## MAX33011E/12E/14E/15E +5V, 5Mbps CAN Transceiver with $\pm 65\text{V}$ Fault Protection, Fault Detection and Reporting, $\pm 25\text{V}$ CMR, and $\pm 45\text{kV}$ ESD Protection

### General Description

The MAX33011E/MAX33012E, and MAX33014E/MAX33015E are a family of +5V control area network (CAN) transceivers with integrated protection for industrial applications. These devices have extended  $\pm 65\text{V}$  fault protection on the CAN bus for equipment where overvoltage protection is required. The CAN family also incorporates high  $\pm 45\text{kV}$  ESD HBM protection and an input common-mode range (CMR) of  $\pm 25\text{V}$ , exceeding the ISO 11898 specification of  $-2\text{V}$  to  $+7\text{V}$ , and well suited for applications where ground planes from different systems are shifting relative to each other.

This CAN family incorporates a fault-detection feature where it monitors the CANH and CANL line for faults like overcurrent, overvoltage, and transmission failure. When a fault is detected, the FAULT pin goes high, which triggers an external interrupt with the local CAN controller, and the driver and receiver lines are placed in recessive mode. The system clock then drives the TXD pin and a fault code is transmitted through the RXD line back to the controller. When the specific fault code is transmitted and the system is programmed to alert local service personnel, they are able to troubleshoot and debug the problem quicker, providing valuable diagnostics and decreased equipment downtime. In addition, the family features a variety of options to address common CAN application requirements: low-current standby mode, slow slew rate for improved EMI performance, silent-mode to disable the transmitter, low level translation to interface with low-voltage controllers, and loopback mode for remote self diagnostics.

These devices are specified for data rates up to 5Mbps. The transceivers include a dominant timeout to prevent bus lockup caused by controller error or by a fault on the TXD input. When TXD remains in the dominant state (low) for longer than  $t_{\text{DOM}}$ , the driver is switched to the recessive state, releasing the bus.

The MAX33011E/MAX33012E are in a standard 8-pin SOIC package and the MAX33014E/MAX33015E are in a 10-pin TDFN-EP package. This family of devices operates over the  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  temperature range.

