

LV8968BB

LV8968BB Evaluation Board User's Manual

Overview

The LV8968BB evaluation board (EVB) provides a comprehensive platform to evaluate the LV8968BB functionalities for industrial and automotive applications. Maximum recommended power level is 250 W. Various optional periphery is included to support motor control implementations from simple sensor-less BEMF commutation, to complex field oriented algorithms. A microcontroller is NOT provided with this kit to allow customers to utilize their favorite solutions. The kit can be used as a shield to an Arduino DUE board.

Features

- General purpose Automotive 3Phase Gate Driver for 8 V to 25 V Applications
- Power MOSFET: 40 V, 85 A, 5.7 m Ω
- Interface to Microcontroller
- Plug-in Interface for Arduino Due Interface for Other Microcontrollers

Required:

- 20 V or Greater Power Supply with >10 A Output Current
- Arduino Due or
- Alternative Microcontroller Board with
 - ◆ 3 or more PWM Generators
 - ◆ 15 or more Digital IO Pins
 - ◆ 6 Analog IO Pins
 - ◆ 50pin Ribbon Cable and Connector
- 3 Phase PMSM Motor with 12 V Nominal Voltage and up to 200 W Power

Optional Periphery

- 7.5 V Regulator for Arduino Due or Other Microcontrollers
- Dual Current Sense Amplifier for Triple Shunt Current Sensing
- Star Point Comparator for BEMF Sensing Algorithms
- Low Voltage Charge Pump for Operation below 8 V
- PWM Oscillator plus Potentiometer for Speed Control Utilizing the PWM Interface of the LV8968
- Two Undedicated Pushbutton Switches for Microcontroller Use

Figure 2. EVB Description

DETAILED DESCRIPTION

Power Up Initial Testing

The LV8968 EVB is designed to operate at 12 V (typ) with an operating voltage range from 8 V to 25 V. The power supply should be able to supply enough current to run the intended motor. If connected to an appropriate power supply either via the power Jack connector (J3), or the wire clamps (J2), the green VS LED and 7.5 V supply LED will light up.

Now it is possible to activate the LV8968 through its WAKE pin using the red switch (SW1) in the center. The IC will power up with its default settings (for details consult the LV8968 Datasheet) and put out 3.3 V on its VCC supply (green VCC LED). The default settings are configured such that a microcontroller can instantly drive a motor. The IC will react to a high on the control lines and drive the corresponding power stage. Without a microcontroller to tell it what to do however, the LV8968 cannot accomplish much. Before proceeding further it is therefore necessary to power the EVB down and connect an appropriate microcontroller.

Table 1. POWER SUPPLY CURRENT

Power up procedure	Effect	Supply Current
Apply 12 V (typ) at J2 or J3	VS LEDs turn green, 7.5 V supply comes active and 7.5 V LED turns green	11 mA
Flip Wake switch SW1	V3RO and V3RI supply 3.3 V. VCC supply comes active and VCC LED turns green.	30 mA

Reverse Polarity Protection and Power Surges

The LV8968 EVB includes two reverse polarity protection circuits:

- Power jack connector J3 features a reverse polarity zener diode which is rated 3.9 A max. Power surges during motor braking or re-generation will not be fed

back into the supply and must be dealt with on the EVB by controlled braking, etc.

- Connector J2 bypasses the zener diode. This input is reverse polarity protected through the body diode of MOSFET T7 which is of the same type as an inverter. The gate of T7 is connected to a charge pump fed by inverter phases.

Once the LV8968 starts driving the power stage inverter, the switching of the phase voltages will charge the gate voltage of T7, turn on the MOSFET, and as a result bypass the reverse polarity body diode. Consequently a braking motor will feed it's energy back into the supply. Once the motor is stopped, T7 will lose it's gate charge and the reverse polarity protection will become active again.

Caution: When driving a high power load, ensure to make adequate arrangements to filter supply ripples.

Microcontroller Interface

Two microcontroller interfaces are available: an Arduino shield connection and a dual row pin header. The LV8968 is compatible with 3.3 V and 5 V level digital input signals. In order to bring the open drain outputs of the IC to the same level it may be necessary to raise the VCC voltage via SPI access from 3.3 V(default) to 5 V.

- Arduino Shield

The LV8968 EVB can act as an Arduino DUE shield and will plug directly onto an Arduino DUE board model R3-E. The Arduino board is then supplied from the EVB 7.5 V power supply and the pinout has been chosen to be supported by the Arduino peripheral circuitry.

- Dual row 50 pin header (J4)

For users who prefer to use other microcontrollers, a 25x2 pin connector has been provided.

