

**2.85V - 18V, 6A, High-Efficiency, Wide-Input, Synchronous, Step-Down Converter with Integrated Telemetry via I2C Interface** 

**The Future of Analog IC Technology**

## **DESCRIPTION**

The MP8861 is a high-frequency, synchronous, rectified, step-down, switch-mode converter with an I<sup>2</sup>C control interface. The MP8861 offers a fully integrated solution that achieves 6A of continuous output current with excellent load and line regulation over a wide input supply range.

The output voltage level can be controlled onthe-fly through an I2C serial interface. The reference voltage range can be adjusted from 0.6V to 1.108V in 4mV steps. The voltage slew rate, frequency, current limit, hiccup/latch-off protection, enable, and power-save mode (PSM) are also selectable through the I2C interface.

Constant-on-time (COT) control operation provides fast transient response. An open-drain power good (PG) pin indicates that the output voltage is in the nominal range. Full protection features include over-voltage protection (OVP), over-current protection (OCP), and thermal shutdown.

The MP8861 is available in a QFN-14 (3mmx4mm) package.

## **FEATURES**

- Wide 2.85V to 18V Operating Input Range
- 6A Continuous Output Current
- 1% Internal Reference Accuracy
- I2C Programmable Reference Range from 0.6V to 1.108V in 4mV Steps with Slew Rate Control
- 5% Accuracy Output Voltage and Output Current Monitoring via I2C
- Selectable PFM/PWM Mode, Adjustable Frequency and Current Limit through I2C
- Four Different Selectable I2C Addresses
- External Soft Start (SS)
- Open-Drain Power Good (PG) Indication
- Output Over-Voltage Protection (OVP)
- Hiccup/Latch-Off Over-Current Protection (OCP)
- VOUT Adjustable up to 5.5V using FB pin
- Available in a QFN-14 (3mmx4mm) Package

## **APPLICATIONS**

- Solid-State Drives (SSD)
- Flat-Panel Televisions and Monitors
- Digital Set-Top Boxes
- Distributed Power Systems
- Networking/Servers

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

**NOTES:** 

1) Exceeding these ratings may damage the device.<br>2) The maximum allowable power dissipation is a

- The maximum allowable power dissipation is a function of the maximum junction temperature  $T_J$  (MAX), the junctionto-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature TA. The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_D$  $(MAX) = (T_J (MAX) - T_A)/\theta_{JA}$ . Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.

# **ELECTRICAL CHARACTERISTICS**

## VIN = 12V,  $T_J$  = -40°C to +125°C <sup>(5)</sup>, typical value is tested at  $T_J$  = +25°C, unless otherwise noted.

## **ELECTRICAL CHARACTERISTICS** *(continued)*

## VIN = 12V, T<sub>J</sub> = -40°C to +125°C <sup>(5)</sup>, typical value is tested at T<sub>J</sub> = +25°C, unless otherwise noted.

**NOTES:**

## **PIN FUNCTIONS**

## **BLOCK DIAGRAM**

**Figure 2: Functional Block Diagram** 

## **OPERATION**

#### **Pulse-Width Modulation (PWM) Operation**

The MP8861 is a fully integrated, synchronous, rectified, step-down, switch-mode converter. The MP8861 uses constant-on-time (COT) control to provide fast transient response and ease loop stabilization. Figure 3 shows the simplified ramp compensation block.

At the beginning of each cycle, the high-side MOSFET (HS-FET) turns on whenever the ramp voltage  $(V_{\text{Ramp}})$  is lower than the error amplifier output voltage  $(V_{EAO})$ , which indicates an insufficient output voltage. The on period is determined by both the output voltage and input voltage to make the switching frequency fairly constant over the input voltage range.

After the on period elapses, the HS-FET enters the off state. By cycling the HS-FET on and off, the converter regulates the output voltage. The integrated low-side MOSFET (LS-FET) turns on when the HS-FET is in its off state to minimize conduction loss.

Shoot-through occurs when both the HS-FET and LS-FET are turned on at the same time, causing a dead short between the input and GND and reducing efficiency dramatically. The MP8861 prevents shoot-through by generating a dead time (DT) internally between the HS-FET off and LS-FET on period and the LS-FET off and HS-FET on period. The MP8861 enters either heavy-load operation or light-load operation depending on the amplitude of the output current.