### Applications

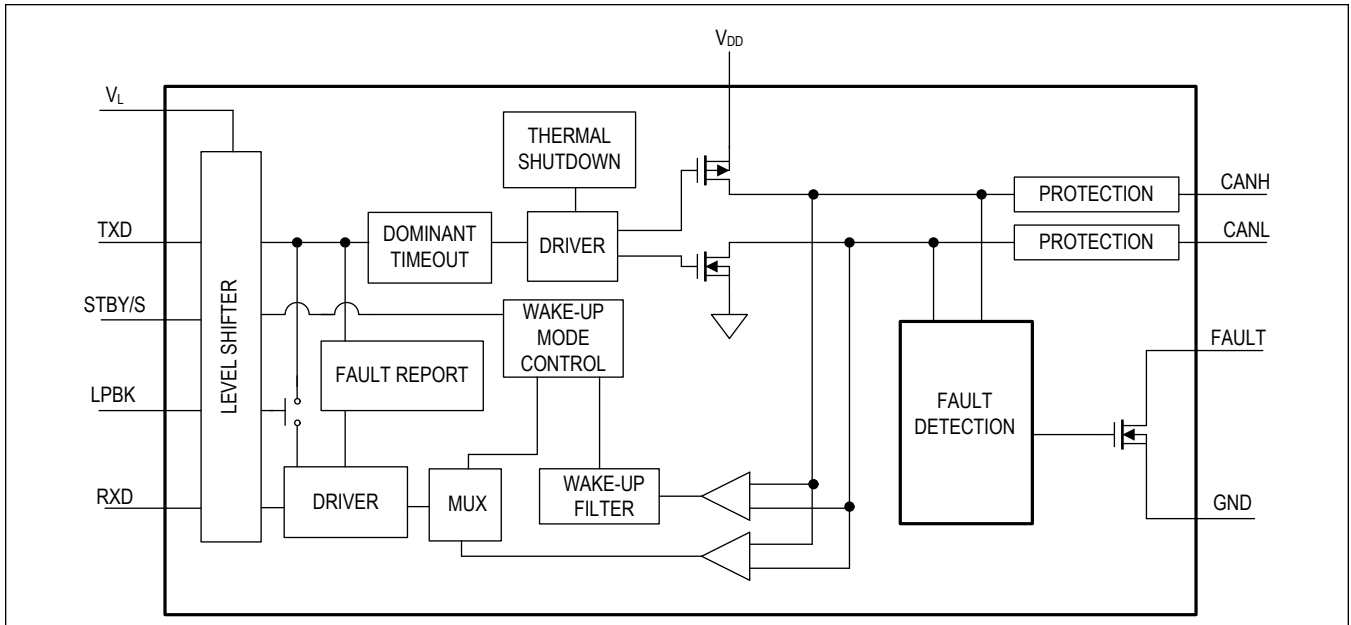

- Industrial Automation
- Building Automation
- Vending Machines
- Security Systems
- Heavy Equipment/Machinery

### Benefits and Features

- Integrated Protection Increases Robustness
  - $\pm 65\text{V}$  Fault-Tolerant CANH and CANL
  - $\pm 45\text{kV}$  ESD HBM (Human Body Model)
  - $\pm 30\text{kV}$  IEC Air-Gap and  $\pm 12\text{kV}$  IEC Contact
  - $\pm 25\text{V}$  Extended Common-Mode Input Range (CMR)
  - Transmitter Dominant Timeout Prevents Lockup
  - Short-Circuit Protection Limits Driver Current
  - Thermal Shutdown
- Family Provides Flexible Design Options
  - 1.62V to 5.5V Logic-Supply ( $V_L$ ) Range (MAX33014E and MAX33015E)
  - Silent Mode S Disables Transmitter (MAX33011E and MAX33015E)
  - STBY Input for Low-Current, Slow Slew Rate, and Normal Mode (MAX33012E and MAX33014E)
  - LPBK Enables Remote Diagnostics (MAX33014E and MAX33015E)
- Fault Detection and Reporting
  - Detects Overcurrent, Overvoltage, and Transmission Failure
  - Error Code Reporting Through RXD
- Operating Temperature Range of  $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$

[Ordering Information](#) appears at end of data sheet.

#### MAX33011E

#### MAX33012E

# MAX33011E/12E/14E/15E

+5V, 5Mbps CAN Transceiver with ±65V Fault Protection, Fault Detection and Reporting, ±25V CMR, and ±45kV ESD Protection

## MAX33014E

## MAX33015E

## Pin Description

PIN				NAME	FUNCTION
MAX33011E	MAX33012E	MAX33014E	MAX33015E		
1	1	1	1	TXD	Transmit Data Input. TXD is a CMOS/TTL compatible input from a CAN controller with an internal pullup to V <sub>DD</sub> .
—	—	2	2	LPBK	Loopback Mode. When connected to logic-high, the transmitter and receiver are placed in a high-impedance state. Internally, the TXD line drives directly to the RXD line for loopback that can be used for self-diagnostic of the transceiver without disturbing the bus. When loopback mode is not used, connect to GND or leave floating.
2	2	3	3	GND	Ground
3	3	4	4	VDD	Supply Voltage. Bypass V <sub>DD</sub> to GND with a 0.1µF capacitor.

## Pin Description (continued)

PIN				NAME	FUNCTION
MAX33011E	MAX33012E	MAX33014E	MAX33015E		
4	4	5	5	RXD	Receive Data Output. RXD is a CMOS/TTL compatible output from the physical bus lines CANH and CANL.
5	5	6	6	FAULT	Fault Detected Indication. Stays low when fault is not detected. Release to high if an overcurrent, overvoltage, or transmission failure is detected.
—	—	7	7	VL	Logic Supply Input. $V_L$ is the logic supply voltage for the input/output between the CAN transceiver and controller. $V_L$ allows full compatibility from +1.62V to +5.5V logic on all digital lines. Bypass to GND with a 0.1 $\mu$ F capacitor. Connect $V_L$ to $V_{DD}$ for 5V logic compatibility.
6	6	8	8	CANL	CAN Bus Line Low
7	7	9	9	CANH	CAN Bus Line High
8	—	—	10	S	Silent Mode Input. Drive S low to enable TXD and to operate in normal mode. Drive S high to disable the transmitter. A 26.1k $\Omega$ external resistor can be used to connect the S pin to ground for slow slew mode.
—	8	10	—	STBY	Standby Mode Input. A logic-high on STBY pin selects the standby mode. In standby mode, the transmitter is disabled, and the receiver is in low-power mode. A logic-low on STBY pin puts the transceiver in normal operating mode. A 26.1k $\Omega$ external resistor can be used to connect the STBY pin to ground for slow slew mode.

