

## Dual Matched Low Noise Precision Op Amp and Dual High Speed Low Noise Precision Op Amp

### FEATURES

- Guaranteed  $80\mu\text{V}$  Max.  $V_{OS}$
- Guaranteed  $6.0\text{nV}/\sqrt{\text{Hz}}$  10Hz Voltage Noise Density
- Guaranteed  $3.9\text{nV}/\sqrt{\text{Hz}}$  1kHz Voltage Noise Density
- Guaranteed  $1\mu\text{V}/^\circ\text{C}$  Max.  $V_{OS}$  Drift
- Guaranteed 1 Million Min. Voltage Gain
- Guaranteed Matching Characteristics
- Guaranteed  $10\text{V}/\mu\text{s}$  Min. Slew Rate (OP-237)

### APPLICATIONS

- Instrumentation Amplifiers
- Low Level Signal Processing
- Low Noise Audio Amplifiers
- Strain Gauge Amplifiers

### DESCRIPTION

The OP-227 is a dual matched precision op amp which combines low offset, low noise, and high gain with excellent matching characteristics. Typical individual amplifier specifications of  $20\mu\text{V}$   $V_{OS}$ ,  $0.2\mu\text{V}/^\circ\text{C}$  drift,  $10\text{nA}$   $I_B$  and  $2.8\text{nV}/\sqrt{\text{Hz}}$  10Hz noise voltage density make the OP-227 an impressive performer in terms of single amplifiers. Matching characteristics are specified with guaranteed limits on all critical parameters including  $V_{OS}$ ,  $V_{OS}$  drift,  $I_{BIAS}$  and CMRR (see the Features section), which make the OP-227 an ideal choice for two and three op amp instrumentation amplifier applications.

The OP-237 offers DC specifications identical to the OP-227 and is decompensated for higher speed operation at inverting gains greater than 5.

**Precision Amplifier Drives  $300\Omega$  Load to  $\pm 10\text{V}$   
with 0.05% Accuracy**

**Matching Characteristic;  
Drift of Offset Voltage Match  
of Representative Units**

# OP-227/OP-237

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage (Note 9)	± 22V
Internal Power Dissipation	500mW
Input Voltage	Equal to Supply Voltage
Output Short-Circuit Duration	Indefinite
Differential Input Current (Note 8)	± 25mA
Storage Temperature Range	-65°C to +150°C
Operating Temperature	
OP-227A/237A/227C/237C	-55°C to +125°C
OP-227E/237E/227G/237G	-25°C to +85°C
Lead Temperature Range (Soldering, 10 sec.)	300°C

The ● denotes the specifications which apply over the full operating temperature range.

For MIL-STD components, please refer to LTC 883C data sheet for test listing and parameters.

**Note 1:** Input offset voltage measurements are performed by automated test equipment approximately 0.5 seconds after application of power.

**Note 2:** Long-Term Input Offset Voltage Stability refers to the average trend line of  $V_{OS}$  vs Time over extended periods after the first 30 days of operation.

**Note 3:** Sample tested.

**Note 4:** Parameter is guaranteed by design.

**Note 5:** See test circuit and frequency response curve for 0.1Hz to 10Hz tester.

**Note 6:** See test circuit for current noise measurement.

**Note 7:** The input offset drift performance is within the specifications un-nulled or when nulled with  $R_p = 8k\Omega$  to  $20k\Omega$ .

**Note 8:** The inputs are protected by back-to-back diodes. Current limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds  $\pm 0.7V$ , the input current should be limited to 25mA.

**Note 9:** The  $V^+$  supply terminals are completely independent and may be powered by separate supplies if desired (this approach, however, would sacrifice the advantages of the power supply rejection ratio matching). The  $V^-$  supply terminals are both connected to the common substrate and must be tied to the same voltage. Both  $V^-$  pins should be used.

**MATCHING CHARACTERISTICS** See notes on page 3.

## APPLICATIONS INFORMATION

### Noise Testing

The 0.1Hz to 10Hz peak-to-peak noise of the OP-227/OP-237 is measured in the test circuit shown. The frequency response of this noise tester indicates that the 0.1Hz corner is defined by only one zero. The test time to measure 0.1Hz to 10Hz noise should not exceed 10 seconds, as this time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1Hz.

Measuring the typical 60nV peak-to-peak noise performance of the OP-227/OP-237 requires special test precautions:

- The device should be warmed up for at least five minutes. As the op amp warms up, its offset voltage changes typically  $3\mu\text{V}$  due to its chip temperature increasing  $10^\circ\text{C}$  to  $20^\circ\text{C}$  from the moment the power supplies are turned on. In the 10 second measurement interval these temperature-induced effects can easily exceed tens of nanovolts.
- For similar reasons, the device must be well shielded from air currents to eliminate the possibility of thermoelectric effects in excess of a few nanovolts, which would invalidate the measurements.
- Sudden motion in the vicinity of the device can also "feed through" to increase the observed noise.

