Synchronous Buck Converter - Step Down
3.0 A

NCP6343

The NCP6343 is a synchronous buck converter optimized to supply the different sub systems of portable applications powered by one cell Li−Ion or three cell Alkaline/NiCd/NiMH batteries. The device is able to deliver up to 3.0 A, with programmable output voltage from 0.6 V to 1.4 V. It can share the same output rail with another DCDC and works as a transient load helper. Operation at a 3 MHz switching frequency allows the use of small components. Synchronous rectification and automatic PWM/PFM transitions improve overall solution efficiency. The NCP6343 is in a space saving, low profile 1.99 x 1.34 mm CSP−15 package.

Features

- Input Voltage Range from 2.3 V to 5.5 V: Battery and 5 V Rail Powered Applications
- Programmable Output Voltage: 0.6 V to 1.4 V in 6.25 mV Steps
- Modular Output Stage Drive Strength for Increased Efficiency Depending on the Output Current
- 3 MHz Switching Frequency with On Chip Oscillator
- Uses 470 nH Inductor and 22 μF Capacitors for Optimized Footprint and Solution Thickness
- PFM/PWM Operation for Optimum Increased Efficiency
- Ultra Low 0.8 μA Off Mode Current
- Low 35 μA Quiescent Current
- I^2C Control Interface with Interrupt and Dynamic Voltage Scaling Support
- Thermal Protections and Temperature Management
- Transient Load Helper: Share the Same Rail with Another DCDC
- Small 1.99 x 1.34 mm / 0.4 mm Pitch CSP Package
- These are Pb−Free Devices

Typical Applications

- Smartphones
- Webtablets

Table 1. PIN FUNCTION DESCRIPTION

Pin	Name	Type	Description
REFERENCE			
D1	AVIN	Analog Input	**Analog Supply.** This pin is the device analog and digital supply. Could be connected directly to the VIN plane or to a dedicated 1.0 μF ceramic capacitor. Must be equal to PVIN.
E1	AGND	Analog Ground	**Analog Ground.** Analog and digital modules ground. Must be connected to the system ground.
CONTROL AND SERIAL INTERFACE			
D2	EN	Digital Input	**Enable Control.** Active high will enable the part. Do not leave this pin floating.
E2	SCL	Digital Input	I^2C interface **Clock** line. There is an internal pull down resistor on this pin; could be left open if not used
D3	SDA	Digital Input/Output	I^2C interface Bi−directional **Data** line. There is an internal pull down resistor on this pin; could be left open if not used
DCDC CONVERTER			
A1, B1, C1	PVIN	Power Input	**Switch Supply.** These pins must be decoupled to ground by a 10 μF ceramic capacitor. It should be placed as close as possible to these pins. All pins must be used with short heavy connections. Must be equal to AVIN.
A2, B2	SW	Power Output	**Switch Node.** These pins supply drive power to the inductor. Typical application uses 0.470 μH inductor; refer to application section for more information. All pins must be used with short heavy connections.
A3, B3, C3, C2	PGND	Power Ground	**Switch Ground.** This pin is the power ground and carries the high switching current. High quality ground must be provided to prevent noise spikes. To avoid high−density current flow in a limited PCB track, a local ground plane that connects all PGND pins together is recommended. Analog and power grounds should only be connected together in one location with a trace.
E3	FB	Analog Input	**Feedback Voltage input.** Must be connected to the output capacitor positive terminal with a trace, not to a plane. This is the positive input to the error amplifier.

Table 2. MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Analog and power pins: AVIN, PVIN, SW, FB	V_A	−0.3 to + 6.0	V
Digital pins: SCL, SDA, EN: Input Voltage Input Current	 V_{DG} I_{DG}	 −0.3 to V_A +0.3 ≤ 6.0 10	 V mA
Human Body Model (HBM) ESD Rating (Note 1)	ESD HBM	2000	V
Machine Model (MM) ESD Rating (Note 1)	ESD MM	150	V
Charged Device Model (CDM) ESD Rating (Note 1)	ESD CDM	2000	V
Latch Up Current: (Note 2) Digital Pins All Other Pins	I_{LU}	 ±10 ±100	mA
Storage Temperature Range	T_{STG}	−65 to + 150	°C
Maximum Junction Temperature	T_{JMAX}	−40 to +150	°C
Moisture Sensitivity (Note 3)	MSL	Level 1	

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. This device series contains ESD protection and passes the following ratings:
   Human Body Model (HBM) ±2.0 kV per JEDEC standard: JESD22−A114.
   Machine Model (MM) ±150 V per JEDEC standard: JESD22−A115.
   Charged Device Model (CDM) ±2.0 kV per JEDEC standard: JESD22−C101 Class IV.
2. Latch up Current per JEDEC standard: JESD78 class II.
3. Moisture Sensitivity Level (MSL): 1 per IPC/JEDEC standard: J−STD−020A.

Table 3. OPERATING CONDITIONS (Note 4)

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
AV_{IN}, PV_{IN}	Power Supply	AVIN = PVIN	2.3		5.5	V
T_A	Ambient Temperature Range		−40	25	+85	°C
T_J	Junction Temperature Range (Note 5)		−40	25	+125	°C
$R_{\theta JA}$	Thermal Resistance Junction to Ambient (Note 6)	CSP−15 on Demo−board	−	65	−	°C/W
P_D	Power Dissipation Rating (Note 7)	T_A ≤ 85°C	−	615	−	mW
P_D	Power Dissipation Rating (Note 7)	T_A = 65°C	−	923	−	mW
L	Inductor for DCDC converter (Note 4)		−	0.47	−	μH
Co	Output Capacitor for DCDC Converter (Note 4)		28	−	55	μF
Cin	Input Capacitor for DCDC Converter (Note 4)		4.7	−	−	μF

4. Including de−ratings (Refer to the Application Information section of this document for further details)
5. The thermal shutdown set to 150°C (typical) avoids potential irreversible damage on the device due to power dissipation.
6. The $R_{\theta JA}$ is dependent of the PCB heat dissipation.
7. The maximum power dissipation (P_D) is dependent by input voltage, maximum output current and external components selected.

$$R_{\theta JA} = \frac{125 - T_A}{P_D}$$

Table 4. ELECTRICAL CHARACTERISTICS (Note 9)
Min and Max Limits apply for T_A = −40°C to +85°C, AVIN = PVIN = 3.6 V and default configuration, unless otherwise specified.
Typical values are referenced to T_A = +25°C, AVIN = PVIN = 3.6 V and default configuration, unless otherwise specified.