**Figure 3: Simplified Compensation Block** 

#### **Switching Frequency**

The MP8861 uses constant-on-time (COT) control, so there is no dedicated oscillator in the IC. The input voltage is fed into the one-shot on-timer through the internal frequency resistor. The duty ratio is VOUT/VIN, and the switching

frequency is fairly constant over the input voltage range. The MP8861's switching frequency can be adjusted by setting the two bits D[5:4] in register 02 through the I<sup>2</sup>C communication. When the output voltage setting is low and the input voltage is high, the switching on-time may be limited by the internal minimum on-time limit, and the switching frequency decreases. Table 1 shows the maximum switching frequency vs. the output voltage when  $VIN = 12V$  and  $VIN = 5V$ .

#### **Table 1: Maximum Frequency Selection vs. Output Voltage**

#### **Forced PWM Operation**

When the MP8861 works in forced pulse-width modulation (PWM) mode, the MP8861 enters continuous conduction mode (CCM), where the HS-FET and LS-FET repeat the on/off operation, even if the inductor current is zero or a negative value. The switching frequency  $(F_{SW})$ is fairly constant. Figure 4 shows the timing diagram during this operation.

**Figure 4: Forced PWM Operation** 

#### **Light-Load Operation**

When the MP8861 works in auto-PWM or autopulse-frequency modulation (PFM) mode in light-load operation, the MP8861 reduces the switching frequency automatically to maintain high efficiency, and the inductor current drops

almost to zero. When the inductor current reaches zero, the LS-FET driver goes into tristate (Hi-Z) (see Figure 5). The output capacitors discharge slowly to GND through R1 and R2. This operation improves device efficiency greatly when the output current is low.

**Figure 5: Light-Load Operation** 

Light-load operation is also called skip mode because the HS-FET does not turn on as frequently as it does during heavy-load condition. The frequency at which the HS-FET turns on is a function of the output current. As the output current increases, the current modulator regulation time period becomes shorter, the HS-FET turns on more frequently. and the switching frequency increases. The output current reaches critical levels when the current modulator time is zero and can be determined with Equation (1):

$$
I_{\text{OUT}} = \frac{(V_{\text{IN}} - V_{\text{OUT}}) \times V_{\text{OUT}}}{2 \times L \times F_{\text{SW}} \times V_{\text{IN}}}
$$
(1)

The MP8861 reverts to PWM mode once the output current exceeds the critical level. Afterward, the switching frequency remains fairly constant over the output current range.

The MP8861 can operate in PFM mode under light load to improve efficiency (low-power mode). The MP8861 can also operate in forced PWM mode at any load condition. The mode is selectable through the I<sup>2</sup>C control. To enable low-power mode, set the Mode bit to 0. To disable low-power mode, set the Mode bit to 1, and the converter works in forced PWM mode. The Mode bit is set to 0 (PFM) by default.

#### **Operating without an External Ramp**

The traditional constant-on-time (COT) control scheme is intrinsically unstable if the output capacitor's ESR is not large enough to be an effective current-sense resistor. Ceramic capacitors cannot be used as output capacitors,

typically. The MP8861 has built-in, internal ramp compensation to ensure that the system is stable, even without the help of the output capacitor's ESR. The pure ceramic capacitor solution can reduce the output ripple, total BOM cost, and board area significantly.

### **VCC Regulator**

A 3.5V internal regulator powers most of the internal circuitries. A 470nF decoupling capacitor is needed to stabilize the regulator and reduce ripple. This regulator takes the VIN input and operates in the full VIN range. After EN is pulled high and VIN is greater than 3.5V, the output of the regulator is in full regulation. When VIN is lower than 3.5V, the output voltage decreases and follows the input voltage. A 0.47μF ceramic capacitor is required for decoupling.

#### **Error Amplifier (EA)**

The error amplifier (EA) compares the FB voltage against the internal 0.6V reference (REF) and outputs a PWM signal. The reference voltage can be programmed from 0.6V to 1.108V via the I2C. The optimized internal ramp compensation minimizes the external component count and simplifies the control loop design.

