MPS

The Future of Analog IC Technology®

DESCRIPTION

The MP2158A is a monolithic step-down, switch-mode converter with built-in internal power MOSFETs. It achieves 1A of continuous output current from a 2.5V to 6V input voltage with excellent load and line regulation. The output voltage can be regulated as low as 0.6V.

The constant-on-time control scheme provides fast transient response and eases loop stabilization. Fault condition protection includes cycle-by-cycle current limiting and thermal shutdown.

The MP2158A is available in a small QFN-8 (1.5mmx2mm) package and requires only a minimal number of readily available, standard, external components.

The MP2158A is ideal for a wide range of applications, including high-performance DSPs, FPGAs, PDAs, and portable instruments.

FEATURES

* Very Low I_Q of 17µA
* Default 1.5MHz Switching Frequency
* 1.5% V_{FB} Accuracy
* EN and Power Good for Power Sequencing
* Wide 2.5V to 6V Operating Input Range
* Output Adjustable from 0.6V
* Up to 1A of Output Current
* 100% Duty Cycle in Dropout
* 120mΩ and 90mΩ Internal Power MOSFET Switches
* Cycle-by-Cycle Over-Current Protection
* Short-Circuit Protection with Hiccup Mode
* Stable with Low ESR Output Ceramic Capacitors
* Available in a QFN-8 (1.5mmx2mm) Package

APPLICATIONS

* Wireless/Networking Cards
* Portable Instruments
* Battery-Powered Devices
* Low Voltage I/O System Power

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance.

QFN-8(1.5mmx2mm)
ABSOLUTE MAXIMUM RATINGS [1]

Supply voltage (V_{IN}) 6.5V
V_{SW} ....
   -0.3V (-1.5V for <20ns&-4V for <8ns) to 6.5V
                              (10V for <10ns)
All other pins ....-0.3V to 6.5 V
Junction temperature ....150°C
Lead temperature ....260°C
Continuous power dissipation (T_A = +25°C) [2]
.... 1.14W
Storage temperature................ -65°C to +150°C

Recommended Operating Conditions [3]

Supply voltage (V_{IN}) ....2.5V to 6V
Operating junction temp. (T_J)... -40°C to +125°C

Thermal Resistance [4] $θ_{JA}$ $θ_{JC}$

QFN-8 (1.5mmx2mm)............ 110 ..... 55... °C/W

NOTES:
1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance $θ_{JA}$, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX)-T_A)/$θ_{JA}$. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.

ELECTRICAL CHARACTERISTICS

V_{IN} = 5V, T_A = +25°C, unless otherwise noted.

| Parameter	Symbol	Condition	Min	Typ	Max	Units
Feedback voltage	V_{FB}	2.5V $\leqslant$ V_{IN} $\leqslant$ 6V, T_A = 25°C	-1.5	0.600	+1.5	V/%

PIN FUNCTIONS

| Pin #	Name	Description
1	EN	**On/off control.**
2	FB	**Feedback.** An external resistor divider from output to AGND tapped to FB sets the output voltage.
3	AGND	**Analog ground for internal control circuit.**
4	OUT	**Input sense for output voltage.**
5	PGND	**Power ground.**
6	SW	**Switch output.**
7	VIN	**Supply voltage.** The MP2158A operates from a +2.5V to +6V unregulated input. C1 is needed to prevent large voltage spikes from appearing at the input.
8	PG	**Power good indicator.** The output of PG is an open-drain structure with an internal pull-up resistor to VIN. PG is pulled up to VIN when the FB voltage is within ±10% of the regulation level. If the FB voltage is out of that regulation range, it is low.

FUNCTIONAL BLOCK DIAGRAM
Figure 1: MP2158A Block Diagram

OPERATION

The MP2158A uses constant-on-time control with input voltage feed-forward control to stabilize the switching frequency over a full input range. During light loads, the MP2158A employs a proprietary control of low-side switches and inductor currents to eliminate ringing on the switching node and improve efficiency.

Constant-On-Time Control

When compared to the fixed-frequency PWM control, the constant-on-time control offers a simpler control loop and faster transient response. By using input voltage feed-forward, the MP2158A maintains a near constant switching frequency across the input and output voltage range. The on time of the switching pulse can be estimated using Equation (1):

$$T_{ON} = \frac{V_{OUT}}{V_{IN}} \cdot 0.667 \mu s \qquad (1)$$

To prevent inductor current runaway during the load transient, the MP2158A sets the minimum off time to 60ns. This minimum off time limit does not affect the operation of the MP2158A in its steady state in any way.

Light-Load Operation

In a light-load condition, the MP2158A uses a proprietary control scheme to save power and improve efficiency. The MP2158A uses a zero current cross circuit to detect if the inductor current is starting to reverse. The low-side switch turns off when the inductor current starts to reverse and triggers discontinuous conduction mode (DCM) operation.

The delay for the internal circuit propagation time is typically 50ns. This means that the inductor current continues falling after the ZCD is triggered in this delay. If the inductor current falling slew rate is too fast (V_{OUT} is high or close to V_{IN}), the low-side MOSFET turns off, the inductor current may be negative, and the MP2158A will not be able to enter DCM operation. If DCM is required, the off time of the low-side MOSFET in CCM should be longer than 100ns (2 times the propagation delay). For example, if V_{IN} is 3.6V and Vo is 3.3V, the off

time in CCM is 55ns. It is difficult to enter DCM at a light load. Using a smaller inductor can help the MP2158A enter DCM more easily.

Enable

When the input voltage is greater than the under-voltage lockout (UVLO) threshold (typically 2.3V), the MP2158A is enabled by pulling EN higher than 1.2V. Leaving EN floating or grounded disables the MP2158A. There is an internal 1MΩ resistor from EN to ground.