DETAILED OPERATING DESCRIPTION

Detailed Descriptions

The NCP6343 is voltage mode stand alone synchronous DC to DC converter optimized to supply different sub systems of portable applications powered by one cell Li−Ion or three cells Alkaline/NiCd/NiMh. The IC can deliver up to 3 A at an I^2C selectable voltage ranging from 0.60 V to 1.40 V. It can share the same output rail with another DCDC and works as a transient load helper without sinking current on shared rail. A 3 MHz switching frequency allows the use of smaller output filter components. Synchronous rectification and automatic PWM/PFM transitions improve overall solution efficiency. Forced PWM is also configurable. Operating modes, configuration, and output power can be easily selected either by programming a set of registers using an I^2C compatible interface capable of operation up to 3.4 MHz. Default I^2C settings are factory programmable.

DC to DC Buck Operation

The converter is a synchronous rectifier type with both high side and low side integrated switches. Neither external transistor nor diodes are required for NCP6343 operation. Feedback and compensation network are also fully integrated. The converter can operate in two different modes: PWM and PFM. The transition between PWM/PFM modes can occur automatically or the switcher can be placed in forced PWM mode by I^2C programming (PWM bits of COMMAND register).

PWM (Pulse Width Modulation) Operating Mode

In medium and high load conditions, NCP6343 operates in PWM mode from a fixed clock and adapts its duty cycle to regulate the desired output voltage. In this mode, the inductor current is in CCM (Continuous Current Mode) and the voltage is regulated by PWM. The internal N−MOSFET switch operates as synchronous rectifier and is driven complementary to the P−MOSFET switch. In CCM, the lower switch (N−MOSFET) in a synchronous converter provides a lower voltage drop than the diode in an asynchronous converter, which provides less loss and higher efficiency.

PFM (Pulse Frequency Modulation) Operating Mode

In order to save power and improve efficiency at low loads the NCP6343 operates in PFM mode as the inductor drops into DCM (Discontinuous Current Mode). The upper FET on time is kept constant and the switching frequency is variable. Output voltage is regulated by varying the switching frequency which becomes proportional to loading current. As it does in PWM mode, the internal N−MOSFET operates as synchronous rectifier after each P−MOSFET on−pulse. When load increases and current in inductor becomes continuous again, the controller automatically turns back to PWM mode.

Forced PWM

The NCP6343 can be programmed to only use PWM and disable the transition to PFM if so desired. (PWM bits of COMMAND register).

Output Stage

NCP6343 is a high output current capable integrated DC to DC converter. To supply such a high current, the internal MOSFETs need to be large. The output stage is composed of 8 modules that can be individually Enabled / Disabled by setting the MODULE register.

Inductor Peak Current Limitation

NCP6343 is a 2.0 A to 3.0 A output current capable. During normal operation, peak current limitation will monitor and limit the current through the inductor. This current limitation is particularly useful when size and/or height constrain inductor power. The user can select peak current to keep inductor within its specifications. The peak current can be set by writing IPEAK[1..0] bits in LIMCONF register.

Table 5. Ipeak VALUES

IPEAK[1..0]	Default Inductor Peak Current (A)
00	2.9 A for 2.0 A output current
01	2.9 A for 2.0 A output current
10	3.4 A for 2.5 A output current
11	3.9 A for 3.0 A output current

Output Voltage

Output voltage is set internally by integrated resistor bridge and error amplifier that drives the PWM/PFM controller. No extra component is needed to set output voltage. However, writing in the Vout[6..0] bits of the PROG register will change settings. Output voltage level can be programmed in the 0.6 V to 1.4 V range by 6.25 mV steps.

Under Voltage Lock Out (UVLO)

NCP6343 core does not operate for voltages below the Under Voltage lock Out (UVLO) level. Below UVLO threshold, all internal circuitry (both analog and digital) is held in reset.

NCP6343 operation is guaranteed down to VUVLO when battery voltage is dropping off. To avoid erratic on / off behavior, a maximum 200 mV hysteresis is implemented. Restart is guaranteed at 2.5 V when VBAT voltage is recovering or rising.

Thermal Management

Thermal shutdown (TSD)

The thermal capability of IC can be exceeded due to step down converter output stage power level. A thermal protection circuitry is therefore implemented to prevent the IC from damage. This protection circuitry is only activated

when the core is in active mode (output voltage is turned on). During thermal shut down, output voltage is turned off.

When NCP6343 returns from thermal shutdown, it can re−start in 2 different configurations depending on REARM bit in the LIMCONF register (see register description section):

- If REARM = 0 then NCP6343 does not re−start after TSD. To restart, an EN pin toggle is required.
- If REARM = 1, NCP6343 re−starts with register values set prior to thermal shutdown.

A Thermal shut down interrupt is raised upon this event.

Thermal shut down threshold is set at 150°C (typical) when the die temperature increases and, in order to avoid erratic on / off behavior, a 30°C hysteresis is implemented. After a typical 150°C thermal shut down, NCP6343 will resume to normal operation when the die temperature cools to 120°C.