A noise-voltage density test is recommended when measuring noise on a large number of units. A 10Hz noise voltage density measurement will correlate well with a 0.1Hz to 10Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the  $1/f$  corner frequency.

Current noise is measured in the circuit shown and calculated by the following formula:

$$i_n = \frac{[e^2_{no} - (130\text{nV})^2]^{1/2}}{1\text{M}\Omega \times 100}$$

The OP-227/OP-237 achieves its low noise, in part, by operating the input stage at  $120\mu\text{A}$  versus the typical  $10\mu\text{A}$  of most other op amps. Voltage noise is inversely proportional, while current noise is directly proportional to the square root of the stage current. Therefore, the OP-227/OP-237 current noise will be relatively high. At low frequencies, the low  $1/f$  current noise corner frequency ( $\approx 120\text{Hz}$ ) minimizes current noise to some extent.

0.1Hz to 10Hz Noise Test Circuit

0.1Hz to 10Hz p-p Noise Tester Frequency Response

\*DEVICE UNDER TEST  
NOTE: ALL CAPACITOR VALUES ARE FOR  
NON-POLARIZED CAPACITORS ONLY.

## APPLICATIONS INFORMATION

In most practical applications, however, current noise will not limit system performance. This is illustrated in the total noise versus source resistance plot, where total noise =  $[(\text{voltage noise})^2 + (\text{current noise} \times R_S)^2 + (\text{resistor noise})^2]^{1/2}$ .

Three regions can be identified as a function of source resistance:

- (i)  $R_S \leq 400\Omega$  - Voltage noise dominates

- (ii)  $400\Omega \leq R_S \leq 50k\Omega$  at 1kHz Resistor noise dominates  
 $400\Omega \leq R_S \leq 8k\Omega$  at 10Hz

- (iii)  $R_S > 50k\Omega$  at 1kHz Current noise dominates  
 $R_S > 8k\Omega$  at 10Hz

Clearly the OP-227/OP-237 should not be used in region (iii), where total system noise is at least six times higher than the voltage noise of the op amp, i.e., the low voltage noise specification is completely wasted.

## APPLICATIONS INFORMATION

### OP AMP MATCHING

#### Advantages of Matched Dual Op Amps

In many applications the performance of a system depends on the matching between two operational amplifiers rather than the individual characteristics of the two op amps. Two or three op amp instrumentation amplifiers, tracking voltage references and low drift active filters are some of the circuits requiring matching between two op amps.

The well-known triple op amp configuration illustrates these concepts. Output offset is a function of the difference between the offsets of the two halves of the OP-227/OP-237. This error cancellation principle holds for a considerable number of input referred parameters in addition to offset voltage and its drift with temperature. Input bias current will be the average of the two non-inverting input currents ( $I_B^+$ ). The difference between these two currents ( $I_{OS}^+$ ) is the offset current of the instrumentation amplifier. The difference between the inverting input currents ( $I_{OS}^-$ ) will cause errors flowing through R1, R2, and R3. Common mode and power supply rejections will be dependent only on the match between the two amplifiers (assuming perfect resistor matching).

The concepts of common mode and power supply rejection ratio match ( $\Delta\text{CMRR}$  and  $\Delta\text{PSRR}$ ) are best demonstrated with a numerical example:

Assume  $\text{CMRR}_A = +1.0\mu\text{V}/\text{V}$  or 120dB,  
 and  $\text{CMRR}_B = +0.75\mu\text{V}/\text{V}$  or 122.5dB,  
 then  $\Delta\text{CMRR} = 0.25\mu\text{V}/\text{V}$  or 132dB;  
 if  $\text{CMRR}_B = -0.75\mu\text{V}/\text{V}$  which is still 122.5dB,  
 then  $\Delta\text{CMRR} = 1.75\mu\text{V}/\text{V}$  or 115dB.

Clearly, the OP-227/OP-237, by specifying and guaranteeing all of these matching parameters, can significantly improve the performance of matching dependent circuits.

Three Op Amp Instrumentation Amplifier

- Trim R8 for gain
- Trim R9 for DC common mode rejection
- Trim R10 for AC common mode rejection

Typical performance of the instrumentation amplifier:

- Input offset voltage =  $60\mu\text{V}$
- Input bias current =  $\pm 15\text{nA}$
- Input offset current =  $\pm 20\text{nA}$
- Input noise =  $0.08\mu\text{Vp-p}$
- Power bandwidth ( $V_O = \pm 10\text{V}$ ) = 250kHz

APPLICATIONS INFORMATION
