NCP1597B

Buck Regulator - Synchronous

1 MHz, 2 A

The NCP1597B is a fixed 1 MHz, high−output−current, synchronous PWM converter that integrates a low−resistance, high−side P−channel MOSFET and a low−side N−channel MOSFET. The NCP1597B utilizes internally compensated current mode control to provide good transient response, ease of implementation and excellent loop stability. It regulates input voltages from 4.0 V to 5.5 V down to an output voltage as low as 0.8 V and is able to supply up to 2 A.

The NCP1597B has features including fixed internal switching frequency (Fsw), and an internal soft−start to limit inrush current. Using the EN pin, shutdown supply current is reduced to 3 μA maximum.

Other features include cycle−by−cycle current limiting, short−circuit protection, power saving mode and thermal shutdown.

Features

- Input Voltage Range: from 4.0 V to 5.5 V
- Internal 140 mΩ High−Side Switching P−Channel MOSFET and 90 mΩ Low−Side N−Channel MOSFET
- Fixed 1 MHz Switching Frequency
- Cycle−by−Cycle Current Limiting
- Overtemperature Protection
- Internal Soft−Start
- Start−up with Pre−Biased Output Load
- Adjustable Output Voltage Down to 0.8 V
- Power Saving Mode During Light Load
- These are Pb−Free Devices

Applications

- DSP Power
- Hard Disk Drivers
- Computer Peripherals
- Home Audio
- Set−Top Boxes
- Networking Equipment
- LCD TV
- Wireless and DSL/Cable Modem
- USB Power Devices

PIN DESCRIPTIONS

Pin No	Symbol	Description
1	EN	Logic input to enable the part. Logic high turns on the part and a logic low disables it. An internal pullup forces the part into an enable state when no external bias is present on the pin.
2	V_{CC}	Input supply pin for internal bias circuitry. A 0.1 μF ceramic bypass capacitor is preferred to connect to this pin.
3	V_{CCP}	Power input for the power stage
4	AGND	Analog ground pin. Connect to thermal pad.
5	FB	Feedback input pin of the Error Amplifier. Connect a resistor divider from the converter's output voltage to this pin to set the converter's output voltage.
6	NC	No connection
7, 8	LX	The drains of the internal MOSFETs. The output inductor should be connected to these pins.
9, 10	PGND	Power ground pins. Connect to thermal pad.
EP	PAD	Exposed pad of the package provides both electrical contact to the ground and good thermal contact to the PCB. This pad must be soldered to the PCB for proper operation.

APPLICATION CIRCUIT

DETAILED DESCRIPTION

Overview

The NCP1597B is a synchronous PWM controller that incorporates all the control and protection circuitry necessary to satisfy a wide range of applications. The NCP1597B employs internally compensated current mode control to provide good transient response, ease of implementation and excellent stability. The features of the NCP1597B include a precision reference, fixed 1 MHz switching frequency, a transconductance error amplifier, an integrated high−side P−channel MOSFET and low−side N−Channel MOSFET, internal soft−start, and very low shutdown current. The protection features of the NCP1597B include internal soft−start, pulse−by−pulse current limit, and thermal shutdown.

Reference Voltage

The NCP1597B incorporates an internal reference that allows output voltages as low as 0.8 V. The tolerance of the internal reference is guaranteed over the entire operating temperature range of the controller. The reference voltage is trimmed using a test configuration that accounts for error amplifier offset and bias currents.

Oscillator Frequency

A fixed precision oscillator is provided. The oscillator frequency range is 1 MHz with $\pm$13% variation.

Transconductance Error Amplifier

The transconductance error amplifier's primary function is to regulate the converter's output voltage using a resistor divider connected from the converter's output to the FB pin of the controller, as shown in the applications Schematic. If a Fault occurs, the amplifier's output is immediately pulled to GND and PWM switching is inhibited.

Internal Soft−Start

To limit the startup inrush current, an internal soft start circuit is used to ramp up the reference voltage from 0 V to its final value linearly. The internal soft start time is 1 ms typically.

Output MOSFETs

The NCP1597B includes low $R_{DS(on)}$, both high−side P−channel and low−side N−channel MOSFETs capable of delivering up to 2.0 A of current. When the controller is disabled or during a Fault condition, the controller's output stage is tri−stated by turning OFF both the upper and lower MOSFETs.

Adaptive Dead Time Gate Driver

In a synchronous buck converter, a certain dead time is required between the low side drive signal and high side drive signal to avoid shoot through. During the dead time, the body diode of the low side FET freewheels the current. The body diode has much higher voltage drop than that of the MOSFET, which reduces the efficiency significantly. The longer the body diode conducts, the lower the efficiency. In NCP1597B, the drivers and MOSFETs are integrated in a single chip. The parasitic inductance is minimized. Adaptive dead time control method is used in NCP1597B to prevent the shoot through from happening and minimizing the diode conduction loss at the same time.

