

NCV8675

Linear Regulator - Low Dropout, Very Low I_q , Reset, Reset Delay

350 mA

The NCV8675 is a precision 5.0 V and 3.3 V fixed output, low dropout integrated voltage regulator with an output current capability of 350 mA. Careful management of light load current consumption, combined with a low leakage process, achieve a typical quiescent ground current of 34 μ A.

NCV8675 is pin for pin compatible with NCV4275 and it could replace this part when very low quiescent current is required.

The output voltage is accurate within $\pm 2.0\%$ for D²PAK-5 package and $\pm 2.5\%$ for DPAK-5 package, and maximum dropout voltage is 600 mV at full rated load current.

It is internally protected against input transients, input supply reversal, output overcurrent faults, and excess die temperature. No external components are required to enable these features.

Features

- 5 V and 3.3 V Fixed Output (2.5 V Version Available Upon Request)
- $\pm 2.0\%$ or $\pm 2.5\%$ Output Accuracy, Over Full Temperature Range
- 34 μ A Typical Quiescent Current at $I_{out} = 100 \mu$ A, 50 μ A Maximum up to 85°C
- 600 mV Maximum Dropout Voltage at 350 mA Load Current
- Wide Input Voltage Operating Range of 4.5 V to 45 V
- Internal Fault Protection
 - ◆ -42 V Reverse Voltage
 - ◆ Short Circuit/Overcurrent
 - ◆ Thermal Overload
- AEC-Q100 Qualified
- EMC Compliant
- NCV Prefix for Automotive and Other Applications Requiring Site and Control Changes
- These are Pb-Free Devices

NCV8675

Figure 34. Application Circuits

Circuit Description

The NCV8675 is an integrated low dropout regulator that provides 5.0 V 350 mA, or 3.3 V 350 mA protected output and a signal for power on reset. The regulation is provided by a PNP pass transistor controlled by an error amplifier with a bandgap reference, which gives it the lowest possible drop out voltage and best possible temperature stability. The output current capability is 350 mA, and the base drive quiescent current is controlled to prevent over saturation when the input voltage is low or when the output is overloaded. The regulator is protected by both current limit and thermal shutdown. Thermal shutdown occurs above 150°C to protect the IC during overloads and extreme ambient temperatures. The delay time for the reset output is adjustable by selection of the timing capacitor. See Figure 34, Test Circuit, for circuit element nomenclature illustration.

Regulator

The error amplifier compares the reference voltage to a sample of the output voltage (V_{out}) and drives the base of a PNP series pass transistor by a buffer. The reference is a bandgap design to give it a temperature-stable output. Saturation control of the PNP is a function of the load current and input voltage. Oversaturation of the output power device is prevented, and quiescent current in the ground pin is minimized.

Regulator Stability Considerations

The input capacitor (C_{in}) is necessary to stabilize the input impedance to avoid voltage line influences. The output capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability. The capacitor value and type should be based on cost, availability, size and temperature constraints. Ceramic, tantalum, or electrolytic capacitors of 22 μ F, or greater, are stable with very low ESR values. Refer to

Figure 2 for specific ESR ratings. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures (-25°C to -40°C), both the capacitance and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information. The value for the output capacitor C_{out} shown in Figure 13, Test Circuit, should work for most applications; however, it is not necessarily the optimized solution.

Reset Output

The reset output is used as the power on indicator to the microcontroller. This signal indicates when the output voltage is suitable for reliable operation of the controller. It pulls low when the output is not considered to be ready. RO is pulled up to V_{out} by an external resistor, typically 5.0 k Ω in value. The input and output conditions that control the Reset Output and the relative timing are illustrated in Figure 35, Reset Timing. Output voltage regulation must be maintained for the delay time before the reset output signals a valid condition. The delay for the reset output is defined as the amount of time it takes the timing capacitor on the delay pin to charge from a residual voltage of 0 V to the upper timing threshold voltage V_{DU} of 1.3 V. The charging current for this is I_D of 4 μ A and D pin voltage in steady state is typically 2.4 V. By using typical IC parameters with a 47 nF capacitor on the D Pin, the following time delay is derived:

$$t_{RD} = C_D * V_{DU} / I_D$$

$$t_{RD} = 47 \text{ nF} * (1.3 \text{ V}) / 4 \mu\text{A} = 15.3 \text{ ms}$$

Other time delays can be obtained by changing the C_D capacitor value. The Delay Time can be reduced by decreasing the capacitance of C_D . Using the formula above, Delay can be reduced as desired. Leaving the Delay Pin open is not desirable as it can result in unwanted signals being coupled onto the pin.

NCV8675

Figure 35. Reset Timing

Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 36) is:

$$P_{D(max)} = [V_{in(max)} - V_{out(min)}]I_{out(max)} + V_{I(max)}I_q \tag{1}$$

where

- $V_{in(max)}$ is the maximum input voltage,
- $V_{out(min)}$ is the minimum output voltage,
- $I_{out(max)}$ is the maximum output current for the application,
- I_q is the quiescent current the regulator consumes at $I_{Q(max)}$.

Once the value of $P_{D(max)}$ is known, the maximum permissible value of $R_{\theta JA}$ can be calculated:

$$R_{\theta JA} = \frac{150^{\circ}C - T_A}{P_D} \tag{2}$$

The value of $R_{\theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\theta JA}$'s less than the calculated value in Equation 2 will keep the die temperature below 150°C.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

Figure 36. Single Output Regulator with Key Performance Parameters Labeled

Heatsinks

A heatsink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\theta JA}$:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \tag{3}$$

where

- $R_{\theta JC}$ is the junction-to-case thermal resistance,
- $R_{\theta CS}$ is the case-to-heatsink thermal resistance,
- $R_{\theta SA}$ is the heatsink-to-ambient thermal resistance.

$R_{\theta JC}$ appears in the package section of the data sheet. Like $R_{\theta JA}$, it too is a function of package type. $R_{\theta CS}$ and $R_{\theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heatsink data sheets of heatsink manufacturers.

Thermal, mounting, and heatsinking considerations are discussed in the ON Semiconductor application note AN1040/D.

NCV8675

EMC-Characteristics: Conducted Susceptibility

All EMC-Characteristics are based on limited samples and no part of production test according to 47A/658/CD IEC62132-4 (direct Power Injection).

Test Conditions

Supply Voltage $V_{in} = 12\text{ V}$
 Temperature $T_A = 23^\circ\text{C} + -5^\circ\text{C}$
 Load $R_L = 100\ \Omega$

Direct power Injection

33d Bm (Note 1) forward power CW for global pin (Note 2)
 17 dBm (Note 1) forward power CW for local pin (Note 3)

Acceptance Criteria

Amplitude Dev. max 4% of Output Voltage
 Reset outputs remain in correct state + -1 V

1. dBm means dB milli-Watts, $P_{(\text{dBm})} = 10 \log(P_{(\text{mW})})$
2. A global pin carries a signal or power which enters or leaves the application board
3. A local pin carries a signal or power which does not leave the application board. It remains on the application board as a signal between two components
