

## MAX31328

## ±3.5ppm, I<sup>2</sup>C RTC with Integrated Crystal and Power Management

### General Description

The MAX31328 is a low-cost, extremely accurate, I<sup>2</sup>C real-time clock (RTC) with an integrated temperature-compensated crystal oscillator (TCXO) and crystal. The device incorporates a battery input and maintains accurate timekeeping when main power to the device is interrupted. The integration of the crystal resonator enhances the long-term accuracy of the device and eliminates the external crystal requirement in the system. The MAX31328 is available in a 10-pin LGA package.

The RTC maintains seconds, minutes, hours, day, date, month, and year information. The date at the end of the month is automatically adjusted for months with fewer than 31 days, including corrections for leap year. The clock operates in either 24-hour or 12-hour format with an AM/PM indicator. Two programmable time-of-day alarms and a programmable square-wave output are provided. Address and data are transferred serially through an I<sup>2</sup>C bidirectional bus. A precision temperature-compensated voltage reference and comparator circuit monitors the status of V<sub>CC</sub> to detect power failures and automatically switch to the backup supply when necessary. Additionally, the  $\overline{\text{RST}}$  pin is monitored as a pushbutton input for generating a microprocessor reset.

### Applications

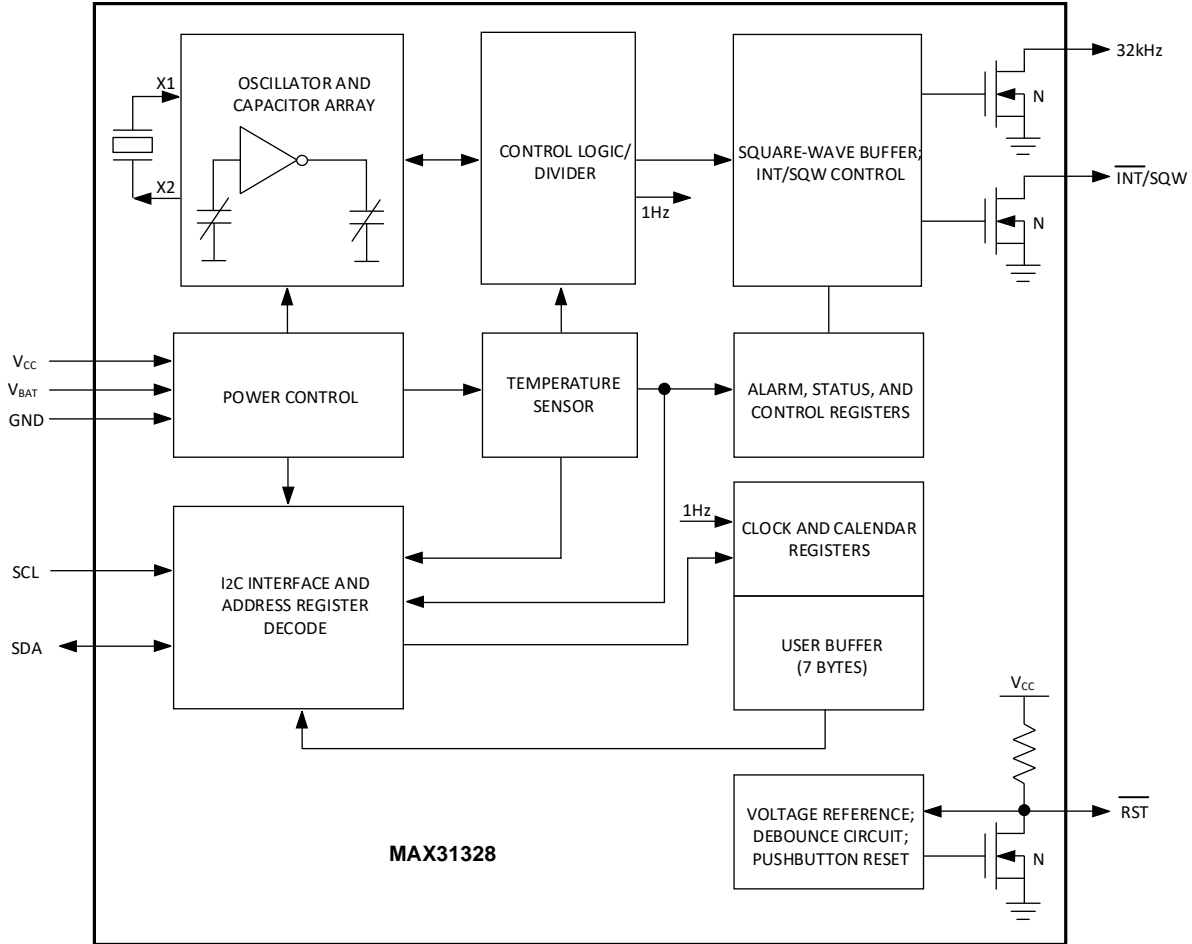

- Servers
- Power Meters
- Telematics
- Global Positioning System

### Benefits and Features

- Highly Accurate RTC Completely Manages All Timekeeping Functions
  - Complete Clock Calendar Functionality, Including Seconds, Minutes, Hours, Day, Date, Month, and Year with Leap-Year Compensation Up to 2100
  - Low Timekeeping Battery Current of 660nA
  - Timekeeping Accuracy ±3.5ppm (±0.302 seconds/day) from -40°C to +85°C
  - Two Time-of-Day Alarms
  - Temperature-Compensated Programmable Square-Wave Output
  - Register for Aging Trim
  - $\overline{\text{RST}}$  Output/Pushbutton Reset Debounce Input
  - Digital Temperature Sensor with ±3°C Accuracy
  - +2.3V to +5.5V Supply Voltage
- Simple Serial Interface Connects to Most Microcontrollers
  - I<sup>2</sup>C Interface (400kHz)
- Battery-Backup Input for Continuous Timekeeping
  - Low-Power Operation Extends Battery-Backup Run Time
  - 3.3V Operation
- Operating Temperature Range: -40°C to +85°C
- 5mm x 5mm 10-Pin LGA Package

[Ordering Information](#) and package information appear at end of data sheet.

Simplified Block Diagram

## Absolute Maximum Ratings

Voltage Range on Any Pin Relative to Ground .....-0.3V to +6V

Operating Temperature Range .....-40°C to +85°C

Junction Temperature.....+125°C

