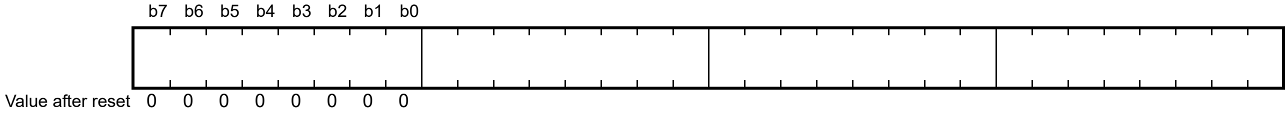
USBHS.D1FIFOLL 4006 001Ch, USBHS.D1FIFOHH 4006 001Fh



Bit	Symbol	Bit name	Description	R/W
b31 to b0	FIFOPORT*1	FIFO Port	Read receive data from the FIFO buffer or write transmit data to the FIFO buffer by accessing these bits.	R/W

Note 1. The valid bits depend on the MBW[1:0] and BIGEND settings in the associated port selection register.

Three FIFO ports are provided:

- CFIFO
- D0FIFO
- D1FIFO.

Each FIFO port is configured with:

- A port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer and writing of data to the FIFO buffer
- A port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that selects the pipe assigned to the FIFO port
- A port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

Each FIFO port has the following constraints:

- Access to the FIFO buffer for DCP control transfers is through the CFIFO port
- Access to the FIFO buffer for DMA or DTC transfers is through the D0FIFO or D1FIFO port
- The D0FIFO and D1FIFO ports can also be accessed by the CPU
- When using functions specific to the FIFO port, such as the DMA or DTC transfer function, you cannot change the pipe number selected in the CURPIPE[3:0] bits of the Port Selection Register
- Registers configuring one FIFO port do not affect other FIFO ports
- The same pipe must not be assigned to two or more FIFO ports

- There are two FIFO buffer states, one giving access rights to the CPU and the other to the serial interface engine (SIE). When the SIE has access rights, the FIFO buffer cannot be accessed by the CPU.

FIFOPORT bit (FIFO Port)

When the FIFOPORT bit is accessed, the USBHS reads the received data from the FIFO buffer or writes the transmission data to the FIFO buffer. The FIFO port register can be accessed only when the FRDY flag in the associated port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) is 1.

The valid bits in the FIFO port register depend on the MBW[1:0] and BIGEND settings in the port selection register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL). See Table 33.6 to Table 33.8.

Table 33.6 Endian operation in 32-bit access (MBW[1:0] = 10b)

BIGEND	CFIFO, D0FIFO, D1FIFO b31 to b24	CFIFO, D0FIFO, D1FIFO b23 to b16	CFIFO, D0FIFO, D1FIFO b15 to b8	CFIFO, D0FIFO, D1FIFO b7 to b0	Remarks
0	Located at N+3	Located at N+2	Located at N+1	Located at N+0	Transmit data is sent from the address N+0. Receive data is stored from the address N+0.
1	Located at N+0	Located at N+1	Located at N+2	Located at N+3	Transmission data is sent from the address N+3. Receive data is stored from the address N+3.

Table 33.7 Endian operation in 16-bit access (MBW[1:0] = 01b)

BIGEND	CFIFOL, D0FIFOL, D1FIFOL b15 to b8	CFIFOL, D0FIFOL, D1FIFOL b7 to b0	CFIFOH, D0FIFOH, D1FIFOH b15 to b8	CFIFOH, D0FIFOH, D1FIFOH b7 to b0	Remarks
0	Access prohibited*1		Located at N+1	Located at N+0	Transmit data is sent from the address N+0. Receive data is stored from the address N+0.
1	Located at N+0	Located at N+1	Access prohibited*1		Transmit data is sent from the address N+1. Receive data is stored from the address N+1.

Note 1. Writing to or reading from these areas is prohibited.

Table 33.8 Endian operation in 8-bit access (MBW[1:0] = 00b)

BIGEND	CFIFOLL, D1FIFOLL, D0FIFOLL	CFIFOHH, D1FIFOHH, D0FIFOHH
0	Access prohibited*1	Located at N+0
1	Located at N+0	Access prohibited*1

Note 1. Writing to or reading from these locations is prohibited.

33.2.8 CFIFO Port Selection Register (CFIFOSEL)

Address(es): USBHS.CFIFOSEL 4006 0020h

b15	RCNT	Read Count Mode	0: Clear DTLN[11:0] flags in the FIFO port control register to 000h when all receive data is read from CFIFO 1: Decrement DTLN[11:0] flags each time receive data is read from CFIFO.	R/W

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the CFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

ISEL bit (FIFO Port Access Direction when DCP Is Selected)

After writing a new value to the ISEL bit while the DCP is the selected pipe, read this bit to check that the written value agrees with the read value before proceeding to the next process. Set the ISEL and CURPIPE[3:0] bits simultaneously.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the CFIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (CFIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the CFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the CFIFOCTR.DTLN[11:0] flags to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits.

33.2.9 D0FIFO Port Selection Register (D0FIFOSEL) D1FIFO Port Selection Register (D1FIFOSEL)

Address(es): USBHS.D0FIFOSEL 4006 0028h, USBHS.D1FIFOSEL 4006 002Ch

b13	DCLRM	Auto FIFO Buffer Clear Mode after Specified Pipe is Read	0: Disable auto buffer clear mode 1: Enable auto buffer clear mode.	R/W
b14	REW	Buffer Pointer Rewind	0: Do not rewind buffer pointer (writing 0 has no effect) 1: Rewind buffer pointer.	W
b15	RCNT	Read Count Mode	0: Clear DTLN[11:0] flags in the FIFO port control register to 000h when all receive data is read from DnFIFO (after read of a single plane in double buffer mode) 1: Decrement DTLN[11:0] flags each time receive data is read from DnFIFO. n = 0, 1.	R/W

Do not specify the same pipe number in the CURPIPE[3:0] bits in the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers. When the CURPIPE[3:0] bits in the D0FIFOSEL and D1FIFOSEL registers are set to 0000b, no pipe is selected.

Do not change the pipe number while DMA or DTC transfer is enabled.

CURPIPE[3:0] bits (FIFO Port Access Pipe Specification)

The CURPIPE[3:0] bits specify the pipe number used to read or write data through the DnFIFO port. After writing to these bits, read them to check that the written value agrees with the read value before proceeding to the next process. Do not set the same pipe number to the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

During FIFO buffer access, the pipe specification is maintained until the access is complete, even if the software attempts to change the CURPIPE[3:0] setting. Access continues after the current value is written back to the CURPIPE[3:0] bits.

BIGEND bit (FIFO Port Endian Control)

Use the BIGEND bit to set the byte endian order of the D0FIFO or D1FIFO port to be the same as that selected in the endian selection register (MDE).

MBW[1:0] bits (FIFO Port Access Bit Width)

The MBW[1:0] bits specify the bit width for accessing the DnFIFO port.

When the selected pipe is receiving, after a write to these bits starts a data read from the FIFO buffer, do not change the bits until all of the data is read. When reading the FIFO buffer, read with the access size set in MBW.

When the selected pipe is transmitting, set the CURPIPE[3:0] and MBW[1:0] bits simultaneously. The bit width cannot be changed from 8-bit to 16- or 32-bit, or from 16-bit to 32-bit while data is being written to the FIFO buffer.

An odd number of bytes can also be written through byte-access control even when 16- or 32-bit width is selected.

DREQE bit (DMA/DTC Transfer Request Enable)

The DREQE bit enables or disables issuing of DMA or DTC transfer requests. Only change the settings of DREQE bit when the CURPIPE[3:0] bits are 0000b.

To enable DMA or DTC transfer requests, set this bit to 1 after setting the CURPIPE[3:0] bits to 0000b, and then set the CURPIPE[3:0] bits to the PIPE number for the transfer.

DCLRM bit (Auto FIFO Buffer Clear Mode after Specified Pipe is Read)

The DCLRM bit enables or disables automatic FIFO buffer clearing after data in the selected pipe is read.

When this bit is set to 1, on receiving a zero-length packet while the FIFO buffer assigned to the selected pipe is empty, or when reading of a received short packet is complete while the PIPECFG.BFRE bit is 1, the USBHS sets the BCLR bit in the FIFO port control register to 1.

When using the USBHS with the SOFCFG.BRDYM bit set to 1, set this bit to 0.

REW bit (Buffer Pointer Rewind)

The REW bit specifies whether or not to rewind the buffer pointer.

When the selected pipe is receiving, setting this bit to 1 while the FIFO buffer is being read allows re-reading of the FIFO buffer from the first data. In double-buffering when reading is already in progress, this setting enables reading either FIFO buffer from the first entry.

Do not set this bit to 1 while simultaneously changing the CURPIPE[3:0] bits. Before setting the bit to 1, always check that the FRDY flag is 1.

To rewrite to the FIFO buffer from the first data for the transmitting pipe, use the BCLR bit.

RCNT bit (Read Count Mode)

When the RCNT bit set to 0, the USBHS clears the DnFIFOCTR.DTLN[11:0] flags (n = 0, 1) to 0 on finishing reading all of the received data in the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits, or after reading a single plane in double buffer mode.

With this bit set to 1, the USBHS decrements the value in the CFIFOCTR.DTLN[11:0] flags each time it reads data received from the FIFO buffer assigned to the pipe specified in the CURPIPE[3:0] bits. When accessing DnFIFO with the PIPECFG.BFRE bit set to 1, set the RCNT bit to 0.

33.2.10 CFIFO Port Control Register (CFIFOCTR) D0FIFO Port Control Register (D0FIFOCTR) D1FIFO Port Control Register (D1FIFOCTR)

Address(es): USBHS.CFIFOCTR 4006 0022h, USBHS.D0FIFOCTR 4006 002Ah, USBHS.D1FIFOCTR 4006 002Eh

Value after reset:	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b11 to b0	DTLN[11:0]	Receive Data Length Flag	Receive data length The meaning of the values differs depending on the RCNT bit setting in the port selection register. For details, see the description of the DTLN[11:0] bits.	R
b12	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b13	FRDY	FIFO Port Ready Flag	0: FIFO port access disabled 1: FIFO port access enabled.	R
b14	BCLR	CPU Buffer Clear	0: No operation 1: Clear FIFO buffer on the CPU side. Writing 0 to this bit has no effect. This bit is read as 0.	R/W
b15	BVAL	FIFO Buffer Valid Flag	0: Invalid (writing 0 has no effect) 1: Writing ended. Set this bit to 1 when data is completely written to the FIFO buffer on the CPU side for the selected pipe (CURPIPE[3:0] setting).	R/W

The CFIFOCTR, D0FIFOCTR, and D1FIFOCTR registers correspond to the CFIFO, D0FIFO, and D1FIFO buffers.

DTLN[11:0] flags (Receive Data Length Flag)

The DTLN[11:0] flags indicate the length of the receive data.

While the FIFO buffer is being read, the DTLN[11:0] bits indicate different values depending on the DnFIFOSEL.RCNT bit (n = 0, 1), as follows:

- RCNT = 0:
  The USBHS sets the DTLN[11:0] flags to indicate the length of the receive data until the CPU or DMA/DTC has read all of the received data in the FIFO buffer (or until it has read a single plane in double buffer mode).
  While the PIPECFG.BFRE bit is 1, the USBHS retains the length of the receive data until the BCLR bit is set to 1, even after all the data is read.
- RCNT = 1:
  The USBHS decrements the value indicated in the DTLN[11:0] flags each time the CPU or DMA/DTC reads the receive data from the FIFO buffer. (The value is decremented by 1 when MBW[1:0] = 00b, by 2 when MBW[1:0] = 01b, and by 4 when MBW[1:0] = 10b.)
  The USBHS sets these flags to 0 when all the data is read from the FIFO buffer. In double buffer mode, if data is received in one FIFO buffer plane before all of the data is read from the other plane, the USBHS sets these bits to indicate the length of the receive data in the latter plane when all of the data is read from the former plane.
  When the RCNT bit is 1, reading the DTLN[11:0] flags while the FIFO buffer is being read returns the latest value within 150 ns after the FIFO port read cycle.

FRDY flag (FIFO Port Ready Flag)

The FRDY flag indicates whether the FIFO port can be accessed by the CPU or DMA/DTC.

In the following cases, the USBHS sets the FRDY flag to 1 but data cannot be read through the FIFO port because there is no data to be read:

- A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty
- A short packet is received and the data is completely read while the PIPECFG.BFRE bit is 1.

In these cases, set the BCLR bit to 1 to clear the FIFO buffer, and enable transmission and reception of the next data.

BCLR bit (CPU Buffer Clear)

Set the BCLR bit to 1 to clear the FIFO buffer on the CPU for the selected pipe.

When double buffer mode is set for the FIFO buffer assigned to the selected pipe, the USBHS clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the DCP is the selected pipe, setting the BCLR bit to 1 allows the USBHS to clear both sets of FIFO buffers regardless of whether the CPU or SIE has access rights. To clear the buffer when the SIE has access rights, set the DCPCTR.PID[1:0] bits to 00b (NAK response) before setting the BCLR bit to 1.

When the selected pipe is not the DCP, only write 1 to the BCLR bit while the FRDY flag in the FIFO port control register is 1 (set by the USBHS).

BVAL bit (FIFO Buffer Valid Flag)

Set the BVAL bit to 1 when data is completely written to the FIFO buffer on the CPU for the pipe selected in CURPIPE[3:0].

When the selected pipe is transmitting, set this bit to 1 in the following cases:

- To transmit a short packet, set this bit to 1 after data is written
- To transmit a zero-length packet, set this bit to 1 before data is written to the FIFO buffer
- Set this bit to 1 after the specified number of data bytes is written for the pipe in continuous transfer mode, where the number is a natural integer multiple of the maximum packet size and less than the buffer size.

The USBHS then switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When the selected pipe is in use for transmission, simultaneously setting the BVAL flag and the BCLR bit to 1 causes the USBHS to clear the data that is already written and enables transmission of a zero-length packet. When data of the maximum packet size is written for the pipe in non-continuous transfer mode, the USBHS sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

Only write 1 to the BVAL flag while the FRDY bit is 1 (set by the USBHS). When the selected pipe is receiving, do not set the BVAL flag to 1.

33.2.11 Interrupt Enable Register 0 (INTENB0)

Address(es): USBHS.INTENB0 4006 0030h

b14	RSME	Resume Interrupt Request Enable	0: Disable interrupt request 1: Enable interrupt request.	R/W
b15	VBSE	VBUS Interrupt Request Enable	0: Disable interrupt request 1: Enable interrupt request.	R/W

Note: The RSME, DVSE, and CTRE bits can only be set to 1 in device controller mode. Do not set these bits to 1 in host controller mode.

When a status flag in the INTSTS0 register sets to 1 and the associated interrupt request enable bit setting in the INTENB0 register is 1, the USBHS issues a USBHS interrupt request.

Regardless of the INTENB0 register setting, the status flag in the INTSTS0 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB0 register is switched from 0 to 1 while the associated status flag in the INTSTS0 register is set to 1, a USBHS interrupt is requested.

33.2.12 Interrupt Enable Register 1 (INTENB1)

Address(es): USBHS.INTENB1 4006 0032h

b15	OVRCRE	OVRCRE Interrupt Request Enable	0: Disable interrupt request 1: Enable interrupt request.	R/W

When a status flag in the INTSTS1 register sets to 1 and the associated interrupt request enable bit setting in the INTENB1 register is 1, the USBHS issues a USBHS interrupt request.

Regardless of the INTENB1 register setting, the status flag in the INTSTS1 register sets to 1 in response to a state change that satisfies the associated condition.

When an interrupt request enable bit in the INTENB1 register is switched from 0 to 1 while the associated status flag in the INTSTS1 register is set to 1, a USBHS interrupt is requested.

33.2.13 BRDY Interrupt Enable Register (BRDYENB)

Address(es): USBHS.BRDYENB 4006 0036h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPEBRDYE [9:0]	BRDY Interrupt Request Enable for Pipes [9:0]*1	0: Disable interrupt request 1: Enable interrupt request.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.

The BRDYENB register enables or disables the INTSTS0.BRDY bit to be set to 1 when a BRDY interrupt is detected for each pipe.

When a status flag in the BRDYSTS register sets to 1 and the associated PIPEBRDYEn (n = 9 to 0) bit setting in the BRDYENB register is 1, the INTSTS0.BRDY flag sets to 1. In this case, if the BRDYE bit in INTENB0 is 1, the USBHS generates a BRDY interrupt request. While at least one PIPEBRDYEn flag indicates 1, the INTSTS0.BRDY flag sets to 1 when the associated interrupt request enable bit in the BRDYENB register is changed from 0 to 1 by software.

33.2.14 NRDY Interrupt Enable Register (NRDYENB)

Address(es): USBHS.NRDYENB 4006 0038h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDYE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPENRDYE [9:0]	NRDY Interrupt Enable for Pipes [9:0]*1	0: Disable interrupt request 1: Enable interrupt request.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.

The NRDYENB register enables or disables the INTSTS0.NRDY bit to be set to 1 when a NRDY interrupt is detected for each pipe.

When a status flag in the NRDYSTS register sets to 1 and the associated PIPENRDYEn (n = 0 to 9) bit setting in the NRDYENB register is 1, the INTSTS0.NRDY flag sets to 1. In this case, if the NRDYE bit in INTENB0 is 1, the USBHS generates a NRDY interrupt request. While at least one PIPEBRDYEn flag indicates 1, the INTSTS0.NRDY flag sets to 1 when the associated interrupt request enable bit in the NRDYENB register is changed from 0 to 1 by software.

33.2.15 BEMP Interrupt Enable Register (BEMPENB)

Address(es): USBHS.BEMPENB 4006 003Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMPE[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPEBEMPE [9:0]	BEMP Interrupt Enable for Pipes [9:0]*1	0: Disable interrupt request 1: Enable interrupt request.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.

The BEMPENB register enables or disables the INTSTS0.BEMP bit to be set to 1 when a BEMP interrupt is detected for each pipe.

