

### DESCRIPTION

The MP6910A is a fast turn-off intelligent rectifier for flyback converters that combines a 100V power switch that replaces diode rectifiers for high efficiency. The chip regulates the forward voltage drop of the internal power switch to about 65mV and turns off before the voltage goes negative.

### FEATURES

- Integrated 15mΩ, 100V Power Switch
- Compatible with Energy Star
- VDD Range from 8.3V to 24V
- 65mV  $V_{DS}$  Regulation Function <sup>(1)</sup>
- Max 250kHz Switching Frequency
- Supports High-Side and Low-Side Rectification
- Available in SOIC-8 Package

### APPLICATIONS

- Laptop Adapters
- QC and USB Quick Charger
- High-Efficiency Flyback Converter

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

#### NOTE:

 Y: Year code  
 WW: Week code

## PACKAGE REFERENCE

## PIN FUNCTIONS

Pin #	Name	Description
1, 4	VS	<b>MOSFET source.</b> VS is also used as the reference for VDD.
2	VDD	<b>Supply voltage.</b>
3	SENSE	<b>MOSFET drain voltage sensing.</b>
5 - 8	VD	<b>MOSFET drain.</b>

**ABSOLUTE MAXIMUM RATINGS** <sup>(2)</sup>

VDD to VS .....	-0.3V to +25V
VD to VS.....	-1.5V to +100V
SENSE to VS.....	-1V to +180V
Maximum operating frequency .....	250kHz
Continuous drain current (T <sub>C</sub> = 25°C) .....	11.8A
Continuous drain current (T <sub>C</sub> = 100°C) .....	7.5A
Pulsed drain current <sup>(3)</sup> .....	50A
Maximum power dissipation <sup>(4)</sup> .....	1.8W
Junction temperature .....	150°C
Lead temperature (solder) .....	260°C
Storage temperature .....	-55°C to +150°C

**ESD Rating**

Human-body model (HBM)	
Sense pin.....	+1200V, -2000V
Other pins.....	±2000V
Charged-device model (CDM).....±2000V	

**Recommended Operation Conditions** <sup>(5)</sup>

VDD to VS .....	8.3V to 24V
Operating junction temp. (T <sub>J</sub> ) ..	-40°C to +125°C

<b>Thermal Resistance</b> <sup>(6)</sup>	<b>θ<sub>JA</sub></b>	<b>θ<sub>JC</sub></b>
SOIC-8 .....	67 .....	30 ... °C/W

**NOTES:**

- 2) Exceeding these ratings may damage the device.
- 3) Repetitive Rating: Pulse width=100µs, duty cycle limited by maximum junction temperature
- 4) T<sub>A</sub> = +25°C. The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub>(MAX), the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub>(MAX) = (T<sub>J</sub>(MAX)-T<sub>A</sub>)/θ<sub>JA</sub>. Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 5) The device is not guaranteed to function outside of its operating conditions.
- 6) Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

VDD = 12V, T<sub>J</sub> = -40 ~ 125°C, unless otherwise noted.

Parameter	Symbol	Conditions	Min	Typ	Max	Units
VDD voltage range			8.3		24	
VDD UVLO rising			6.2	7.2	8.2	V

**Operation in 30W Flyback Application**

$V_{IN} = 265V_{AC}$ ,  $I_{OUT} = 2.5A$

## BLOCK DIAGRAM

Figure 1: Functional Block Diagram

## OPERATION

The MP6910A supports operation in flyback converters. The control circuitry controls the gate in forward mode and turns the gate off when the MOSFET current is fairly low.

### Blanking

The control circuitry contains a blanking function. When the integrated MOSFET turns on, the circuitry ensures that the on state lasts for a specific amount of time. The turn-on blanking time is  $t_{MIN}$  (~1.0 $\mu$ s), which determines the minimum on time. During the turn-on blanking period, the turn-off threshold is not blanked completely, but changes the threshold voltage to about +50mV (instead of -30mV). This ensures that MP6910A can always be turned off, even during the turn-on blanking period (although it does so more slowly).

### Under-Voltage Lockout (UVLO)

When the VDD is below the under-voltage lockout (UVLO) threshold, the MP6910A is in sleep mode, and the integrated MOSFET remains off.

