Lead-free Green

PAM2841

1.5A SW CURRENT, 40V PRECISION WLED DRIVER

Description

The PAM2841 is a white LED driver, capable of driving 10 or more WLEDs in series (depending on forward voltage of the LEDs) with a range of input voltages from 2.7V to 5.5V.

The PAM2841 features over current protection, over voltage protection, under voltage lockout and over temperature protection, which prevent the device from damage.

LED dimming can be done by four methods as described in the Application Information hereinafter.
Features

- Capable of Driving 10 or More WLEDs
- Chip Enable with Soft-Start
- Analog and PWM Dimming
- Peak Efficiency up to 90%
- Low Quiescent Current
- Fixed Frequency of 1MHz
- Over Current Protection
- Over Voltage Protection
- Thermal Protection
- UVLO
- **Totally Lead-Free & Fully RoHS Compliant (Notes 1 & 2)**
- **Halogen and Antimony Free. "Green" Device (Note 3)**

Applications

- WLED Driver System

Notes: 1. No purposely added lead. Fully EU Directive 2002/95/EC (RoHS) & 2011/65/EU (RoHS 2) compliant.
2. See http://www.diodes.com/quality/lead_free.html for more information about Diodes Incorporated's definitions of Halogen- and Antimony-free, "Green" and Lead-free.
3. Halogen- and Antimony-free "Green" products are defined as those which contain <900ppm bromine, <900ppm chlorine (<1500ppm total Br + Cl) and <1000ppm antimony compounds.

Application Information

Inductor Selection

The selection of the inductor affects steady state operation as well as transient behavior and loop stability. These factors make it the most important component in power regulator design. There are three important inductor specifications, inductor value, DC resistance and saturation current. Considering inductor value alone is not enough.

The inductor value determines the inductor ripple current. Choose an inductor that can handle the necessary peak current without saturation, the inductor DC current given by:

$I_{IN\_DC} = V_{OUT}*I_{OUT}/(V_{IN}*\eta)$ η = efficiency.

Inductor values can have ±20% tolerance with no current bias. When the inductor current approaches saturation level, its inductance can decrease 20% to 35% from the 0A value depending on how the inductor vendor defines saturation current. Using an inductor with a smaller inductance value causes discontinuous PWM when the inductor current ramps down to zero before the end of each switching cycle. This reduces the boost converter's maximum output current, causes large input voltage ripple and reduces efficiency. Large inductance value provides much more output current and higher conversion efficiency. For these reasons, an inductor within 4.7µH to 22µH value range is recommended.

Schottky Diode Selection

The high switching frequency of the PAM2841 demands a high-speed rectification for optimum efficiency. Ensure that the diode average and peak current rating exceeds the average output current and peak inductor current. In addition, the diode's reverse breakdown voltage must exceed the open protection voltage.

Input and Output Capacitor Selection

Input Capacitor

At least a 1µF input capacitor is recommended to reduce the input ripple and switching noise for normal operating conditions. Larger value and lower ESR (Equivalent Series Resistance) may be needed if the application require very low input ripple. It follows that ceramic capacitors are a good choice for applications. Note that the input capacitor should be located as close as possible to the device.

Output Capacitor

The output capacitor is mainly selected to meet the requirement for the output ripple and loop stability. This ripple voltage is related to the capacitor's capacitance and its equivalent series resistance (ESR). A output capacitor of 1µF minimum is recommended and maybe need a larger capacitor. The total output voltage ripple has two components: the capacitive ripple caused by the charging and discharging on the output capacitor, and the ohmic ripple due to the capacitor's equivalent series resistance (ESR):

$V_{RIPPLE} = V_{RIPPLE(C)} + V_{RIPPLE(ESR)}$
$V_{RIPPLE(C)} \approx \frac{1}{2}*(L/C_{OUT}*((V_{OUT(MAX)} - V_{IN(MIN)})))*(I^2_{PEAK} - I^2_{OUT})$
$V_{RIPPLE(ESR)} = I_{PEAK}*R_{ESR(COUT)}$

Where I_{PEAK} is the peak inductor current.

Multilayer ceramic capacitors are an excellent choice as they have extremely low ESR and are available in small footprints. Capacitance and ESR variation with temperature should be considered for best performance in applications with wide operating temperature ranges.