#### **Enable (EN)**

EN is a digital control pin that turns the regulator, including the I2C block, on and off. Drive EN high to turn on the regulator. Drive EN low to turn off the regulator. An internal 1.5MΩ resistor is connected from EN to ground. EN can operate with an 18V input voltage, which allows EN to be directly connected to VIN for automatic start-up. When the external EN is high, set the EN bit to 0 in register 01 to stop the HS-FET and LS-FET from switching. The MP8861 resumes switching by setting the EN bit to 1.

## **Under-Voltage Lockout (UVLO)**

Under-voltage lockout (UVLO) protects the chip from operating at an insufficient supply voltage. The MP8861 UVLO comparator monitors the input voltage, VIN, and output voltage of the VCC regulator. The MP8861 is active when the voltages exceed the UVLO rising threshold.

#### **Soft Start (SS) and Pre-Bias Start-Up**

Soft start (SS) prevents the converter output voltage from overshooting during start-up. When the chip starts up, the internal circuitry generates a soft-start voltage that ramps up from 0V to VCC. When SS is lower than REF, the error amplifier uses SS as the reference. When SS is higher than REF, the error amplifier uses REF as the reference.

The approximate typical soft-start time can be calculated with Equation (2):

$$
t_{ss}(ms) = \frac{V_{ref}(V) \times C_{ss}(nF)}{7\mu A}
$$
 (2)

Where  $V_{ref}$  is reference voltage.

If the output of the MP8861 is pre-biased to a certain voltage during start-up, the IC disables the switching of both the HS-FET and LS-FET until the voltage on the internal SS capacitor exceeds the sensed output voltage at FB.

The MP8861 also provides a selectable softstop function, which defines the output discharge behavior after EN shutdown. By default, the output is not controlled after EN shutdown. If setting the Soft Stop control bit D[3] to 1 in register 02 via the  $I^2C$ , the output is discharged linearly to zero in a quarter of the soft-start time.

#### **Over-Current Protection (OCP)**

The MP8861 has a default, hiccup, cycle-bycycle, over-current limiting control. The currentlimit circuit employs both high-side current limit and a low-side "valley" current-sensing algorithm. The MP8861 uses the  $R_{DS(ON)}$  of the LS-FET as a current-sensing element for the valley current limit. If the magnitude of the highside current-sense signal is above the currentlimit threshold, the PWM on pulse is terminated, and the LS-FET is turned on. Afterward, the inductor current is monitored by the voltage between GND and SW. GND is used as the positive current sensing node, so GND should be connected to the source terminal of the bottom MOSFET. PWM is not allowed to initiate a new cycle before the inductor current falls to the valley threshold.

After the cycle-by-cycle over-current limit occurs, the output voltage drops until VOUT is below the under-voltage (UV) threshold (typically 60% below the reference). Once UV is triggered, the MP8861 enters hiccup mode to restart the part periodically. This protection mode is especially useful when the output is dead shorted to ground. The average shortcircuit current is reduced greatly to alleviate thermal issues and protect the regulator. The MP8861 exits hiccup mode once the overcurrent condition is removed.

Short the output to ground first, and then power on the part. The MP8861's I2C is disabled in this condition. The I2C resumes operation after the short circuit is removed. When the Hiccup OCP bit D[1] in register 01 is set to 0 by the I<sup>2</sup>C, a latch-off occurs if OCP is triggered, and FB UVP is triggered.

#### **Power Good (PG)**

Power good (PG) indicates whether the output voltage is in the normal range compared to the internal reference voltage. PG is an open-drain structure. An external pull-up supply is required. During power-up, the PG output is pulled low. This indicates to the system to remain off and keep the load on the output to a minimum. This helps reduce inrush current at start-up.

When the output voltage is higher than 90% and lower than 115% of the internal reference voltage and the soft start is finished, then the PG signal is pulled high. When the output voltage is lower than 85% after the soft start finishes, the PG signal remains low. When the output voltage is higher than 115% of the internal reference, PG is switched low. The PG signal rises high again after the output voltage drops below 105% of the internal reference voltage.

PG implements an adjustable deglitch time via the I2C whenever VOUT crosses the UV/OV rising and falling threshold. This guarantees the correct indication when the output voltage is scaled through the  $I^2C$ .

The PG output is pulled low immediately when EN UVLO, input UVLO, OCP, or overtemperature protection (OTP) is triggered.