Thermal Warnings

In addition to the TSD, the die temperature monitoring will flag potential die over temperature. A thermal warning and thermal pre−warning are implemented which can inform the processor through two different interrupts (accessible via I^2C) that NCP6343 is close to its thermal shutdown so that preventive measures to cool down die temperature can be taken by software.

The Warning threshold is set by hardware to 135°C typical when the die temperature increases. The Pre−Warning threshold is set by default to 105°C, but can be changed by user by setting the TPWTH[1..0] bits in the LIMCONF register.

Active Output Discharge

To make sure that no residual voltage remains in the power supply rail, an active discharge path can ground the NCP6343 output voltage.

For maximum flexibility, this feature can be easily disabled or enabled with DISCHG bit in PGOOD register

However the discharged path is activated during the first 100 μs after battery insertion.

Enabling

The EN pin controls NCP6343 start up: EN pin Low to High transition starts the power up sequencer. If EN is made low, the DC to DC converter is turned off and device enters:

- In Sleep Mode if Sleep_Mode I^2C bit is high,
- In Off Mode if Sleep_Mode I^2C bit is low.

When EN pin is set to a high level, the DC to DC converter can be enabled / disabled depending of the state of the EN bit of the PROG register: If EN I^2C bit is high, DCDC is activated, If EN I^2C is low the DC to DC converter is turned off and device enters:

- In Sleep Mode if Sleep_Mode I^2C bit is high,
- In Off Mode if Sleep_Mode I^2C bit is low.

The EN pin should not be left floating.

Power Up Sequence (PUS)

In order to power up the circuit, the input voltage AVIN has to rise above the VUVLO threshold. This triggers the internal core circuitry power up which is the “Wake Up Time” (including “Bias Time”).

This delay is internal and cannot be bypassed. EN pin transition within this delay corresponds to the “Initial power up sequence” (IPUS):

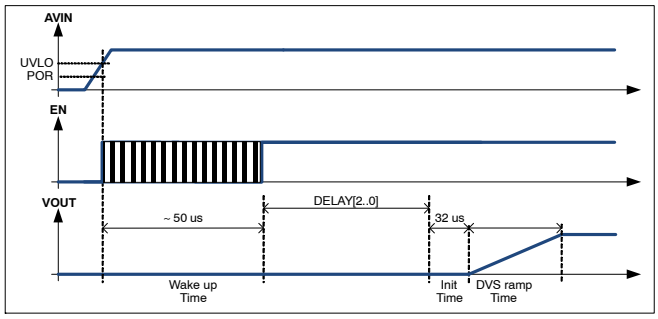

Figure 33. Initial Power Up Sequence

In addition a user programmable delay will also take place between end of Core circuitry turn on (Wake Up Time and Bias Time) and Init time: The DELAY[2..0] bits of TIME register will set this user programmable delay with a 2 ms resolution. With default delay of 0 ms, the NCP6343 IPUS takes roughly 85 μs, means DCDC output voltage will be ready within 110 μs.

NOTE: During the Wake Up time, the I^2C interface is not active. Any I^2C request to the IC during this time period will result in a NACK reply.

Normal, Quick and Fast Power Up Sequence

The previous description applies only when the EN transitions during the internal core circuitry power up (Wake up and calibration time). Otherwise 3 different cases are possible:

Enabling the part by setting EN pin from Off Mode will result in “Normal power up sequence” (NPUS, with DELAY;[2..0]).

Enabling the part by setting EN pin from Sleep Mode will result in “Quick power up sequence” (QPUS, with DELAY;[2..0]).

Enabling the part by setting EN bits of the PROG register (whereas EN is already high results in “Fast power up sequence” (FPUS, without DELAY[2..0]).

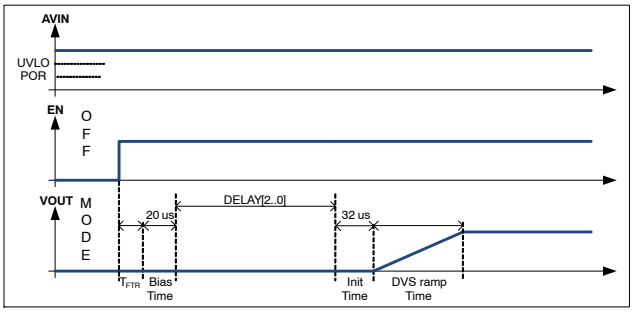

Figure 34. Normal Power Up Sequence (EN pin)

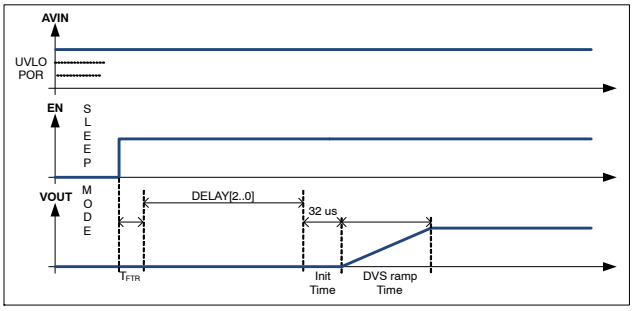

Figure 35. Quick Power Up Sequence (EN pin)

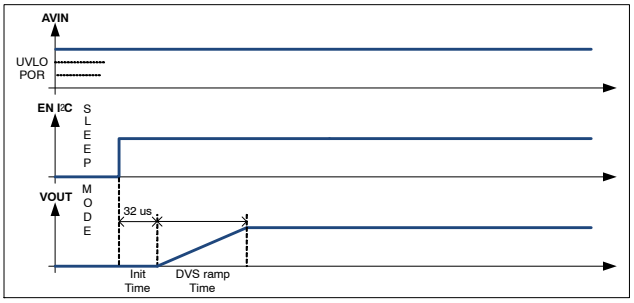

Figure 36. Fast Power Up Sequence (EN bit)

In addition the delay set in DELAY[2..0] bits in TIME register will apply only for the EN pins turn ON sequence (NPUS and QPUS).