When a status flag in the BEMPSTS register sets to 1 and the associated PIPEBEMPEn (n = 0 to 9) bit setting in the BEMPENB register is 1, the INTSTS0.BEMP flag sets to 1. In this case, if the BEMPE bit in INTENB0 is 1, the USBHS generates a BEMP interrupt request. While at least one PIPEBEMPEn flag indicates 1, the INTSTS0.BEMP flag sets to 1 when the associated interrupt request enable bit in the BEMPENB register is changed from 0 to 1 by software.

33.2.16 SOF Output Configuration Register (SOFCFG)

Address(es): USBHS.SOFCFG 4006 003Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TRNENSEL	—	BRDYM	INTL	EDGESTS	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	x	0	0	0	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b3 to b0	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b4	EDGESTS	Interrupt Edge Processing Status Flag*1	Indicates 1 during the edge processing of an edge interrupt output signal.	R
b5	INTL	Interrupt Output Sense Select*2	0: Edge detection 1: Level detection.	R/W
b6	BRDYM	PIPEBRDY Interrupt Status Clear Timing*3	0: Clear BRDY flag through software 1: Clear BRDY flag by the USBHS through a data read from the FIFO buffer or data write to the FIFO buffer.	R/W
b7	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b8	TRNENSEL	Transaction-Enabled Time Select*4	0: Not low-speed communication 1: Low-speed communication.	R/W
b15 to b9	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note 1. Confirm that the EDGESTS flag is 0 before stopping the clock supply to the USBHS.
Note 2. When the INTL bit is set to 0, to stop the PHY clock (LPSTS.SUSPENDM = 0) after clearing the interrupt status, write 0 to the LPSTS.SUSPENDM bit after confirming that the EDGESTS flag is cleared to 0.
Note 3. When setting the BRDYM bit to 1, set the INTL bit to 1.
Note 4. The setting in the TRNENSEL bit is only valid in host controller mode. Even in host controller mode, the setting of this bit has no effect on the transaction-enabled time during high-speed communication.

EDGESTS flag (Interrupt Edge Processing Status Flag)

The EDGESTS flag indicates 1 during the edge processing of an edge interrupt output signal. Confirm that this flag is 0 before stopping the PHY clock.

BRDYM bit (PIPEBRDY Interrupt Status Clear Timing)

The BRDYM bit specifies how the BRDY interrupt status flags for the pipes are cleared.

TRNENSEL bit (Transaction-Enabled Time Select)

When the USB port is in use for full- or low-speed communications, the TRNENSEL bit specifies the timing with which the USBHS issues tokens in a frame (transaction-enabled time).

Set this bit to 1 when a low-speed device is connected through a hub. The bit is only valid in host controller mode. Set this bit to 0 when the interface is in use as a device controller.

33.2.17 PHY Setting Register (PHYSET)

Address(es): USBHS.PHYSET 4006 003Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HSEB	—	—	—	REPSTART	—	REPSEL[1:0]		—	—	CLKSEL[1:0]		CDPEN	—	PLLRESET	DIRPD
Value after reset:	x	x	x	x	0	x	0	0	x	x	1	1	0	x	1	1

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	DIRPD	Power-Down Control	0: Do not enter low power mode 1: Enter low power mode.	R/W
b1	PLLRESET	PLL Reset Control*1	0: Disable PLL reset control for UTMI_PHY 1: Enable PLL reset control for UTMI_PHY.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CDPEN	Charging Downstream Port Enable	0: Disable downstream port charging 1: Enable downstream port charging.	R/W
b5, b4	CLKSEL[1:0]	Input System Clock Frequency	b5 b4 0 0: 12 MHz 0 1: Setting prohibited 1 0: 20 MHz 1 1: 24 MHz.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	REPSEL[1:0]	Terminating Resistance Adjustment Cycle	b9 b8 0 0: No cycle is set 0 1: Adjust terminating resistance at 16-second intervals 1 0: Adjust terminating resistance at 64-second intervals 1 1: Adjust terminating resistance at 128-second intervals.	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11	REPSTART	Forcibly Start Terminating Resistance Adjustment	0: Force terminating resistance adjustment to start 1: Do not force terminating resistance adjustment to start.	R/W
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	HSEB	CL-only mode	0: Disable CL-only mode 1: Enable CL-only mode.	R/W

Note 1. Because the value of the PLLRESET bit is 1 after a reset, changing the setting after release from the reset state is not required. Do not set the PLLRESET bit to 1 after setting the PLLRESET bit to 0. Operation is not guaranteed.

CLKSEL[1:0] bits (Input System Clock Frequency)

The CLKSEL[1:0] bits select the transfer clock source for the USBHS.

For the transfer clock generated in the USB-PHY internal PLL, these bits set the input clock frequency. To input the clock source from the EXTAL pin, the USB 2.0 clock specification must be strictly followed.

Writing to the CKSEL[1:0] bits is invalid in CL-only mode because the internal PLL is stopped (see the description for HSEB bit (CL-only mode)). For the clock settings, see section 33.3.3, Supplying the Clock.

HSEB bit (CL-only mode)

The HSEB bit selects whether the USBHS operates in CL-only mode. High-speed transfer by the USBHS requires the use of internal high-speed analog circuits including the PLL, clock, and data recovery (CDR) circuit in the USB-PHY block.

CL-only mode limits the transfer to the USB 1.1 specification (full- and low-speed transfer only). Power consumption can be reduced by stopping the internal PLL of the PHY module and other high-speed analog circuits.

In CL-only mode, the USBHS requires supply clocks of 48 MHz and 60 MHz, generated in the Clock Generation Circuit. For the clock supply method, see section 9, Clock Generation Circuit.

33.2.18 Interrupt Status Register 0 (INTSTS0)

Address(es): USBHS.INTSTS0 4006 0040h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b2 to b0	CTSQ[2:0]	Control Transfer Stage Flag*1	b2 b0 0 0 0: Idle or setup stage 0 0 1: Control read data stage 0 1 0: Control read status stage 0 1 1: Control write data stage 1 0 0: Control write status stage 1 0 1: Control write (no data) status stage 1 1 0: Control transfer sequence error.	R
b3	VALID	USB Request Reception Flag*1	0: Setup packet not received 1: Setup packet received.	R/(W) *3
b6 to b4	DVSQ[2:0]	Device State*1	Indicates the device state. b6 b4 0 0 0: Powered state 0 0 1: Default state 0 1 0: Address state 0 1 1: Configured state 1 x x: Suspend state.	R
b7	VBSTS	VBUS Input Status Flag	0: USBHS_VBUS pin is low 1: USBHS_VBUS pin is high.	R
b8	BRDY	BRDY Interrupt Status Flag	0: No BRDY interrupt occurred 1: BRDY interrupt occurred.	R
b9	NRDY	NRDY Interrupt Status Flag	0: No NRDY interrupt occurred 1: NRDY interrupt occurred.	R
b10	BEMP	BEMP Interrupt Status Flag	0: No BEMP interrupt occurred 1: BEMP interrupt occurred.	R
b11	CTRT	Control Transfer Stage Transition Interrupt Status Flag*2	0: No control transfer stage transition interrupt occurred 1: Control transfer stage transition interrupt occurred.	R/(W) *3
b12	DVST	Device State Transition Interrupt Status Flag*2	0: No device state transition interrupt occurred 1: Device state transition interrupt occurred.	R/(W) *3
b13	SOFR	Frame Number Refresh Interrupt Status Flag	0: No SOF interrupt occurred 1: SOF interrupt occurred.	R/(W) *3

Bit	Symbol	Bit name	Description	R/W
b14	RESM	Resume Interrupt Status Flag*2, *4	0: No resume interrupt occurred 1: Resume interrupt occurred.	R/(W) *3
b15	VBINT	VBUS Interrupt Status Flag*4	0: No VBUS interrupt occurred on detecting a change in the USBHS_VBUS pin 1: VBUS interrupt occurred on detecting a change in the USBHS_VBUS pin.	R/(W) *3

x: Don't care

Note 1. The CTSQ[2:0], VALID, and DVSQ[2:0] flags are only valid in device controller mode.

Note 2. The status of the CTRT, DVST, and RESM flags are changed only in device controller mode. Set the associated interrupt enable bits to 0 (disabled) in host controller mode.

Note 3. To clear the CTRT, DVST, SOFR, RESM, or VBINT flags, write 0 only to the flags to be cleared. Write 1 to the other flags. Do not write 0 to the status flags indicating 0.

Note 4. The USBHS detects a change in the status in the RESM or VBINT flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software.

BRDY flag (BRDY Interrupt Status Flag)

The BRDY flag indicates the BRDY interrupt state. For the conditions that cause the flag to be set, see section 33.2.13, BRDY Interrupt Enable Register (BRDYENB).

The USBHS clears the BRDY flag to 0 when 0 is written to the BRDYSTS.PIPEBRDYn (n = 0 to 9) flags for all pipes for which the BRDY interrupt is enabled (BRDYENB.PIPEBRDYEn bits). Writing 0 to the BRDY flag in the software does not clear the flag.

NRDY flag (NRDY Interrupt Status Flag)

The NRDY flag indicates the NRDY interrupt state. For the conditions that cause the flag to be set, see section 33.2.14, NRDY Interrupt Enable Register (NRDYENB).

The USBHS clears the NRDY flag to 0 when 0 is written to the NRDYSTS.PIPENRDYn (n = 0 to 9) flags for all pipes for which the NRDY interrupt is enabled (NRDYENB.PIPENRDYEn bits). Writing 0 to the NRDY flag in the software does not clear the flag.

BEMP flag (BEMP Interrupt Status Flag)

The BEMP indicates the BEMP interrupt state. For the conditions that cause the flag to be set, see section 33.2.15, BEMP Interrupt Enable Register (BEMPENB).

The USBHS clears the BEMP flag to 0 when 0 is written to the BEMPSTS.PIPEBEMPn (n = 0 to 9) flags for all pipes for which the BEMP interrupt is enabled (BEMPENB.PIPEBEMPEn bits). Writing 0 to the BEMP flag in the software does not clear the flag.

CTRT flag (Control Transfer Stage Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the CTSQ[2:0] bits and sets the CTRT flag to 1 on detecting a transition in the control transfer stage. When a control transfer stage transition interrupt occurs, clear the CTRT flag before the USBHS detects the next control transfer stage transition.

Values read from the CTRT flag in host controller mode are invalid.

DVST flag (Device State Transition Interrupt Status Flag)

In device controller mode, the USBHS updates the value of the PL1CTRL1.DVSQ[3:0] bits and sets the DVST flag to 1 on detecting a change in the device state. When a device state transition interrupt occurs, clear the DVST flag before the USBHS detects the next device state transition.

Values read from the DVST flag in host controller mode are invalid.

SOFR flag (Frame Number Refresh Interrupt Status Flag)

In host controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number when the DVSTCTR0.UACT bit is set to 1 by software. An SOFR interrupt is detected every 1 ms.

In device controller mode, the USBHS sets the SOFR flag to 1 on updating the frame number. An SOFR interrupt is detected every 1 ms. The USBHS can detect an SOFR interrupt through the SOF complementation function even when a corrupted SOF packet is received from the USB host. See section 33.3.13, SOF Complementation Function.

RESM flag (Resume Interrupt Status Flag)

In device controller mode, the USBHS sets the RESM flag to 1 on detecting the falling edge of the signal on the USBHS_DP pin in the Suspend state (PL1CTRL1.DVSQ[3:0] = 01xxb).

Values read from the RESM flag in host controller mode are invalid.

VBINT flag (VBUS Interrupt Status Flag)

The USBHS sets the VBINT flag to 1 on detecting a level change (high to low or low to high) in the USBHS_VBUS pin input value. The USBHS sets the VBSTS flag to indicate the USBHS_VBUS pin input value. When a VBINT interrupt occurs, eliminate transient elements by reading the VBSTS flag at least three times through software processing and check that the values read are the same.

33.2.19 Interrupt Status Register 1 (INTSTS1)

Address(es): USBHS.INTSTS1 4006 0042h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRCR	BCHG	—	DTCH	ATTCH	—	L1RSMEND	LPMEND	—	EOFERR	SIGN	SACK	—	—	—	PDDETINT
Value after reset:	0	0	x	0	0	x	0	0	x	0	0	0	x	x	x	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	PDDETINT	PDDET Detection Interrupt Status Flag*1	0: No PDDET interrupt occurred 1: PDDET interrupt occurred.	R/(W) *2
b3 to b1	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b4	SACK	Setup Transaction Normal Response Interrupt Status Flag	0: No SACK interrupt occurred 1: SACK interrupt occurred.	R/(W) *2
b5	SIGN	Setup Transaction Error Interrupt Status Flag	0: No SIGN interrupt occurred 1: SIGN interrupt occurred.	R/(W) *2
b6	EOFERR	EOF Error Detection Interrupt Status Flag	0: No EOFERR interrupt occurred 1: EOFERR interrupt occurred.	R/(W) *2
b7	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b8	LPMEND	LPM Transaction End Interrupt Status Flag	0: No LPMEND interrupt occurred 1: LPMEND interrupt occurred.	R/(W) *2
b9	L1RSMEND	L1 Resume End Interrupt Status Flag	0: No L1RSMEND interrupt occurred 1: L1RSMEND interrupt occurred.	R/(W) *2
b10	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b11	ATTCH	USB Connection Detection Interrupt Status Flag	0: No ATTCH interrupt occurred 1: ATTCH interrupt occurred.	R/(W) *2
b12	DTCH	USB Disconnection Detection Interrupt Status Flag	0: No DTCH interrupt occurred. 1: DTCH interrupt occurred	R/(W) *2
b13	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b14	BCHG	USB Bus Change Interrupt Status Flag*1	0: No BCHG interrupt occurred 1: BCHG interrupt occurred.	R/(W) *2
b15	OVRCR	OVRCR Interrupt Status Flag*1	0: No OVRCR interrupt occurred 1: OVRCR interrupt occurred.	R/(W) *2

Note: Only enable the status change interrupts indicated in the flags in INTSTS1 in host controller mode, except for the PDDET detection interrupt.

Note 1. The USBHS detects a change in the status in the PDDETINT, BCHG, or OVRCR flag even while the clock supply is stopped (LPSTS.SUSPENDM = 0), and it requests the interrupt when the associated interrupt request bit is 1. Enable the clock supply before clearing the status by software. No other interrupts can be detected while the clock supply is stopped (LPSTS.SUSPENDM = 0).

Note 2. To clear the flags in INTSTS1, write 0 only to the flags to be cleared. Write 1 to the other bits.

PDDETINT flag (PDDET Detection Interrupt Status Flag*[1])

The USBHS sets the PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value. When the PDDETINT interrupt is generated, perform debouncing by reading the PDDETSTS flag at least three times through software processing and checking that the values read are the same.

SACK flag (Setup Transaction Normal Response Interrupt Status Flag)

The SACK flag indicates the status of the setup transaction normal response interrupt in host controller mode.

The USBHS detects the SACK interrupt and sets this bit to 1 when an ACK response is returned from a peripheral device during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

Values read from the SACK flag in device controller mode are invalid.

SIGN flag (Setup Transaction Error Interrupt Status Flag)

The SIGN flag indicates the status of setup transaction error interrupts in host controller mode.

The USBHS detects the SIGN interrupt and sets this bit to 1 when an ACK response is not returned from a peripheral device three consecutive times during the setup transactions issued by the USBHS. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the SIGN interrupt when any of the following response conditions occur for three consecutive setup transactions:

- Timeout is detected by the USBHS when the peripheral device has returned no response
- A corrupted ACK packet is received
- A handshake other than ACK (NAK, NYET, or STALL) is received.

Values read from the SIGN flag in device controller mode are invalid.

EOFERR flag (EOF Error Detection Interrupt Status Flag)

The EOFERR flag indicates the status of EOF error detection interrupts in host controller mode.

The USBHS detects the EOFERR interrupt and sets this bit to 1 on detecting that communication did not complete at the EOF2 timing defined in the USB 2.0 specification. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

After detecting the EOFERR interrupt, the USBHS controls the hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt was detected to 0
- Puts the port in which the EOFERR interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and re-enumerate the USB port.

Values read from the EOFERR flag in device controller mode are invalid.

LPMEND flag (LPM Transaction End Interrupt Status Flag)

The PLPMEND flag indicates the status of LPM transaction end interrupts in host controller mode.

When the HL1CTRL1.L1REQ bit sets to 1, the USBHS sends an LPM token. When the LPM transaction is ended because a response from the function device or a timeout is detected, the USBHS sets this flag to 1.

Values read from the LPMEND flag in device controller mode are invalid.

L1RSMEND flag (L1 Resume End Interrupt Status Flag)

The L1RSMEND flag indicates the status of L1 resume end interrupts in host controller mode.

When performing resume processing after transitioning to the L1 state because an ACK was received in response to an LPM token, the USBHS sets this flag to 1.

Values read from the L1RSMEND flag in device controller mode are invalid.

ATTCH flag (USB Connection Detection Interrupt Status Flag)

The ATTCH flag indicates the status of USB attach detection interrupts in host controller mode.

The USBHS detects the ATTCH interrupt and sets this bit to 1 on detecting a J- or K-state on the full- or low-speed signal level for 2.5 µs. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects the ATTCH interrupt on any of the following conditions:

- K-state, SE0, or SE1 changes to J-state, and J-state continues for 2.5 µs
- J-state, SE0, or SE1 changes to K-state, and K-state continues for 2.5 µs.

Values read from the ATTCH flag in device controller mode are invalid.

DTCH flag (USB Disconnection Detection Interrupt Status Flag)

The DTCH flag indicates the status of USB detach detection interrupts in host controller mode.

The USBHS detects the DTCH interrupt and sets this bit to 1 on detecting a USB bus detach event. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS detects bus detach events based on the USB 2.0 specification.