Soft Start

The MP2158A has a built-in soft start that ramps up the output voltage in a controlled slew rate, avoiding overshoot at start-up. The soft-start time is typically about 1.15ms.

Power Good Indicator

The MP2158A uses an open-drain with a 550kΩ pull-up resistor as a power good indicator (PG). When FB is within +/-10% of the regulation voltage (i.e. 0.6V), PG is pulled up to VIN by the internal resistor. If the FB voltage is out of the +/-10% window, PG is pulled to ground by an internal MOSFET. The MOSFET has a maximum R_{dson} of less than 400Ω.

Current Limit

The MP2158A has a 2A minimum current limit for the high-side switch. When the high-side switch hits its current limit, the MP2158A enters the hiccup threshold until the current drops. This prevents the inductor current from rising and possibly damaging the components.

Short Circuit and Recovery

The MP2158A enters short-circuit protection mode when the current limit is hit and tries to recover from the short circuit by entering hiccup mode. In short-circuit protection, the MP2158A disables the output power stage, discharges a soft-start capacitor, and automatically tries to soft start again. If the short-circuit condition still holds after the soft start ends, the MP2158A repeats this operation until the short circuit disappears and the output rises back to regulation level.

APPLICATION INFORMATION

COMPONENT SELECTION

Setting the Output Voltage

The external resistor divider sets the output voltage (see Typical Application on page 1). The feedback resistor R1 cannot be too large or too small, considering the trade-off for a dynamic circuit and stability in the circuit. Set R1 to around 120kΩ to 200kΩ. R2 is then given by Equation (2):

$$R2 = \frac{R1}{\frac{V_{out}}{0.6} - 1} \qquad (2)$$

The feedback circuit is shown in Figure 2.

Figure 2: Feedback Network

Table 1 lists the recommended resistor values for common output voltages.

Table 1: Resistor Selection for Common Output Voltages

V_{OUT} (V)	R1 (kΩ)	R2 (kΩ)
1.0	200 (1%)	300 (1%)
1.2	200 (1%)	200 (1%)
1.8	200 (1%)	100 (1%)
2.5	200 (1%)	63.2 (1%)
3.3	200 (1%)	44.2 (1%)

Selecting the Inductor

A 0.68µH to 2.2µH inductor is recommended for most applications. For the highest efficiency, choose an inductor with a DC resistance of less than 15mΩ. For most designs, the inductance value can be derived from Equation (3):

$$L_1 = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{OSC}} \qquad (3)$$

Where ΔI_L is the inductor ripple current.

Set the inductor current to approximately 30% of the maximum load current. The maximum inductor peak current is calculated in Equation (4):

$$I_{L(MAX)} = I_{LOAD} + \frac{\Delta I_L}{2} \qquad (4)$$

Selecting the Input Capacitor

The input current to the step-down converter is discontinuous and requires a capacitor to supply the AC current to the step-down converter while maintaining the DC input voltage. Use low ESR capacitors for the best performance. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR values and small temperature coefficients. For most applications, a 10µF capacitor is sufficient. For a higher output voltage, a 22µF capacitor may be needed to improve system stability.

Since the input capacitor absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated with Equation (5):

$$I_{C1} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \qquad (5)$$

The worse-case condition occurs at $V_{IN} = 2V_{OUT}$, shown in Equation (6):

$$I_{C1} = \frac{I_{LOAD}}{2} \qquad (6)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum or ceramic. When using electrolytic or tantalum capacitors, use a small, high-quality ceramic capacitor (0.1Mf) and place it as close to the IC as possible. When using ceramic capacitors, make sure that they have enough capacitance to provide a sufficient charge to prevent an excessive voltage ripple at the input. The input voltage ripple caused by capacitance can be estimated with Equation (7):

$$\Delta V_{IN} = \frac{I_{LOAD}}{f_S \times C1} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \qquad (7)$$

Selecting the Output Capacitor

The output capacitor (C2) is required to maintain the DC output voltage. Ceramic, low ESR capacitors are recommended to keep the output voltage ripple low. The output voltage ripple can be estimated with Equation (8):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_S \times L_1} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times \left(R_{ESR} + \frac{1}{8 \times f_S \times C2}\right) \quad (8)$$

Where L_1 is the inductor value and R_{ESR} is the equivalent series resistance (ESR) value of the output capacitor.

When using ceramic capacitors, the impedance at the switching frequency is dominated by the capacitance, which mainly causes output voltage ripples. For simplification, the output voltage ripple can be estimated with Equation (9):

$$\Delta V_{OUT} = \frac{V_{OUT}}{8 \times f_S^2 \times L_1 \times C2} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (9)$$

When using tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated with Equation (10):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_S \times L_1} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times R_{ESR} \quad (10)$$

The characteristics of the output capacitor affect the stability of the regulation system.

PCB Layout Guidelines

Efficient PCB layout is critical for achieving stable operation. Poor layout design can result in poor line or load regulation and stability issues. For best results, refer to Figure 3 and follow the guidelines below:

1. Place the high-current paths (GND, VIN, and SW) as close to the device as possible with short, direct, and wide traces.

2. Place the input capacitor as close to VIN and GND as possible.

3. Place the external feedback resistors next to FB.

4. Keep the switching node (SW) short and away from the feedback network.

Figure 3: Recommended PCB Layout

Design Example

Below is a design example following the application guidelines for the specifications:

Table 2: Design Example

V_{IN}	5V
V_{OUT}	1.2V
f_{SW}	1500kHz

The detailed application schematic is shown in Figure 4. The typical performance and circuit waveforms are shown in the Typical Performance Characteristics section on page 4. For more device applications, please refer to the related evaluation board datasheets.