Storage Temperature Range ..... -40°C to +85°C

Lead Temperature (soldering, 10s) ..... +260°C

Soldering Temperature (reflow, 2 times max.) ..... +260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Electrical Characteristics

(V<sub>CC</sub> or V<sub>BAT</sub> = +2.3V to +5.5V, T<sub>A</sub> = -40°C to +85°C, unless otherwise noted. Typical values are at V<sub>CC</sub> = +3.3V, V<sub>BAT</sub> = +3.0V, and T<sub>A</sub> = +25°C, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS
<b>RECOMMENDED OPERATING CONDITIONS (Note 1)</b>

( $V_{CC}$  or  $V_{BAT} = +2.3V$  to  $+5.5V$ ,  $T_A = -40^{\circ}C$  to  $+85^{\circ}C$ , unless otherwise noted. Typical values are at  $V_{CC} = +3.3V$ ,  $V_{BAT} = +3.0V$ , and  $T_A = +25^{\circ}C$ , unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
STOP Setup Time	$t_{SU:STO}$		0.6			$\mu s$
Maximum Capacitive Load for Each Bus Line	$C_B$	(Note 10)		400		pF
Capacitance for SDA, SCL	$C_{I/O}$			10		pF
SCL Spike Suppression	$t_{SP}$			30		ns
Pushbutton Debounce	$PB_{DB}$			250		ms
Reset Active Time	$t_{RST}$			250		ms
Oscillator Stop Flag (OSF) Delay	$t_{OSF}$	(Note 11)		100		ms
Temperature Conversion Time	$t_{CONV}$			125	200	ms

**Note 1:** Limits at  $-40^{\circ}C$  are guaranteed by design and not production tested.

**Note 2:** All voltages are referenced to ground.

**Note 3:**  $I_{CCA}$  - SCL clocking at max frequency = 400kHz.

**Note 4:** Current is the averaged input current, which includes the temperature conversion current.

**Note 5:** The  $\overline{RST}$  pin has an internal 50k $\Omega$  pullup resistor to  $V_{CC}$ .

**Note 6:** After this period, the first clock pulse is generated.

**Note 7:** A device must internally provide a hold time of at least 300ns for the SDA signal (referred to the  $V_{IH(MIN)}$  of the SCL signal) to bridge the undefined region of the falling edge of the SCL.

**Note 8:** The maximum  $t_{HD:DAT}$  needs only to be met if the device does not stretch the low period ( $t_{LOW}$ ) of the SCL signal.

**Note 9:** A fast-mode device can be used in a standard-mode system, but the requirement  $t_{SU:DAT} \geq 250ns$  must then be met. This is automatically the case if the device does not stretch the low period of the SCL signal. If such a device does stretch the low period of the SCL signal, it must output the next data bit to the SDA line  $t_{R(MAX)} + t_{SU:DAT} = 1000 + 250 = 1250ns$  before the SCL line is released.

**Note 10:**  $C_B$ : Total capacitance of one bus line in pF.

**Note 11:** The parameter  $t_{OSF}$  is the period of time the oscillator must be stopped for the OSF flag to be set over the voltage range of  $0V \leq V_{CC} \leq V_{CC(MAX)}$  and  $2.3V \leq V_{BAT} \leq 3.4V$ .