After detecting the DTCH interrupt, the USBHS controls hardware as follows, regardless of the associated interrupt enable bit setting:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt was detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

The software must terminate all pipes in which communications are being carried out and invoke the wait state for attaching to the USB port (waiting for ATTCH interrupt generation).

Values read from the DTCH flag in device controller mode are invalid.

BCHG flag (USB Bus Change Interrupt Status Flag*1)

The BCHG flag indicates the status of USB bus change interrupts in host controller mode.

The USBHS detects the BCHG interrupt and sets this bit to 1 when a change in the full-speed signal level occurs on the USB port. This includes any change from J-state, K-state, or SE0 to J-state, K-state, or SE0. If the associated interrupt enable bit is set to 1 by software, the USBHS generates the interrupt.

The USBHS sets the SYSSTS0.LNST[1:0] flags to indicate the input state of the USB port. When a BCHG interrupt occurs, eliminate transient elements by repeat reading the LNST[1:0] bits by software until the same value is read at least three times.

Changes in the USB bus state can be detected while the PHY clock is stopped.

Values read from the BCHG flag in device controller mode are invalid.

OVRCR flag (OVRCR Interrupt Status Flag*1)

The OVRCR flag indicates the input status on the USBHS_OVCUR0A pin or changes on the USBHS_OVCUR0B pin. If the INTENB1.OVRCRE bit sets to 1, the USBHS requests the interrupt.

The USBHS sets the SYSSTS0.OVCMON[1:0] flags to indicate the input state of the USBHS_OVCUR0A and USBHS_OVCUR0B pins.

These pins allow overcurrent detection by software in host controller mode. To implement this function, connect the overcurrent signal from the external power supply IC that supplies VBUS to connected USB devices to the OVCUR0A or OVCUR0B pin. On detection of an OVRCR interrupt, eliminate transients by repeatedly reading the OVCMON[1:0] flags through the software until the same value is read at least three times.

33.2.20 BRDY Interrupt Status Register (BRDYSTS)

Address(es): USBHS.BRDYSTS 4006 0046h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPEBRDY[9:0]	BRDY Interrupt Status Flag for Pipe[9:0]*1	0: No BRDY interrupt occurred 1: BRDY interrupt occurred.	R/(W)*2
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.

Note 2. When the SOFCFG.BRDYM bit is set to 0, to clear the status indicated in the PIPEBRDY[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.
When the SOFCFG.BRDYM bit is set to 0, clear BRDY interrupts before accessing the FIFO.

PIPEBRDY[9:0] flags (BRDY Interrupt Status Flag for Pipe[9:0])

When the BRDY interrupt is detected, the USBHS sets the associated bit in the PIPEBRDY[9:0] flags to 1. For details on BRDY interrupts, see section 33.3.6.1, BRDY interrupt.

33.2.21 NRDY Interrupt Status Register (NRDYSTS)

Address(es): USBHS.NRDYSTS 4006 0048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPENRDY[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPENRDY[9:0]	NRDY Interrupt Status Flag for Pipe[9:0]*1	0: No NRDY interrupt occurred 1: NRDY interrupt occurred.	R/(W)*2
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.

Note 2. To clear the status indicated in the PIPENRDY[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPENRDY[9:0] flags (NRDY Interrupt Status Flag for Pipe[9:0])

If an internal NRDY interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPENRDY[9:0] flags to 1. For details on NRDY interrupts, see section 33.3.6.2, NRDY interrupt.

33.2.22 BEMP Interrupt Status Register (BEMPSTS)

Address(es): USBHS.BEMPSTS 4006 004Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMP[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	PIPEBEMP[9:0]	BEMP Interrupt Status Flag for Pipe[9:0]*1	0: No BEMP interrupt occurred 1: BEMP interrupt occurred.	R/(W) *2
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Each bit number corresponds to the same pipe number.
Note 2. To clear the status indicated in the PIPEBEMP[9:0] flags, write 0 only to the bits to be cleared. Write 1 to the other bits.

PIPEBEMP[9:0] flags (BEMP Interrupt Status Flag for Pipe[9:0])

If an BEMP interrupt is detected while the PID[1:0] bits in a pipe control register are 01b (BUF response), the USBHS sets the associated bit in the PIPEBEMP[9:0] flags to 1. For details on BEMP interrupts, see section 33.3.6.3, BEMP interrupt.

33.2.23 Frame Number Register (FRMNUM)

Address(es): USBHS.FRMNUM 4006 004Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after reset:	0	0	x	x	x	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b10 to b0	FRNM[10:0]	Frame Number Flag	Latest frame number	R
b13 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	CRCE	CRC Error Detection Status Flag	0: No error occurred 1: Error occurred.	R/(W)
b15	OVRN	Overrun/Underrun Detection Status Flag	0: No error occurred 1: Error occurred.	R/(W)

Note: The OVRN flag is for debugging. Design the timing so that no overrun or underrun occurs in the system.

FRNM[10:0] flags (Frame Number Flag)

The USBHS sets the FRNM[10:0] flags to indicate the latest frame number, which is updated every 1 ms, when an SOF packet is issued or received.

CRCE flag (CRC Error Detection Status Flag)

The CRCE flag sets to 1 when a CRC error or bit stuffing error occurs during isochronous transfer. On detecting a CRC error, the USBHS generates an internal NRDY interrupt.

To clear the CRCE flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

OVRN flag (Overrun/Underrun Detection Status Flag)

The OVRN flag sets to 1 when an overrun or underrun error occurs during isochronous transfer. To clear the flag, write 0 to it while writing 1 to the other bits in the FRMNUM register.

In host controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the time to issue an OUT token comes before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the time to issue an IN token comes when no FIFO buffer planes are empty.

In device controller mode, the OVRN flag sets to 1 on any of the following conditions:

- For a transmitting isochronous pipe, the IN token is received before all of the transmit data is written to the FIFO buffer
- For a receiving isochronous pipe, the OUT token is received when no FIFO buffer planes are empty.

33.2.24 µFrame Number Register (UFRMNUM)

Address(es): USBHS.UFRMNUM 4006 004Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DVCHG	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Value after reset:	0	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b2 to b0	UFRNM[2:0]	Microframe Number	Microframe number	R
b14 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	DVCHG	Device State Change	0: Disable writes to the USBADDR.STSRECOV0[2:0] and USBADDR.USBADDR[6:0] bits 1: Enable writes to the USBADDR.STSRECOV0[2:0] and USBADDR.USBADDR[6:0] bits.	R/W

UFRNM[2:0] flags (Microframe Number)

The USBHS sets the UFRNM[2:0] flags to indicate the microframe number during high-speed operation. When not in high-speed operation, the USBHS sets these bits to 00h.

Read these bits repeatedly until the same value is read twice.

33.2.25 USB Address Register (USBADDR)

Address(es): USBHS.USBADDR 4006 0050h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	STSRECOV0[2:0]			—	USBADDR[6:0]						
Value after reset:	x	x	x	x	x	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b6 to b0	USBADDR[6:0]	USB Address Flag	In device controller mode, these flags indicate the USB address assigned by the host when the USBHS processed the SET_ADDRESS request successfully.	R
b7	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b10 to b8	STSRECOV0[2:0]	Status Recovery	• Recovery in device controller mode b10 b8 0 0 1:Return to the full-speed connection and Default state 0 1 0:Return to the full-speed connection and Address state 0 1 1:Return to the full-speed connection and Configured state 1 0 0:Return to the suspend connection and Suspend state 1 0 1:Return to the high-speed connection and Default state 1 1 0:Return to the high-speed connection and Address state 1 1 1:Return to the high-speed connection and Configured state. Other settings are prohibited. • Recovery in host controller mode b10 b8 0 1 0:Return to the low-speed state (bits DVSTCTR0.RHST[2:0] = 001b) 1 0 0:Return to the full-speed state (bits DVSTCTR0.RHST[2:0] = 010b) 1 1 0:Return to the high-speed state (bits DVSTCTR0.RHST[2:0] = 011b). Other settings are prohibited.	R/W
b15 to b11	—	Reserved	The read value is undefined. The write value should be 0.	R/W

USBADDR[6:0] flags (USB Address Flag)

In device controller mode, the USBADDR[6:0] flags indicate the USB address received when the USBHS processed a SetAddress request successfully. The USBHS sets the USBADDR[6:0] bits to 00h on detecting a USB bus reset.

In host controller mode, the USBADDR[6:0] bits are invalid.

STSRECOV0[2:0] bits (Status Recovery)

Use the STSRECOV[3:0] bits to resume the state of the internal sequencer on recovering from USB power shut-off. For details, see section 33.3.17, Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts.

Writing to these bits is enabled while the DVCHGR.DVCHG bit is set to 1.

33.2.26 USB Request Type Register (USBREQ)

Address(es): USBHS.USBREQ 4006 0054h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BREQUEST[7:0]								BMREQUESTTYPE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	BMREQUESTTYPE[7:0]	Request Type	USB request bmRequestType value	R/W*1
b15 to b8	BREQUEST[7:0]	Request	USB request bRequest value	R/W*1

Note 1. In device controller mode, these bits can be read, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

BMREQUESTTYPE[7:0] bits (Request Type)

The BMREQUESTTYPE[7:0] bits hold the bmRequestType value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

BREQUEST[7:0] bits (Request)

The BREQUEST[7:0] bits hold the bRequest value of USB requests.

- In host controller mode:
  Set these bits to the value of the USB request data in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the value of the USB request data in reception setup transactions. Writing to the bits has no effect.

33.2.27 USB Request Value Register (USBVAL)

Address(es): USBHS.USBVAL 4006 0056h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WVALUE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	WVALUE[15:0]	Value	USB request wValue value	R/W*1

Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WVALUE[15:0] bits (Value)

The WVALUE[15:0] bits hold the wValue value of USB requests.

- In host controller mode:
  Set these bits to the wValue value for USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the wValue value of USB requests in reception setup transactions. Writing to the bits has no effect.

33.2.28 USB Request Index Register (USBINDX)

Address(es): USBHS.USBINDX 4006 0058h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WINDEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	WINDEX[15:0]	Index	USB request wIndex value	R/W*1

Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WINDEX[15:0] bits (Index)

The WINDEX[15:0] bits hold the wIndex value of USB requests.

- In host controller mode:
  Set these bits to the wIndex value of USB requests in transmission setup transactions. Do not change the value of

the bits while the DCPCTR.SUREQ bit is 1.

- In device controller mode:
  These bits indicate the wIndex value of USB requests received in reception setup transactions. Writing to the bits has no effect.

33.2.29 USB Request Length Register (USBLENG)

Address(es): USBHS.USBLENG 4006 005Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WLENTUH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	WLENTUH[15:0]	Length	USB request wLength value	R/W*1

Note 1. In device controller mode, these bits are readable, but writing to them has no effect. In host controller mode, these bits are both read/write bits.

WLENTUH[15:0] bits (Length)

The WLENTUH[15:0] bits hold the wLength value of USB requests.

- In host controller mode:
  Set the wLength value of USB requests in transmission setup transactions. Do not change the value of the bits while the DCPCTR.SUREQ bit is 1.
- In device controller mode:
  These bits indicate the wLength value of USB requests in reception setup transactions. Writing to the bits has no effect.

33.2.30 DCP Configuration Register (DCPCFG)

Address(es): USBHS.DCPCFG 4006 005Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CNTMD	SHTNAK	—	—	DIR	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	0	0	x	x	0	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DIR	Transfer Direction	0: Data receiving direction 1: Data transmitting direction.	R/W
b6, b5	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b7	SHTNAK	Pipe Blocking on End of Transfer	0: Keep pipe open after transfer ends 1: Disable pipe after transfer ends.	R/W
b8	CNTMD	Continuous Transfer Mode	0: Non-continuous transfer mode 1: Continuous transfer mode.	R/W
b15 to b9	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note 1. Only set the bits in this register while the PID is NAK. Before setting the bits, check that the DCPCTR.PBUSY bit is 0, and then change the DCPCTR.PID[1:0] bits for the DCP from BUF to NAK. If the PID[1:0] bits are changed to NAK by the USBHS, checking the PBUSY bit through software is not necessary.

DIR bit (Transfer Direction)

In host controller mode, the DIR bit sets the transfer direction of the data stage and status stage for control transfers. In device controller mode, set the DIR bit to 0.

SHTNAK bit (Pipe Blocking on End of Transfer)

The SHTNAK bit specifies whether to change PID to NAK on transfer end when the selected pipe is receiving. It is only valid when the selected pipe is receiving.

When the SHTNAK bit is 1, the USBHS changes the DCPCTR.PID[1:0] bits for the DCP to NAK on determining that a transfer has ended. The USBHS determines transfer end on the following condition:

- A short packet, including a zero-length packet, is successfully received.

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit indicates whether transfer through the default control pipe is in continuous transfer mode.

33.2.31 DCP Maximum Packet Size Register (DCPMAXP)

Address(es): USBHS.DCPMAXP 4006 005Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	—	—	—	—	MXPS[6:0]						
Value after reset:	0	0	0	0	x	x	x	x	x	1	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b6 to b0	MXPS[6:0]	Maximum Packet Size*1	Maximum data payload specification (maximum packet size) for the DCP	R/W
b11 to b7	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0]	Device Select*2	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b 0 0 1 0: Address 0010b 0 0 1 1: Address 0011b 0 1 0 0: Address 0100b 0 1 0 1: Address 0101b 0 1 1 0: Address 0110b 0 1 1 1: Address 0111b 1 0 0 0: Address 1000b 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b Other settings are prohibited.	R/W

Note 1. Only set the MXPS[6:0] bits while PID is NAK. Before setting this bit, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the CFIFOSEL.CURPIPE[3:0] bits to 0000b. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary. After the MXPS[6:0] bits are set and the DCP is set to the CURPIPE[3:0] bits in a port select register, clear the buffer by setting the BCLR bit the port control register to 1.

Note 2. Only set the DEVSEL[3:0] bits while PID is NAK and the DCPCTR.SUREQ bits are 0. Before setting these bits, check that the CSSTS and PBUSY flags are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK), and the DCPCTR.SUREQ[3:0] bits to 0. If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through software is not necessary.

MXPS[6:0] bits (Maximum Packet Size)

The MXPS[6:0] bits specify the maximum data payload (maximum packet size) for the DCP. The initial value is 40h (64 bytes). Set the bits to a USB 2.0-compliant value. Do not write to the FIFO buffer or set PID = BUF while MXPS[6:0] is set to 0.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target peripheral device for a control transfer. Set up the device address in the associated DEVADDm (m = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

33.2.32 DCP Control Register (DCPCTR)

Address(es): USBHS.DCPCTR 4006 0060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	SUREQ	CSCLR	CSSTS	SUREQCLR	—	—	SQCLR	SQSET	SQMON	PBUSY	PINGE	—	CCPL	PID[1:0]	
Value after reset:	0	0	0	0	x	x	x	0	0	1	0	0	x	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b1, b0	PID[1:0]	Response PID	b1 b0 0 0: NAK response 0 1: BUF response (depends on buffer state) 1 0: STALL response 1 1: STALL response.	R/W
b2	CCPL	Control Transfer End Enable	0: Disable control transfer completion 1: Enable control transfer completion.	R/W
b3	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b4	PINGE	PING Token Issue Enable*1	0: Disable PING token 1: Enable normal PING operation.	R/W
b5	PBUSY	Pipe Busy Flag	0: DCP not used for the USB bus 1: DCP in use for the USB bus.	R
b6	SQMON	Sequence Toggle Bit Monitor Flag	0: DATA0 1: DATA1.	R
b7	SQSET	Sequence Toggle Bit Set*1	Sets the sequence toggle bit in DCP transfers. 0: Invalid (writing 0 has no effect) 1: Set the expected value for the next transaction to DATA1. This bit is read as 0.	R/W
b8	SQCLR	Sequence Toggle Bit Clear*1	Clears the sequence toggle bit in DCP transfers. 0: Invalid (writing 0 has no effect) 1: Clear the expected value for the next transaction to DATA0. This bit is read as 0.	R/W
b10, b9	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b11	SUREQCLR	SUREQ Bit Clear	Clears the SUREQ bit in host controller mode. 0: Invalid (writing 0 has no effect) 1: Clear SUREQ to 0. This bit is read as 0.	R/W
b12	CSSTS	CSSTS Status Flag	0: Start-split (SSPLIT) transaction, or processing for devices that are not using split transactions, in progress. 1: Complete-split (CSPLIT) transaction in progress.	R
b13	CSCLR	CSSTS Status Flag Clear	Clears the CSSTS flag in host controller mode for split transactions, resuming the next DCP transfer from SSPLIT. 0: Invalid (writing 0 has no effect) 1: Clear CSSTS to 0. This bit is read as 0.	R/W
b14	SUREQ	SETUP Token Transmission	Sets up token transmission in host controller mode. 0: Invalid (writing 0 has no effect) 1: Transmit setup packet.	R/W
b15	BSTS	Buffer Status Flag	0: Buffer access disabled 1: Buffer access enabled.	R

Note 1. Only set the SQSET, SQCLR, and PINGE bits while PID is NAK. Before setting these bits, check that the CSSTS and PBUSY bits are 0, and then change the DCPCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the DCPCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY bits through the software is not necessary.

PID[1:0] bits (Response PID)

The PID[1:0] bits control the USB response type during control transfers.

In host controller mode, to change the PID[1:0] setting from NAK to BUF:

- When the transmitting direction is set:
  a. Write all of the transmit data to the FIFO buffer while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  b. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the OUT transaction (or PING transaction).
- When the receiving direction is set:
  c. Check that the FIFO buffer is empty (or empty the buffer) while the DVSTCTR0.UACT bit is 1 and PID is NAK.
  d. Set PID[1:0] bits to 01b (BUF).
  The USBHS then executes the IN transaction.

The USBHS changes the PID[1:0] setting as follows:

- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- When a reception error, such as a CRC error, is detected three times consecutively, the USBHS sets PID[1:0] to NAK (00b)
- On receiving the STALL handshake, the USBHS sets PID[1:0] to STALL (11b).