Pins are placed at 2.54 mm pitch, the exact connectivity depends on the microcontroller used and has to be configured by the user.

Table 2 below provides the pin mapping and descriptions for both solutions.

NOTE: Reverse Polarity Protection MOSFET T7 gate voltage is selected by R76 or R86.
 R76 is Bootstrap voltage GH1-3.
 R86 is Charge Pump voltage.

Figure 3. Reverse Polarity Protection Schematic

System Control

The LV8968 is configured by default to make it easy to control a motor without any SPI setup. To activate the motor power stage it is necessary to apply a high signal on EN along with the phase control signals. Be aware that the low side FETs are activated by low levels, while the high side signals are activated by high levels. A low on EN will disable the output stage.

In default state all errors are disabled and dead time is set at maximum (3.2 us) which can interfere with efficient motor drive. To gain control over the system parameters it is necessary to communicate via SPI interface. The SPI interface expects full duplex communication. Data is latched at the rising clock edge and should change at the falling clock edge. The CSB signal must go high after every data transmission. For further information consult the LV8968 datasheet.

To enable useful motor applications with this EVB, two pushbutton switches SW2 and SW3 are provided, as well as a PWM generator with a potentiometer for PWM control. See below for more information on their use.

System Monitoring

The red KEY switch (SW1) is provided to tie WAKE to VS. A high on WAKE activates the LV8968 from sleep mode. VCC goes high which would normally power up the external microcontroller. For the EVB this approach was not practical, so WAKE as well as 7V5 are brought out to the interface to be monitored by the microcontroller. (It is possible to drive WAKE from the microcontroller if it is not pulled high via SW1). In a typical motor application WAKE might be tied to the ignition key signal. In order to prevent a low on WAKE from disabling the system and the motor, the LV8968 will ignore WAKE as long as EN is held high by the microcontroller.

Two other important system signals should be monitored closely by the microcontroller: DIAG and VMCRES. DIAG will go low for system errors and warnings, while a low on VMCRES indicates a watchdog violation. The watchdog is initially disabled and must be activated by SPI access. In the final application VMCRES should be connected to the microcontroller master reset, on the EVB this is not practical as watchdog errors will interfere with programming and debug operations.

7.5 V Regulator (U6)

Power to the microcontroller board is provided by the on-board linear regulator NCV317M which supplies 7.5 V and up to 500 mA to:

- The 7.5 V LED
- The optional charge pump
- The PWM generator
- The Arduino DUE board

7.5V Regulator

Figure 6. 7.5 V Regulator Schematic

PWM Generator (U2, U3)

Motor control applications are typically controlled via a PWM signal. This EVB allows two ways to generate a motor control PWM:

1. An external PWM signal can be fed directly to the PWM pin which is right next to the PWM generator circuit. This pin has a pullup to VS so it can be driven from a function generator as well as an open drain/collector transistor. To activate external PWM control place jumper JP2 (next to the PWM circuit) from pin1 to pin3.

2. Per default, an on board PWM generator will supply a VS level 100 Hz PWM signal to the LV8968. The blue Potentiometer VR1 controls the duty cycle from 0% to 100%.

In either case, the LV8968 level shifts the high voltage PWM signal to a digital VCC level signal which appears on RXD to be decoded by the microcontroller. See Figure 7 for details. The analog output of the potentiometer AD2 also appears at the microcontroller interface to be measured directly.

PWM OSC

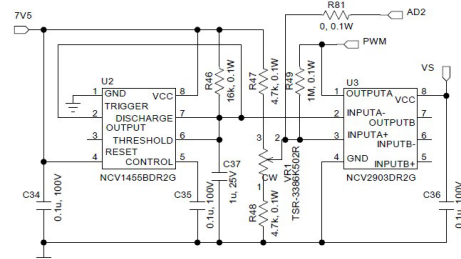

Figure 7. PWM Generator Schematic

Switches (SW2, SW3)

Two pushbutton switches to GND are included on the EVB to provide some additional motor control user interface. They can be used for motor ON/OFF and direction changes, or to cycle through demo programs, etc. These switches require microcontroller ports with pullup to function properly.

Current Sense Amplifier (U4)

The LV8968 includes one programmable gain fast current sense amplifier. For applications that need 2 or 3 current sense amplifiers, the EV-Kit includes a dual current sense amplifier IC NCV33072DR2G to amplify the phase currents for phases U and W with a gain matching the default setting of the LV8968 on-chip current sense amplifier.