## Detailed Description

The MAX33011E/MAX33012E and MAX33014E/MAX33015E are a family of fault-protected CAN transceivers with fault detection and fault reporting. They are designed for applications where expeditious troubleshooting is important to increase the up time of important control systems, addressing common faults like overcurrent, overvoltage, and transmission failure. These devices are ideal for harsh industrial applications with a number of integrated robust protection features that improve the reliability of end equipment. These devices provide a link between the CAN protocol controller and the physical wires of the bus lines in a CAN. They can be used for DeviceNet™, CAN Kingdom, and CANOpen™ applications as well.

All CAN transceivers in the family are fault protected up to  $\pm 65V$ , making them suitable for applications where overvoltage protection is required. These devices are rated up to a high  $\pm 45kV$  ESD of human body model (HBM), suitable for protection during the manufacturing process, and even in the field where there is a human interface for installation and maintenance. In addition, a common-mode voltage range of  $\pm 25V$  enables communication in noisy environments where there are ground plane differences between different systems due to the close proximity of heavy equipment machinery or operation from different transformers. Dominant timeout prevents the bus from being blocked by a hung-up microcontroller, and the outputs CANH and CANL are short-circuit current-limited and protected against excessive power dissipation by thermal shutdown circuitry that places the driver outputs in a high-impedance state.

The MAX33011E/MAX33012E and MAX33014E/MAX33015E can operate up to 5Mbps. This family has the option to slow the slew rate to  $8V/\mu s$  to minimize EMI, enabling the use of unshielded-twisted or parallel cable. The MAX33011E/MAX33012E are packaged in an industry-standard 8-pin SO, while the MAX33014E/MAX33015E are packaged in a 10-pin TDFN. This family of robust CAN transceivers has an operating temperature from  $-40^{\circ}C$  to  $+125^{\circ}C$ .

### $\pm 65V$ Fault Protection

These devices feature  $\pm 65V$  of fault protection. The CANH and CANL data lines are capable of withstanding a short from  $-65V$  to  $+65V$ . This extended overvoltage range makes it suitable for applications where accidental shorts to power supply lines are possible due to human intervention.

### Transmitter

The transmitter converts a single-ended input signal (TXD) from the local CAN controller to differential outputs for the bus lines CANH and CANL. The truth table for the transmitter and receiver is provided in [Table 1](#).

**Table 1. Transmitter and Receiver Truth Table (When Not Connected to the Bus)**

STBY	TXD	TXD LOW TIME	CANH	CANL	BUS STATE	RXD
LOW	LOW	$< t_{DOM}$	HIGH	LOW	DOMINANT	LOW
LOW	LOW	$> t_{DOM}$	$V_{DD}/2$	$V_{DD}/2$	RECESSIVE	HIGH
LOW	HIGH	X	$V_{DD}/2$	$V_{DD}/2$	RECESSIVE	HIGH

X = Don't care

### Transmitter Output Protection

This family of CAN transceivers protects the transmitter output stage against a short-circuit to a positive or negative voltage by limiting the driver current. See the CANH and CANL short-circuit current TOC graphs. Thermal shutdown further protects the devices from excessive temperatures that may result from a short. The transmitter returns to normal operation once the short is removed.