In device controller mode, the USBHS changes the PID[1:0] setting as follows:

- On receiving a setup packet, the USBHS sets PID[1:0] to NAK (00b). The USBHS then sets the INTSTS0.VALID flag to 1, and the PID[1:0] setting cannot be changed until the software clears the VALID flag to 0.
- When the PID[1:0] bits are set to BUF (01b) by software and the USBHS has received data exceeding MaxPacketSize, the USBHS sets PID[1:0] to STALL (11b)
- On detecting a control transfer sequence error, the USBHS sets PID[1:0] to STALL (1xb)
- On detecting a USB bus reset, the USBHS sets PID[1:0] to NAK.

The USBHS does not check the PID[1:0] setting while processing a SET_ADDRESS request.

CCPL bit (Control Transfer End Enable)

In device controller mode, setting the CCPL bit to 1 enables the status stage of the control transfer to be completed. When the bit is set to 1 by software while the associated PID[1:0] bits are set to BUF, the USBHS completes the control transfer status stage.

During control read transfers, the USBHS transmits the ACK handshake in response to the OUT transaction from the USB host. During control write or no-data control transfers, it transmits the zero-length packet in response to the IN transaction from the USB host. On detecting a SET_ADDRESS request, the USBHS operates in auto response mode from the setup stage up to status stage completion regardless of the CCPL bit setting.

The USBHS changes the CCPL bit from 1 to 0 on receiving a new setup packet. The software cannot write 1 to the bit while the INTSTS0.VALID bit is 1. The bit is initialized by a USB bus reset.

In host controller mode, always write 0 to the CCPL bit.

PINGE bit (PING Token Issue Enable)

In host controller mode, when the software sets the PINGE bit to 1, the USBHS issues a PING token for transfer in the transmitting direction, which triggers the transfer to start. If an ACK handshake is detected in the PING transaction, the OUT transaction is executed in the next transaction. If a NAK or NYET handshake is detected in the OUT transaction, the PING transaction is executed in the next transaction.

If the software sets this bit to 0, the USBHS issues no PING token for transfer in the transmitting direction. All transfers in the transmitting direction are executed in the OUT transaction.

PBUSY flag (Pipe Busy Flag)

The PBUSY bit indicates whether DCP is used for the transaction when USBHS changes the PID[1:0] bits from BUF to NAK. The USBHS changes the PBUSY flag from 0 to 1 on start of a USB transaction for the selected pipe. It changes the PBUSY flag from 1 to 0 on completion of one transaction.

After PID is set to NAK by software, the value in the PBUSY flag indicates whether changes to pipe settings can proceed.

For details, see section 33.3.7.1, Pipe control register switching procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON bit indicates the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

The USBHS toggles the bit on normal completion of the transaction. It does not toggle the bit, however, when a DATA-PID mismatch occurs during a transfer in the receiving direction.

In device controller mode, the USBHS sets the SQMON bit to 1 (specifies DATA1 as the expected value) on successful reception of the setup packet.

In device controller mode, the USBHS does not reference this bit during IN or OUT transactions at the status stage, and it does not toggle the bit on normal completion.

SQSET bit (Sequence Toggle Bit Set)

The SQSET bit specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SQCLR bit (Sequence Toggle Bit Clear)

The SQCLR bit specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during a DCP transfer. It is read as 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

SUREQCLR bit (SUREQ Bit Clear)

In host controller mode, setting the SUREQCLR bit to 1 clears the SUREQ bit to 0. The bit is read as 0.

If transfer stops while the SUREQ bit is set to 1 in a setup transaction, set the SUREQCLR bit to 1 through software. This is not necessary at the end of a normal setup transaction, because the USBHS automatically clears the SUREQ bit to 0.

Only control the SUREQ bit through the SUREQCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a bus disconnection was detected.

In device controller mode, always write 0 to the SUREQCLR bit.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split state in split transactions for pipes that are not isochronous. The USBHS sets the CSSTS flag to 1 at the beginning of a complete-split transaction and sets the flag back to 0 when it detects transaction completion.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSSTS Status Flag Clear)

In host controller mode, setting the CSCLR bit to 1 clears the CSSTS bit to 0.

Set this bit to 1 through software when forcing the next transfer to restart from start-split in transfers using split transactions. This is not necessary at the end of a successful complete-split transaction in a normal split transaction, because the USBHS automatically clears the CSSTS flag to 0.

Only control the CSSTS flag through the CSCLR bit while the DVSTCTR0.UACT bit is 0. When UACT is 0, communication is halted or no transfer is occurring because a port disconnection was detected. Writing 1 to this bit while the CSSTS flag is 0 has no effect; the flag remains 0.

In device controller mode, always write 0 to this bit.

SUREQ bit (SETUP Token Transmission)

In host controller mode, setting the SUREQ bit to 1 triggers the USBHS to transmit the setup packet. After completing the setup transaction process, the USBHS generates either the SACK or SIGN interrupt and clears the SUREQ bit to 0. The USBHS also clears the SUREQ bit to 0 when the software sets the SUREQCLR bit to 1.

Before setting the SUREQ bit to 1, set the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, and USBLENG appropriately to transmit the wanted USB request in the setup transaction. Also check that the PID[1:0] bits for the DCP are set to NAK. After setting the SUREQ bit to 1, do not change the DCPMAXP.DEVSEL[3:0] bits, USBREQ, USBVAL, USBINDX, or USBLENG until the setup transaction is complete (SUREQ bit = 1). Write 1 to the SUREQ bit only when transmitting the setup token. Otherwise, write 0.

In device controller mode, always write 0 to this bit.

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the status of access to the DCP FIFO buffer. The meaning of this flag varies as follows depending on the CFIFOSEL.ISEL setting:

- When ISEL = 0, the bit indicates whether receive data can be read from the buffer
- When ISEL = 1, the bit indicates whether transmit data can be written to the buffer.

33.2.33 Pipe Window Select Register (PIPESEL)

Address(es): USBHS.PIPESEL 4006 0064h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b3 to b0	PIPESEL[3:0]	Pipe Window Select	b3 b0 0 0 0 0: No pipe selected 0 0 0 1: Pipe 1 0 0 1 0: Pipe 2 0 0 1 1: Pipe 3 0 1 0 0: Pipe 4 0 1 0 1: Pipe 5 0 1 1 0: Pipe 6 0 1 1 1: Pipe 7 1 0 0 0: Pipe 8 1 0 0 1: Pipe 9. Other settings are prohibited.	R/W
b15 to b4	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Set pipes 1 to 9 using the PIPESEL, PIPECFG, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN registers (n = 0 to 9).

After selecting the pipe in the PIPESEL register, pipe functions must be set in the associated PIPECFG, PIPEMAXP, and PIPEPERI registers. PIPEnCTR, PIPEnTRE, and PIPEnTRN can be set independently of the pipe selection in this register.

PIPESEL[3:0] bits (Pipe Window Select)

The PIPESEL[3:0] bits select the pipe number associated with the PIPECFG, PIPEMAXP, and PIPEPERI registers used for data writing and reading. Selecting a pipe number in the PIPESEL[3:0] bits allows writing to and reading from PIPECFG, PIPEMAXP, and PIPEPERI associated with the selected pipe number.

When PIPESEL[3:0] = 0000b, 0 is read from all of the bits in PIPECFG, PIPEMAXP, and PIPEPERI. Writing to these bits has no effect.

33.2.34 Pipe Configuration Register (PIPECFG)

Address(es): USBHS.PIPECFG 4006 0068h

R/W

Note 1. Only set the TYPE[1:0], SHTNAK, and EPNUM[3:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 2. Only set the BFRE, DBLB, and DIR bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 3. To change the BFRE, DBLB, or DIR bit after completing USB communication on the selected pipe, in addition to the constraints described in note 2, write 1 and 0 to the PIPEnCTR.ACLRM bit continuously through software and clear the FIFO buffer assigned to the pipe.

EPNUM[3:0] bit (Endpoint Number)

The EPNUM[3:0] bits specify the endpoint number for the selected pipe. Setting 0000b indicates the pipe not used.

Set these bits so that the combination of the DIR and EPNUM[3:0] settings is different from those for other pipes. (The EPNUM[3:0] bits can be set to 0000b for all pipes.)

DIR bit (Transfer Direction)

The DIR bit specifies the transfer direction for the selected pipe.

When the software sets this bit to 0, the USBHS uses the selected pipe for receiving. When the software sets this bit to 1, the USBHS uses the selected pipe for transmitting.

SHTNAK bit (Pipe Disabled at End of Transfer)

The SHTNAK bit specifies whether to change the PIPEnCTR.PID[1:0] bits to 00b (NAK) at the end of transfer when the selected pipe is set in the receiving direction. The bit is valid for pipes 1 to 5 in the receiving direction.

When the software sets this bit to 1 for a receiving pipe, the USBHS changes the associated PIPEnCTR.PID[1:0] bits to 00b (NAK) on determining the transfer end. The USBHS determines that the transfer has ended on the following conditions:

- Short packet data (including a zero-length packet) was successfully received
- The transaction counter is used and the number of packets specified for the transaction counter were successfully received.

CNTMD bit (Continuous Transfer Mode)

The CNTMD bit specifies whether to operate the selected pipe in continuous transfer mode. The bit is valid for pipes 1 to 5 of the bulk transfer type.

Based on this bit setting, the USBHS determines the completion of transmission or reception for the FIFO buffer allocated to the selected pipe as shown in Table 33.9.

Table 33.9 Relationship between the CNTMD setting and methods for determining completion of FIFO buffer transmission or reception

CNTMD bit setting	Methods for determining readable state and transmittable state
0	Condition for FIFO buffer readable state in receiving direction (DIR = 0): • The USBHS received one packet.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of (1) or (2) of the following is satisfied: (1) Software (or DMAC/DTC) wrote data of the maximum packet size to the FIFO buffer. (2) Software (or DMAC/DTC) wrote data of the short packet size (including 0 bytes) to the FIFO buffer and set the BVAL flag in the port control register to 1.
1	Condition for FIFO buffer readable state in receiving direction (DIR = 0): (1) The byte count of data received in the FIFO buffer allocated to the selected pipe is equal to the allocated byte count ((BUFSIZE + 1) × 64). (2) The USBHS received a short packet, other than a zero-length packet. (3) The USBHS received a zero-length packet when data was already contained in the FIFO buffer allocated to the selected pipe. (4) Software received the number of packets specified for the transaction counter set for the selected pipe.
	Conditions for FIFO buffer transmittable state in transmitting direction (DIR = 1): When one of (1) to (3) of the following is satisfied. (1) The amount of data written by software (or DMAC/DTC) is equal to the size of the FIFO buffer allocated to the selected pipe. (2) The software (or DMAC/DTC) wrote data of smaller size than that of the FIFO buffer allocated to the selected pipe (including 0 bytes) and set the BVAL flag in the port control register to 1. (3) The software (or DMAC/DTC) wrote data of smaller size than that of one FIFO buffer allocated to the selected pipe (including 0 bytes) and asserted the DENDx_N signal on the last write.

DBLB bit (Double Buffer Mode)

The DBLB bit selects either single or double buffer mode for the FIFO buffer used by the selected pipe. The bit is valid for pipes 1 to 5.

When the software sets this bit to 1, the USBHS allocates twice the FIFO buffer size specified in the PIPEBUF.BUFSIZE[5:0] bits for the selected pipe. The FIFO buffer size that the USBHS allocates to the selected pipe is as follows:

$$(\text{BUFSIZE} + 1) \times 64 \times (\text{DBLB} + 1)\ [\text{bytes}]$$

BFRE bit (BRDY Interrupt Operation Specification)

The BFRE bit specifies the BRDY interrupt generation timing from the USBHS to the CPU for the selected pipe.

When the software sets the BFRE bit to 1 and the selected pipe is in the receiving direction, the USBHS detects the transfer completion and generates the BRDY interrupt on reading the packet.

When a BRDY interrupt is generated with this setting, the software must write 1 to the BCLR bit in the port control register. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to the BCLR bit.

When the BFRE bit is set to 1 by software and the selected pipe is in the transmitting direction, the USBHS does not generate the BRDY interrupt. For details, see section 33.3.6.1, BRDY interrupt.

TYPE[1:0] bits (Transfer Type)

The TYPE[1:0] bits specify the transfer type for the pipe selected in the PIPESEL.PIPESEL[3:0] bits. Before setting PID to BUF and starting USB communication on the selected pipe, set the TYPE[1:0] bits to a value other than 00b.

33.2.35 Pipe Buffer Register (PIPEBUF)

Address(es): USBHS.PIPEBUF 4006 006Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Value after reset:	x	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b7 to b0	BUFNMB[7:0]	Buffer Number	Specifies the FIFO buffer number of the selected pipe (04h to 87h).	R/W
b9, b8	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b14 to b10	BUFSIZE[4:0]	Buffer Size	00h: 64 bytes 01h: 128 bytes ... 1Fh: 2 KB.	R/W
b15	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note 1. Only set the bits in the PIPEBUF register while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

BUFNMB[7:0] bits (Buffer Number)

The BUFNMB[7:0] bits specify the first block number of the FIFO buffer to be allocated to the selected pipe.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

$$\text{Block number: BUFNMB to block number: BUFNMB} + (\text{BUFSIZE} + 1) \times (\text{DBLB} + 1) - 1$$

Set a value within the memory size range for these bits (0 [00h] to 8640 [87h] for 8.5 KB), while observing the following conditions:

- 00h is for DCP only
- 04h is for pipe 6 only, but is available for other pipes when pipe 6 is not used. When pipe 6 is selected, writes to these bits are disabled. The USBHS automatically allocates 04h to the BUFNMB bits for pipe 6.
- 05h is for pipe 7 only, but is available for other pipes when pipe 7 is not used. When pipe 7 is selected, writes to these bits are disabled. The USBHS automatically allocates 05h to the BUFNMB bits for pipe 7.
- 06h is for pipe 8 only, but is available for other pipes when pipe 8 is not used. When pipe 8 is selected, writes to these bits are disabled. The USBHS automatically allocates 06h to the BUFNMB bits for pipe 8.
- 07h is for pipe 9 only, but is available for other pipes when pipe 9 is not used. When pipe 9 is selected, writes to these bits are disabled. The USBHS automatically allocates 07h to the BUFNMB bits for pipe 9.

BUFSIZE[4:0] bits (Buffer Size)

The BUFSIZE[4:0] bits specify the FIFO buffer size (number of blocks) to be allocated to the selected pipe. One block is 64 bytes.

When the software sets the DBLB bit to 1, the USBHS allocates twice the FIFO buffer size specified in these bits to the selected pipe. The DBLB = 1 setting is valid for pipes 1 to 5.

The USBHS allocates the FIFO buffer blocks to the selected pipe as follows:

$$(\text{BUFSIZE} + 1) \times 64 \times (\text{DBLB} + 1)\ [\text{bytes}]$$

Set the value within the following range:

- For pipes 1 to 5, set a value from 00h to 1Fh (up to 2 KB)
- For pipes 6 to 9, only set a value of 00h (64 bytes).

33.2.36 Pipe Maximum Packet Size Register (PIPEMAXP)

Address(es): USBHS.PIPEMAXP 4006 006Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DEVSEL[3:0]				—	MXPS[10:0]										
Value after reset:	0	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b10 to b0	MXPS[10:0] *1, *2	Maximum Packet Size	• Pipes 1 and 2 1 byte (001h) to 1024 bytes (400h) • Pipes 3 to 5 8 bytes (008h), 16 bytes (010h), 32 bytes (020h), 64 bytes (040h), 512 bytes (200h) (Bits 2 to 0 not supported.) • Pipes 6 to 9 1 byte (001h) to 64 bytes (040h) (Bits 10 to 7 not supported.)	R/W
b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b15 to b12	DEVSEL[3:0] *3	Device Select	b15 b12 0 0 0 0: Address 0000b 0 0 0 1: Address 0001b ... 1 0 0 1: Address 1001b 1 0 1 0: Address 1010b 1011 to 1111: Reserved.	R/W

Note 1. The initial value of the MXPS[10:0] bits is 00h when no pipe is selected in the PIPESEL.PIPESEL[3:0] bits and 40h when a pipe is selected.

Note 2. Only set the MXPS[10:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the

PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the CSSTS and PBUSY flags through the software is not necessary.

Note 3. Only set the DEVSEL[3:0] bits while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

MXPS[10:0] bits (Maximum Packet Size)

The MXPS[10:0] bits specify the maximum data payload (maximum packet size) for the selected pipe.

Set these bits to the appropriate value for each transfer type based on the USB 2.0 specification. When MXPS[10:0] = 0, do not write to the FIFO buffer or set PID to BUF. These writes have no effect.

To communicate on an isochronous pipe using a split transaction, set the value in the MXPS[10:0] bits to 188 bytes or less.

DEVSEL[3:0] bits (Device Select)

In host controller mode, the DEVSEL[3:0] bits specify the address of the target device for USB communication. Set up the device address in the associated DEVADDm (m = 0 to A) register first, and then set these bits to the corresponding value. To set the DEVSEL[3:0] bits to 0010b, for example, first set the address in the DEVADD2 register.

In device controller mode, set these bits to 0000b.

33.2.37 Pipe Cycle Control Register (PIPEPERI)

Address(es): USBHS.PIPEPERI 4006 006Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Value after reset:	x	x	x	0	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b2 to b0	IITV[2:0]	Interval Error Detection Interval	Specifies the interval error detection timing for the selected pipe as the n-th power of 2 of the frame timing.	R/W
b11 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	IFIS	Isochronous IN Buffer Flush	0: Do not flush buffer 1: Flush buffer.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only set the IITV[2:0] bits while PID is NAK. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

PIPEPERI selects whether the buffer is flushed or not when an interval error occurred during isochronous IN transfers, and sets the interval error detection interval for pipes 1 to 9.

IITV[2:0] bits (Interval Error Detection Interval)

To change the IITV[2:0] bits to another value after they are set and USB communication is performed, set the PIPEnCTR.PID[1:0] bits to 00b (NAK) and then set the PIPEnCTR.ACLRM bit to 1 to initialize the interval timer.