**Note 12:** This delay applies only if the oscillator is enabled and running. If the  $\overline{EOSC}$  bit is 1,  $t_{REC}$  is bypassed and  $\overline{RST}$  immediately goes high. The state of  $\overline{RST}$  does not affect the I<sup>2</sup>C interface, RTC, or TCXO.

### Pushbutton Reset Timing

### Power-Switch Timing

### Data Transfer on I<sup>2</sup>C Serial Bus

Typical Operating Characteristics

(T<sub>A</sub> = +25°C, V<sub>CC</sub> = 3.3V, V<sub>BAT</sub> = 3.0V, unless otherwise noted.)

## Pin Configurations

PIN	NAME	FUNCTION
1	32kHz	32kHz Output. This open-drain pin requires an external pullup resistor. When enabled, the output operates on either power supply. It may be left open if not used.
2	V <sub>CC</sub>	DC Power Pin for Primary Power Supply. This pin should be decoupled using a 0.1µF to 1.0µF capacitor. If not used, connect to ground.
3	INT/SQW	Active-Low Interrupt or Square-Wave Output. This open-drain pin requires an external pullup resistor connected to a supply at 5.5V or less. This multifunction pin is determined by the state of the INTCN bit in the Control Register (0Eh). When INTCN is set to logic 0, this pin outputs a square wave and its frequency is determined by RS2 and RS1 bits. When INTCN is set to logic 1, then a match between the timekeeping registers and either of the alarm registers activates the INT/SQW pin (if the alarm is enabled). It is because the INTCN bit is set to logic 1 when power is first applied, that the pin defaults to an interrupt output with alarms disabled. The pullup voltage can be up to 5.5V, regardless of the voltage on V <sub>CC</sub> . If not used, this pin can be left unconnected.
4	RST	Active-Low Reset. This pin is an open-drain input/output. It indicates the status of V <sub>CC</sub> relative to the V <sub>PF</sub> specification. As V <sub>CC</sub> falls below V <sub>PF</sub> , the RST pin is driven low. When V <sub>CC</sub> exceeds V <sub>PF</sub> , for t <sub>RST</sub> , the RST pin is pulled high by the internal pullup resistor. The active-low, open-drain output is combined with a debounced pushbutton input function. This pin can be activated by a pushbutton reset request. It has an internal 50kΩ nominal value pullup resistor to V <sub>CC</sub> . No external pullup resistors should be connected. If the oscillator is disabled, t <sub>REC</sub> is bypassed and RST immediately goes high.
5, 6	N.C.	No Connection. Must be connected to ground.
7	GND	Ground
8	V <sub>BAT</sub>	Backup Power-Supply Input. When using the device with the V <sub>BAT</sub> input as the primary power source, this pin should be decoupled using a 0.1µF to 1.0µF low-leakage capacitor. When using the device with the V <sub>BAT</sub> input as the backup power source, the capacitor is not required. If V <sub>BAT</sub> is not used, connect to ground.
9	SDA	Serial Data Input/Output. This pin is the data input/output for the I <sup>2</sup> C serial interface. This open-drain pin requires an external pullup resistor. The pullup voltage can be up to 5.5V, regardless of the voltage on V <sub>CC</sub> .
10	SCL	Serial Clock Input. This pin is the clock input for the I <sup>2</sup> C serial interface and is used to synchronize data movement on the serial interface. Up to 5.5V can be used for this pin, regardless of the voltage on V <sub>CC</sub> .

## Detailed Description

The MAX31328 is a serial RTC driven by a temperature-compensated 32kHz crystal oscillator (TCXO). The TCXO provides a stable and accurate reference clock, and maintains the RTC to within ±2 minutes per year accuracy from -40°C to +85°C. The TCXO frequency output is available at the 32kHz pin. The RTC is a low-power clock/calendar with two programmable time-of-day alarms and a programmable square-wave output. The  $\overline{\text{INT}}/\text{SQW}$  provides either an interrupt signal due to alarm conditions or a square-wave output. The clock/calendar provides seconds, minutes, hours, day, date, month, and year information. The date at the end of the month is automatically adjusted for months with fewer than 31 days, including corrections for leap year. The clock operates in either the 24-hour or 12-hour format with an AM/PM indicator. The internal registers are accessible through an I<sup>2</sup>C bus interface. A temperature-compensated voltage reference and comparator circuit monitors the level of  $V_{\text{CC}}$  to detect power failures and to automatically switch to the backup supply when necessary. The  $\overline{\text{RST}}$  pin provides an external pushbutton function and acts as an indicator of a power-fail event.

The block diagram shows the main elements of MAX31328. The eight blocks can be grouped into four functional groups: TCXO, power control, pushbutton reset function, and RTC. Their operations are described separately in the following sections.

### 32kHz TCXO

The temperature sensor, oscillator, and control logic form the TCXO. The controller reads the output of the on-chip temperature sensor and uses a lookup table to determine the capacitance required, adds the aging correction, and then sets the internal capacitance selection registers. New values, including changes to the aging correction, are loaded only when a change in the temperature value occurs or when a user-initiated temperature conversion is completed. Temperature conversion occurs on initial application of  $V_{\text{CC}}$  and once every 64 seconds afterwards.