Note that the sleep mode needs about 150 µs to be established.

DC to DC converter Shut Down

When shutting down the device, no shut down sequence is required. Output voltage is disabled and, depending on the DISCHG bit state of PGOOD register, output may be discharged.

Shutdown is initiated by either grounding the EN pin (Hardware Shutdown) or by clearing the EN I^2C bit (Software shutdown) in PROG register.

In hardware shutdown (EN = 0), the internal core is still active and I^2C accessible.

NCP6343 shuts internal core down when AVIN falls below UVLO.

Dynamic Voltage Scaling (DVS)

This converter supports dynamic voltage scaling (DVS) allowing the output voltage to be reprogrammed via I^2C commands and provides the different voltages required by the processor. The change between set points is managed in a smooth fashion without disturbing the operation of the processor.

When programming a higher voltage, output raises with controlled dV/dt defined by DVSup bit in TIME register (default 6.25 mV/0.166 µs). When programming a lower voltage, output will decrease in equidistant steps defined by DVSdown[1..0] bits in TIME register (default 6.25 mV/2.666 µs).

DVS sequence is automatically initiated by changing output voltage settings.

The DVS transition mode can be changed with the DVSMODE bit in COMMAND register:

- In forced PWM mode when accurate output voltage control is needed.

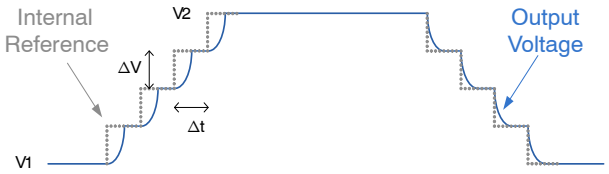

Figure 37. DVS in Forced PWM Mode Diagram

- In Auto mode when output voltage has not to be discharged. Note that approximately 30 µs is needed to transition from PFM mode to PWM mode.

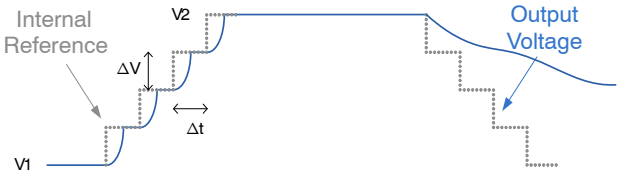

Figure 38. DVS in Auto Mode Diagram

Power Good

To indicate the output voltage level is established, a power good signal is available.

The power good signal is high when the channel is off and goes low when enabling the channel. Once the output voltage reaches 95% of the expected output level, the power good logic signal becomes high (ACK_PG, SEN_PG bits).

During operation when the output drops below 90% of the programmed level the power good logic signal goes low, indicating a power failure. When the voltage rises again to above 95% the power good signal goes high again.

During a positive DVS sequence, when target voltage is higher than initial voltage, the Power Good logic signal will be set low during output voltage ramping and transition to high once the output voltage reaches 95% of the target voltage. When the target voltage is lower than the initial voltage, Power Good logic signals will remain at high level during transition.

Power Good signal during normal operation can be disabled by clearing the PGDCDC bit in PGOOD register.

Power Good operation during DVS can be controlled by setting / clearing the bit PGDVS in PGOOD register

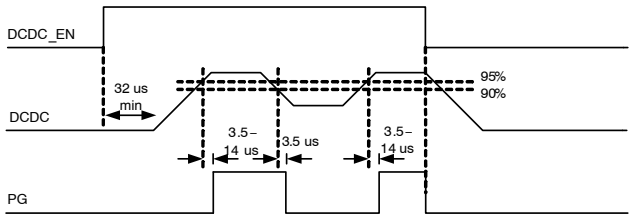

Figure 39. Power Good Signal

Interrupt

The interrupt controller continuously monitors internal interrupt sources, generating an interrupt signal when a system status change is detected (dual edge monitoring).

Table 6. INTERRUPT SOURCES

Interrupt Name	Description
TSD	Thermal Shut Down
TWARN	Thermal Warning
TPREW	Thermal Pre Warning
UVLO	Under Voltage Lock Out
IDCDC	DCDC current Over / below limit
PG	Power Good

Individual bits generating interrupts will be set to 1 in the INT_ACK register (I^2C read only registers), indicating the interrupt source. INT_ACK register is automatically reset by an I^2C read. The INT_SEN register (read only register) contains real time indicators of interrupt sources.

When the host reads the INT_ACK registers the interrupt register INT_ACK is cleared.

Figure 40 is UVLO event example:
INT_SEN/INT_MSK/INT_ACK and an I^2C read access behavior.

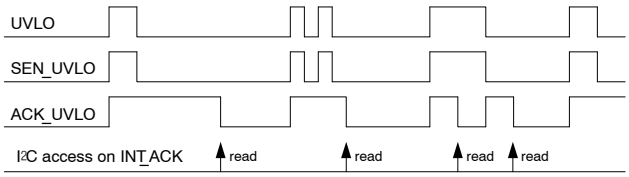

Figure 40. Interrupt Operation Example

Configurations

Default output voltages, enables, DCDC modes, current limit and other parameters can be factory programmed upon request. The default configuration pre−defined is depicted below:

Table 7. DEFAULT CONFIGURATIONS

Configuration	NCP6343	NCP6343A	NCP6343B	NCP6343D
Default I^2C address PID product id. RID revision id. FID feature id.	0x1C 12h xxh 00h	0x14 12h xxh 02h	0x1C 12h xxh 01h	0x14 12h xxh 03h

I²C Compatible Interface

NCP6343 can support a subset of I²C protocol Detailed below.

