## 3.3 V Quad LVCMOS Differential Line Receiver Translator

### Description

The NB3N4666C is a quad-channel LVDS line receiver/translator offering data rates up to 400 Mbps (200 MHz) and low power consumption. The NB3N4666C receiver incorporates input fail-safe protection circuit that provides a known output voltage under input open-circuit and terminated (100 Ω) conditions. The four independent inputs accept differential signals such as: M-LVDS, LVDS, LVPECL and HCSL and translates them to a single-ended, 3.3 V LVCMOS.

The NB3N4666C also offers active high and active low enable/disable inputs (EN and  $\overline{\text{EN}}$ ) that allow users to control outputs of all four receivers. These inputs enable or disable the receivers and switch the outputs to an active or high impedance state respectively (see Table 2). The high impedance mode feature helps to reduce the quiescent power consumption to less than 10 mW typical, when the outputs of one or more NB3N4666C devices are multiplexed together.

### Features

- Accepts M-LVDS, LVDS, LVPECL and HCSL Differential Input Signal Levels
- Maximum Data Rate of 400 Mbps
- Maximum Clock Frequency of 200 MHz
- 25 ps Typical Channel-to-Channel Skew
- 3.3 ns Maximum Propagation Delay
- 3.3 V  $\pm 10\%$  Power Supply
- High Impedance Outputs When Disabled
  - ♦ Low Quiescent Power < 10 mW Typical
- Supports Open and Terminated Input Fail-safe
- $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  Ambient Operating Temperature
- 16-Pin TSSOP, 5.0 mm x 4.4 mm x 1.2 mm
- These are Pb-Free Devices

### Applications

- Point-to-point Data Transmission
- Backplane Receivers
- Clock Distribution Networks
- Multidrop Buses

### Fail-Safe Feature

The multi-level receiver's internal fail-safe circuitry is designed to provide fail-safe protection for floating/open or terminated receiver inputs, and will output a stable High-level voltage state.

**Open Input Pins.** The NB3N4666C is a quad receiver device, and if an application requires only 1, 2 or 3 receivers, the unused channel(s) inputs should be left OPEN. The internal input circuitry will ensure a HIGH stable output state for open inputs.

**Terminated Input.** If the driver to the input is disconnected, in a TRI-STATE or power-off condition, the output will again be in a HIGH state, even with a 100-Ω termination resistor across the input pins.

Do not connect unused receiver inputs to ground or any other voltages.

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

3. Guaranteed by design and characterization. Not tested in production.
4. Output short-circuit current (I<sub>OS</sub>) is specified as magnitude only; a minus sign indicates direction only. Note that only one output should be shorted at a time; do not exceed the maximum junction temperature specification (150°C).
5. The V<sub>CMR</sub> range is reduced for larger V<sub>ID</sub>. Example: if V<sub>ID</sub> = 400 mV, the V<sub>CMR</sub> is 0.2 V to 2.2 V. A V<sub>ID</sub> up to V<sub>CC</sub> may be applied to the IN/ $\overline{\text{IN}}$  inputs with the Common-Mode voltage set to V<sub>CC</sub>/2. Propagation delay and Differential Pulse skew decrease when V<sub>ID</sub> is increased from 200 mV to 400 mV. Skew specifications apply for 200 mV ≤ V<sub>ID</sub> ≤ 800 mV over the common-mode range.
6. Tested with 100 MHz input frequency on all channels, EN = V<sub>CC</sub>,  $\overline{\text{EN}}$  = GND.

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

7. Generator waveform for all tests, unless otherwise specified:  $f = 50\text{ MHz}$ ,  $C_L = 10\text{ pF}$  (includes jig capacitance),  $t_r$  and  $t_f$  (10% to 90%)  $\leq 2\text{ ns}$  for  $INx/INx$ .
8.  $f_{MAX}$  generator input conditions:  $t_r = t_f < 1\text{ ns}$  (10% to 90%), 50% duty cycle, differential (1.05 V to 1.35 V peak to peak). Output Criteria: 40% – 60% duty cycle,  $V_{OL}$  (max 0.4 V),  $V_{OH}$  (min 2.7 V),  $C_L = 10\text{ pF}$  (stray plus probes)
9. Measured from the differential crosspoint of the input to  $V_{CC}/2$  of the output.
10.  $t_{SKEW(O-O)}$  is defined as skew between outputs of the same device at the same supply voltage and with equal load conditions.
11.  $t_{SKEW(PP)}$  is defined as skew between outputs on different devices operating at the same supply voltages and with equal load conditions. Using the same type of inputs on each device, the outputs are measured at the differential cross points.
12.  $t_{SKEW(P)}$  is the magnitude difference in the differential propagation delay time between the positive-going edge and the negative-going edge of the same channel.

## NB3N4666C

The above phase noise data was captured using Agilent E5052A/B. The data displays the input phase noise and output phase noise used to calculate the additive phase jitter at a specified integration range. The additive RMS phase jitter contributed by the device (integrated between 12 kHz and 20 MHz) is 161 fs.

The additive RMS phase jitter performance of the fanout buffer is highly dependent on the phase noise of the input source.

To obtain the most precise additive phase noise measurement, it is vital that the source phase noise be notably lower than that of the DUT. If the phase noise of the source is greater than the noise floor of the device under test, the source noise will dominate the additive phase jitter calculation and lead to an incorrect negative result for the additive phase noise within the integration range. The Figure above is a good example of the NB3N4666C source generator phase noise having a significantly lower floor than the DUT and results in an additive phase jitter of 161 fs.

NB3N4666C Additive RMS Phase Jitter @ 100 MHz  
 12 kHz to 20 MHz = 161 fs

$$\begin{aligned} \text{Additive RMS Phase Jitter} &= \sqrt{(\text{Source} + \text{DUT})^2 - (\text{Source})^2} \\ &= \sqrt{(278.49)^2 - (227.25)^2} \\ &= 161 \text{ fs} \end{aligned}$$