### Power Control

This function is provided by a temperature-compensated voltage reference and a comparator circuit that monitors the  $V_{\text{CC}}$  level. When  $V_{\text{CC}}$  is greater than  $V_{\text{PF}}$ , the part is powered by  $V_{\text{CC}}$ . When  $V_{\text{CC}}$  is less than  $V_{\text{PF}}$  but greater than  $V_{\text{BAT}}$ , the MA31328 is powered by  $V_{\text{CC}}$ . If  $V_{\text{CC}}$  is less than  $V_{\text{PF}}$  and is less than  $V_{\text{BAT}}$ , the device is powered by  $V_{\text{BAT}}$ . See Table 1.

Table 1. Power Control

SUPPLY CONDITION	ACTIVE SUPPLY
$V_{\text{CC}} < V_{\text{PF}}, V_{\text{CC}} < V_{\text{BAT}}$	$V_{\text{BAT}}$
$V_{\text{CC}} < V_{\text{PF}}, V_{\text{CC}} > V_{\text{BAT}}$	$V_{\text{CC}}$
$V_{\text{CC}} > V_{\text{PF}}, V_{\text{CC}} < V_{\text{BAT}}$	$V_{\text{CC}}$
$V_{\text{CC}} > V_{\text{PF}}, V_{\text{CC}} > V_{\text{BAT}}$	$V_{\text{CC}}$

To preserve the battery, the first time  $V_{\text{BAT}}$  is applied to the device, the oscillator does not start up until  $V_{\text{CC}}$  exceeds  $V_{\text{PF}}$ , or until a valid I<sup>2</sup>C address is written to the part. Typical oscillator startup time is less than one second. Approximately 2 seconds after  $V_{\text{CC}}$  is applied, or a valid I<sup>2</sup>C address is written, the device makes a temperature measurement and applies the calculated correction to the oscillator. Once the oscillator is running, it continues to run as long as a valid power source is available ( $V_{\text{CC}}$  or  $V_{\text{BAT}}$ ), and the device continues to measure the temperature and correct the oscillator frequency every 64 seconds. On the first application of power ( $V_{\text{CC}}$ ) or when a valid I<sup>2</sup>C address is written to the part ( $V_{\text{BAT}}$ ), the time and date registers are reset to 01/01/00 01 00:00:00 (DD/MM/YY DOW HH:MM:SS).

### $V_{\text{BAT}}$ Operation

There are several modes of operation that affect the amount of  $V_{\text{BAT}}$  current that is drawn. While the device is powered by  $V_{\text{BAT}}$  and the serial interface is active, active battery current,  $I_{\text{BATA}}$ , is drawn. When the serial interface is inactive, timekeeping current ( $I_{\text{BATT}}$ ), which includes the averaged temperature conversion current,  $I_{\text{BATTTC}}$ , is used (refer to [Application Note 3644: Power Considerations for Accurate Real-Time Clocks](#) for details). Temperature conversion current,  $I_{\text{BATTTC}}$ , is specified since the system must be able to support the periodic higher current pulse and still maintain a

valid voltage level. Data retention current,  $I_{BATTDR}$ , is the current drawn by the part when the oscillator is stopped ( $\overline{EOSC} = 1$ ). This mode can be used to minimize battery requirements for times when maintaining time and date information is not necessary, e.g., while the end system is waiting to be shipped to a customer.

### Pushbutton Reset Function

The MAX31328 provides for a pushbutton switch to be connected to the  $\overline{RST}$  output pin. When the MAX31328 is not in a reset cycle, it continuously monitors the  $\overline{RST}$  signal for a falling edge. If an edge transition is detected, the MAX31328 debounces the switch by pulling the  $\overline{RST}$  low. After the internal timer has expired ( $PB_{DB}$ ), the MAX31328 continues to monitor the  $\overline{RST}$  line. If the line is still low, the MAX31328 continuously monitors the line looking for a rising edge. Upon detecting release, the MAX31328 forces the  $\overline{RST}$  pin low and holds it low for  $t_{RST}$ . The  $\overline{RST}$  is also used to indicate a power-fail condition. When  $V_{CC}$  is lower than  $V_{PF}$ , an internal power-fail signal is generated, which forces the  $\overline{RST}$  pin low. When  $V_{CC}$  returns to a level above  $V_{PF}$ , the  $\overline{RST}$  pin is held low for approximately 250ms ( $t_{REC}$ ) to allow the power supply to stabilize. If the oscillator is not running (see the *Power Control* section) when  $V_{CC}$  is applied,  $t_{REC}$  is bypassed and  $\overline{RST}$  immediately goes high. Assertion of the  $\overline{RST}$  output, whether by pushbutton or power-fail detection, does not affect the internal operation of the MAX31328.