I²C Communication Description

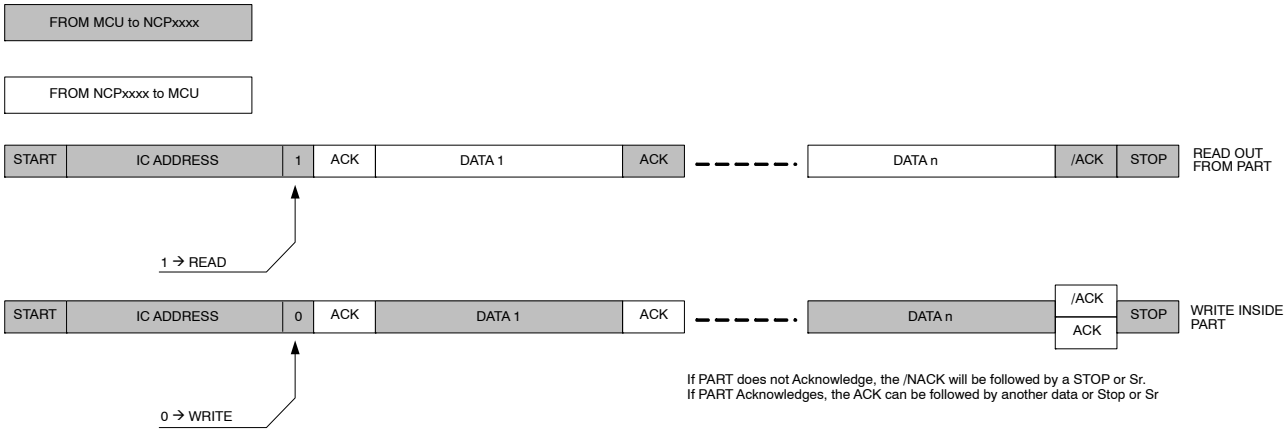

Figure 41. General Protocol Description

The first byte transmitted is the Chip address (with the LSB bit set to 1 for a read operation, or set to 0 for a Write operation). The following data will be:

- In case of a Write operation, the register address (@REG) pointing to the register we want to write in followed by the data we will write in that location. The writing process is auto−incremental, so the first data will be written in @REG, the contents of @REG are incremented and the next data byte is placed in the location pointed to by @REG + 1 ..., etc.
- In case of read operation, the NCP6343 will output the data from the last register that has been accessed by the last write operation. Like the writing process, the reading process is auto−incremental.

Read Out from Part

The Master will first make a “Pseudo Write” transaction with no data to set the internal address register. Then, a stop then start or a Repeated Start will initiate the read transaction from the register address the initial write transaction has pointed to:

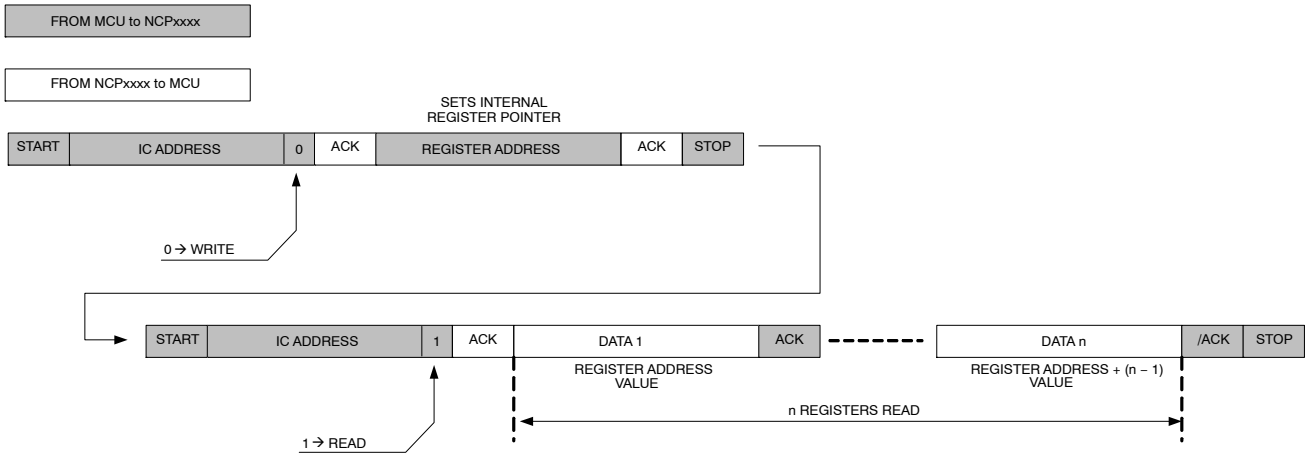

Figure 42. Read Out from Part

The first WRITE sequence will set the internal pointer to the register we want access to. Then the read transaction will start at the address the write transaction has initiated.