#### **Input Over-Voltage Protection (VIN OVP)**

The MP8861 monitors VIN to detect an input over-voltage event. This function is active only when the output is in an over-voltage (OV) or soft-stop condition. When the output is in overvoltage protection (OVP), or soft stop is enabled, output discharge is enabled to charge the input voltage high. When the input voltage exceeds the input OVP threshold, both the HS-FET and LS-FET stop switching.

#### **Output Over-Voltage Protection (OVP)**

The MP8861 monitors both FB and VOUT to detect an over-voltage event. An internal comparator monitors FB. When the FB voltage rises higher than 125% of the internal reference voltage, the controller enters dynamic regulation mode, and the input voltage may be charged up during this time. When input OVP is triggered, the IC stops switching. If OVP mode is set to auto-retry in the  $I^2C$ , the IC begins switching once the input voltage drops below the VIN OVP recover threshold. Otherwise, the MP8861 latches off. OVP auto-retry mode or latch-off mode occurs only if the soft start has finished.

Dynamic regulation mode can be operated by turning on the low side until the low-side negative current limit is triggered. Then the body diode of the HS-FET free-wheels the current.

The output power charges the input, which may trigger the VIN OVP function. In VIN OVP, neither the HS-FET or LS-FET turn on and stop charging VIN. If the output is still over-voltage and the input voltage drops below the VIN OVP threshold, repeat the operation. If the output voltage is below 110% of the internal reference voltage, then the MP8861 exits output OVP.

#### **Output Absolute Over-Voltage Protection (OVP\_ABS)**

The MP8861's VOUT can be adjusted by the output reference voltage and the external resistor dividers. The MP8861's output voltage must be lower than the absolute OVP threshold (typically 6.5V). The MP8861 monitors VOUT to detect absolute OVP. When VOUT is larger than 6.5V, the controller enters dynamic regulation mode if the OVP Retry bit is set to 1 in the I2C register 01. Otherwise, the MP8861

latches off when output OVP and input OVP are both triggered. Absolute OVP works once both the input voltage and EN are higher than their rising thresholds. This means that this function can work even during a soft start.

#### **Thermal Shutdown**

Thermal shutdown prevents the chip from operating at exceedingly high temperatures. When the silicon die reaches temperatures that exceed 160°C, the entire chip shuts down. When the temperature is less than its lower threshold (typically 140°C), the chip is enabled again.

The D[1] and D[2] bits can be monitored in register 06 for more information about IC silicon temperature.

#### **Floating Driver and Bootstrap Charging**

An external bootstrap capacitor powers the floating power MOSFET driver. This floating driver has its own UVLO protection. This UVLO's rising threshold is 2.4V with a 150mV hysteresis. The bootstrap capacitor voltage is regulated by VIN internally through D1, M1, C4, L1, and C2 (see Figure 6). If  $V_{\text{BST}}$  -  $V_{\text{SW}}$  exceeds 3.3V, U1 regulates M1 to maintain a 3.3V BST voltage across C4.

#### **Start-Up and Shutdown**

If VIN, VCC, and EN exceed their respective thresholds, the chip starts up. The reference block starts first, generating stable reference voltages and currents, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuitries. Several events can shut down the chip: EN low, VIN low, VCC low, thermal shutdown, OVP latch, and OCP latch. In the shutdown procedure, the signaling path is blocked first to avoid any fault triggering. The EAO voltage and the internal supply rail are then pulled down.

#### **I 2 C Control and Default Output Voltage**

When the MP8861 is enabled, the output voltage is determined by the FB resistors with a programmed soft-start time. Afterward, the I2C bus can communicate with the master. If the chip does not receive I2C communication signal continuously, it can work well through FB and perform behavior similar to a traditional non-I2C part. The output voltage is determined by the resistor dividers R1, R2, and FB reference voltage. Vout can be calculated using Equation (3):

$$
V_{\text{OUT}} = V_{\text{REF}} \times (\frac{R1 + R2}{R2})
$$
 (3)

Note that the output voltage cannot be set higher than an absolute OVP threshold (typically 6.5V).

#### **I 2 C Slave Address**

To support multiple devices used on the same I 2C bus, A0 can be used to select four different addresses. A resistor divider from VCC to GND can achieve an accurate reference voltage. Connect A0 to this reference voltage to set a different I<sup>2</sup>C slave address (see Figure 7). The internal circuit changes the  $I^2C$  address accordingly.