### Real-Time Clock

With the clock source from the TCXO, the RTC provides seconds, minutes, hours, day, date, month, and year information. The date at the end of the month is automatically adjusted for months with fewer than 31 days, including corrections for leap year. The clock operates in either the 24-hour or 12-hour format with an AM/PM indicator. The clock provides two programmable time-of-day alarms and a programmable square-wave output. The  $\overline{INT/SQW}$  pin either generates an interrupt due to an alarm condition or outputs a square-wave signal, and the selection is controlled by the bit  $INTCN$ .

### Clock and Calendar

The time and calendar information is obtained by reading the appropriate register bytes. The register map illustrates the RTC registers. The time and calendar data are set or initialized by writing the appropriate register bytes. The contents of the time and calendar registers are in the binary-coded decimal (BCD) format. The MAX31328 can be run in either 12-hour or 24-hour mode. Bit 6 of the hours register is defined as the 12- or 24-hour mode select bit. When high, the 12-hour mode is selected. In the 12-hour mode, bit 5 is the AM/PM bit with logic-high being PM. In the 24-hour mode, bit 5 is the 20-hour bit (20–23 hours). The century bit (bit 7 of the month register) is toggled when the years register overflows from 99 to 00.

The day-of-week register increments at midnight. Values that correspond to the day of week are user-defined but must be sequential (i.e., if 1 equals Sunday, then 2 equals Monday, and so on). Illogical time and date entries result in undefined operation.

When reading or writing the time and date registers, secondary (user) buffers are used to prevent errors when the internal registers update. When reading the time and date registers, the user buffers are synchronized to the internal registers on any  $START$  and when the register pointer rolls over to zero. The time information is read from these secondary registers, while the clock continues to run. This eliminates the need to reread the registers in case the main registers update during a read.

The countdown chain is reset whenever the seconds register is written. Write transfers occur on the acknowledge from the MAX31328. To avoid rollover issues, once the countdown chain is reset, the remaining time and date registers must be written within one second. The 1Hz square-wave output, if enabled, transitions high 500ms after the seconds data transfer, provided the oscillator is already running.

### Alarms

The MAX31328 contains two time-of-day/date alarms. Alarm 1 can be set by writing to registers 07h to 0Ah. Alarm 2 can be set by writing to registers 0Bh to 0Dh. The alarms can be programmed (by the Alarm Enable and  $INTCN$  bits of the Control Register) to activate the  $\overline{INT/SQW}$  output on an alarm match condition. Bit 7 of each of the time-of-day/date alarm registers are mask bits (Table 2). When all the mask bits for each alarm are logic 0, an alarm only occurs when the values in the timekeeping registers match the corresponding values stored in the time-of-day/date alarm registers. The alarms can also be programmed to repeat every second, minute, hour, day, or date. Table 2 shows the possible settings. Configurations not listed in the table result in illogical operation.

The DY/ $\overline{DT}$  bits (bit 6 of the alarm day/date registers) control whether the alarm value stored in bits 0 to 5 of that register reflects the day of the week or the date of the month. If DY/ $\overline{DT}$  is written to logic 0, the alarm is the result of a match with date of the month. If DY/ $\overline{DT}$  is written to logic 1, the alarm is the result of a match with day of the week.

When the RTC register values match alarm register settings, the corresponding Alarm Flag 'A1F' or 'A2F' bit is set to logic 1. If the corresponding Alarm Interrupt Enable 'A1IE' or 'A2IE' is also set to logic 1 and the INTCN bit is set to logic 1, the alarm condition activates the  $\overline{INT}/SQW$  signal. The match is tested on the once-per-second update of the time and date registers.

Table 2. Alarm Mask Bits

DY/ $\overline{DT}$	ALARM REGISTER MASK BITS (BIT 7)				ALARM RATE
	A1M4	A1M3	A1M2	A1M1	
X	1	1	1	1	Alarm once per second
X	1	1	1	0	Alarm when seconds match
X	1	1	0	0	Alarm when minutes and seconds match
X	1	0	0	0	Alarm when hours, minutes, and seconds match
0	0	0	0	0	Alarm when date, hours, minutes, and seconds match
1	0	0	0	0	Alarm when day, hours, minutes, and seconds match

DY/ $\overline{DT}$	ALARM REGISTER MASK BITS (BIT 7)			ALARM RATE
	A2M4	A2M3	A2M2	
X	1	1	1	Alarm once per minute (00 seconds of every minute)
X	1	1	0	Alarm when minutes match
X	1	0	0	Alarm when hours and minutes match
0	0	0	0	Alarm when date, hours, and minutes match
1	0	0	0	Alarm when day, hours, and minutes match

## I<sup>2</sup>C Interface

The I<sup>2</sup>C interface is accessible whenever either V<sub>CC</sub> or V<sub>BAT</sub> is at a valid level. If a microcontroller connected to the MAX31328 resets because of a loss of V<sub>CC</sub> or other event, it is possible that the microcontroller and MAX31328 I<sup>2</sup>C communications could become unsynchronized, e.g., the microcontroller resets while reading data from the MAX31328. When the microcontroller resets, the MAX31328 I<sup>2</sup>C interface may be placed into a known state by toggling serial clock (SCL) until SDA is observed to be at a high level. At that point, the microcontroller should pull SDA low while SCL is high, generating a START condition.

