

## Quad Driver for GaAs FET or PIN Diode Switches and Attenuators

Rev. V7

### Features

- High Voltage CMOS Technology
- Four Channel
- Positive Voltage Control
- CMOS device using TTL input levels
- Low Power Dissipation
- Low Cost Lead-Free SOIC-16 Plastic Package
- Halogen-Free “Green” Mold Compound
- RoHS\* Compliant

### Description

The MADR-009190-000100 is a four channel driver used to translate TTL control inputs into gate control voltages for GaAs FET microwave switches and attenuators. High speed analog CMOS technology is utilized to achieve low power dissipation at moderate to high speeds, encompassing most microwave switching applications. The output HIGH level is optionally 0 to 2 V (relative to GND) to optimize the intermodulation products of FET control devices at low frequencies. For driving PIN diode circuits, the outputs are nominally switched between +5 V & -5 V. The actual driver output voltages will be lower when driving large currents due to the resistance of the output devices.

## Handling Procedures

Please observe the following precautions to avoid damage:

## Static Sensitivity

Silicon Integrated Circuits are sensitive to electrostatic discharge (ESD) and can be damaged by static electricity. Proper ESD control techniques should be used when handling these devices.

## Output Resistance vs. Temperature<sup>6</sup>

6. Output resistance were measured under the condition of V<sub>CC</sub> = +5 V, V<sub>OPT</sub> = +5 V, and V<sub>EE</sub> = -5 V, with load resistors from outputs to ground.

7. Unused logic inputs must be tied to either GND or  $V_{CC}$ .

8. MACOM recommends that  $V_{CC}$  be powered on before  $V_{EE}$ , and powered off after  $V_{EE}$ .

9. 0.01  $\mu$ F decoupling capacitors are required on the power supply lines.

10.  $V_{OPT}$  is grounded in most cases when FETs are driven. To improve the intermodulation performance and the 1 dB compression point of GaAs control devices at low frequencies,  $V_{OPT}$  can be increased to between 1 and 2 V. The nonlinear characteristics of the GaAs control devices will approximate performance at 500 MHz. It should be noted that the control current that is on the GaAs MMICs will increase when positive controls are applied.

11. When this driver is used to drive PIN diodes,  $V_{OPT}$  is often set to +5 V, with  $V_{EE}$  set to -5 V.

16. Only one section of MADR-009190 is shown. The other three sections will have equivalent performance.

### Description of Circuit

The MADR-009190 provides four pairs of complementary outputs that are each capable of driving a maximum of  $\pm 35$  mA into a load. In addition, with proper capacitor selection (C3 & C4) used in parallel with the current setting resistor (R1 & R2), additional spiking current can be achieved.

To achieve the Non-Inverting and Inverting complementary voltages, each output is switched between two internal FETs. The FETs are connected to  $V_{OPT}$  for the positive output and  $V_{EE}$  for the negative output.  $V_{OPT}$  and  $V_{EE}$  are adjustable for various configurations and have the following limitations:  $V_{EE}$  can be no more negative than -10.5 volts;  $V_{OPT}$  can be no more positive than +5.5 volts and  $V_{OPT}$  must always be less than or equal to  $V_{CC}$ . Increasing  $V_{OPT}$  beyond  $V_{CC}$  will prevent the device from switching states when commanded to by the logic input. The most common configuration is to drive  $V_{EE}$  at -5.0 volts with  $V_{CC}$  and  $V_{OPT}$  tied together at +5.0 volts.