The IITV[2:0] bits are not provided for pipes 3 to 5. Write 000b to bit positions of the IITV[2:0] bits associated with pipes 3 to 5.

IFIS bit (Isochronous IN Buffer Flush)

The IFIS bit specifies whether to flush the buffer when the pipe specified in the PIPESEL.PIPESEL[3:0] bits is used for isochronous IN transfers.

In device controller mode when the selected pipe is for isochronous IN transfers, the USBHS automatically clears the FIFO buffer if the USBHS fails to receive the IN token from the USB host within the interval set in the IITV[2:0] bits in terms of frames.

When double buffering is specified (PIPECFG.DBLB = 1), the USBHS only clears the data in the previously used plane.

The USBHS clears the FIFO buffer on receiving the SOF packet immediately after the frame in which the USBHS expected to receive the IN token. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time the SOF packet is expected to be received by using the internal complementation function.

In host controller mode, set the IITV[2:0] bits to 000b.

Set the IITV[2:0] bits to 000b when the selected pipe is not used for isochronous transfers.

33.2.38 Pipe n Control Register (PIPEnCTR) (n = 1 to 9)

Address(es): USBHS.PIPE1CTR 4006 0070h, USBHS.PIPE2CTR 4006 0072h, USBHS.PIPE3CTR 4006 0074h, USBHS.PIPE4CTR 4006 0076h, USBHS.PIPE5CTR 4006 0078h, USBHS.PIPE6CTR 4006 007Ah, USBHS.PIPE7CTR 4006 007Ch, USBHS.PIPE8CTR 4006 007Eh, USBHS.PIPE9CTR 4006 0080h

b10	ATREPM	Auto Response Mode*1, *3	0: Disable auto response mode 1: Enable auto response mode.	R/W
b11	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b12	CSSTS	CSSTS Status Flag	0: Start-split (SSPLIT) transaction, or processing for devices that are not using split transactions, in progress. 1: Complete-split (CSPLIT) transaction in progress.	R
b13	CSCLR	CSPLIT Status Clear	Clears the CSSTS flag for pipe n. 0: Invalid (writing 0 has no effect) 1: Clear CSSTS to 0.	W
b14	INBUFM	Transmit Buffer Monitor Flag*3	0: No data to be transmitted is in the FIFO buffer 1: Data to be transmitted is in the FIFO buffer.	R
b15	BSTS	Buffer Status Flag	0: Buffer access disabled 1: Buffer access enabled.	R

Note 1. Only set the ATREPM bit while PID is NAK. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 2. Only set the ACLRM bit while PID is NAK and before the pipe is selected in the CURPIPE[3:0] bits in the port select register. Before setting this bit, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

Note 3. The ATREPM bit and the INBUFM flag in the PIPE6CTR to PIPE9CTR registers are reserved. The read value is undefined. The write value must be 0.

PID[1:0] bits (Response PID)

The PID[1:0] bits specify the response type for the next transaction on the selected pipe.

The default PID[1:0] setting is NAK. Change the PID[1:0] setting to BUF to use the associated pipe for USB transfer. Table 33.10 and Table 33.11 show the basic operations of the USBHS (when there are no errors in the communication packets) based on the PID[1:0] bit setting.

After changing the PID[1:0] setting from BUF to NAK through the software during USB communication on the selected pipe, check that the PBUSY bit is 1 to see if USB transfer on the selected pipe has actually entered the NAK state. If the USBHS changes the PID[1:0] bits to NAK, checking the PBUSY bit through the software is not necessary.

The USBHS changes the PIPEnCTR.PID[1:0] setting in the following cases:

- The USBHS sets PID to NAK on recognizing completion of the transfer when the selected pipe is in the receiving direction and the PIPECFG.SHTNAK bit for the selected pipe is set to 1 by software
- The USBHS sets PID to STALL (11b) on receiving a data packet with a payload exceeding the maximum packet size of the selected pipe
- The USBHS sets PID to NAK on detecting a USB bus reset in device controller mode
- The USBHS sets PID to NAK on detecting a reception error, such as a CRC error, three consecutive times in host controller mode
- The USBHS sets PID to STALL (11b) on receiving the STALL handshake in host controller mode.

To specify the response type, set the PID[1:0] bits as follows:

- To transition from NAK (00b) to STALL, set 10b
- To transition from BUF (01b) to STALL, set 11b
- To transition from STALL (11b) to NAK, set 10b and then 00b
- To transition from STALL to BUF, set 00b (NAK) and then 01b (BUF).

Table 33.10 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in host controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Does not depend on the setting	Does not depend on the setting	Does not issue tokens
01b (BUF)	Bulk or Interrupt	Does not depend on the setting	Issues tokens when the DVSTCTR0.UACT bit is 1 and the FIFO buffer associated with the selected pipe is ready for transmission and reception. Does not issue tokens when the DVSTCTR0.UACT bit is 0 or the FIFO buffer associated with the selected pipe is not ready for transmission or reception.
	Isochronous	Does not depend on the setting.	Issues tokens when the DVSTCTR0.UACT bit is 1, regardless of the state of the FIFO buffer associated with the selected pipe. Does not issue tokens when UACT = 0.
10b (STALL) or 11b (STALL)	Does not depend on the setting.	Does not depend on the setting.	Does not issue tokens.

Table 33.11 Operation of the USBHS based on the PIPEnCTR.PID[1:0] setting in device controller mode

PID[1:0] value	Transfer type (TYPE[1:0] value)	Transfer direction (DIR value)	USBHS operation
00b (NAK)	Bulk or Interrupt	Does not depend on the setting	Returns NAK in response to the token from the USB host
	Isochronous	Receiving direction (DIR = 0)	Returns nothing in response to the token from the USB host
		Transmitting direction (DIR = 1)	Transmits a zero-length packet in response to the token from the USB host
01b (BUF)	Bulk	Receiving direction (DIR = 0)	Receives data and returns ACK or NYET in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK. Returns ACK in response to the PING token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Interrupt	Receiving direction (DIR = 0)	Receives data and returns ACK response in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, returns NAK.
	Bulk or Interrupt	Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the FIFO buffer associated with the selected pipe is ready for transmission. Otherwise, returns NAK.
	Isochronous	Receiving direction (DIR = 0)	Receives data in response to the OUT token from the USB host if the FIFO buffer associated with the selected pipe is ready for reception. Otherwise, discards the data.
		Transmitting direction (DIR = 1)	Transmits data in response to the token from the USB host if the associated FIFO buffer is ready for transmission. Otherwise, transmits a zero-length packet.
10b (STALL) or 11b (STALL)	Bulk or Interrupt	Does not depend on the setting.	Returns STALL in response to the token from the USB host
	Isochronous	Does not depend on the setting.	Returns nothing in response to the token from the USB host

PBUSY flag (Pipe Busy Flag)

The PBUSY flag indicates whether the selected pipe is being used for the current transaction.

The USBHS changes the PBUSY bit from 0 to 1 on start of the USB transaction for the selected pipe, and changes the PBUSY bit from 1 to 0 on completion of one transaction.

Reading the PBUSY bit by software after PID is set to NAK allows you to check whether changing the pipe setting is possible. For details, see section 33.3.7.1, Pipe control register switching procedures.

SQMON flag (Sequence Toggle Bit Monitor Flag)

The SQMON flag indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe.

When the selected pipe is not the isochronous transfer type, the USBHS toggles the SQMON flag on successful completion of the transaction. However, the USBHS does not toggle the SQMON flag when a DATA-PID mismatch occurs during transfer in the receiving direction.

SQSET bit (Sequence Toggle Bit Set)

Setting the SQSET bit to 1 through the software causes the USBHS to set DATA1 as the expected value of the sequence toggle bit for the next transaction on the selected pipe.

SQCLR bit (Sequence Toggle Bit Clear)

Setting the SQCLR bit to 1 through the software causes the USBHS to clear the expected value of the sequence toggle bit for the next transaction on the selected pipe to DATA0.

In host controller mode, when this bit is set to 1 for a bulk OUT transfer pipe, the USBHS starts the next transfer for the selected pipe from a PING token.

ACLRM bit (Auto Buffer Clear Mode)

The ACLRM bit enables or disables auto buffer clear mode for the selected pipe. To completely clear the data in the FIFO buffer allocated to the selected pipe, write 1 and then 0 to the ACLRM bit continuously.

Table 33.12 shows the data cleared by writing 1 and 0 continuously to the ACLRM bit and the cases in which this processing is required.

Table 33.12 Data cleared by the USBHS when ACLRM = 1

Number	Data cleared by setting the ACLRM bit	Situations requiring data clear
1	All data in the FIFO buffer allocated to the selected pipe (two FIFO buffers in double buffer mode)	When clearing all data in the FIFO buffer allocated to the selected pipe
2	Interval count value when the selected pipe is the isochronous transfer type	When resetting the interval count value

ATREPM bit (Auto Response Mode)

The ATREPM bit enables or disables auto response mode for the selected pipe.

This bit can be set to 1 in device controller mode when the selected pipe is the bulk transfer type. When the bit is set to 1, the USBHS responds to the token from the USB host as follows:

- When the selected pipe is set for bulk IN transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 1):
  a. When the ATREPM bit = 1 and PID = BUF, the USBHS transmits a zero-length packet in response to the IN token.
  b. The USBHS updates (allows toggling of) the sequence toggle bit (DATA-PID) each time the USBHS receives ACK from the USB host. In a single transaction, the IN token is received, a zero-length packet is transmitted, and then ACK is received. The USBHS does not generate the BRDY or BEMP interrupt.
- When the selected pipe is set for bulk OUT transfers (PIPECFG.TYPE[1:0] = 01b and PIPECFG.DIR = 0):

  When the ATREPM bit = 1 and PID = BUF, the USBHS returns NAK in response to the OUT token or PING token and generates an NRDY interrupt.

For USB communication in auto response mode, set the ATREPM bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode. When the selected pipe uses isochronous transfer, always set this bit to 0.

In host controller mode, always set the ATREPM bit to 0.

CSSTS flag (CSSTS Status Flag)

In host controller mode, the CSSTS flag indicates the complete-split status of a split transaction. It is valid for pipes that are not the isochronous transfer type.

The USBHS sets the CSSTS flag to 1 at the beginning of the complete-split transaction, and sets the CSSTS flag to 0 on detecting completion of the complete-split transaction. If a detach event is detected during the transaction, the CSSTS flag might stay set to 1. In this case, clear the CSSTS flag by setting the CSCLR bit to 1.

Values read from the CSSTS flag in device controller mode are invalid.

CSCLR bit (CSPLIT Status Clear)

In host controller mode, if the software sets the CSCLR bit to 1, the USBHS clears the CSSTS flag to 0. In split transactions, set the CSCLR bit to 1 by software to force the next transfer to restart from start-split. Because the USBHS automatically clears the CSSTS flag to 0 at the end of a successful complete-split transaction in a normal split transaction, clearing the flag through software is not required. Only clear the CSSTS flag using the CSCLR bit when the DVSTCTR0.UACT bit is set to 0 or when no transfer was made after a detach detect. If the CSCLR bit is set to 1 while the CSSTS flag is 0, the CSSTS flag remains 0.

In device controller mode, always write 0 to the CSCLR bit.

INBUFM flag (Transmit Buffer Monitor Flag)

The INBUMFM flag indicates the FIFO buffer status for the selected pipe in the transmitting direction.

When the selected pipe is set in the transmitting direction (PIPECFG.DIR = 1), the USBHS sets this bit to 1 when the CPU or DMA/DTC completes writing data to at least one FIFO buffer plane.

The USBHS sets this bit to 0 when the USBHS completes transmission of data from the FIFO buffer plane to which all the data is written. In double buffer mode (PIPECFG.DBLB = 1), the USBHS sets the INBUFM flag to 0 when the USBHS completes transmission of data from the two FIFO buffer planes before the CPU or DMA/DTC completes writing data to one FIFO buffer plane.

The INBUFM flag indicates the same value as the BSTS flag when the selected pipe is in the receiving direction (PIPECFG.DIR = 0).

BSTS flag (Buffer Status Flag)

The BSTS flag indicates the FIFO buffer status for the selected pipe. The meaning of the BSTS flag depends on the PIPECFG.DIR, PIPECFG.BFRE, and DnFIFOSEL.DCLRM settings, as shown in Table 33.13.

Table 33.13 BSTS flag operation

DIR value	BFRE value	DCLRM value	Meaning of BSTS flag
0	0	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
		1	Setting prohibited
	1	0	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 when the software sets the BCLR bit in the port control register to 1 after the data read is complete
		1	Sets to 1 when receive data can be read from the FIFO buffer, and clears to 0 on completion of data read
1	0	0	Sets to 1 when transmit data can be written to the FIFO buffer, and clears to 0 on completion of data write
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

33.2.39 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5)

Address(es): USBHS.PIPE1TRE 4006 0090h, USBHS.PIPE2TRE 4006 0094h, USBHS.PIPE3TRE 4006 0098h, USBHS.PIPE4TRE 4006 009Ch, USBHS.PIPE5TRE 4006 00A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b7 to b0	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b8	TRCLR	Transaction Counter Clear	0: Invalid (writing 0 has no effect) 1: Clear current counter value.	R/W
b9	TRENB	Transaction Counter Enable	0: Disable transaction counter 1: Enable transaction counter.	R/W
b15 to b10	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note: Only change the PIPEnTRE settings while the PIPEnCTR.CSSTS flag is 0 and the PIPEnCTR.PID[1:0] bits are 00b (NAK response). Only change the PIPEnCTR.PID[1:0] bits of the selected pipe from 01b (BUF response) to 00b (NAK response) after confirming that the value of the PIPEnCTR.PBUSY and PIPEnCTR.CSSTS flags is 0. However, software processing to check the PIPEnCTR.PBUSY flag is not required if the USBHS has changed the PID[1:0] bits to 00b (NAK response).

TRCLR bit (Transaction Counter Clear)

When the TRCLR bit sets to 1, the USBHS clears the count value of the transaction counter associated with the selected pipe and then clears the TRCLR bit to 0.

TRENB bit (Transaction Counter Enable)

The TRENB bit enables or disables the transaction counter.

For receiving pipes, setting the TRENB bit to 1 after setting the total number of the packets to be received in the PIPEnTRN.TRNCNT[15:0] bits through the software allows the USBHS to control hardware on having received the number of packets equal to the TRNCNT[15:0] setting as follows:

- When the PIPECFG.SHTNAK bit is 1, the USBHS changes the PID bits to NAK for the associated pipe on having received the number of packets equal to the TRNCNT[15:0] setting
- When the PIPECFG.BFRE bit is 1, the USBHS asserts the BRDY interrupt on having received the number of packets equal to the TRNCNT[15:0] setting and then reading the last received data.

For transmitting pipes, set the TRENB bit to 0.

When the transaction counter is not used, set this bit to 0. When the transaction counter is used, set the TRNCNT[15:0] bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

33.2.40 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5)

Address(es): USBHS.PIPE1TRN 4006 0092h, USBHS.PIPE2TRN 4006 0096h, USBHS.PIPE3TRN 4006 009Ah, USBHS.PIPE4TRN 4006 009Eh, USBHS.PIPE5TRN 4006 00A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRNCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	TRNCNT[15:0]	Transaction Counter*1	• When written to: Specifies the total packets (number of transactions) to be received by pipe n. • When read from: When PIPEnTRE.TRENB is 0, indicates the specified number of transactions. When PIPEnTRE.TRENB is 1, indicates the current transaction count.	R/W

Note 1. Only set the TRNCNT[15:0] bits while PID is NAK and PIPEnTRE.TRENB is 0. Before setting these bits, check that the PIPEnCTR.CSSTS and PIPEnCTR.PBUSY flags are 0, and then change the PIPEnCTR.PID[1:0] bits from 01b (BUF) to 00b (NAK). If the PIPEnCTR.PID[1:0] bits are changed to 00b (NAK) by the USBHS, checking the PBUSY flag through the software is not necessary.

The PIPEnTRN registers retain their settings during a USB bus reset.

TRNCNT[15:0] bits (Transaction Counter)

The USBHS increments the value of the TRNCNT[15:0] bits by one when all of the following conditions are satisfied on receiving the packet:

- The PIPEnTRE.TRENB bit is 1
- (TRNCNT[15:0] set value ≠ current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

The USBHS clears the value of the TRNCNT[15:0] bits to 0 when any of the following conditions is satisfied.

All of the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- (TRNCNT[15:0] set value = current counter value + 1) on receiving the packet
- The payload of the received packet agrees with the PIPEMAXP.MXPS[8:0] setting.

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The USBHS received a short packet.

Both the following conditions are satisfied:

- The PIPEnTRE.TRENB bit = 1
- The PIPEnTRE.TRCLR bit was set to 1 by software.

For transmitting pipes, set the TRNCNT[15:0] bits to 0. When the transaction counter is not used, set the TRNCNT[15:0] bits to 0.

Setting the number of transactions to be transferred to the TRNCNT[15:0] bits is enabled only when the PIPEnTRE.TRENB bit is 0. To set the number of transactions to be transferred, set the TRCLR bit to 1 to clear the current counter value before setting the PIPEnTRE.TRENB bit to 1.

