

Single/Dual/Quad, +1.8V/10 μ A, SOT23, Beyond-the-Rails Op Amps

MAX4240-MAX4244

General Description

The MAX4240–MAX4244 family of micropower op amps operate from a single +1.8V to +5.5V supply or dual $\pm 0.9V$ to $\pm 2.75V$ supplies and have Beyond-the-Rails™ inputs and rail-to-rail output capabilities. These amplifiers provide a 90kHz gain-bandwidth product while using only 10 μ A of supply current per amplifier. The MAX4241/MAX4243 have a low-power shutdown mode that reduces supply current to less than 1 μ A and forces the output into a high-impedance state. Although the minimum operating voltage is specified at +1.8V, these devices typically operate down to +1.5V. The combination of ultra-low-voltage operation, beyond-the-rails inputs, rail-to-rail outputs, and ultra-low power consumption makes these devices ideal for any portable/two-cell battery-powered system.

These amplifiers have an input common-mode range that extends 200mV beyond each rail, and their outputs typically swing to within 9mV of the rails with a 100k Ω load. Beyond-the-rails input and rail-to-rail output characteristics allow the full power-supply voltage to be used for signal range. The combination of low input offset voltage, low input bias current, and high open-loop gain makes them suitable for low-power/low-voltage precision applications.

The MAX4240 is offered in a space-saving 5-pin SOT23 package. All specifications are guaranteed over the -40°C to +85°C extended temperature range.

Applications

Two-Cell Battery-Powered Systems	Strain Gauges
Portable/Battery-Powered Electronic Equipment	Sensor Amplifiers
Digital Scales	Cellular Phones
	Notebook Computers
	PDA's

Selector Guide

PART	NO. OF AMPS	SHUTDOWN	PIN-PACKAGE
MAX4240	1	—	5-pin SOT23
MAX4241	1	Yes	8-pin μ MAX/SO
MAX4242	2	—	8-pin μ MAX/SO
MAX4243	2	Yes	10-pin μ MAX, 14-pin SO
MAX4244	4	—	14-pin SO

Beyond-the-Rails is a trademark and μ MAX is a registered trademark of Maxim Integrated Products, Inc.

Features

- ◆ **Ultra-Low-Voltage Operation:**
Guaranteed Down to +1.8V
Typical Operation to +1.5V
- ◆ **Ultra-Low Power Consumption:**
10 μ A Supply Current per Amplifier
1 μ A Shutdown Mode (MAX4241/MAX4243)
Up to 200,000 Hours Operation from Two AA Alkaline Cells
- ◆ **Beyond-the-Rails Input Common-Mode Range**
- ◆ **Outputs Swing Rail-to-Rail**
- ◆ **No Phase Reversal for Overdriven Inputs**
- ◆ **200 μ V Input Offset Voltage**
- ◆ **Unity-Gain Stable for Capacitive Loads up to 200pF**
- ◆ **90kHz Gain-Bandwidth Product**
- ◆ **Available in Space-Saving 5-Pin SOT23 and 8-Pin μ MAX® Packages**

MAX4240-MAX4244

Single/Dual/Quad, +1.8V/10µA, SOT23, Beyond-the-Rails Op Amps

Detailed Description

Beyond-the-Rails Input Stage

The MAX4240–MAX4244 have Beyond-the-Rails inputs and rail-to-rail output stages that are specifically designed for low-voltage, single-supply operation. The input stage consists of separate NPN and PNP differential stages, which operate together to provide a common-mode range extending to 200mV beyond both supply rails. The crossover region of these two pairs of supply rails. The input offset voltage is typically 200µV. Low operating supply voltage, low supply current, beyond-the-rails common-mode input range, and rail-to-rail outputs make this family of operational amplifiers an excellent choice for precision or general-purpose, low-voltage battery-powered systems.

Since the input stage consists of NPN and PNP pairs, the input bias current changes polarity as the common-mode voltage passes through the crossover region. Match the effective impedance seen by each input to reduce the offset error caused by input bias currents flowing through external source impedances (Figures 1a and 1b). The combination of high source impedance plus input capacitance (amplifier input capacitance plus stray capacitance) creates a parasitic pole that produces an underdamped signal response. Reducing input capacitance or placing a small capacitor across the feedback resistor improves response in this case.