When the master sends an 8-bit address value, the 7-bit I2C address should be followed by 0 or 1 to indicate a write or read operation, respectively. Table 2 shows the recommended I 2C address selection by the A0 voltage.

**Figure 7: I2C Slave Address Selection Set-Up** 

**Table 2: Recommended I**2**C Slave Address Selection by A0 Resistor Divider** 

<b>A0 Upper</b>	A0 Lower	I <sup>2</sup> C Slave Address

500	300	110 0011	63H	
300	500	110 0101	65H	
100	No connect	110 0111	67H	

## **I 2C INTERFACE**

#### **I 2 C Serial Interface Description**

The I<sup>2</sup>C is a two-wire, bidirectional, serial interface consisting of a data line (SDA) and a clock line (SCL). The lines are pulled to a bus voltage externally when they are idle. When connecting to the line, a master device generates the SCL signal and device address and arranges the communication sequence. The MP8861 interface is an I<sup>2</sup>C slave. The I<sup>2</sup>C interface adds flexibility to the power supply solution. The output voltage, transition slew rate, and other parameters can be controlled by the I 2C interface instantaneously.

#### **Data Validity**

One clock pulse is generated for each data bit transferred. The data on the SDA line must be stable during the high period of the clock. The high or low state of the data line can only change when the clock signal on the SCL line is low (see Figure 8).

**Figure 8: Bit Transfer on the I2C Bus** 

Start and stop are signaled by the master device, which signifies the beginning and the end of the I2C transfer. The start condition is defined as the SDA signal transitioning from high to low while the SCL is high. The stop condition is defined as the SDA signal transitioning from low to high while the SCL is high (see Figure 9).

**Figure 9: Start and Stop Conditions** 

Start and stop conditions are always generated by the master. The bus is considered to be busy after the start condition, and is considered to be free again after a minimum of 4.7μs after the stop condition. The bus remains busy if a repeated start (Sr) is generated instead of a stop condition. The start (S) and repeated start (Sr) conditions are identical functionally.

#### **Transfer Data**

Every byte put on the SDA line must be eight bits long. Each byte must be followed by an acknowledge bit. The acknowledge-related clock pulse is generated by the master. The transmitter releases the SDA line (high) during the acknowledge clock pulse. The receiver must pull down the SDA line during the acknowledge clock pulse so that it remains low stably during the high period of this clock pulse.

Data transfers follow the format shown in Figure 10. After the start condition (S), a slave address is sent. This address is seven bits long followed by an eighth data direction bit (r/w). A zero indicates a transmission (write), and a one indicates a request for data (read). A data transfer is always terminated by a stop condition (P) generated by the master. However, if a master still wishes to communicate on the bus, it can generate a repeated start condition (Sr) and address another slave without first generating a stop condition.

**Figure 10: Complete Data Transfer** 

The MP8861 requires a start condition, a valid I 2C address, a register address byte, and a data byte for a single data update. After receiving each byte, the MP8861 acknowledges this by pulling the SDA line low during the high period of a single clock pulse. A valid I2C address selects the MP8861. The MP8861 performs an update on the falling edge of the LSB byte.

#### **I 2 C Write and Read Sequence Example**

**I 2C Read Example – Read Register**

## **REGISER DESCRIPTION**

#### **Register Map**

The MP8861 contains six write or read registers. Register 00 is the output voltage selection register. Register 01 is the first system control register and can be used to set the slew rate, hiccup OCP, etc. Register 02 is the second system control register and can be used to set the switching frequency, current limit, etc.

Register 03 and register 04 are output current and output voltage indicating registers, respectively. Register 05 is the IC ID register. Register 06 is the IC status indication register and can be used to check if the IC is in OCP, OTP, etc. The register map is shown below.

#### **Register Description**

#### **1) Reg00 VSEL**

Register 00 is the output reference voltage selection register. The MP8861 default output voltage is determined by the FB resistor divider after the MP8861 power start-up or EN start-up. The reference voltage is adjustable from 0.6V to 1.108V. Before adjusting the output reference voltage, the bit GO\_BIT of the first system control register 01 should be set to 1, and then the reference voltage can be adjusted by the lower seven bits of register 00. When the

output reference voltage setting command is finished, GO\_BIT auto-resets to 0 to prevent false operation of the VOUT scaling. GO\_BIT should be set to 1 before adjusting the output reference voltage via the I<sup>2</sup>C.