Pulse Width Modulation

A high−speed PWM comparator, capable of pulse widths as low as 50 ns, is included in the NCP1597B. The inverting input of the comparator is connected to the output of the error amplifier. The non−inverting input is connected to the the current sense signal. At the beginning of each PWM cycle, the CLK signal sets the PWM flip−flop and the upper MOSFET is turned ON. When the current sense signal rises above the error amplifier's voltage then the comparator will reset the PWM flip−flop and the upper MOSFET will be turned OFF.

Power Save Mode

If the load current decreases, the converter will enter power save mode operation automatically. During power save mode, the converter skips switching and operates with reduced frequency, which minimizes the quiescent current and maintain high efficiency.

Current Sense

The NCP1597B monitors the current in the upper MOSFET. The current signal is required by the PWM comparator and the pulse−by−pulse current limiter.

PROTECTIONS

Undervoltage Lockout (UVLO)

The under voltage lockout feature prevents the controller from switching when the input voltage is too low to power the internal power supplies and reference. Hysteresis must be incorporated in the UVLO comparator to prevent resistive drops in the wiring or PCB traces from causing ON/OFF cycling of the controller during heavy loading at power up or power down.

Overcurrent Protection (OCP)

NCP1597B detects high side switch current and then compares to a voltage level representing the overcurrent threshold limit. If the current through the high side FET exceeds the overcurrent threshold limit for seven consecutive switching cycles, overcurrent protection is triggered.

Once the overcurrent protection occurs, hiccup mode engages. First, hiccup mode, turns off both FETs and discharges the internal compensation network at the output of the OTA. Next, the IC waits typically 2 ms and then resets the overcurrent counter. After this reset, the circuit attempts another normal soft−start. During soft−start, the overcurrent protection threshold is increased to prevent false overcurrent detection while charging the output capacitors. Hiccup mode reduces input supply current and power dissipation during a short circuit. It also allows for much improved system up−time, allowing auto−restart upon removal of a temporary short−circuit.

Pre−Bias Startup

In some applications the controller will be required to start switching when its output capacitors are charged anywhere from slightly above 0 V to just below the regulation voltage. This situation occurs for a number of reasons: the converter's output capacitors may have residual charge on them or the converter's output may be held up by a low current standby power supply. NCP1597B supports pre−bias start up by holding the low side FETs off till soft start ramp reaches the FB Pin voltage.

Thermal Shutdown

The NCP1597B protects itself from over heating with an internal thermal monitoring circuit. If the junction temperature exceeds the thermal shutdown threshold both the upper and lower MOSFETs will be shut OFF.

APPLICATION INFORMATION

Programming the Output Voltage

The output voltage is set using a resistive voltage divider from the output voltage to FB pin (see Figure 25). So the output voltage is calculated according to Eq.1.

$$V_{out} = V_{FB} \cdot \frac{R_1 + R_2}{R_2} \quad \text{(eq. 1)}$$

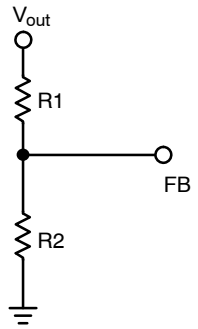

Figure 25. Output divider

Inductor Selection

The inductor is the key component in the switching regulator. The selection of inductor involves trade−offs among size, cost and efficiency. The inductor value is selected according to the equation 2.

$$L = \frac{V_{out}}{f \cdot I_{ripple}} \cdot \left(1 - \frac{V_{out}}{V_{in(max)}}\right) \quad \text{(eq. 2)}$$

Where V_{out} − the output voltage;
f − switching frequency, 1.0 MHz;
I_{ripple} − Ripple current, usually it's 20% − 30% of output current;
$V_{in(max)}$ − maximum input voltage.

Choose a standard value close to the calculated value to maintain a maximum ripple current within 30% of the maximum load current. If the ripple current exceeds this 30% limit, the next larger value should be selected.

The inductor's RMS current rating must be greater than the maximum load current and its saturation current should be about 30% higher. For robust operation in fault conditions (start−up or short circuit), the saturation current should be high enough. To keep the efficiency high, the series resistance (DCR) should be less than 0.1 Ω, and the core material should be intended for high frequency applications.

Output Capacitor Selection

The output capacitor acts to smooth the dc output voltage and also provides energy storage. So the major parameter necessary to define the output capacitor is the maximum allowed output voltage ripple of the converter. This ripple is related to capacitance and the ESR. The minimum capacitance required for a certain output ripple can be calculated by Equation 4.

$$C_{OUT(min)} = \frac{I_{ripple}}{8 \cdot f \cdot V_{ripple}} \quad \text{(eq. 3)}$$

Where V_{ripple} is the allowed output voltage ripple.

The required ESR for this amount of ripple can be calculated by equation 5.

$$ESR = \frac{V_{ripple}}{I_{ripple}} \quad \text{(eq. 4)}$$

Based on Equation 2 to choose capacitor and check its ESR according to Equation 3. If ESR exceeds the value from Eq.4, multiple capacitors should be used in parallel.

Ceramic capacitors can be used in most of the applications. In addition, both surface mount tantalum and through−hole aluminum electrolytic capacitors can be used as well.