33.2.41 Device Address m Configuration Register (DEVADDm) (m = 0 to A)

Address(es): USBHS.DEVADD0 4006 00D0h, USBHS.DEVADD1 4006 00D2h, USBHS.DEVADD2 4006 00D4h, USBHS.DEVADD3 4006 00D6h, USBHS.DEVADD4 4006 00D8h, USBHS.DEVADD5 4006 00DAh, USBHS.DEVADD6 4006 00DCh, USBHS.DEVADD7 4006 00DEh, USBHS.DEVADD8 4006 00E0h, USBHS.DEVADD9 4006 00E2h, USBHS.DEVADDA 4006 00E4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	UPPHUB[3:0]				HUBPORT[2:0]			USBSPD[1:0]		—	—	—	—	—	—
Value after reset:	x	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b5 to b0	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b7, b6	USBSPD[1:0]	Transfer Speed of Communication Target Device	b7 b6 0 0: Do not use DEVADDm 0 1: Low speed 1 0: Full speed 1 1: High speed.	R/W
b10 to b8	HUBPORT[2:0]	Communication Target Connecting Hub Port	b10 b8 0 0 0: Connect directly to the USBHS port 001 to 111: Port number of the hub.	R/W
b14 to b11	UPPHUB[3:0]	Communication Target Connecting Hub Register	b14 b11 0 0 0 0: Connect directly to the USBHS port 0001 to 1010: USB address of the hub 1011 to 1111: Reserved.	R/W
b15	—	Reserved	The read value is undefined. The write value should be 0.	R/W

The DEVADDm register specifies the transfer speed of the peripheral device that is the communication target for pipes 0 to 9.

In host controller mode, set all DEVADDm bits before starting communication to any pipes. Only change the bits in DEVADDm when no valid pipes are using the bit settings. A valid pipe is defined as one that satisfies both of the following conditions:

- DEVADDm is selected in the DEVSEL[3:0] bits
- The PID[1:0] bits are set to BUF for the selected pipe, or the selected pipe is the DCP with the DCPCTR.SUREQ bit set to 1.

In device controller mode, set all bits in this register to 0.

USBSPD[1:0] bits (Transfer Speed of Communication Target Device)

The USBSPD[1:0] bits specify the USB transfer speed of the target peripheral device. In host controller mode, the USBHS generates packets based on the USBSPD[1:0] setting. In device controller mode, set these bits to 00b.

HUBPORT[2:0] bits (Communication Target Connecting Hub Port)

In host controller mode, the USBHS generates packets based on the HUBPORT[2:0] setting when performing a split transaction.

UPPHUB[3:0] bits (Communication Target Connecting Hub Register)

In host controller mode, the USBHS generates packets based on the UPPHUB[3:0] setting when performing a split transaction.

33.2.42 Low Power Control Register (LPCTRL)

Address(es): USBHS.LPCTRL 4006 0100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	HWUPM	—	—	—	—	—	—	—

b7	HWUPM	Resume Return Mode Setting	0: Hardware does not recover while CPU clock inactive 1: Hardware recovers while CPU clock inactive.	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b15 to b9	—	Reserved	The read value is undefined. The write value should be 0.	R/W

HWUPM bit (Resume Return Mode Setting)

The HWUPM bit specifies whether to enable hardware processing for return from low power mode even while the CPU clock is inactive.

In device controller mode, processing for return from low power mode on detecting Resume is enabled even while the CPU clock is inactive.

This bit specifies whether to detect Resume while the CPU clock is inactive. The PL1CTRL1.L1EXTMD bit controls whether to make a hardware return. To make a hardware return from the LPM L1 low power state while the CPU clock is inactive, set this bit and the PL1CTRL1.L1EXTMD bit to 1.

33.2.43 Low Power Status Register (LPSTS)

Address(es): USBHS.LPSTS 4006 0102h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	SUSPENDM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	0	x	0	x	x	x	0	x	x	x	x	0	x	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b2	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7 to b4	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11 to b9	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b12	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b13	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b14	SUSPENDM	UTMI SuspendM Control	0: UTMI suspension mode 1: UTMI normal mode.	R/W
b15	—	Reserved	The read value is undefined. The write value should be 0.	R/W

SUSPENDM bit (UTMI SuspendM Control)

The SUSPENDM bit controls the SuspendM signal to be sent to the PHY designed under the UTMI specification. The initial value is 0 with the UTMI is in suspension mode.

Set this bit to 1 to supply the PHY clock to operate the USB2.0 host or device controller.

In compliance with the UTMI specification, clock output is normally controlled by the SuspendM signal. When the SUSPENDM bit is 0, the clock to LINK is stopped. Because the PHY in this MCU follows the UTMI specification, setting the SUSPENDM bit to 1 is required to supply the PHY clock. For the clock settings, see section 33.3.3, Supplying the Clock.

When the SUSPENDM bit is 0, the USBHS cannot be written to but can be read from. The registers listed in Table 33.14 are writable even when the SUSPENDM bit is 0.

Table 33.14 Registers that can be written to by software when SUSPENDM = 0

Address	Register or bit name
4006 0000h	SYSCFG register
4006 0002h	BUSWAIT register
4006 0032h	INTENB1.PDDETINTE bit
4006 0100h	LPCTRL register
4006 0102h	LPSTS register
4006 0140h	BCCTRL register

The value written to the SYSCFG register while the PHY clock is inactive is updated only after the PHY clock begins oscillating. The PHY clock oscillates in the following cases described in this section.

When SUSPENDM bit is set to 1, the PLLSTA.PLLLOCK flag is set to 1 after the predetermined time has passed. The USB-PHY internal PLL is stopped when the SUSPENDM bit is set to 0.

For details on CL-only mode, see section 33.2.17, PHY Setting Register (PHYSET).

If the PL1CTRL1.L1EXTMD bit is 0, setting or clearing of this bit is controlled by software. If the PL1CTRL1.L1EXTMD bit is 1, transitions to the L1 or L2 state of this bit are controlled by software and recovery from the L1 or L2 state is controlled by hardware.

33.2.44 Battery Charging Control Register (BCCTRL)

Address(es): USBHS.BCCTRL 4006 0140h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b9	PDDETSTS	PDDET Status Flag	0: The PDDET pin is at low level. 1: The PDDET pin is at high level.	R
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. All bits in the BCCTRL register can be changed while the UTMI clock is inactive.

Note 2. In device controller mode, set the IDPSRCE, IDMSINKE, VDPSRCE, IDPSINKE, and VDMSRCE bits to 1 after setting the SYSCFG.DRPD bit to 0.

IDPSRCE bit (IDPSRC Control)

In device controller mode, set the IDPSRCE bit to 1 to perform data contact detection.

The Battery Charging Standard provides two ways to handle data contact detection, one through the software and one using hardware to contact the data line. The IDPSRE bit uses the hardware method.

When the IDPSRE bit is set to 1, the USBHS enables the IDP_SRC circuit and, at the same time, controls D- pull-down. (D- pull-down is controlled with the VUH_DMPULLDOWN signal.)

IDMSINKE bit (IDMSINK Control)

In device controller mode, set the IDMSINKE bit to 1 to perform primary detection.

VDPSRCE bit (VDPSRC Control)

In device controller mode, set the VDPSRCE bit to 1 to perform primary detection.

IDPSINKE bit (IDPSINK Control)

In device controller mode, set the IDPSINKE bit to 1 to perform secondary detection. In host controller mode, set this bit to 1 to enable the portable device detection circuit.

VDMSRCE bit (VDMSRC Control)

In device controller mode, set the VDMSRCE bit to 1 to perform secondary detection. Setting this bit to 1 enables the DCP detection circuit. In host controller mode, set this bit to 1 when a portable device is detected. Setting this bit to 1 allows the device that is performing primary detection to determine the charger detection method.

DCPMODE bit (DCP Mode Control)

Set the DCPMODE bit to 1 to operate as a dedicated charging port (DCP). Setting this bit to 1 disables USB communication.

CHGDETSTS flag (CHGDET Status Flag)

The CHGDETSTS flag indicates the charger port detection state.

PDDETSTS flag (PDDET Status Flag)

The PDDETSTS flag indicates the following states based on the controller mode:

- In host controller mode: PD detection state
- In device controller mode: DCP detection state.

33.2.45 Function L1 Control Register 1 (PL1CTRL1)

Address(es): USBHS.PL1CTRL1 4006 0144h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	L1EXTMD	—	—	HIRDTHR[3:0]				DVSQ[3:0]				L1NEGOMD	L1RESPMD[1:0]		L1RESPEN
Value after reset:	x	0	x	x	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	L1RESPEN	L1 Response Enable	0: Do not support LPM 1: Support LPM.	R/W
b2, b1	L1RESPMD[1:0]	L1 Response Mode	b2 b1 0 0: NYET response 0 1: ACK response 1 0: STALL response 1 1: Response based on L1NEGOMD setting.	R/W
b3	L1NEGOMD	L1 Response Negotiation Control	0: Return ACK when received HIRD is larger than HIRDTHR[3:0]. Otherwise (including when HIRD = HIRDTHR[3:0]), return NYET. 1: Return ACK when received HIRD is smaller than HIRDTHR[3:0]. Otherwise (including when HIRD = HIRDTHR[3:0]), return NYET. This bit is only valid when the L1RESPMD[1:0] value is 11b.	R/W
b7 to b4	DVSQ[3:0]	DVSQ Extension Flag	b7 b4 0 0 0 0: Powered state 0 0 0 1: Default state 0 0 1 0: Address state 0 0 1 1: Configured state 0 1 x x: Suspend state 1 0 x x: L1 state.	R
b11 to b8	HIRDTHR[3:0]	L1 Response Negotiation Threshold Value	HIRD threshold value used when the L1RESPMD[1:0] bits are 11b. The format is the same as the HIRD field in HL1CTRL.	R/W
b13, b12	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b14	L1EXTMD	PHY Control Mode at L1 Return	0: Do not set LPSTS.SUSPENDM bit through hardware when Host K is received 1: Set LPSTS.SUSPENDM bit through hardware when Host K is received.	R/W
b15	—	Reserved	The read value is undefined. The write value should be 0.	R/W

L1RESPEN bit (L1 Response Enable)

If the USBHS receives an LPM token while the L1RESPEN bit is 0, it returns no response. If the USBHS receives an

LPM token while this bit is 1, it returns a response based on the L1RESPMD[1:0] setting.

L1RESPMD[1:0] bits (L1 Response Mode)

When the L1RESPEN bit is set to 1, the USBHS returns a response to the LPM token based on the setting in the L1RESPMD[1:0] bits.

L1NEGOMD bit (L1 Response Negotiation Control)

The L1NEGOMD bit specifies the negotiation function for the HIRD value.

HIRDTHR[3:0] bits (L1 Response Negotiation Threshold Value)

The HIRDTHR[3:0] bits specify the HIRD threshold value used for L1NEGOMD. The format of the set value is the same as the HIRD field in HL1CTRL.

L1EXTMD bit (PHY Control Mode at L1 Return)

The L1EXTMD bit specifies the LPSTS.SUSPENDM bit control method when a host K signal is received in the L1 state while the LPSTS.SUSPENDM bit is 0 and the PHY is inactive.

Similar to the Suspend constraints, because the minimum host K period is 50 µs, the PHY might not recover within the host K period specified for software settings on return. The initial value is within software control, so set this bit to 1 during the initialization process when the L1 state is supported.

The LPSTS.SUSPENDM bit is controlled by software on transition to the L1 state regardless of the setting in this bit. It is not cleared by hardware.

When this bit is set to 1, the LPSTS.SUSPENDM bit is also set to 1 on return from L2.

33.2.46 Function L1 Control Register 2 (PL1CTRL2)

Address(es): USBHS.PL1CTRL2 4006 0146h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	RWEMON	HIRDMON[3:0]				—	—	—	—	—	—	—	—
Value after reset:	x	x	x	0	0	0	0	0	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b7 to b0	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b11 to b8	HIRDMON[3:0]	HIRD Value Monitor	When set, indicates that the HIRD field value reflects the last-received LPM token.	R
b12	RWEMON	RWE Value Monitor	When set, indicates that the RWE bit value reflects the last-received LPM token.	R
b15 to b13	—	Reserved	The read value is undefined. The write value should be 0.	R/W

HIRDMON[3:0] bits (HIRD Value Monitor)

Access the HIRDMON[3:0] bits when monitoring the HIRD field value of the received LPM token. The bits reflect the HIRD field value of the last received LPM token.

RWEMON bit (RWE Value Monitor)

Access the RWEMON bit when monitoring the RWE field value of the received LPM token. The bits reflect the RWE field value of the last received LPM token.

33.2.47 Host L1 Control Register 1 (HL1CTRL1)

Address(es): USBHS.HL1CTRL1 4006 0148h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	L1STATUS[1:0]		L1REQ
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	L1REQ	L1 Transition Request	Set this bit to 1 when requesting a transition to the L1 state. This bit is cleared to 0 by the hardware when the LPM transaction is complete.	R/W
b2, b1	L1STATUS [1:0]	L1 Request Completion Status	Indicates the result of the LPM transaction made by the L1REQ bit: b2 b1 0 0: ACK received 0 1: NYET received 1 0: STALL received 1 1: Transaction error.	R
b15 to b3	—	Reserved	The read value is undefined. The write value should be 0.	R/W

L1REQ bit (L1 Transition Request)

Set the L1REQ bit to 1 to transition to the L1 state. When the USBHS detects that this bit is 1, it starts the LPM transaction. The USBHS clears this bit to 0 through hardware on completion of the transaction.

L1STATUS[1:0] bits (L1 Request Completion Status)

The L1STATUS[1:0] bits indicate the result of the LPM transaction initiated by the L1REQ bit.

33.2.48 Host L1 Control Register 2 (HL1CTRL2)

Address(es): USBHS.HL1CTRL2 4006 014Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BESL	—	—	L1RWE	HIRD[3:0]				—	—	—	—	L1ADDR[3:0]			
Value after reset:	0	x	x	0	0	0	0	0	x	x	x	x	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b3 to b0	L1ADDR[3:0]	LPM Token DeviceAddress	Specify the value to be set in the ADDR field of the LPM token	R/W
b7 to b4	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b11 to b8	HIRD[3:0]	LPM Token HIRD	Specify the value to be set in the HIRD field of the LPM token	R/W
b12	L1RWE	LPM Token L1 RemoteWake Enable	Specify the value to be set in the RWE field of the LPM token	R/W
b14, b13	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b15	BESL	BESL & Alternate HIRD	Selects the K-State drive period on L1 Resume	R/W

L1ADDR[3:0] bits (LPM Token DeviceAddress)

The L1ADDR[3:0] bits specify the value to be set in the ADDR field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

HIRD[3:0] bits (LPM Token HIRD)

The HIRD[3:0] bits specify the value to be set in the HIRD field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1. Table 33.15 shows the relationship between the HIRD settings and the HIRD field values.

Table 33.15 Relationship between the HIRD bit settings and the HIRD field values

HIRD[3:0] setting	When BESL = 0	When BESL = 1
0000b	50 µs (setting prohibited)	75 µs
0001b	125 µs	100 µs
0010b	200 µs	150 µs
0011b	275 µs	250 µs
0100b	350 µs	350 µs
0101b	425 µs	450 µs
0110b	500 µs	950 µs
0111b	575 µs	1950 µs
1000b	650 µs	2950 µs
1001b	725 µs	3950 µs
1010b	800 µs	4950 µs
1011b	875 µs	5950 µs
1100b	950 µs	6950 µs
1101b	1025 µs (setting prohibited)	7950 µs
1110b	1100 µs (setting prohibited)	8950 µs
1111b	1175 µs (setting prohibited)	9950 µs

Note: The set value of the HIRD bit is used for the host K drive period on host resume and for the host K period on remote wakeup.

L1RWE bit (LPM Token L1 RemoteWake Enable)

The L1RWE bit specifies the value to be set in the RWE field of the LPM token that the USBHS transmits when the HL1CTRL1.L1REQ bit is set to 1.

The USBHS does not control detection of the remote wakeup signal in the L1 state with this bit. The remote wakeup signal is controlled by the DVSTCTR0.RWUPE bit, as with Suspend.

BESL bit (BESL & Alternate HIRD)

The BESL bit selects the K-state drive period on L1 Resume. For details, see the description of the HIRD bits.

33.2.49 Deep Software Standby USB Transceiver Control/Pin Monitor Register (DPUSR0R)

b1	FIXPHYPD	USB Transceiver Control Fix for PLL	0: Normal mode 1: Invoke/recover from Deep Software Standby mode.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

33.3 Operation

33.3.1 System Control

This section describes register settings required for initializing the USBHS and controlling power consumption.

33.3.1.1 Setting data to the USBHS registers

Setting the SYSCFG.USBE bit to 1 after starting the PHY clock supply enables and starts USBHS operation. For information on how to supply the PHY clock, see section 33.3.3, Supplying the Clock.

33.3.1.2 Selecting the controller function

The USBHS can operate as a host or device controller.

Use the SYSCFG.DCFM bit to select one of these USBHS functions. The DCFM bit must be changed in the initial settings immediately after a reset or in the D+ pull-up-disabled state (SYSCFG.DPRPU bit = 0) and D+ and D- pull-down-disabled state (SYSCFG.DRPD bit = 0).

33.3.2 Controlling the USB data bus using resistors

The USBHS provides pull-up and pull-down resistors for the D+ and D- lines. Pull these lines up or down by setting the SYSCFG.DPRPU and DRPD bits.

In device controller mode, confirm that connection to the USB host is made, and then set the SYSCFG.DPRPU bit to 1 and pull up the D+ line (in full-speed communication).

When the SYSCFG.DPRPU bit is set to 0 during communication with a PC, the USBHS disables the pull-up resistor for the USB data line, thereby notifying the USB host of disconnection.

In host controller mode, set the SYSCFG.DRPD bit to 1 to pull down the D+ and D- lines.

Table 33.16 shows the settings for controlling the resistors for the USB data bus. Control the USB data bus appropriately for your system using the DRPD and DPRPU bit settings.

Table 33.16 Control settings for the USB data bus resistors (excluding OTG operation)

SYSCFG register settings		USB data bus control		
DRPD bit	**DPRPU bit**	**D-Line**	**D+Line**	**Function**
0	0	Open	Open	When resistors not used
0	1	Open	Pull-Up	When operating as a device controller at full-speed
1	0	Pull-Down	Pull-Down	When operating as a host controller
1	1	—	—	Setting prohibited except during OTG operation

33.3.3 Supplying the Clock

Table 33.17 shows the two input clocks required for the USBHS.