Table 3 shows the output reference voltage selection chart from 0.6V to 1.108V via the I<sup>2</sup>C.

D[6:0]	VOUT (V)	D[6:0]	VOUT (V)	D[6:0]	VOUT (V)	D[6:0]	VOUT (V)

**Table 3: Output Reference Voltage Selection Chart** 

## **2) Reg01 SysCntlreg1**

Register 01 is the first system control register.

The highest bit, EN, can be used to turn the part on or off when the external EN is high. When the external EN is high, after part shuts down by setting the EN bit to 0, and then the HS-FET and LS-FET stop switching. The part resumes switching by setting the EN bit to 1 again. When the external EN is low, the converter is off, and the I2C shuts down.

Set GO\_BIT to 1 to enable the I<sup>2</sup>C authority of writing the output reference. When the command is finished, GO\_BIT auto-resets to 0 to prevent false operation of the VOUT scaling.

The IC switches to forced PWM mode when GO\_BIT is set to 1 to achieve a smooth output waveform during the output dynamic scaling. After the output scaling is complete, GO BIT is set to 0 automatically, and the IC operation mode switches to the original mode set by the Mode bit.

The 3-bit Slew Rate D[5:3] is used for slew rate selection during the output voltage dynamic scaling. A proper slew rate reduces the inrush current, voltage overshoot, and voltage undershoot. Eight different slew rate levels can be selected.

The bit Retry OVP defines the protection mode when OVP is triggered. When Retry OVP is set to 1, the part enters auto-recovery when OVP is removed. When Retry OVP is set to 0, the part latches off once output OVP occurs, and VIN OVP is triggered until VIN or EN are toggled.

The bit Hiccup OCP defines the over-current protection mode. When Hiccup OCP is set to 1, the part enters hiccup mode when OCP and UVP are both triggered. When Hiccup OCP is set to 0, the part enters latch-off when OCP and UVP are both triggered.

The lowest bit, Mode, is used for selecting forced PWM or auto-PFM/PWM mode at light load. When Mode is set to 0, auto-PFM/PWM mode is enabled at light load. When Mode is set to 1, forced PWM mode is enabled at light load.

#### **3) Reg02 SysCntlreg2**

Register 02 is the second system control register.

The highest two bits of PG Deglitch Time D[7:6] defines the power good signal rising and falling edge delay times. When output OVP or UVP is triggered, the PG signal turns low or high after a delay time. There are four levels of PG delay time that can be programmed by the I<sup>2</sup>C in different conditions.

The two Switching Frequency bits D[5:4] are used for switching frequency selection. The MP8861 supports up to 1.25MHz of switching frequency by setting the two bits to 11. The MP8861 maximum programmable switching frequency is limited by internal minimum ontime (see Table 1).

The bit Soft Stop defines the output voltage discharge behavior after EN shutdown. When Soft Stop is set to 0, the output voltage is not controlled after EN shutdown. When Soft Stop is set to 1, the output voltage is discharged linearly to zero with the set soft-stop time.

The lowest three bits, Current Limit Adjust D[2:0], are used for peak and valley currentlimit selection. There are eight levels of current limit that can be selected for different application conditions.

#### **4) Reg03 Output Current**

Register 03 is an output current-indicating register. After the part starts up, the DC output current information can be read through the I2C communication.

When the inductor current is in discontinuous conduction mode (DCM), the output current sense is not very accurate. The Mode bit can be set to 1 (PWM mode) for good current sensing accuracy at light load.

When the inductor current enters CCM, the output current sense accuracy is excellent (typical accuracy is 5% when the output current is higher than 2A).

Table 4 shows the output current chart from 0A to 6.75A.

#### **Table 4: Output Current Chart**

#### **5) Reg04 Output Voltage**

Register 04 is an output voltage-indicating register. After the part starts up, the output voltage can be read through the I2C communication. In light load, if the mode bit is set to 0, the MP8861 works in PFM mode. At extremely light-load or no-load condition, the ADC only works when the first pulse comes, and then the MP8861 refreshes the output voltage register before entering sleep mode.