### Transmitter-Dominant Timeout

These devices feature a transmitter-dominant timeout ( $t_{DOM}$ ) that prevents erroneous CAN controllers from clamping the bus to a dominant level by maintaining a continuous low TXD signal. When TXD remains in the dominant state (low) for greater than  $t_{DOM}$ , the transmitter is disabled, releasing the bus to a recessive state (Figure 4). After a dominant timeout fault, the transmitter is re-enabled when receiving a rising edge at TXD. The transmitter-dominant timeout limits the minimum possible data rate to 9kbps for standard CAN protocol.

### Receiver

The receiver reads the differential input from the bus line CANH and CANL and transfers this data as a single-ended output RXD to the CAN controller. It consists of a comparator that senses the difference  $V_{DIFF} = (CANH - CANL)$ , with respect to an internal threshold of 0.7V. If  $V_{DIFF} > 0.9V$ , a logic-low is present on RXD. If  $V_{DIFF} < 0.5V$ , a logic-high is present. The CANH and CANL common-mode range is  $\pm 25V$  in normal mode and  $\pm 12V$  in standby mode. RXD is a logic-high when CANH and CANL are shorted or terminated and undriven.

### Fault Detection and Reporting

This family of devices has fault detection for overcurrent, overvoltage, and transmission failure in normal mode operation. The detection of faults and reporting them out to the local CAN controller provide additional information that benefits the troubleshooting of a given problem in a CAN bus system, reducing down time, improving equipment efficiencies, and keeping service costs down.

To enable fault detection upon power-up, 100 low-to-high transitions need to pass through TXD, which is typically 1 or 2 CAN frame messages depending on data payload size (classic or extended format) and which protocol is used. Fault detection is not enabled in standby and silent mode. After the 100 low-to-high transitions on TXD, if a fault is detected, then another 16 low-to-high transitions on TXD are required to shift out the fault code shown in Table 2. In addition, 10 more pulses are needed to clear the fault.

**Table 2. Fault Detection and Reporting**

FAULT	CONDITION (FAULT DETECTION ENABLED)	FAULT CODE	POSSIBLE CAUSE
Overcurrent	$>85mA$	101010	<ul style="list-style-type: none"> <li>CANH shorted to CANL</li> <li>CANH connected to GND and CANL connected to <math>V_{DD}</math></li> </ul>
Overvoltage	$CANH > +29V$ or $CANL < -29V$	101100	<ul style="list-style-type: none"> <li>CMR fault</li> </ul>
Transmission Failure	RXD unchanged for 10 consecutive pulses, recommended minimum frequency = 200kHz	110010	<ul style="list-style-type: none"> <li>Open load (both termination resistors missing) on CANH and CANL</li> <li>Exceeds driver's common-mode range</li> <li>CANH and/or CANL connected to a fixed voltage source</li> </ul>

#### Overvoltage Detection

Overvoltage detection is triggered when CANH is above approximately +29V or CANL is below approximately -29V. This indicates that the CAN bus has likely violated the CMR range or that a short fault on CANH and/or CANL has occurred and is beyond the  $\pm 29V$  threshold. Once overvoltage detection is triggered, the FAULT pin transitions from low to high and the fault code is clocked out of RXD through TXD.

**Overcurrent Detection**

Overcurrent detection is triggered when there is a high current path from  $V_{DD}$  to GND through a short from CANH to CANL. In addition, shorts far away from the CAN node may not be detected due to high cable impedance. See [Figure 7](#) for overcurrent detection maximum operating frequency versus cable length as a reference. A Cat5e copper-clad aluminum cable is used. The maximum frequency will vary with the type of cable.

Figure 7. Overcurrent Detection Operating Frequency vs. Cable Length

**Transmission Failure Detection**

Transmission failure detection is triggered when the signal on RXD does not match TXD for 10 consecutive cycles after fault detection is enabled. This can occur when both termination resistors are missing. Other scenarios include, but are not limited to, shorting CANH to GND or CANL to  $V_{DD}$  resulting in the differential signal not meeting the receiver's  $V_{IH}$  and  $V_{IL}$  specification.

## Fault Reporting

When a fault occurs and the FAULT pin goes high, the CANH and CANL lines are placed in high impedance, and a 6-bit fault code of the first detected fault condition is stored in an internal register. 16 low-to-high transitions need to go through TXD to shift the fault code out through RXD.

