply voltages with output load connected to ground, the worst-case power dissipation $P_{D(\text{MAX})}$ occurs when the supply current is maximum and the output voltage at half of either supply voltage for a given load resistance. $P_{D(\text{MAX})}$ is approximately (since I_S actually changes with output load current) given by:

$$P_{D(\text{MAX})} = (2 \cdot V_S \cdot I_{S(\text{MAX})}) + (V_S/2)^2/R_L$$

Example: For an LTC6227 in a 8-lead MS package operating on $\pm 5V$ supplies and driving a 250 Ω load to ground, the worst-case power dissipation is approximately given by $P_{D(\text{MAX})}/\text{Amp} = (10 \cdot 7.4\text{mA}) + (5/2)^2/250 = 99\text{mW}$. If both channels are loaded identically, the total power dissipation is 198mW.

At the Absolute Maximum ambient operating temperature, the junction temperature under these conditions will be:

$$T_J = T_A + (P_D \cdot \theta_{JA}) = 125 + 0.198 \cdot 35 = 132^\circ\text{C}$$

which is less than the absolute maximum junction temperature for the LTC6227.

Refer to the Pin Configuration section for thermal resistances of various packages

Board Layout and Bypass Capacitors

High speed and RF board layout techniques should be applied due to the very high speeds of the signals involved. For the LTC6226 SOIC-8 package option, the feedback should be taken from the FB pin rather than from the output pin, to reduce signal trace length.

Stray capacitances at the $-IN$ and $+IN$ pins should be made as low as possible to reduce stability degradation.

APPLICATIONS INFORMATION

For single supply applications, it is recommended that high quality 0.1 μ F||1000pF ceramic bypass capacitors be placed directly between each V⁺ pin and its closest V⁻ pin with short connections. The V⁻ pins (including the Exposed Pad) should be tied directly to a low impedance ground plane with minimal routing. For dual (split) power supplies, it is recommended that additional high quality 0.1 μ F||1000pF ceramic capacitors be used to bypass V⁺ pins to ground and V⁻ pins to ground, again with minimal routing.

Noise Considerations

The ultralow input referred voltage noise of of 1nV/ $\sqrt{\text{Hz}}$ is equivalent to that of an 60 Ω resistor. As with all BJT input amplifiers, lowering input referred noise is achieved by increasing the collector current of the input differential pair, which increases the input referred current noise.

Figure 3 shows the LTC6226 in a typical gain configuration.

Figure 3.

As can be seen, the input referred noise spectral density of the gain stage (e_T) can be calculated by the following equations:

$$e_T^2 = e_n^2 + i_n^2 R_{EQ}^2 + 4kTR_{EQ}$$

Where

$R_{EQ} = R_{S2} + R_{S1} || R_F$, k is the Boltzmann constant and T is the temperature (in Kelvin).

Op amp input referred noise dominates the input referred noise of the gain stage when

$$R_{EQ} \ll e_n^2 / 4kT$$

Resistor noise dominated the input referred noise of the gain stage when

$$R_{EQ} \gg e_n^2 / 4kT \text{ and } R_{EQ} \ll 4kT / i_n^2$$

Op amp input referred current noise dominates the input referred noise when

$$R_{EQ} \gg 4kT / i_n^2$$

With an input referred voltage noise spectral density of 1nV/Hz and an input referred current noise of 2.4pA/Hz, it is easy to see that the gain stage's input referred noise is dominated by op amp voltage noise when $R_{EQ} \ll 60\Omega$ and by resistor noise when

$$60\Omega \ll R_{EQ} \ll 2.9k\Omega.$$

Above an R_{EQ} of 2.9k Ω , input referred current noise dominates.

Distortion/Noise Trade-Off

As evident from the previous section, gain stage noise can be reduced by reducing R_{EQ} . However, reducing R_{EQ} has its disadvantages. In addition to increasing power dissipation in the presence of large output signals, the use of smaller resistors for a given gain results in increased distortion, because the internal nonlinearities of the op amp worsen with increasing load current. In addition, smaller resistors decrease op amp gain and hence can affect bandwidth. Hence when designing a system using the LTC6226/LTC6227, it is recommended that the resistor values be limited only by the system noise requirements with the caveat that the effect of the impedances' parasitic capacitances shouldn't affect the gain below the intended bandwidth. For example, for a feedback resistor of 5k Ω , a parasitic capacitor of 400fF will impact gain at frequencies above 79MHz.

TYPICAL APPLICATIONS

Figure 4. Transparent Driver for 16-Bit ADC

16-Bit High Performance Transparent ADC Driver

The ultralow noise and distortion performance of the LTC6226/LTC6227 makes it an excellent candidate for driving high sample rate high resolution ADCs. Figure 4 shows the LTC6227 driven by a differential input, driving an AD7380, a 4Msps, 16-bit ADC. Figure 5 shows the FFT obtained with a -0.5 dBFS, 50kHz input signal. Spurious free dynamic range is an excellent 108.5dB with an SNR of 91dB. Increasing the input frequency to 100kHz results in excellent performance as well, with a THD of -100 dBc, SNR of 89dB and SFDR of 104.9dB.

16-Bit ADC Driver Performance
 Input Signal = -0.5 dBFS
 $f_{\text{SMPL}} = 4$ Msps, $f_{\text{IN}} = 50$ kHz

Figure 5. Measured Performance of LTC6227 Based Driver Driving the AD7380

High Performance Single Ended to Differential 16-Bit ADC Driver

In many applications, the signal to be digitized is single ended, whereas the A/D Converter needs differential inputs to maximize performance. The LTC6227 can be used to implement a Single-Ended to differential ADC driver as shown in Figure 6. One channel is configured in unity gain and drives another channel configured in an inverting gain stage of 1, both outputs drive the LTC2323-16 through an RC filter. Figure 7 shows the FFT obtained with a -1 dBFS 156.25kHz input signal, with a demanding 5Msps sample rate. The obtained SNR of 81 dB is equivalent to that of the ADC by itself, thus there is no degradation due to the driver. The SFDR obtained is 84dB.

TYPICAL APPLICATIONS

High Speed Low Voltage Low Noise Instrumentation Amplifier with High CMRR

Figure 8 shows a three op amp instrumentation amplifier with a gain of 10V/V which can operate on a wide range of supply voltages. The resistors are implemented using instances of the LT5401, a matched resistor array chip. The resistor matching of U3 is crucial in achieving high common mode rejection. The front end gain stage resistors were also implemented using instances of the LT5401, but can be implemented using other means as well, since they are not crucial for common mode

rejection. Implementing them using the LT5401 minimizes gain variation across temperature. The amplifiers were implemented using instances of the LTC6227MS8, and supply voltages of $\pm 1.5V$ were used. Figure 9 shows the measured frequency response, and Figure 10 shows the measured CMRR of the instrumentation amplifier, with the single ended output observed. Figure 11 shows the transient response for a 150mV_{p-p} input square wave. The low offset and 1/f noise allow for wide band operation down to DC. The broadband input referred noise of 4.6nV/ \sqrt{Hz} is dominated by the resistors.