Table 33.17 Input clocks

Input clock name	Description
PCLKA	Peripheral module clock A input. There is no constraint on the frequency of the PCLKA input.
PHY clock	PHY clock generated from external input or internal supply • External input: The clock is generated by the USB-PHY internal PLL based on a 12-MHz, 20-MHz, or 24-MHz clock supplied to the EXTAL pin from outside the MCU. For the external clock specifications, especially the jitter characteristics, strictly follow the specifications of ±50 ppm. • Internal supply: The clock is generated by supplying 48 MHz and 60 MHz to the USB-PHY module and selecting CL-only mode (PHYSET.HSEB). High-speed operation is not supported with this mode.

Figure 33.2 illustrates the PHY clock settings.

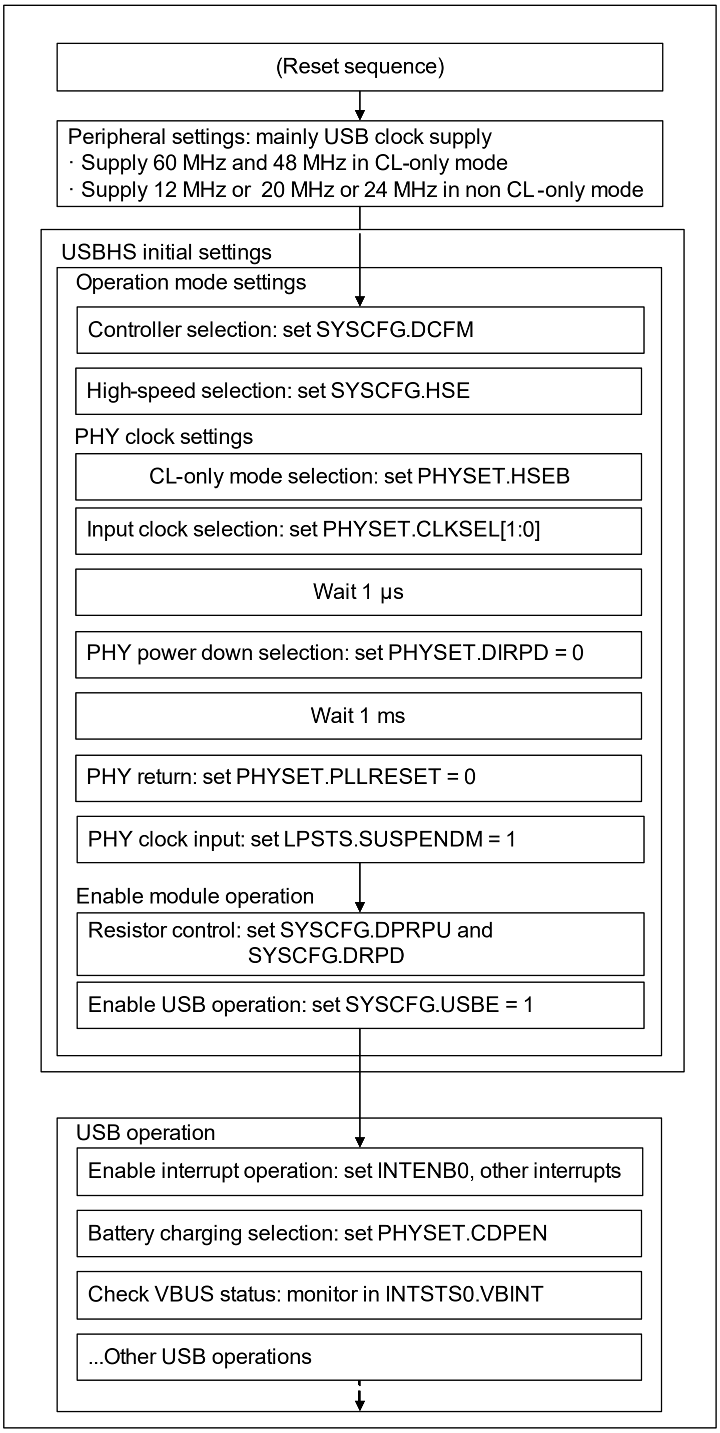

Figure 33.2 PHY clock settings

33.3.4 Constraints on Stopping the Clock

PCLKA and PHY clock can be stopped during disconnection or suspension. However, to stop any of these clocks while the USB is suspended in device controller mode, the stopped clock must be resupplied using the resume interrupt. The PHY clock must be resupplied within 5.5 ms after the resume interrupt is generated.

33.3.5 Interrupts

Table 33.18 lists the interrupt sources in the USBHS. When an interrupt generation condition is satisfied and the interrupt output is enabled using the associated interrupt enable register, the USBHS issues a USBHS interrupt request to the Interrupt Controller Unit (ICU) and a USBHS interrupt is generated.

Table 33.18 Interrupt sources (1 of 2)

Flag to be set to 1	Interrupt name	Interrupt source	Applicable controller function	Status flag
VBINT	VBUS interrupt	• A change in the state of the USB_VBUS input pin is detected (low to high or high to low)	Host or function*1	INTSTS0.VBSTS
RESM	Resume interrupt	• A change in the state of the USB bus is detected in the Suspend state (J-state to K-state or J-state to SE0)	Function	—
SOFR	Frame number update interrupt	In host controller mode: • An SOF packet with a different frame number is transmitted In device controller mode: • When SOFRM is 0: An SOF packet with a different frame number is received • When SOFRM is 1: Failed to receive an SOF packet with the μ frame number 0 because the packet is corrupted.	Host or function	—
DVST	Device state transition interrupt	• A device state transition is detected because of one of the following: - USB bus reset is detected - Suspend state is detected - SET_ADDRESS request is received - SET_CONFIGURATION request is received.	Function	PL1CTRL.DVSQ[3:0]
CTRT	Control transfer stage transition interrupt	• A control transfer stage transition is detected because of one of the following: - Setup stage completed - Control write transfer status stage transition occurred - Control read transfer status stage transition occurred - Control transfer completed - Control transfer sequence error occurred	Function	INTSTS0.CTSQ[2:0]
BEMP	Buffer empty interrupt	• The buffer is empty after all FIFO buffer data is transmitted • A packet larger than the maximum packet size is received	Host or function	BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	In host controller mode: • A STALL response is received from the peripheral device in response to the issued token • The response from the peripheral device in response to the issued token is not received successfully (no response three times consecutively or packet reception error three times consecutively) • An overrun or underrun error occurred during isochronous transfer In device controller mode: • NAK is returned for an IN or OUT token while the PID[1:0] bits were set to 01b (BUF) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer • An interval error occurred during data reception in isochronous transfer	Host or function	NRDYSTS.PIPENRDY
BRDY	Buffer ready interrupt	• The buffer is ready (read or write state)	Host or function	BRDYSTS.PIPEBRDY

Table 33.18 Interrupt sources (2 of 2)

Flag to be set to 1	Interrupt name	Interrupt source	Applicable controller function	Status flag
OVRCR	Overcurrent input change interrupt	• USBHS_OVRCR0A pin or USBHS_OVRCR0B pin state change is detected (low to high or high to low)	Host or function	SYSSTS0.OVCMON[1:0]
BCHG	Bus change interrupt	• USB bus state change is detected	Host	—
DTCH	Device disconnect detection interrupt	• Peripheral device disconnect is detected	Host	—
ATTCH	Device connect detection interrupt	• J-state or K-state is detected on the USB bus for 2.5 µs continuously This interrupt can be used to check whether peripheral devices are connected.	Host	—
EOFERR	EOF error detection interrupt	• An EOF error is detected for a peripheral device	Host	—
SACK	Setup normal interrupt	• A setup transaction normal response (ACK) is received	Host	—
SIGN	Setup error interrupt	• A setup transaction error (no response or ACK packet corruption) is detected three consecutive times	Host	—
PDDETINT	PDDETSTS change detect interrupt	• PDDET pin change is detected	Host or function	BCCTRL.PDDETSTS
LPMEND	LPM transaction end interrupt	• LPM transaction is complete	Host	PL1CTRL.DVSQ[3:0]
L1RSMEND	L1 resume end interrupt	• Resume (from L1 state) processing is complete	Host	PL1CTRL.DVSQ[3:0]

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

33.3.5.1 Selecting the USBHS interrupt detection method

Table 33.19 shows operations for an USBHS interrupt output from the USBHS. In case two or more interrupt sources are generated, the USBHS interrupt output method can be set in the SOFCFG.INTL bit. Set the USBHS interrupt output operation based on your system.

Table 33.19 USBHS interrupt operation

USBHS interrupt output (INTL setting)	When one interrupt source is generated	When two or more interrupt sources are generated
Edge detection (SOFCFG.INTL bit = 0)	Low level output until the source is cleared	When one source is cleared, the USBHS interrupt is negated for 32 clocks at 48 MHz (high pulse output)
Level detection (SOFCFG.INTL bit = 1)	Low level output until the source is cleared	Low level output until all sources are cleared

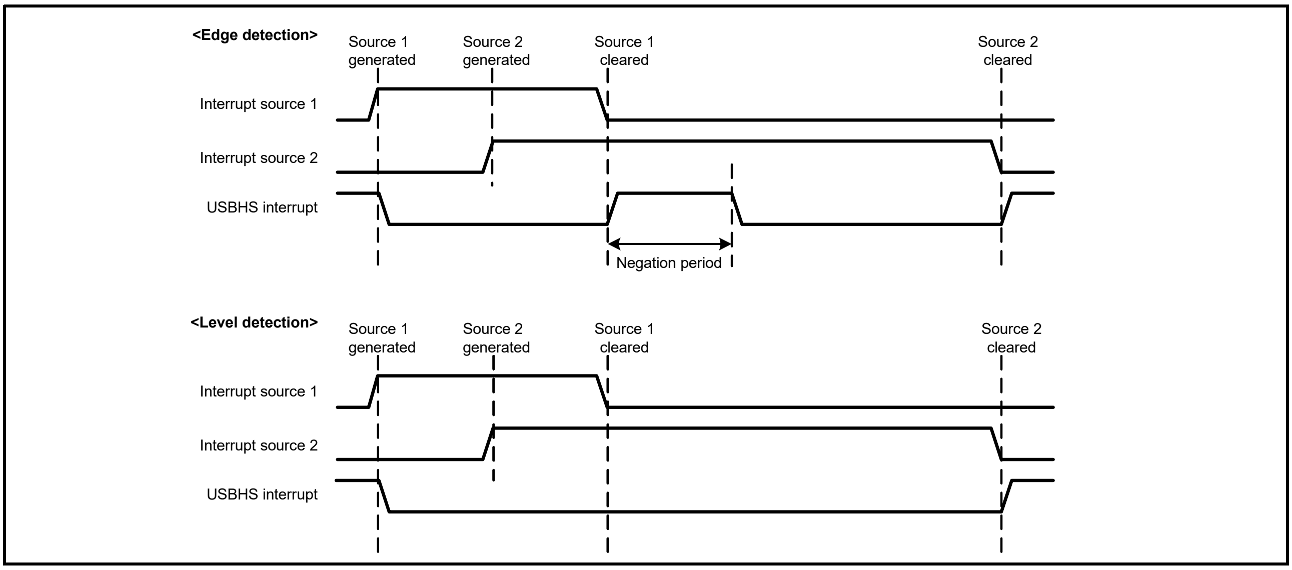

Figure 33.3 USBHS interrupt operation

Figure 33.4 shows an interrupt association chart of the USBHS.

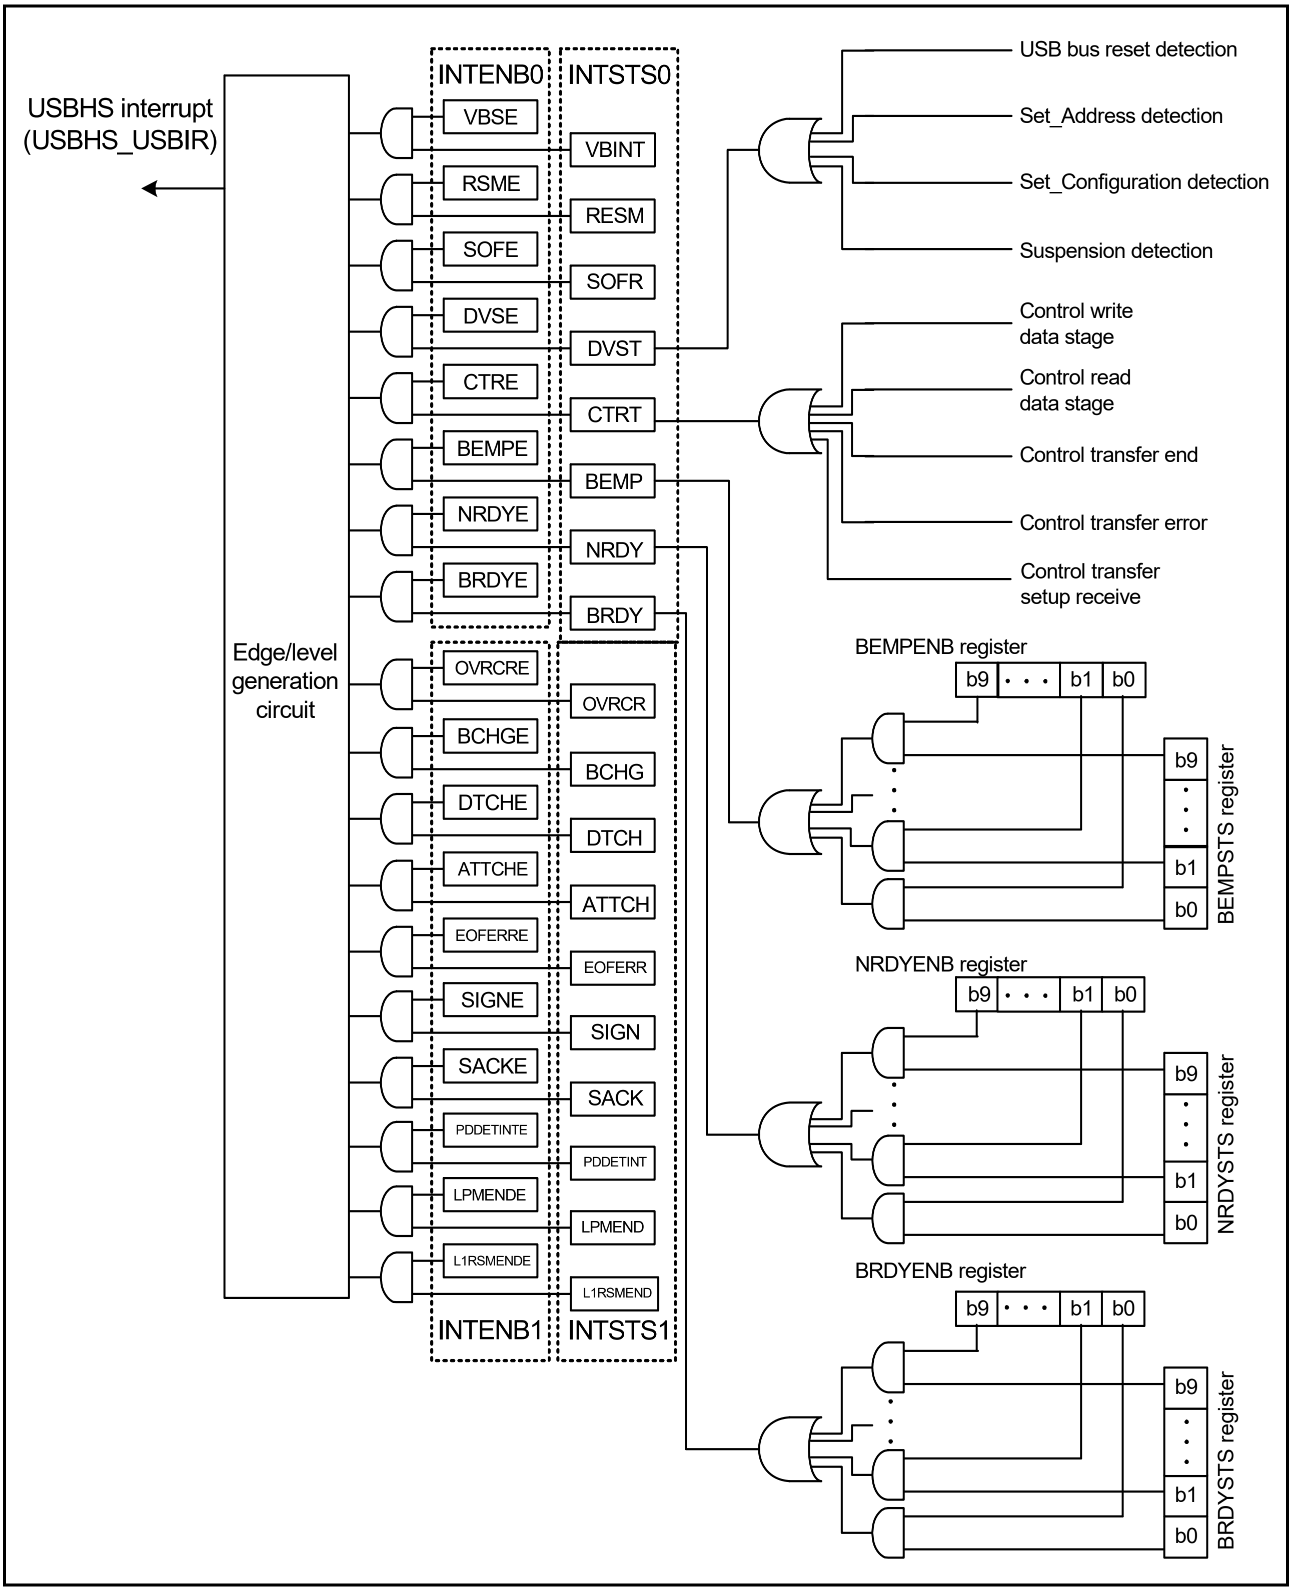

Figure 33.4 USBHS interrupt-related circuits

Table 33.20 shows the interrupts generated by the USBHS.