At this moment, the sensed output voltage is at its maximum value, not the average output voltage. Therefore, the I2C read-back voltage is slightly higher than the set point. When applying some load to the part, a higher sense accuracy can be achieved. The Mode bit can be set to 1 (PWM mode) for good voltage sensing accuracy at light load. Table 5 shows the output voltage chart from 0.5V to 5.643V.

**Table 5: Output Voltage Chart** 

#### **6) Reg05 ID1**

Register 05 is the IC information-indicating register. The highest four bits, Vendor ID D[7:4], are set to 1000 internally.

#### **7) Reg06 Status**

Register 06 is a fault condition-indicating register. The highest four bits, D[7:4], are reserved for future use.

The bit OC is the output over-current indication. When the bit is set to 1, the IC is in hiccup mode or OC latch-off.

The bit OTEW is the die temperature early warning indication. When the bit is set to 1, the IC die temperature is higher than 120°C.

The lowest four bits, IC Revision ID D[3:0],

indicates IC revision information.

The bit PG is output power good indication. When the bit is set to 1, the output power is normal.

## **APPLICATION INFORMATION**

#### **Setting the Output Voltage in a FB Control Loop**

The MP8861 can be controlled by the FB loop. The output voltage can be set by the external resistor dividers. The FB loop reference voltage is a default value (0.72V) and can be programmed by the I2C.

The FB loop network is shown in Figure 11.

**Figure 11: FB Loop Network** 

Choose R1 and R2 with Equation (4):

$$
R2 = \frac{R1}{\frac{V_{\text{OUT}}}{0.72V} - 1}
$$
 (4)

Table 6 lists the recommended feedback resistor values for common output voltages.

**Table 6: Resistor Selection for Common Output Voltages (8)**

$V_{\text{OUT}}(V)$	$R1$ (k $\Omega$ )	$R2$ (kΩ)	$Rt$ (k $\Omega$ )	$L(\mu H)$
1.0	80.6	205	10	1.5
1.2	80.6	121	10	1.5
1.5	80.6	74.4	10	1.5
1.8	80.6	53.6	10	1.5
2.5	80.6	32.4	10	2.2
3.3	80.6	22.6	10	2.2
5	80.6	13.7	10	3.3

**NOTE:** 

6) The recommended parameters are based on a 12V input voltage and 22µFx4 output capacitor. Different input voltage and output capacitor values may affect the selection of R1 and R2. For other components' parameters, please refer to the Typical Application Circuits on page 33-35.

#### **Output Voltage Dynamic Scale**

The output voltage dynamic scaling can be done only via the I<sup>2</sup>C. Refer to Figure 12 and follow the steps below.

1) Write GO\_BIT (reg01[6]) to 1.

2) Write reg00 to set the reference voltage by Output Reference (reg00 [6:0]) simultaneously. When the command is finished, GO\_BIT auto-resets to 0 to prevent false operation of the VOUT scaling.

Repeat the above two steps if the output voltage needs to be changed to a different voltage.

**Figure 12: Output Voltage Dynamic Scale Flow Chart** 

#### **Selecting the Inductor**

Use a 0.47µH to 5µH inductor with a DC current rating at least 25% higher than the maximum load current for most applications. For the highest efficiency, use an inductor with a DC resistance less than 5mΩ. For most designs, the inductance value can be derived from Equation (5):

$$
L_1 = \frac{V_{\text{OUT}} \times (V_{\text{IN}} - V_{\text{OUT}})}{V_{\text{IN}} \times \Delta I_{\text{L}} \times f_{\text{osc}}}
$$
(5)

Where ∆I<sub>L</sub> is the inductor ripple current.

Choose the inductor ripple current to be approximately 30% of the maximum load current.

The maximum inductor peak current can be calculated with Equation (6):

$$
I_{L(MAX)} = I_{LOAD} + \frac{\Delta I_L}{2}
$$
 (6)

Use a larger inductor for improved efficiency under light-load conditions below 100mA.