## I<sup>2</sup>C Serial Data Bus

The MAX31328 supports a bidirectional I<sup>2</sup>C bus and data transmission protocol. A device that sends data onto the bus is defined as a transmitter and a device receiving data is defined as a receiver. The device that controls the message is called a master. The devices that are controlled by the master are slaves. The bus must be controlled by a master device that generates the SCL, controls the bus access, and generates the START and STOP conditions. The MAX31328 operates as a slave on the I<sup>2</sup>C bus. Connections to the bus are made through the SCL input and open-drain SDA I/O lines. Within the bus specifications, a standard mode (100kHz maximum clock rate) and a fast mode (400kHz maximum clock rate) are defined. The MAX31328 works in both modes.

The following bus protocol has been defined (Figure 1):

- Data transfer may be initiated only when the bus is not busy.
- During data transfer, the data line must remain stable whenever the clock line is HIGH. Changes in the data line while the clock line is HIGH are interpreted as control signals.

Accordingly, the following bus conditions have been defined:

**Bus not busy:** Both data and clock lines remain HIGH.

**START data transfer:** A change in the state of the data line from HIGH to LOW, while the clock line is HIGH, defines a START condition.

**STOP data transfer:** A change in the state of the data line from LOW to HIGH, while the clock line is HIGH, defines a STOP condition.

**Data valid:** The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal. The data on the line must be changed during the LOW period of the clock signal. There is one clock pulse per bit of data.

Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between the START and the STOP conditions is not limited, and is determined by the master device. The information is transferred byte-wise and each receiver acknowledges with a ninth bit.

**Acknowledge:** Each receiving device, when addressed, is obliged to generate an acknowledge after the reception of each byte. The master device must generate an extra clock pulse that is associated with this acknowledge bit.

A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse. Of course, setup and hold times must be taken into account. A master must signal an end of data to the slave by not generating an acknowledge bit on the last byte that has been clocked out of the slave. In this case, the slave must leave the data line HIGH to enable the master to generate the STOP condition.

Figures 2 and 3 detail how data transfer is accomplished on the I<sup>2</sup>C bus. Depending upon the state of the R/W bit, two types of data transfer are possible:

**Data transfer from a master transmitter to a slave receiver.** The first byte transmitted by the master is the slave address. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte. Data is transferred with the most significant bit (MSB) first.

**Data transfer from a slave transmitter to a master receiver.** The first byte (the slave address) is transmitted by the master. The slave then returns an acknowledge bit. Next follows a number of data bytes transmitted by the slave to the master. The master returns an acknowledge bit after all received bytes other than the last byte. At the end of the last received byte, a not acknowledge is returned.

The master device generates all the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a repeated START condition. Since a repeated START condition is also the beginning of the next serial transfer, the bus is not released. Data is transferred with the most significant bit (MSB) first.

The MAX31328 can operate in the following two modes:

- **Slave Receiver Mode (MAX31328 Write Mode):** Serial data and clock are received through SDA and SCL. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit. The slave address byte is the first byte received after the master generates the START condition. The slave address byte contains the 7-bit MAX31328 address, which is 1101000, followed by the direction bit (R/W), which is 0 for a write. After receiving and decoding the slave address byte, the MAX31328 outputs an acknowledge on SDA. After the MAX31328 acknowledges the slave address + write bit, the master transmits a word address to the MAX31328. This sets the register pointer on the MAX31328, with the MAX31328 acknowledging the transfer. The master may then transmit zero or more bytes of data, with the MAX31328 acknowledging each byte received. The register pointer increments after each data byte is transferred. The master generates a STOP condition to terminate the data write.
- **Slave Transmitter Mode (MAX31328 Read Mode):** The first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit indicates that the transfer direction is reversed. Serial data is transmitted on SDA by the MAX31328 while the serial clock is input on SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit. The slave address byte is the first byte received after the master generates a START condition. The slave address byte contains the 7-bit MAX31328

address, which is 1101000, followed by the direction bit (R/W), which is 1 for a read. After receiving and decoding the slave address byte, the MAX31328 outputs an acknowledge on the SDA. The MAX31328 then begins to transmit data starting with the register address pointed to by the register pointer. If the register pointer is not written to before the initiation of a read mode, then the first address that is read is the last one stored in the register pointer. The MAX31328 must receive a “not acknowledge” to end a read.