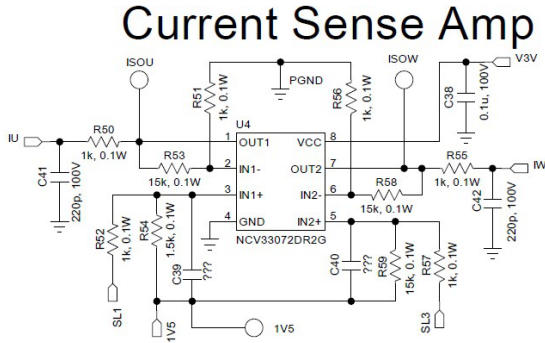

Figure 8. Current Sense Amplifier

BEMF COMPARATOR (U5)

To implement simple BEMF algorithms with the LV8968 a star point comparator NCV33072DR2G is included on the EV-Kit. It compares the virtual star point of phases U, V, and W with the output AOUT of the LV8968. The Gain of the star point signal matches the internal gain of the phase outputs. In order to use this feature, AOUT must be internally switched to the phase voltages of phases U, V, and W via SPI access. By monitoring the output STARCOMP the microprocessor can determine the phase transition of the motor.

Star Comparator

Figure 9. Star Point Comparator Schematic

High Side FET Gate Voltage Supply

The LV8968 uses bootstrapping to supply its high-side gate voltage normally. The evaluation board includes the hardware to implement an external under-voltage or 100% duty cycle charge-pump. The following shows how to configure.

This evaluation board supports three configurations for the high side gate voltage supply.

1. Bootstrap (default)

2. Under voltage Charge pump

3. External Charge pump for 100% output duty

Three type high side gate voltage supply is selected by layout of evaluation board. See Figures 15 ,16, and 17.

1. Bootstrap (default)

Bootstrap voltage is the default function. BS pin is high side FET gate voltage supply. BS voltage is connected by diode and capacitance from VG voltage. VG voltage is 11 V. BS voltage set (VG – Diode) voltage.

See Figure 10 Jumper switch JP1 set to connect 1 pin and 2 pin.

Figure 10. Jumper Switch JP1

2. Under Voltage Charge Pump (U7)

The LV8968 allows two solutions for running a motor at operating voltages below 8 V:

1. The use of logic level FETs and activation of logic level mode via SPI allows operation down to 6V supply without increasing system cost. This mode requires the use of a 3.3 V microcontroller.
2. If standard VGS = 10 V level FETs are required, it is possible to activate an external simple charge pump circuit between the supply voltage VS and the gate voltage regulator input VGIN.

The EVB includes a simple charge pump setup with the NCV33202VDR2G as shown in Figure 16.

To enable the charge pump it is necessary to move jumper JP1 (next to red SW1) from pin1 to pin3. During operation the microcontroller must monitor the supply voltage and activate this charge pump by supplying a 50 kHz clock to CP_CLK. The supply voltage can either be monitored at LV8968 pin AOUT directly, or by reacting to an under voltage DIAG interrupt. For more information consult the LV8968 datasheet.

Charge Pump

Figure 11. Charge Pump Schematic

Figure 12. Jumper Switch JP1

3. External Charge Pump for 100% Output Duty

The evaluation board includes an undervoltage chargepump which can optionally be re-configured to serve as a 100% duty cycle chargepump. For this conversion the comparator NCV33202V at U7 needs to be replaced with a rail to rail comparator NCS20072 with higher output drive. Also diodes D16 and D17 need to be replaced with Schottky types. To see the detailed description of the modifications consult Figures 15 and 16.

The 52 kHz clock signal for the chargepump CP_CLK needs to be provided by the microcontroller via J4 connector pin 4 or Arduino Due pin 13. This can be activated on demand depending on the use case:

1. Under-voltage Chargepump: Activate only during under-voltage. Keeping the chargepump running during normal operation may cause overvoltage damage to the circuit.
2. 100% duty-cycle chargepump: Operate during EN=high but disable during VH overvoltage to prevent overvoltage damage to the circuit.

Figure 13 shows the characteristic chart of the charge pump for 100% drive.

VGIN: VGIN=VS voltage

VG: Power supply pin for (JP1 1 and 2 pin short) low side gate drive the amplifier U7 is changed from NCV33202V to NCS20072.

BS: Charge pump circuit output for high side gate drive.

VGSH: High side gate voltage is 9.5 V at VS=12 V.

LV8968BB

POWER STAGE (T1 – T6)

The sole purpose of the LV8968 is to help a microcontroller drive and monitor the six N-MOSFET power stage in a three-phase inverter configuration. The FETS are 40 V, 85 A NVD5803NT4G with 5.7 mΩ typical on resistance. The FET footprint allows placement of D2PAK or SO8FL packages. The maximum power dissipation is 83 W ($R_{\theta jc}$, $T_C = 25^\circ\text{C}$, see [NVD5803NT4G](#) data sheet).