Dimming Control

There are 4 different types of dimming control methods:

1. Using an External PWM Signal to ENA Pin

With the PWM signal applied to the ENA pin, the PAM2841 is alternately turned on or off by the PWM signal. The LEDs operate at either zero or full current. The average LED current changes proportionally with the duty cycle of the PWM signal. A 0% duty cycle turns off the PAM2841 and leads to zero LED current. A 100% duty cycle generates full current. Also the recommend dimming frequency is between 100Hz and 200Hz.

$I_{AVE} = I_{STATE} * (t_{ON} - t_{STARTUP})/(t_{ON} + t_{OFF})$

Where t_{ON}: on time of a period
$t_{STARTUP}$: 0.85ms
t_{OFF}: off time of a period
I_{STATE}: on state current (full current)

Application Information (Cont.)

Figure 1

2. Using an External PWM Signal to NMOS Gate

When PWM signal is at high level, N MOSFET turned on, then pull Comp pin down, then the LED current should be zero. When PWM signal is at low level, N MOSFET turned off. The circuit uses resistor R1 to set the on state current. The average LED current changes proportionally with the duty cycle of the PWM signal. A 100% duty cycle turns off the PAM2841 and leads to zero LED current. A 0% duty cycle generates full current.

$$I_{AVE} = I_{STATE} * (t_{ON} - t_{STARTUP})/(t_{ON} + t_{OFF})$$

Where t_{ON}: on time of a period
$t_{STARTUP}$: 0.08ms
t_{OFF}: off time of a period
I_{STATE}: on state current (full current)

Also the recommend frequency is between 100 and 500Hz. Frequency<100Hz can naturally cause LEDs to blink visibly.

Figure 2

3. Using a DC Voltage

For some applications, a simple and direct way to control brightness is using an external variable DC voltage to vary the voltage drop on feedback resistor. This will make the PAM2841 adjust the output current to follow the change of feedback voltage. The circuit is shown in Figure 3. As the DC voltage increases, the voltage drop on R4 increases and the voltage drop on R3 decreases. Thus, the LED current decreases. The selection of R4 and R5 will make the current from the variable DC source much smaller than the LED current and much larger than the FB pin current. For VCC range from 0V to 2V, the selection of resistors in Figure 3 gives dimming control of LED current from 0mA to 20mA.

Application Information (Cont.)

Figure 3

4. Using a Filtered PWM Signal

The filtered PWM signal can be considered as an adjustable DC voltage. Such regulated signal is often with some grade of ripple because of some simple configuration of circuit. With appropriated arrangement of PWM frequency and level, and filter parameters, it can be used to replace the variable DC voltage source in dimming control.
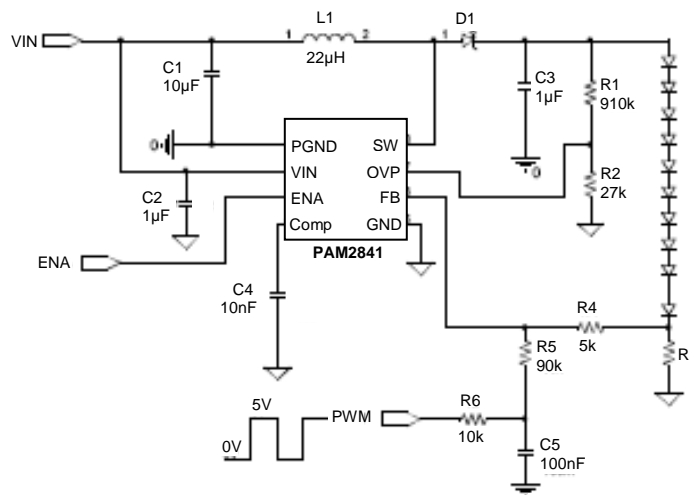

The circuit is shown in Figure 4.

Figure 4

Layout Consideration

As for all switching power supplies, especially those in high frequency and high current ones, layout is an important design step. If layout is not carefully done, the regulator could suffer from instability as well as noise problems.
1. Use separate traces for power ground and signal ground. Power ground and signal ground are connected together to a quite ground (input connector).
2. To prevent radiation of high frequency resonance, proper layout of the high frequency switching path is essential. Minimize the length and area of all traces connecting to the SW pin. The loop including the PWM switch, Schottky diode and output capacitor, contains high current rising and falling in nanosecond and thus it should be kept as short as possible.
3. The input capacitor should be close to both the VIN pin and the GND pin in order to reduce the IC supply ripple.
4. Keep the signal ground traces short and as close to the IC as possible. Small signal components should be placed as close as possible to the IC, thus minimizing control signal noise interference.