Access Type	Write, Read	Write, Read	Write, Read	Write, Read		Write, Read	Write, Read	Write, Read

BITFIELD	BITS	DESCRIPTION	DECODE
EOSC	7	Enable Oscillator Oscillator is always enabled when part is running on V <sub>CC</sub> .	0x0: Oscillator enabled 0x1: Oscillator disabled (only on VBAT)
BBSQW	6	Battery-backed square-wave enable	0x0: INT/SQW pin goes high impedance when V <sub>CC</sub> < V <sub>PF</sub> 0x1: Enables square wave on INT/SQW pin when INTCN = 0 and V <sub>CC</sub> < V <sub>PF</sub>
CONV	5	Temperature Conversion Setting this bit to 1 forces the temperature sensor to convert the temperature into digital code and execute the TCXO algorithm to update the capacitance array to the oscillator. This can only happen when a conversion is not already in progress. The user should check the status bit BSY before forcing the controller to start a new TCXO execution. A user-initiated temperature conversion does not affect the internal 64-second update cycle. A user-initiated temperature conversion does not affect the BSY bit for approximately 2ms. The CONV bit remains at a 1 from the time it is written until the conversion is finished, at which time both CONV and BSY go to 0. The CONV bit should be used when monitoring the status of a user-initiated conversion.	0x0 0x1: Convert temperature and execute TCXO algorithm
RS	4:3	SQW Frequency Select	0x0: 1Hz 0x1: 1.024kHz 0x2: 4.096kHz 0x3: 8.192kHz
INTCN	2	Interrupt Control	0x0: Square wave is output on the INT/SQW pin. 0x1: Alarm interrupts are output on the INT/SQW pin.
A2IE	1	Alarm 2 Interrupt Enable	0x0: Alarm 2 interrupt disabled 0x1: Alarm 2 interrupt enabled
A1IE	0	Alarm 1 interrupt enable	0x0: Alarm 1 interrupt disabled 0x1: Alarm 1 interrupt enabled

### Status (0xF)

#### Status Register

BIT	7	6	5	4	3	2	1	0
Field	OSF	–	–	–	EN32kHz	BSY	A2F	A1F
Reset	0x1	–	–	–	0x1			
Access Type	Read Only	–	–	–	Write, Read	Read Only	Write, Read	Write, Read

BITFIELD	BITS	DESCRIPTION	DECODE
OSF	7	<p>Oscillator Stop Flag</p> <p>A logic 1 in this bit indicates that the oscillator either is stopped or was stopped for some period and may be used to judge the validity of the timekeeping data. This bit is set to logic 1 any time that the oscillator stops. The following are examples of conditions that can cause the OSF bit to be set: 1) The first time when power is applied. 2) The voltages present on both V<sub>CC</sub> and V<sub>BAT</sub> are insufficient to support oscillation. 3) The EOSC bit is turned off in battery-backed mode. 4) External influences on the crystal (i.e., noise, leakage, etc.)</p>	<p>0x0</p> <p>0x1: Indicates that the oscillator is stopped or was stopped for some period</p>
EN32kHz	3	Enable 32kHz output	<p>0x0: 32kHz pin goes to a high impedance state</p> <p>0x1: 32.768kHz square wave is output on the 32kHz pin</p>
BSY	2	<p>Busy Flag</p> <p>This bit indicates the device is busy executing TCXO functions. It goes to logic 1 when the conversion signal to the temperature sensor is asserted and then is cleared when the device is in the 1-minute idle state.</p>	
A2F	1	<p>Alarm 2 flag</p> <p>A logic 1 in the alarm 2 flag bit indicates that the time matched the alarm 2 registers. If the A2IE bit is logic 1 and the INTCN bit is set to logic 1, the INT/SQW pin is also asserted. A2F is cleared when written to logic 0. This bit can only be written to logic 0. Attempting to write to logic 1 leaves the value unchanged.</p>	
A1F	0	<p>Alarm 1 flag</p> <p>A logic 1 in the alarm 1 flag bit indicates that the time matched the alarm 1 registers. If the A1IE bit is logic 1 and the INTCN bit is set to logic 1, the INT/SQW pin is also asserted. A1F is cleared when written to logic 0. This bit can only be written to logic 0. Attempting to write to logic 1 leaves the value unchanged.</p>	

### Aging Offset (0x10)

The aging offset register takes a user-provided value to add to or subtract from the codes in the capacitance array registers. The code is encoded in two's complement, with bit 7 representing the sign bit. One LSB represents one small capacitor to be switched in or out of the capacitance array at the crystal pins. The aging offset register capacitance value is added or subtracted from the capacitance value that the device calculates for each temperature compensation. The offset register is added to the capacitance array during a normal temperature conversion, if the temperature changes from the previous conversion, or during a manual user conversion (setting the CONV bit). To see the effects of the aging register on the 32kHz output frequency immediately, a manual conversion should be started after each aging register change. Positive aging values add capacitance to the array, slowing the oscillator frequency. Negative values

remove capacitance from the array, increasing the oscillator frequency. The change in ppm per LSB is different at different temperatures. The frequency vs. temperature curve is shifted by the values used in this register. At +25°C, one LSB typically provides about 0.1ppm change in frequency. Use of the aging register is not needed to achieve the accuracy as defined in the EC tables but could be used to help compensate for aging at a given temperature. See the *Typical Operating Characteristics* section for a graph showing the effect of the register on accuracy over temperature.