The MAX4240–MAX4244 family's inputs are protected from large differential input voltages by internal 2.2kΩ series resistors and back-to-back triple-diode stacks across the inputs (Figure 2). For differential input voltages (much less than 1.8V), input resistance is typically 45MΩ. For differential input voltages greater than 1.8V, input resistance is around 4.4kΩ, and the input bias current can be approximated by the following equation:

$$I_{BIAS} = (V_{DIFF} - 1.8V) / 4.4k\Omega$$

Figure 1a. Minimizing Offset Error Due to Input Bias Current (Noninverting)

Figure 1b. Minimizing Offset Error Due to Input Bias Current (Inverting)

Figure 2. Input Protection Circuit

Single/Dual/Quad, +1.8V/10 μ A, SOT23, Beyond-the-Rails Op Amps

In the region where the differential input voltage approaches 1.8V, the input resistance decreases exponentially from 45M Ω to 4.4k Ω as the diode block begins conducting. Conversely, the bias current increases with the same curve.

Rail-to-Rail Output Stage

The MAX4240-MAX4244 output stage can drive up to a 10k Ω load and still swing to within 40mV of the rails. Figure 3 shows the output voltage swing of a MAX4240 configured as a unity-gain buffer, powered from a single +2V supply voltage. The output for this setup typically swings from (V_{EE} + 6mV) to (V_{CC} - 8mV) with a 100k Ω load.

Applications Information

Power-Supply Considerations

The MAX4240-MAX4244 operate from a single +1.8V to +5.5V supply (or dual \pm 0.9V to \pm 2.75V supplies) and consume only 10 μ A of supply current per amplifier. A high power-supply rejection ratio of 85dB allows the amplifiers to be powered directly off a decaying battery voltage, simplifying design and extending battery life.

The MAX4240-MAX4244 are ideally suited for use with most battery-powered systems. Table 1 lists a variety of typical battery types showing voltage when fresh, voltage at end-of-life, capacity, and approximate operating time from a MAX4240/MAX4241, assuming nominal conditions for both normal and shutdown modes.

Although the amplifiers are fully guaranteed over temperature for operation down to a +1.8V single supply, even lower-voltage operation is possible in practice. Figures 4 and 5 show the PSRR and supply current as a function of supply voltage and temperature.

Power-Up Settling Time

The MAX4240-MAX4244 typically require 200 μ s to power up after V_{CC} is stable. During this start-up time, the output is indeterminate. The application circuit should allow for this initial delay.

Shutdown Mode

The MAX4241 (single) and MAX4243 (dual) feature a low-power shutdown mode. When the shutdown pin (SHDN) is pulled low, the supply current drops to 1 μ A per amplifier, the amplifier is disabled, and the outputs enter a high-impedance state. Pulling SHDN high or leaving it floating enables the amplifier. Take care to ensure that parasitic leakage current at the SHDN pin does not inadvertently place the part into shutdown mode when SHDN is left floating. Figure 6 shows the output voltage response to a shutdown pulse. The logic threshold for SHDN is always referred to V_{CC} / 2 (not to

GND). When using dual supplies, pull $\overline{\text{SHDN}}$ to V_{EE} to enter shutdown mode.

Load-Driving Capability

The MAX4240-MAX4244 are fully guaranteed over temperature and supply voltage to drive a maximum resistive load of $10\text{k}\Omega$ to $V_{CC} / 2$, although heavier loads can be driven in many applications. The rail-to-rail output stage of the amplifier can be modeled as a current source when driving the load toward V_{CC} , and as a current sink when driving the load toward V_{EE} . The magnitude of this current source/sink varies with supply voltage, ambient temperature, and lot-to-lot variations of the units.

Figures 7a and 7b show the typical current source and sink capability of the MAX4240-MAX4244 family as a function of supply voltage and ambient temperature. The contours on the graph depict the output current

value, based on driving the output voltage to within 50mV, 100mV, and 200mV of either power-supply rail.