NOTE: MOSFET may be changed by application unit or end of FET production. The user may change the MOSFET type depending on their need.

Figure 18 below shows the schematic of phase U as an example. The gate is driven through gate resistors (R7, R8). Between gate and source of each MOSFET, capacitors (C6,

C7) are provided to adjust turn ON time with the gate resistor, and OFF time with gate diodes (D4, D5 not installed). Pull-down resistors (R1, R2) help protect the inverter against unintentional turn-on when the LV8968 is in sleep mode. A number of (unpopulated) snubber placements are also provided across the MOSFETs, to suppress parasitic ringing if necessary. The high-side gate voltage is generated by a capacitive bootstrapping circuit connection between each phase and the supply of the high-side drivers. The bootstrap capacitors are charged from the gate supply during the falling edge of the phase.

NOTE: It is important to start a motor with all phases low, to charge the bootstrap circuit.

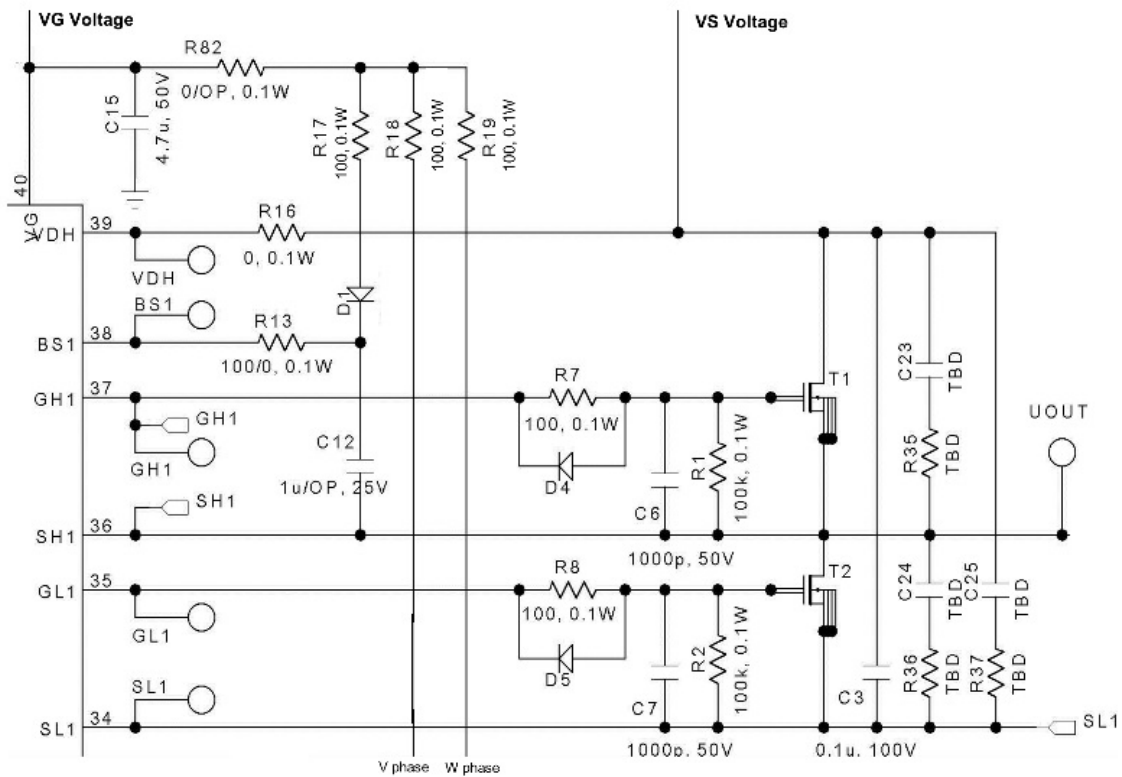

Figure 18. High and Low Side Gate Output Schematic

Shunt Resistance Operation

The EVB facilitates low side shunt current measurement of the three phase currents across shunt resistors R20,21,22. The LV8968BB includes a single programmable gain current sense amplifier which measures the motor current across the center resistor R20. Two additional current sense amplifiers are included on the EVB to measure the currents on the outside resistors. These amplifiers are configured for fixed a gain of 17 with external resistors matching the default gain of the internal amplifier of 7.5. If other gains are desired the resistors need to be reconfigured. See Table 2 for pin locations where the currents can be sampled.

The internal current amplifier of the LV8968BB is capable of single shunt FOC measurements. To enable single shunt current sensing short the solder jumpers RO2 and RO3 as shown in Figure 20. Now the resistance can be adjusted with the parallel configuration R20,21 and 22.