An overcurrent fault timing diagram is shown in [Figure 8](#).

Figure 8. Overcurrent Fault Reporting Timing Diagram

## Fault Clear

The fault condition can be cleared only after the 6-bit fault code is reported through the RXD pin of the chip. Soon after the fault code is reported, send 10 clock pulses through the TXD pin, which deasserts the FAULT pin. The FAULT pin cannot be cleared in standby or silent mode. Fault detection is disabled after fault is cleared and another 100 low-to-high transitions are required on TXD to re-enable fault detection.

## Standby Mode (MAX33012E, MAX33014E)

Drive the STBY pin high for standby mode, which switches the transmitter off and the receiver to a low current and low-speed state. The supply current is reduced to  $60\mu A$  during standby mode. The bus line is monitored by a low differential comparator to detect and recognize a wakeup event on the bus line. Once the comparator detects a dominant bus level longer than  $t_{WAKE}$ , RXD is pulled low. Drive the STBY pin low for normal operation. Fault detection is disabled in standby mode.

## Slow Slew Rate Mode

Connect a  $26.1k\Omega$  resistor between ground and the STBY/S pin. This will put the device in slow slew rate mode where the typical rising slew rate is  $10V/s$  and the typical falling slew rate is  $18V/s$ , enabling the use of unshielded-twisted or parallel cable, compared with normal mode at  $140V/\mu s$  falling and  $180V/\mu s$  rising slew rate. The STBY pin voltage should be between  $0.2V$  to  $0.6V$  to remain in slow slew rate mode. Slow slew rate mode is recommended for transmitter frequencies which have a data rate that is less than  $1Mbps$ .

## Silent Mode (MAX33011E, MAX33015E)

Drive S high to place the device in silent mode. This disables the transmitter regardless of the voltage level at TXD. However, RXD is still active and monitors activity on the bus line. Make sure that the FAULT pin is cleared before entering into silent mode. Fault detection is disabled in silent mode.

---

MAX33011E/12E/14E/15E

+5V, 5Mbps CAN Transceiver with  $\pm 65V$  Fault Protection, Fault Detection and Reporting,  $\pm 25V$  CMR, and  $\pm 45kV$  ESD Protection

**Loopback Mode (MAX33014E, MAX33015E)**

The LPBK pin enables the local CAN controller to perform self-diagnostics. A logic-high to LPBK places the transceiver in a high impedance state to the bus. This allows data to pass internally from the driver to receiver in a loopback test mode without disturbing the bus. When LPBK is connected to the ground, the transceiver operates in normal mode.

**Logic Compatibility (MAX33014E, MAX33015E)**

A separate input  $V_L$  allows the devices to communicate with logic systems down to 1.62V while operating from a +5V supply. This provides a reduced input voltage threshold to the TXD, STBY, S, and LPBK inputs, and provides a logic-high output at RXD that is compatible with the microcontroller's supply rail. The logic compatibility eliminates an external logic level translator and longer propagation delay. Connect  $V_L$  to  $V_{DD}$  to operate with +5V logic systems.

## Applications Information

### Reduced EMI and Reflections

In multidrop CAN applications, it is important to maintain a single linear bus of uniform impedance that is properly terminated at each end. A star, ring, or tree configuration should never be used. Any deviation from the end-to-end wiring scheme creates a stub. High-speed data edges on a stub can create reflections back down to the bus. These reflections can cause data errors by eroding the noise margin of the system. Although stubs are unavoidable in a multidrop system, care should be taken to keep these stubs as short as possible, especially when operating with high data rates.

## Typical Application Circuit

### Multidrop CAN Bus

## Ordering Information

PART NUMBER	TEMP RANGE	PIN-PACKAGE	FEATURE SET
MAX33011EASA+	-40°C to +125°C	8 SO	S
MAX33012EASA+	-40°C to +125°C	8 SO	STBY
MAX33014EATB+	-40°C to +125°C	10 TDFN	STBY, LPBK, VL
MAX33015EATB+	-40°C to +125°C	10 TDFN	S, LPBK, VL

+ Denotes a lead(Pb)-free/RoHS-compliant package.