### Basic Operation

The basic operations of a flyback converter with the MP6910A are listed below.

1. Turn-on phase: The switch current first flows through the body diode of the integrate MOSFET, which generates a negative  $V_{DS}$  across it (less than -500mV). The voltage is much smaller than the turn-on threshold of the control circuitry (-65mV), which turns on the integrated MOSFET after a  $t_{Don}$  (100ns) turn-on delay (see Figure 2).

**Figure 2: Turn-on and Turn-off Delay**

2. Conducting phase: When the integrated MOSFET turns on,  $V_{DS}$  starts to rise according to its on resistance. Once  $V_{DS}$  rises above the turn-on threshold (-65mV), the control circuitry regulates the gate voltage of the integrated MOSFET to keep  $V_{DS}$  around  $-V_{FWD}$  (-65mV), even when the current through the switch is fairly small. This function can make the internal driver voltage fairly low when the MOSFET is turned off to quicken the turn-off speed. This function is still active during the turn-on blanking period, which means that the integrated MOSFET can still be turned off even with a very small duty.

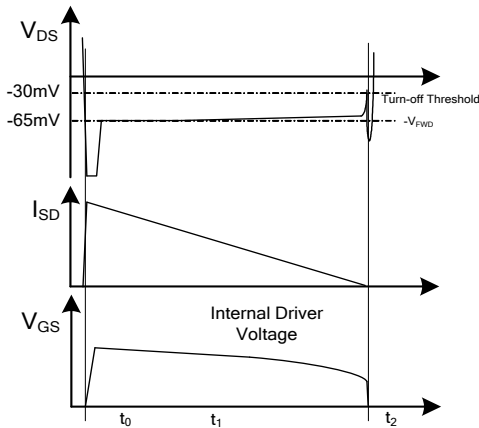

Figure 3 shows the synchronous rectification operation at heavy-load condition. Due to the high current, the internal driver voltage is saturated first. After  $V_{DS}$  rises above  $-V_{FWD}$ , the driver voltage decreases to adjust the  $V_{DS}$  to a typical  $-V_{FWD}$ .

**Figure 3: Synchronous Rectification Operation at Heavy Load**

Figure 4 shows the synchronous rectification operation at light-load condition. Due to the low current, the driver voltage never saturates, but begins to decrease once the integrated MOSFET is turned on and adjusts  $V_{DS}$ .

**Figure 4: Synchronous Rectification Operation at Light Load**

3. Turn-off phase: When  $V_{DS}$  rises to trigger the turn-off threshold (-30mV), the driver voltage of the switch is pulled low after  $t_{Doff}$  (30ns) of turn-off delay time by the control circuitry (see Figure 2). Similar with the turn-on phase, a 200ns blanking time is added after the switch turns off to avoid an erroneous trigger.

**Light-Load Latch-Off Function**

The gate driver of integrated MOSFET in the MP6910A is latched to save the driver loss at light-load condition to improve efficiency. The light-load enter pulse width ( $t_{LL}$ ) is fixed internally (~2.2 $\mu$ s). When the synchronous power switch conducting period is lower than  $t_{LL}$  for longer than light-load enter delay ( $t_{LL-Delay}$ ), MP6910A enters light-load mode and latches off the integrated MOSFET (see Figure 5).

**Figure 5: Entering Light-Load Mode**

During light-load mode, MP6910A monitors the integrated MOSFET body diode conducting period by sensing  $V_{DS}$ . When  $V_{DS}$  exceeds the light-load mode exit pulse width threshold ( $V_{LL-DS}$ ), MP6910A considers the integrated MOSFET body diode conducting time to be completed. If the MOSFET body diode conduction time is longer than  $t_{LL} + t_{LL-H}$  ( $t_{LL-H}$ , light-load enter pulse-width hysteresis), light-load mode finishes and the integrated MOSFET of MP6910A is unlatched to restart synchronous rectification (see Figure 6).

**Figure 6: Exiting Light-Load Mode**

**External Resistor on SENSE**

Over-voltage conditions may lead to damage to the device, so there must be appropriate application design to guarantee safe operation, especially on the high voltage pin.