Maximum Output Capacitor

NCP1597B family has internal 1 ms fixed soft−start and overcurrent limit. It limits the maximum allowed output capacitor to startup successfully. The maximum allowed output capacitor can be determined by the equation:

$$C_{out(max)} = \frac{I_{limss(min)} - I_{load(max)} - \frac{\Delta i_{p-p}}{2}}{V_{out}/T_{SS(min)}} \quad \text{(eq. 5)}$$

Where $T_{SS(min)}$ is the soft−start period (1ms); Δ_{iPP} is the current ripple.

This is assuming that a constant load is connected. For example, with 3.3 V/2.0 A output and 20% ripple, the max allowed output capacitance is 546 μF.

Input Capacitor Selection

The input capacitor can be calculated by Equation 6.

$$C_{in(min)} = I_{out(max)} \cdot D_{max} \cdot \frac{1}{f \cdot V_{in(ripple)}} \quad \text{(eq. 6)}$$

Where $V_{in(ripple)}$ is the required input ripple voltage.

$$D_{max} = \frac{V_{out}}{V_{in(min)}} \text{ is the maximum duty cycle.} \quad \text{(eq. 7)}$$

Power Dissipation

The NCP1597B is available in a thermally enhanced 6−pin, DFN package. When the die temperature reaches +185°C, the NCP1597B shuts down (see the *Thermal−Overload Protection* section). The power dissipated in the device is the sum of the power dissipated from supply current (PQ), power dissipated due to switching the internal power MOSFET (P_{SW}), and the power dissipated due to the RMS current through the internal power MOSFET (PON). The total power dissipated in the package must be limited so the junction temperature does not exceed its absolute maximum rating of +150°C at

maximum ambient temperature. Calculate the power lost in the NCP1597B using the following equations:

1. High side MOSFET

The conduction loss in the top switch is:

$$P_{HSON} = I^2_{RMS\_HSFET} \times R_{DS(on)HS} \quad \text{(eq. 8)}$$

Where:

$$I_{RMS\_FET} = \sqrt{\left(I_{out}^2 + \frac{\Delta I_{PP}^2}{12}\right) \times D} \quad \text{(eq. 9)}$$

ΔI_{PP} is the peak−to−peak inductor current ripple.

The power lost due to switching the internal power high side MOSFET is:

$$P_{HSSW} = \frac{V_{in} \cdot I_{out} \cdot \left(t_r + t_f\right) \cdot f_{SW}}{2} \quad \text{(eq. 10)}$$

t_r and t_f are the rise and fall times of the internal power MOSFET measured at SW node.

2. Low side MOSFET

The power dissipated in the top switch is:

$$P_{LSON} = I_{RMS\_LSFET}^2 \cdot R_{DS(on)LS} \quad \text{(eq. 11)}$$

Where:

$$I_{RMS\_LSFET} = \sqrt{\left(I_{out}^2 + \frac{\Delta I_{PP}^2}{12}\right) \cdot (1 - D)} \quad \text{(eq. 12)}$$

ΔI_{PP} is the peak−to−peak inductor current ripple.

The switching loss for the low side MOSFET can be ignored.

The power lost due to the quiescent current (I_Q) of the device is:

$$P_Q = V_{in} \cdot I_Q \quad \text{(eq. 13)}$$

I_Q is the switching quiescent current of the NCP1597B.

$$P_{TOTAL} = P_{HSON} + P_{HSSW} + P_{LSON} + P_Q \quad \text{(eq. 14)}$$

Calculate the temperature rise of the die using the following equation:

$$T_J = T_C + \left(P_{TOTAL} \cdot \theta_{JC}\right) \quad \text{(eq. 15)}$$

θ_{JC} is the junction−to−case thermal resistance equal to 1.7°C/W. T_C is the temperature of the case and TJ is the junction temperature, or die temperature. The case−to−ambient thermal resistance is dependent on how well heat can be transferred from the PC board to the air. Solder the underside−exposed pad to a large copper GND plane. If the die temperature reaches the thermal shutdown threshold the NCP1597B shut down and does not restart again until the die temperature cools by 30°C.

Layout

As with all high frequency switchers, when considering layout, care must be taken in order to achieve optimal electrical, thermal and noise performance. To prevent noise both radiated and conducted, the high speed switching current path must be kept as short as possible. Shortening the current path will also reduce the parasitic trace inductance of approximately 25 nH/inch. At switch off, this parasitic inductance produces a flyback spike across the NCP1597B switch. When operating at higher currents and input voltages, with poor layout, this spike can generate voltages across the NCP1597B that may exceed its absolute maximum rating. A ground plane should always be used under the switcher circuitry to prevent interplane coupling and overall noise.

The FB component should be kept as far away as possible from the switch node. The ground for these components should be separated from the switch current path. Failure to do so will result in poor stability or subharmonic like oscillation.

Board layout also has a significant effect on thermal resistance. Reducing the thermal resistance from the ground pin and exposed pad onto the board will reduce die temperature and increase the power capability of the NCP1597B. This is achieved by providing as much copper area as possible around the exposed pad. Adding multiple thermal vias under and around this pad to an internal ground plane will also help. Similar treatment to the inductor pads will reduce any additional heating effects.