Data	6:0	

### Temp\_MSB (0x11)

Temperature is represented as a 10-bit code with a resolution of 0.25°C and is accessible at locations 11h and 12h. The temperature is encoded in two's complement format. The upper 8 bits, the integer portion, are at location 11h and the lower 2 bits, the fractional portion, are in the upper nibble at location 12h. For example, 00011001 01b = +25.25°C. Upon power reset, the registers are set to a default temperature of 0°C and the controller starts a temperature conversion. The temperature is read on initial application of V<sub>CC</sub> or I<sup>2</sup>C access on V<sub>BAT</sub> and once every 64 seconds afterwards. The temperature registers are updated after each user-initiated conversion and on every 64-second conversion. The temperature registers are read-only.

## Applications Information

### Power-Supply Decoupling

To achieve the best results when using the device, decouple the  $V_{CC}$  and/or  $V_{BAT}$  power supplies with 0.1µF and/or 1.0µF capacitors. Use a high-quality ceramic surface-mount capacitor if possible. Surface-mount components minimize the lead inductance that improves performance, and ceramic capacitors tend to have adequate high-frequency response for decoupling applications.

If communications during battery operation are not required, the  $V_{BAT}$  decoupling capacitor can be omitted.

### Using Open-Drain Outputs

The  $\overline{INT}/SQW$  and 32kHz outputs are open-drain and, therefore, require external pullup resistors to realize logic-high output levels. The pullup resistor value is typically 10kΩ.

### SDA and SCL Pullup Resistors

SDA is an open-drain output and requires an external pullup resistor to realize a logic-high level. It is because the device does not use clock cycle stretching, that a master using either an open-drain output with a pullup resistor or CMOS output driver (push-pull) could be used for SCL.

### Handling, PCB Layout, and Assembly

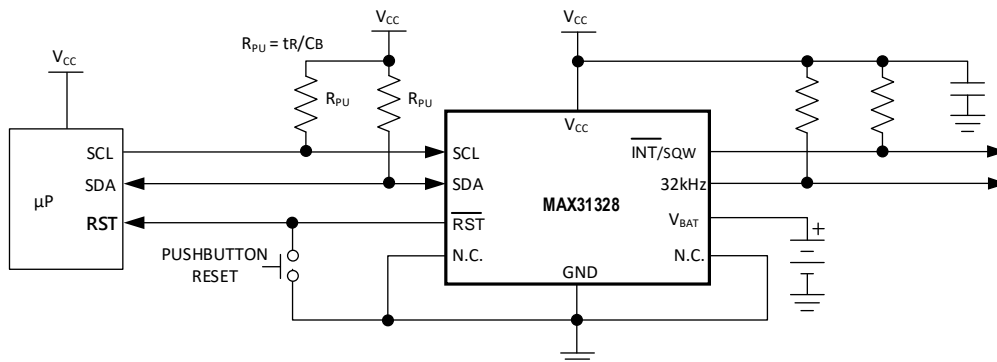

The MAX31328 package contains a quartz tuning-fork crystal. Pick-and-place equipment can be used, but precautions should be taken to ensure that excessive shocks are avoided. Ultrasonic cleaning should be avoided to prevent damage to the crystal.

Avoid running signal traces under the package unless a ground plane is placed between the package and the signal line. All N.C. (no connection) pins must be connected to ground.

Moisture-sensitive packages are shipped from the factory dry packed. Handling instructions listed on the package label must be followed to prevent damage during reflow. Refer to the IPC/JEDEC J-STD-020 standard for moisture-sensitive device (MSD) classifications and reflow profiles. Exposure to reflow is limited to two times the maximum.

Typical Application Circuits

Ordering Information

 T = Tape and reel.

Package Information

[LGA]

Package Code	L1055M+1
Outline Number	<a href="#">21-100481</a>
Land Pattern Number	<a href="#">91-100169</a>
Thermal Resistance, Multi-Layer Board:	
Junction-to-Ambient ( $\theta_{JA}$ )	145.45 °C/W
Junction-to-Case Thermal Resistance ( $\theta_{JC}$ )	66.67 °C/W

For the latest package outline information and land patterns (footprints), go to [www.maximintegrated.com/packages](http://www.maximintegrated.com/packages). Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to [www.maximintegrated.com/thermal-tutorial](http://www.maximintegrated.com/thermal-tutorial).