One common over-voltage condition is when the body diode of the SR MOSFET is turned on, as the forward voltage drop may exceed the negative rating on the SENSE pin. In this case, it is recommended to place an external resistor about 300 $\Omega$  to 1k $\Omega$  between SENSE and the MOSFET drain. But a resistor greater than 1k $\Omega$  is also not recommended for the sampling accuracy of  $V_{DS}$ .

**Typical System Implementations**

Figure 7 shows the typical system implementation for the IC supply derived from output voltage, which is available in low-side rectification. The output voltage is recommended to be in the  $V_{DD}$  range (from 8.3V to 24V).

**Figure 7: IC Supply Derived Directly from Output Voltage**

If the output voltage is out of the VDD range or high-side rectification is used, it is recommended to use an auxiliary winding from the power transformer for the IC supply (see Figure 8 and Figure 9).

**Figure 8: IC Supply Derived from Auxiliary Winding in Low-Side Rectification**

**Figure 9: IC Supply Derived from Auxiliary Winding in High-Side Rectification**

There is another non-auxiliary winding solution for the IC supply, which uses an external LDO circuit from the secondary transformer winding (see Figure 10 and Figure 11). Compared with an auxiliary winding for the IC supply, this solution has a slightly higher power loss, which is dissipated on the LDO circuit, especially when the secondary winding voltage is high.

**Figure 10: IC Supply Derived from Secondary Winding in Low-Side Rectification**

**Figure 11: IC Supply Derived from Secondary Winding in High-Side Rectification**

**Maximum Output Current**

The allowed temperature rise of the MP6910A limits the maximum output current that it can handle. The temperature rise is determined by its own power loss. Generally, for a universal input adapter, the recommended rated output current for MP6910A is 2.5A. For certain designs, the power loss of MP6910A can be calculated to determine the maximum output current.

The power loss of MP6910A can be separated into several parts: controller consumption, integrated MOSFET conduction loss, and so on. If MP6910A works in continuous conduction mode (CCM), reverse-recovery loss of the integrated MOSFET must also be considered. Each part of the loss can be calculated with Equation (1), Equation (2), and Equation (3), respectively:

$$P_{\text{LOSS\_Controller}} = V_{\text{DD}} \times I_{\text{DD}} \quad (1)$$

$$P_{\text{LOSS\_SR\_Conduction}} = f_{\text{SW}} \times \int_0^{t_{\text{s\_on}}} V_{\text{SR\_SD}}(t) \times I_{\text{SR\_SD}}(t) dt \quad (2)$$

$$P_{\text{LOSS\_SR\_RR}} = \frac{1}{2} \times V_{\text{DS}} \times I_{\text{rr}} \times t_{\text{rr}} \times f_{\text{SW}} \quad (3)$$

Where  $V_{\text{DD}}$  is the voltage and  $I_{\text{DD}}$  is the current of MP6910A.  $t_{\text{s\_on}}$  is the SR on period,  $V_{\text{SR\_SD}}$  is the voltage drop from the SR, and  $I_{\text{SR\_SD}}$  is the current flowing through the SR.  $I_{\text{rr}}$  is the peak reverse current and  $t_{\text{rr}}$  is reverse recovery time.

The total loss of MP6910A ( $P_{\text{LOSS}}$ ) is the sum of the above losses. If an RC snubber is adopted, the power loss caused by this snubber should also be taken into consideration.

The junction and case temperature rises can be calculated with the thermal resistance of the junction-to-ambient temperature ( $\theta_{\text{JA}}$ ) and junction-to-case temperature ( $\theta_{\text{JC}}$ ).

The junction temperature must be within ABS (typically 150°C). Calculate  $\Delta T_{JA}$  and  $\Delta T_{JC}$  with Equation (4) and Equation (5):

$$\Delta T_{JA} = P_{LOSS} \times \theta_{JA} \quad (4)$$

$$\Delta T_{JC} = P_{LOSS} \times \theta_{JC} \quad (5)$$

The thermal resistance can be reduced by laying thicker copper layer, placing more thermal dissipation vias and adopting heatsinks and so on. The real maximum output current can be set by considering the real tested data.