Transaction with Real Write then Read

With Stop Then Start

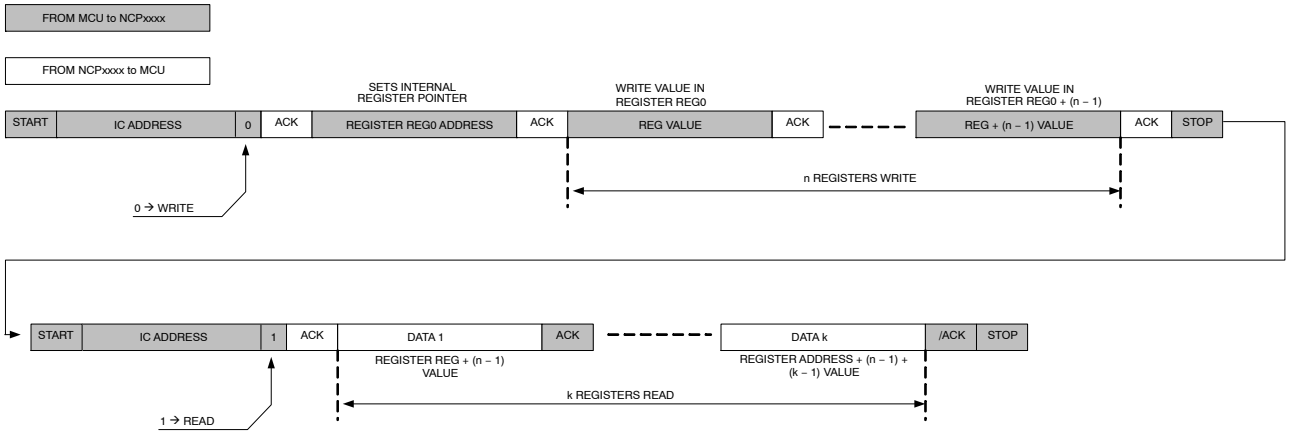

Figure 43. Write Followed by Read Transaction

Write In Part

Write operation will be achieved by only one transaction. After chip address, the MCU first data will be the internal register we want access to, then following data will be the data we want to write in Reg, Reg + 1, Reg + 2, ..., Reg +n.

Write n Registers:

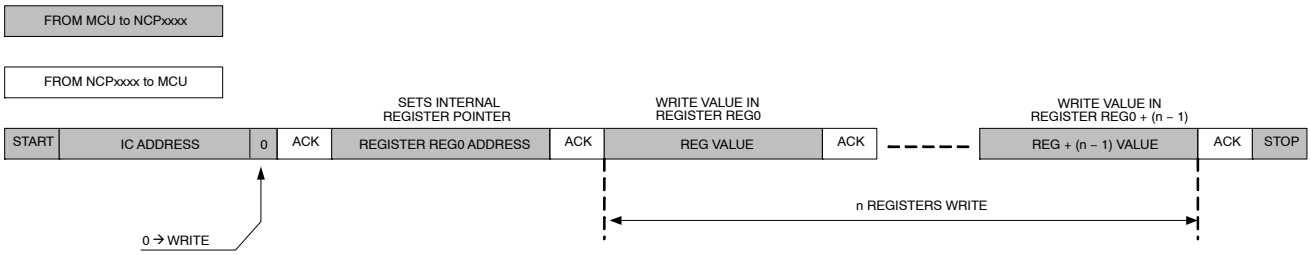

Figure 44. Write In n Registers

I²C Address

NCP6343 has four available I²C address selectable by factory settings (ADD0 to ADD3). Different address settings can be generated upon request to ON Semiconductor. The default address is set to 38h / 39h since the NCP6343 supports 7−bit address only and ignores A0.

Table 9. I²C ADDRESS

I²C Address	Hex	A7	A6	A5	A4	A3	A2	A1	A0
ADD0 (NCP6343S)	W 0x20 R 0x21	0	0	1	0	0	0	0	R/W
	Add	0x10							–

	Add	0x14							–
ADD2 (NCP6343M)	W 0x30 R 0x31	0	0	1	1	0	0	0	R/W
	Add	0x18							–
ADD3 (default) (NCP6343, NCP6343B, NCP6343X)	W 0x38 R 0x39	0	0	1	1	1	0	0	R/W
	Add	0x1C							–

Register Map

Table 10 describes I²C registers.

Registers can be:

R	Read only register
RC	Read then Clear
RW	Read and Write register
Reserved	Address is reserved and register is not physically designed
Spare	Address is reserved and register is physically designed

Table 10. I²C REGISTERS MAP DEFAULT CONFIGURATION (NCP6343)

APPLICATION INFORMATION

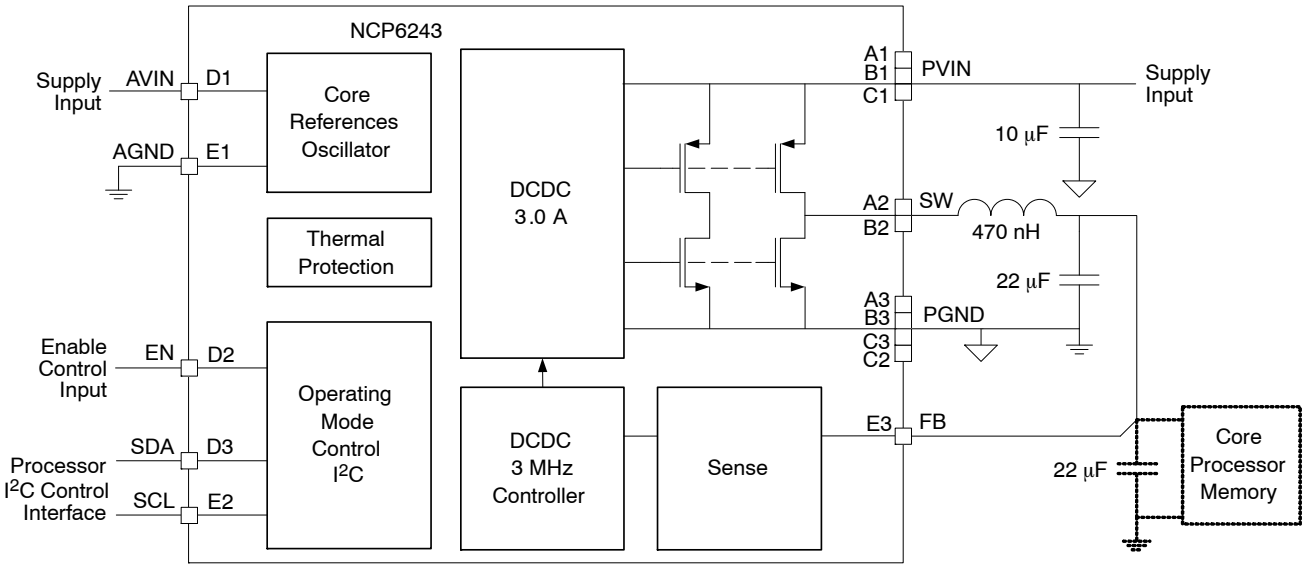

Figure 45. Typical Application Schematic

Output Filter Design Considerations

The output filter introduces a double pole in the system at a frequency of:

$$f_{LC} = \frac{1}{2 \cdot \pi \cdot \sqrt{L \cdot C}}$$

NCP6343 internal compensation network is optimized for a typical output filter comprising a 470 nH inductor and 22 μF capacitor as describes in the basic application schematic is described by Figure 16.

Voltage Sensing Considerations

In order to regulate power supply rail, NCP6343 should sense its output voltage. Thanks to the FB pin, the IC can support two sensing methods:

- Normal case: the voltage sensing is achieved close to the output capacitor. In that case, FB is connected to the output capacitor positive terminal (voltage to regulate).
- Remote sensing: In remote sensing, the power supply rail sense is made close to the system powered by the NCP6343. The voltage to system is more accurate, since PCB line impedance voltage drop is within the regulation loop. In that case, we recommend connecting the FB pin to the system decoupling capacitor positive terminal.

Components Selection

Inductor Selection

The inductance of the inductor is determined by given peak−to−peak ripple current I_{L_PP} of approximately 20% to 50% of the maximum output current I_{OUT_MAX} for a trade−off between transient response and output ripple. The inductance corresponding to the given current ripple is:

$$L = \frac{(V_{IN} - V_{OUT}) \cdot V_{OUT}}{V_{IN} \cdot f_{SW} \cdot I_{L\_PP}}$$

The selected inductor must have high enough saturation current rating to be higher than the maximum peak current that is

$$I_{L\_MAX} = I_{OUT\_MAX} + \frac{I_{L\_PP}}{2}$$

The inductor also needs to have high enough current rating based on temperature rise concern. Low DCR is good for efficiency improvement and temperature rise reduction. Table 29 shows recommended.

Table 29. INDUCTOR SELECTION

Supplier	Part #	Value (μH)	Size (mm) (L x I x T)	DC Rated Current (A)	DCR Max at 25°C (mΩ)
Cyntec	PIFE20161B−R47−MS−11	0.47	2.0 x 1.6 x 1.2	3.9	36

Output Capacitor Selection

The output capacitor selection is determined by output voltage ripple and load transient response requirement. For high transient load performance high output capacitor value must be used. For a given peak−to−peak ripple current I_{L_PP} in the inductor of the output filter, the output voltage ripple across the output capacitor is the sum of three components as below.

$$V_{OUT\_PP} \approx V_{OUT\_PP(C)} + V_{OUT\_PP(ESR)} + V_{OUT\_PP(ESL)}$$

Where $V_{OUT\_PP(C)}$ is a ripple component by an equivalent total capacitance of the output capacitors, $V_{OUT\_PP(ESR)}$ is a ripple component by an equivalent ESR of the output capacitors, and $V_{OUT\_PP(ESL)}$ is a ripple component by an equivalent ESL of the output capacitors. In PWM operation mode, the three ripple components can be obtained by

$$V_{OUT\_PP(C)} = \frac{I_{L\_PP}}{8 \cdot C \cdot f_{SW}}, \text{ and } V_{OUT\_PP(ESR)} = I_{L\_PP} \cdot ESR$$

$$V_{OUT\_PP(ESL)} = \frac{ESL}{ESL + L} \cdot V_{IN}$$

and the peak−to−peak ripple current is

$$I_{L\_PP} = \frac{(V_{IN} - V_{OUT}) \cdot V_{OUT}}{V_{IN} \cdot f_{SW} \cdot L}$$

In applications with all ceramic output capacitors, the main ripple component of the output ripple is $V_{OUT\_PP(C)}$. So that the minimum output capacitance can be calculated regarding to a given output ripple requirement V_{OUT_PP} in PWM operation mode.

$$C_{MIN} = \frac{I_{L\_PP}}{8 \cdot V_{OUT\_PP} \cdot f_{SW}}$$

Input Capacitor Selection

One of the input capacitor selection guides is the input voltage ripple requirement. To minimize the input voltage ripple and get better decoupling in the input power supply rail, ceramic capacitor is recommended due to low ESR and ESL. The minimum input capacitance regarding to the input ripple voltage V_{IN_PP} is

$$C_{IN\_MIN} = \frac{I_{OUT\_MAX} \cdot (D - D^2)}{V_{IN\_PP} \cdot f_{SW}} \quad \text{where} \quad D = \frac{V_{OUT}}{V_{IN}}$$

In addition, the input capacitor needs to be able to absorb the input current, which has a RMS value of

$$I_{IN\_RMS} = I_{OUT\_MAX} \cdot \sqrt{D - D^2}$$

The input capacitor also needs to be sufficient to protect the device from over voltage spike, and normally at least 4.7 μF capacitor is required. The input capacitor should be located as close as possible to the IC. All PGNDs are connected together to the ground terminal of the input cap which then connects to the ground plane. All PVIN are connected together to the Vbat terminal of the input cap which then connects to the Vbat plane.