#### **Selecting the Input Capacitor**

The input current to the step-down converter is discontinuous and therefore requires a capacitor to supply AC current to the step-down converter while maintaining the DC input voltage. Use low ESR capacitors for the best performance. Ceramic capacitors with X5R or X7R dielectrics are recommended because of their low ESR and small temperature coefficients. For most applications, use two 22µF capacitors.

Since C1 absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated with Equation (7):

$$
I_{C1} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}}} \left(1 - \frac{V_{OUT}}{V_{IN}}\right)
$$
 (7)

The worst-case condition occurs at VIN = 2VOUT, shown in Equation (8):

$$
I_{C1} = \frac{I_{LOAD}}{2}
$$
 (8)

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality ceramic capacitor (e.g.: 0.1μF) placed as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide a sufficient charge to prevent excessive voltage ripple at input. The input voltage ripple caused by the capacitance can be estimated with Equation (9):

$$
\Delta V_{IN} = \frac{I_{LOAD}}{f_s \times C1} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)
$$
(9)

#### **Selecting the Output Capacitor**

The output capacitor (C2) maintains the DC output voltage. Use ceramic, tantalum, or low-ESR electrolytic capacitors. For the best results, use low ESR capacitors to keep the output voltage ripple low. The output voltage ripple can be estimated with Equation (10):

$$
\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{f_s \times L_1} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \times \left(R_{\text{ESR}} + \frac{1}{8 \times f_s \times C2}\right)
$$
(10)

Where  $L_1$  is the inductor value, and  $R_{ESR}$  is the equivalent series resistance (ESR) value of the output capacitor.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency and causes the majority of the output voltage ripple. For simplification, the output voltage ripple can be estimated with Equation  $(11)$ :

$$
\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{8 \times f_s^2 \times L_1 \times C2} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right)
$$
(11)

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated with Equation (12):

$$
\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{f_s \times L_1} \times \left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right) \times R_{\text{ESR}}
$$
(12)

The characteristics of the output capacitor also affect the stability of the regulation system. The MP8861 can be optimized for a wide range of capacitance and ESR values.

#### **External Bootstrap Diode**

An external bootstrap diode can enhance the efficiency of the regulator given the following conditions:

- VOUT is 5V or 3.3V
- Duty cycle is high: D > 50%

In these cases, add an external BST diode from VCC to BST (see Figure 13).

#### **Figure 13: Optional External Bootstrap Diode to Enhance Efficiency**

The recommended external BST diode is IN4148, and the recommended BST capacitor value is 0.1uF to 1uF.

#### **Connect VCC to VIN at a Low Input Voltage**

VCC can be connected to VIN directly when VIN is lower than 3.5V. This helps improve the MP8861's low input voltage efficiency performance. To use this application set-up, the VIN spike voltage must be limited below 4V; otherwise, VCC may be damaged.

#### **PCB Layout Guidelines (9)**

Efficient PCB layout is critical for stable operation. For best results, refer to Figure 14 and follow the guidelines below. A four-layer layout is strongly recommended to achieve better thermal performance.

- 1. Place the high-current paths (PGND, VIN, and SW) very close to the device with short, direct, and wide traces.
- 2. Keep the VIN and PGND pads connected with large copper planes.
- 3. Use at least two layers for the VIN and PGND trace to achieve better thermal performance.
- 4. Add several vias close to the VIN and PGND pads to help with thermal dissipation. Place m than one via **adjacent to the inner edge of PGND pad** which connects to AGND pad through low impedance routing or ground plane.
- 5. Place the input capacitors as close to VIN and PGND as possible.
- 6. Place the decoupling capacitor as close to VCC and AGND as possible.
- 7. Add several vias close the the AGND pad, and connect to PGND plane with Kelvin connection.
- 8. Place the external feedback resistors next to FB.
- 9. Ensure that there is no via on the FB trace.
- 10. Keep the switching node SW short and away from the feedback network.
- 11. Keep the BST voltage path (BST, C3, and SW) as short as possible.

**NOTE:** 

9) The recommended layout is based on the Typical Application Circuit on page 33-35.

**Figure 14: Recommend Layout** 

#### **Design Example**

Table 7 is a design example following the application guidelines for the specifications below.

The detailed application schematics are shown in Figure 15 through Figure 21. The typical performance and circuit waveforms are shown in the Typical Performance Characteristics section. For more device applications, please refer to the related evaluation board datasheets.
