- *1 The differential output voltage ($V_{OUT+} - V_{OUT-}$) with respect to the differential input voltage ($V_{IN+} - V_{IN-}$), where $V_{IN+} = -200\text{ mV}$ to 200 mV and $V_{IN-} = 0\text{ V}$ is measured under the circuit shown in **Fig. 2 NL200, G Test Circuit**. Upon the resulting chart, the gain is defined as the slope of the optimum line obtained by using the method of least squares.
- *2 The differential output voltage ($V_{OUT+} - V_{OUT-}$) with respect to the differential input voltage ($V_{IN+} - V_{IN-}$) is measured under the circuit shown in **Fig. 2 NL200, G Test Circuit**. Upon the resulting chart, the optimum line is obtained by using the method of least squares. Non-linearity is defined as the ratio (%) of the optimum line obtained by dividing [Half of the peak to peak value of the (residual) deviation] by [full-scale differential output voltage]. For example, if the differential output voltage is 3.2 V , and the peak to peak value of the (residual) deviation is 22.4 mV , while the input V_{IN+} is $\pm 200\text{ mV}$, the output non-linearity is obtained as follows:

$$NL200 = 22.4 / (2 \times 3200) = 0.35\%$$
- *3 CMRR_{IN} is defined as the ratio of the differential signal gain (when the differential signal is applied between the input pins) to the common-mode signal gain (when both input pins are connected and the signal is applied). This value is indicated in dB.

- *1 CMTI is tested by applying a pulse that rises and falls suddenly ($V_{CM} = 0.5\text{ kV}$) between GND1 on the input side and GND2 on the output side (pins 4 and 5) by using the circuit shown in **Fig. 9 CMTI Test Circuit**. CMTI is defined at the point where the differential output voltage ($V_{OUT+} - V_{OUT-}$) fluctuates 200 mV ($>1\text{ }\mu\text{s}$) or more from the average output voltage.
- *2 This is the value of the transient voltage at the differential output when 1 V_{p-p}, 1 MHz, and 40 ns rise/fall time square wave is applied to both V_{DD1} and V_{DD2} .

- Time to preheat temperature from 120 to 180 °C 120 ± 30 s
- Number of reflows Three

Recommended Temperature Profile of Infrared Reflow

(2) Wave soldering

- Temperature 260 °C or below (molten solder temperature)
- Time 10 seconds or less
- Preheating conditions 120 °C or below (package surface temperature)
- Number of times One (Allowed to be dipped in solder including plastic mold portion.)
- Flux Rosin flux containing small amount of chlorine (The flux with a maximum chlorine content of 0.2 Wt% is recommended.)

(3) Soldering by Soldering Iron

- Peak Temperature (lead part temperature) 350 °C or below
- Time (each pins) 3 seconds or less
- Flux Rosin flux containing small amount of chlorine
(The flux with a maximum chlorine content of 0.2 Wt% is recommended.)

(a) Soldering of leads should be made at the point 1.5 to 2.0 mm from the root of the lead

(b) Please be sure that the temperature of the package would not be heated over 100°C

(4) Cautions

- Flux Cleaning
Avoid cleaning with Freon based or halogen-based (chlorinated etc.) solvents.
- Do not use fixing agents or coatings containing halogen-based substances.

2. Cautions regarding noise

Be aware that when voltage is applied suddenly between the photocoupler's input and output at startup, the output transistor may enter the on state, even if the voltage is within the absolute maximum ratings.

USAGE CAUTIONS

1. Usage cautions

- (1) This product is weak for static electricity by designed with high-speed integrated circuit so protect against static electricity when handling.
- (2) When the primary power supply (V_{DD1}) is off and only the secondary power supply (V_{DD2}) is being applied ($V_{DD1} = 0$ V and $V_{DD2} = 5$ V), V_{OUT+} outputs a low level, and V_{OUT-} outputs a high level ($V_{OUT+} = 1.3$ V TYP., $V_{OUT-} = 3.8$ V TYP.), regardless of the input voltages (V_{IN+} and V_{IN-}).
- (3) The output level of V_{OUT+} and V_{OUT-} might be unstable for several seconds immediately after the secondary power supply (V_{DD2}) is applied while the primary power supply (V_{DD1}) is being applied.

2. Board designing

- (1) By-pass capacitor of more than $0.1 \mu\text{F}$ is used between V_{CC} and GND near device. Also, ensure that the distance between the leads of the photocoupler and capacitor is no more than 10 mm.
- (2) Keep the pattern connected the input (V_{IN+} , V_{IN-}) and the output (V_{OUT+} , V_{OUT-}), respectively, as short as possible.
- (3) Do not connect any routing to the portion of the frame exposed between the pins on the package of the photocoupler. If connected, it will affect the photocoupler's internal voltage and the photocoupler will not operate normally.
- (4) Because the maximum frequency of the signal input to the photocoupler must be lower than the allowable frequency band, be sure to connect an anti-aliasing filter (an RC filter with $R = 68 \Omega$ and $C = 0.01 \mu\text{F}$, for example).
- (5) The signals output from the PS8352A include noise elements such as chopping noise and quantization noise generated internally. Therefore, be sure to restrict the output frequency to the required bandwidth by adding a low-pass filter function (an RC filter with $R = 10 \text{ k}\Omega$ and $C = 150 \text{ pF}$, for example) to the operational amplifier (post amplifier) in the next stage to the PS8352A.

3. Avoid storage at a high temperature and high humidity.