For example, a MAX4241 running from a single +1.8V supply, operating at $T_A = +25^\circ\text{C}$, can source 240μA to within 100mV of V_{CC} and is capable of driving a 7kΩ load resistor to V_{EE} :

$$R_L = \frac{1.8\text{V} - 0.1\text{V}}{240\mu\text{A}} = 7\text{k}\Omega \text{ to } V_{EE}$$

The same application can drive a 3.3kΩ load resistor when terminated in $V_{CC} / 2$ (+0.9V in this case).

Driving Capacitive Loads

The MAX4240–MAX4244 are unity-gain stable for loads up to 200pF (see Load Resistor vs. Capacitive Load graph in *Typical Operating Characteristics*). Applications that require greater capacitive drive capability should use an isolation resistor between the output and the capacitive load (Figure 8). Note that this alternative results in a loss of gain accuracy because R_{ISO} forms a voltage divider with the load resistor.

Power-Supply Bypassing and Layout

The MAX4240–MAX4244 family operates from either a single +1.8V to +5.5V supply or dual ±0.9V to ±2.75V supplies. For single-supply operation, bypass the power supply with a 100nF capacitor to V_{EE} (in this case GND). For dual-supply operation, both the V_{CC}

and V_{EE} supplies should be bypassed to ground with separate 100nF capacitors.

Good PC board layout techniques optimize performance by decreasing the amount of stray capacitance at the op amp's inputs and output. To decrease stray capacitance, minimize trace lengths by placing external components as close as possible to the op amp. Surface-mount components are an excellent choice.

Using the MAX4240-MAX4244 as Comparators

Although optimized for use as operational amplifiers, the MAX4240-MAX4244 can also be used as rail-to-rail I/O comparators. Typical propagation delay depends on the input overdrive voltage, as shown in Figure 9. External hysteresis can be used to minimize the risk of output oscillation. The positive feedback circuit, shown in Figure 10, causes the input threshold to change when the output voltage changes state. The two thresholds create a hysteresis band that can be calculated by the following equations:

$$V_{HYST} = V_{HI} - V_{LO}$$

$$V_{LO} = V_{IN} \times R2 / (R1 + (R1 \times R2 / R_{HYST}) + R2)$$

$$V_{HI} = [(R2 / R1 \times V_{IN}) + (R2 / R_{HYST}) \times V_{CC}] / (1 + R1 / R2 + R2 / R_{HYST})$$

The MAX4240-MAX4244 contain special circuitry to boost internal drive currents to the amplifier output stage. This maximizes the output voltage range over which the amplifiers are linear. In an open-loop comparator application, the excursion of the output voltage is so close to the supply rails that the output stage transistors will saturate, causing the quiescent current to increase from the normal 10µA. Typical quiescent currents increase to 35µA for the output saturating at V_{CC} and 28µA for the output at V_{EE}.

Using the MAX4240-MAX4244 as Ultra-Low-Power Current Monitors

The MAX4240-MAX4244 are ideal for applications powered from a 2-cell battery stack. Figure 11 shows an application circuit in which the MAX4240 is used for monitoring the current of a 2-cell battery stack. In this circuit, a current load is applied, and the voltage drop at the battery terminal is sensed.

The voltage on the load side of the battery stack is equal to the voltage at the emitter of Q1, due to the feedback loop containing the op amp. As the load current increases, the voltage drop across R1 and R2 increases. Thus, R2 provides a fraction of the load current (set by the ratio of R1 and R2) that flows into the emitter of the PNP transistor. Neglecting PNP base current, this current flows into R3, producing a ground-referenced voltage proportional to the load current. Scale R1 to give a voltage drop large enough in comparison to V_{OS} of the op amp, in order to minimize errors.

The output voltage of the application can be calculated using the following equation:

$$V_{OUT} = [I_{LOAD} \times (R1 / R2)] \times R3$$

For a 1V output and a current load of 50mA, the choice of resistors can be R1 = 2Ω, R2 = 100kΩ, R3 = 1MΩ. The circuit consumes less power (but is more susceptible to noise) with higher values of R1, R2, and R3.