Electrical Layout Considerations

Good electrical layout is a key to make sure proper operation, high efficiency, and noise reduction. Electrical layout guidelines are:

- Use wide and short traces for power paths (such as PVIN, VOUT, SW, and PGND) to reduce parasitic inductance and high−frequency loop area. It is also good for efficiency improvement.
- The device should be well decoupled by input capacitor and input loop area should be as small as possible to reduce parasitic inductance, input voltage spike, and noise emission.
- SW node should be a large copper, but compact because it is also a noise source.
- It would be good to have separated ground planes for PGND and AGND and connect the two planes at one point. Try best to avoid overlap of input ground loop and output ground loop to prevent noise impact on output regulation.
- Arrange a “quiet” path for output voltage sense, and make it surrounded by a ground plane.

Thermal Layout Considerations

Good PCB layout helps high power dissipation from a small package with reduced temperature rise. Thermal layout guidelines are:

- A four or more layers PCB board with solid ground planes is preferred for better heat dissipation.
- More free vias are welcome to be around IC to connect the inner ground layers to reduce thermal impedance.
- Use large area copper especially in top layer to help thermal conduction and radiation.
- Use two layers for the high current paths (PVIN, PGND, SW) in order to split current in two different paths and limit PCB copper self heating.

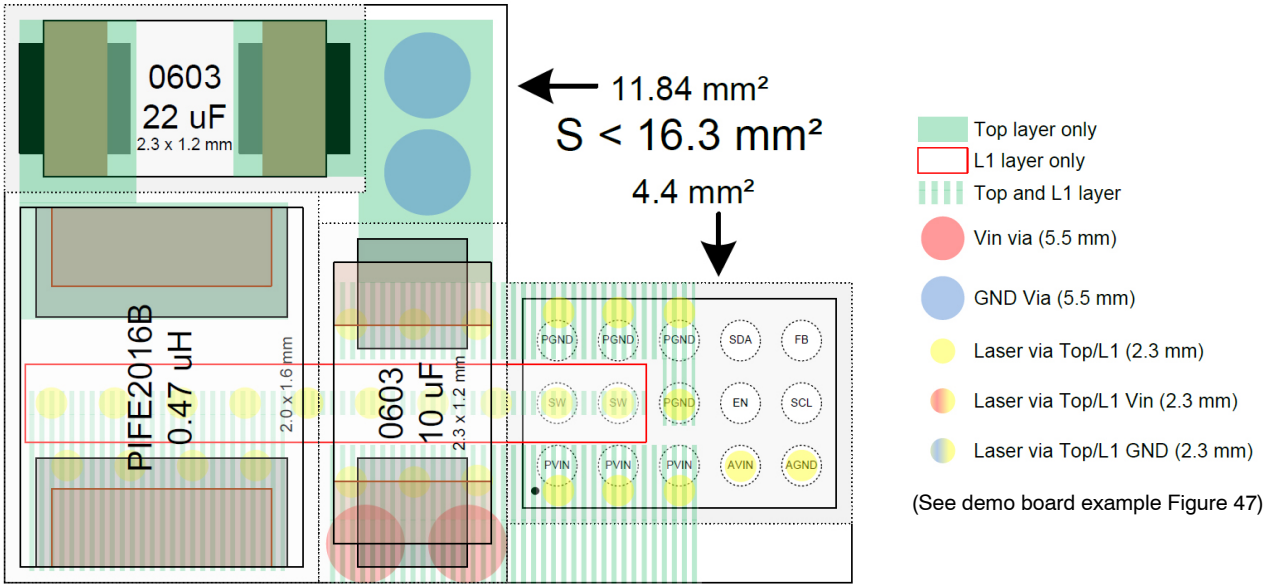

Figure 46. Layout Recommendation

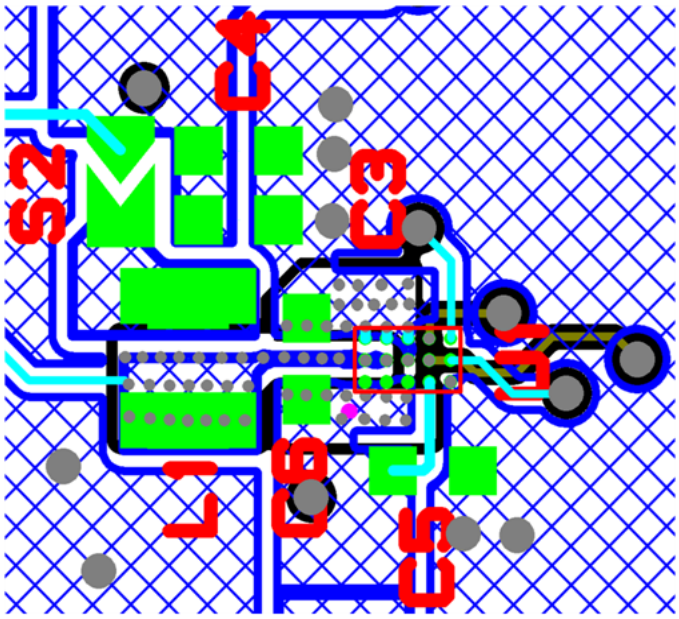

Legend:
In blue are top layer planes and wires
In white are layer1 plane and wires (just below top layer)
Big circles gray are normal vias
Small circles gray are top to layer1 vias

Figure 47. Demo Board Example

Input capacitor placed as close as possible to the IC.

PVIN directly connected to Cin input capacitor, and then connected to the Vin plane. Local mini planes used on the top layer (blue) and layer just below top layer (white) with laser vias.

AVIN connected to the Vin plane just after the capacitor.

AGND directly connected to the GND plane.

PGND directly connected to Cin input capacitor, and then connected to the GND plane: Local mini planes used on the top layer (blue) and layer just below top layer (white) with laser vias.

SW connected to the Lout inductor with trace between input capacitor terminals on top layer (blue) and local mini planes on the layer just below top layer (white) with laser vias.