Table 33.20 USBHS interrupts

Interrupt name	Interrupt status flag	DTC activation	DMAC activation
USBHS_D0FIFO	DMA transfer request 0	Possible	Possible
USBHS_D1FIFO	DMA transfer request 1	Possible	Possible
USBHS_USBIR	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent interrupt, bus change interrupt, device disconnect detection interrupt, device connect detection interrupt, EOF error detection interrupt, normal setup operation interrupt, setup error interrupt, PDDETSTS change detection interrupt, LPM transaction end interrupt, and L1 resume end interrupt	Not possible	Not possible

33.3.6 Interrupt Descriptions

33.3.6.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBHS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBHS generates a BRDY interrupt if the software sets the bit in BRDYENB associated with the given pipe to 1 and INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY flag associated with the pipe to 1.

(a) For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When writing by the CPU to the FIFO buffer is disabled for a pipe (when the BSTS flag is read as 0) and the USBHS has completed packet transmission. In continuous transfer, a BRDY interrupt is generated on completion of the transmission of data from one FIFO buffer.
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

(b) For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS flag is read as 0). No request trigger is generated for transactions in which DATA-PID mismatch has occurred. In continuous transmission or reception mode, the request trigger is not generated when the data is of the specified maximum packet size and the buffer has available space. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.

In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEBRDY flag through the software. In this case, 1s must be written to the associated bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBHS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBHS determines that the last data for a single transfer was received:

- When a short packet including a zero-length packet is received
- When the PIPEnTRN register is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received.

When the data is completely read after any of these conditions is satisfied, the USBHS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer is completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[11:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through software. With these settings, the USBHS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEBRDY flag through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEBRDY flag values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

(a) For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

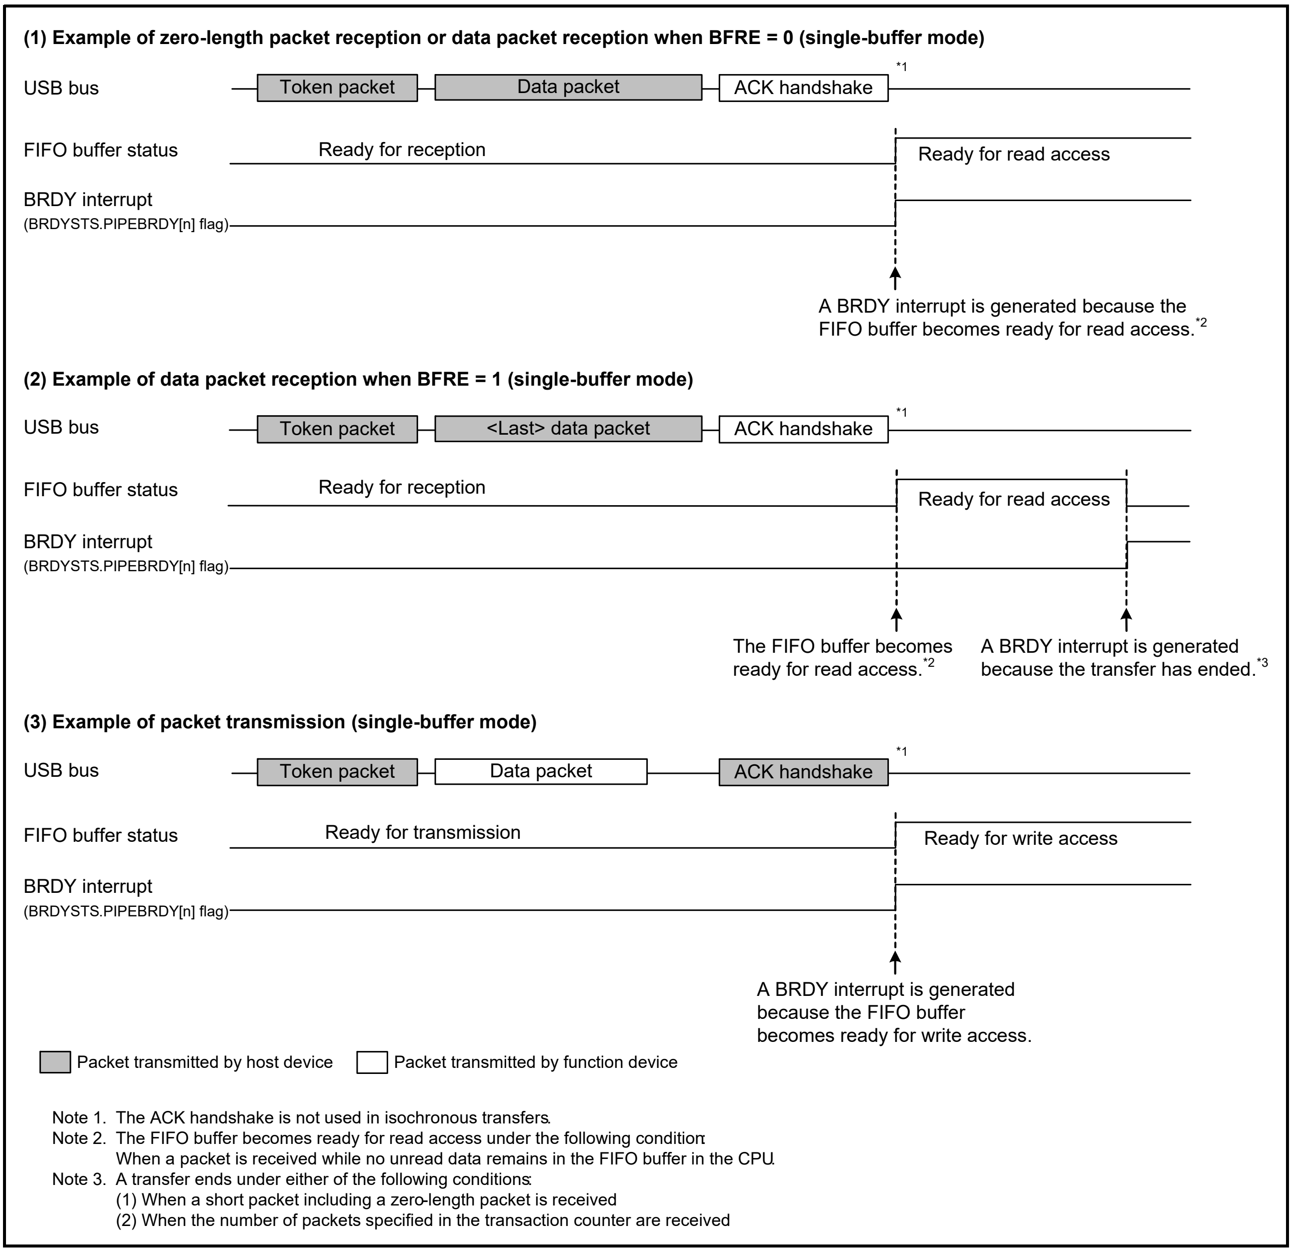
(b) For receiving pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEBRDY flag cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0, and the SOFCFG.INTL bit to 1 for level detection.

Figure 33.5 shows the timing of BRDY interrupt generation.



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no unread data remains in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
(1) When a short packet including a zero-length packet is received
(2) When the number of packets specified in the transaction counter are received

Figure 33.5 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value, as shown in Table 33.21.

Table 33.21 Conditions for clearing the BRDY flag

BRDYM bit	Condition for clearing BRDY flag
0	The USBHS clears the BRDY flag to 0 when all bits in BRDYSTS are set to 0 by software
1	The USBHS clears the BRDY flag to 0 when the BSTS flags for all pipes have cleared to 0

33.3.6.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response) by software, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1. If the associated bit in NRDYENB is set to 1 by software, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHS interrupt.

This section describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode.

(1) In host controller mode when no split transactions occur in the connection

(a) For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPENRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two conditions occurs three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 00b (NAK response)
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (includes STALL for both OUT and PING). In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 11b (STALL response).

(b) For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS discards the received data for the IN token and sets the associated PIPENRDY flag and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe and the CRCE flag to 1.
- When the STALL handshake is received. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In host controller mode when split transactions occur in the connection

(a) For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS sets the associated RDYSTS.PIPENRDY flag for the given pipes to 1 on issuing a start-split transaction and sets the FRMNUM.OVRN flag to 1. The USBHS also transmits a zero-length packet following the OUT token.

- For non-isochronous transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for start-split and complete-split transactions (when timeout is detected before detection of the handshake packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).When an NRDY interrupt is detected on complete-split issuance, the USBHS clears the CSSTS flag to 0.
- When a STALL handshake is received for the complete-split transaction. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0. An interrupt is not detected during setup transaction.

(b) For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the given pipe and the FRMNUM.OVRN flag to 1 on start-split issuance. The USBHS discards the received data for the IN token.
- During bulk-pipe transfers or transfers other than setup transactions with the DCP, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token the USBHS issued on issuance of the start-split or complete-split transactions (when timeout is detected before detection of the data packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When this condition occurs during complete-split, the USBHS clears the CSSTS flag to 0.
- During a complete-split transaction for isochronous transfer or interrupt transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token issued by the USBHS (when a timeout is detected before detection of the DATA packet from the hub)
  - An error is detected in the packet from the hub. On generating this condition for an interrupt transfer pipe, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1, changes the associated PID[1:0] setting for the pipe to 00b (NAK response), and clears the CSSTS flag to 0. On generating this condition for the pipe for isochronous transfers, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, CRCE flag to 1, and clears the CSSTS bit to 0. It does not change the PID[1:0] setting.
- During a complete-split transaction, when the STALL handshake is received for a non-isochronous transfer pipe. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0.
- During a complete-split transaction, when the NYET handshake is received for an isochronous transfer or interrupt transfer pipe for the microframe number = 4. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and the CRCE flag to 1, and clears the CSSTS flag to 0. It does not change the PID[1:0] setting.

(3) In device controller mode

(a) For transmitting pipes

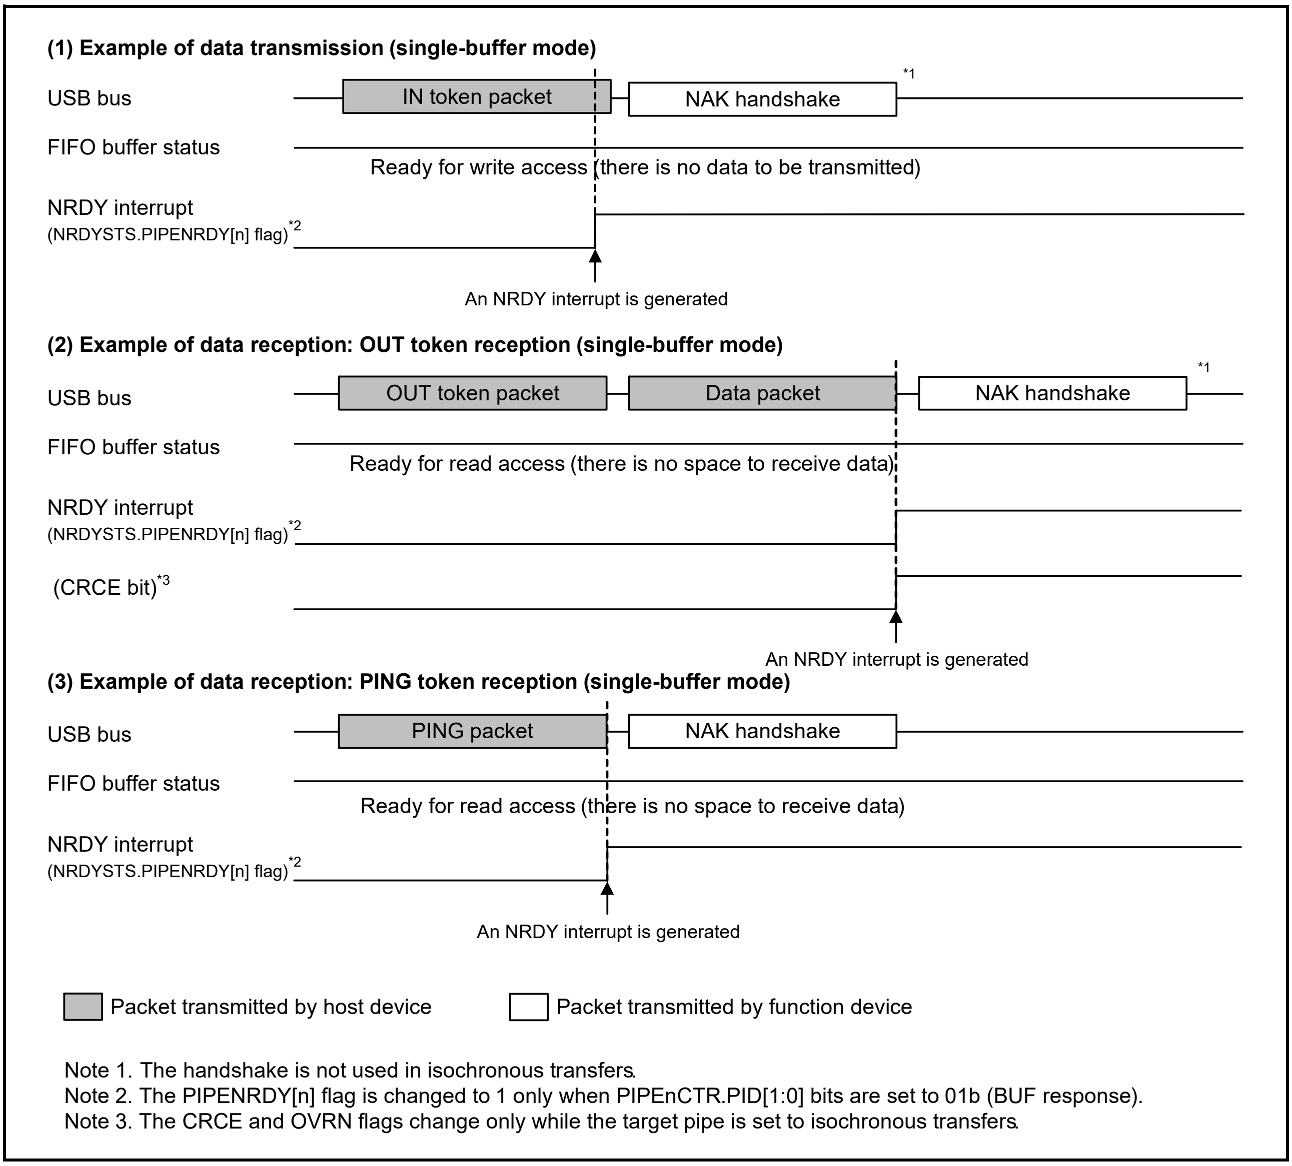
- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS generates an NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPENRDY flag to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBHS transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

(b) For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request on reception of the OUT token and sets the NRDYSTS.PIPENRDY flag to 1 and the FRMNUM.OVRN flag to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY flag to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.

- On receiving a PING token when there is no space available in the FIFO buffer. The USBHS generates an NRDY interrupt request on reception of the PING token, setting the NRDYSTS.PIPENRDY flag to 1.
- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBHS generates an NRDY interrupt request when the SOF is received, and sets the NRDYSTS.PIPENRDY flag to 1.

Figure 33.6 shows the timing of NRDY interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.
Note 2. The PIPENRDY[n] flag is changed to 1 only when PIPEnCTR.PID[1:0] bits are set to 01b (BUF response).
Note 3. The CRCE and OVRN flags change only while the target pipe is set to isochronous transfers.

Figure 33.6 Timing of NRDY interrupt generation in device controller mode

33.3.6.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits in the pipe control register are set to 01b (BUF response) by software, the USBHS sets the associated BEMPSTS.PIPEBEMP flag to 1. If the associated BEMPENB bit is set to 1 by software, the USBHS sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt. This section describes the conditions in which the USBHS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting 1 to the PIPEnCTR.ACLRM or the BCLR bit in the port control register
- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode.

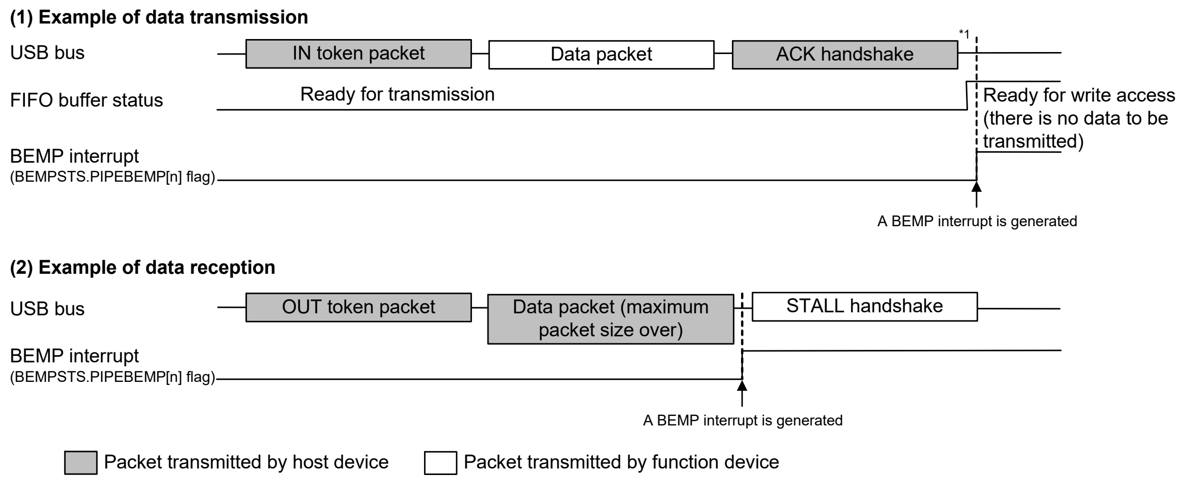
(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBHS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEBEMP flag to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBHS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEBEMP flag clears the status
  - Writing 1 to the BEMPSTS.PIPEBEMP flag has no effect.

Figure 33.7 shows the timing of BEMP interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.

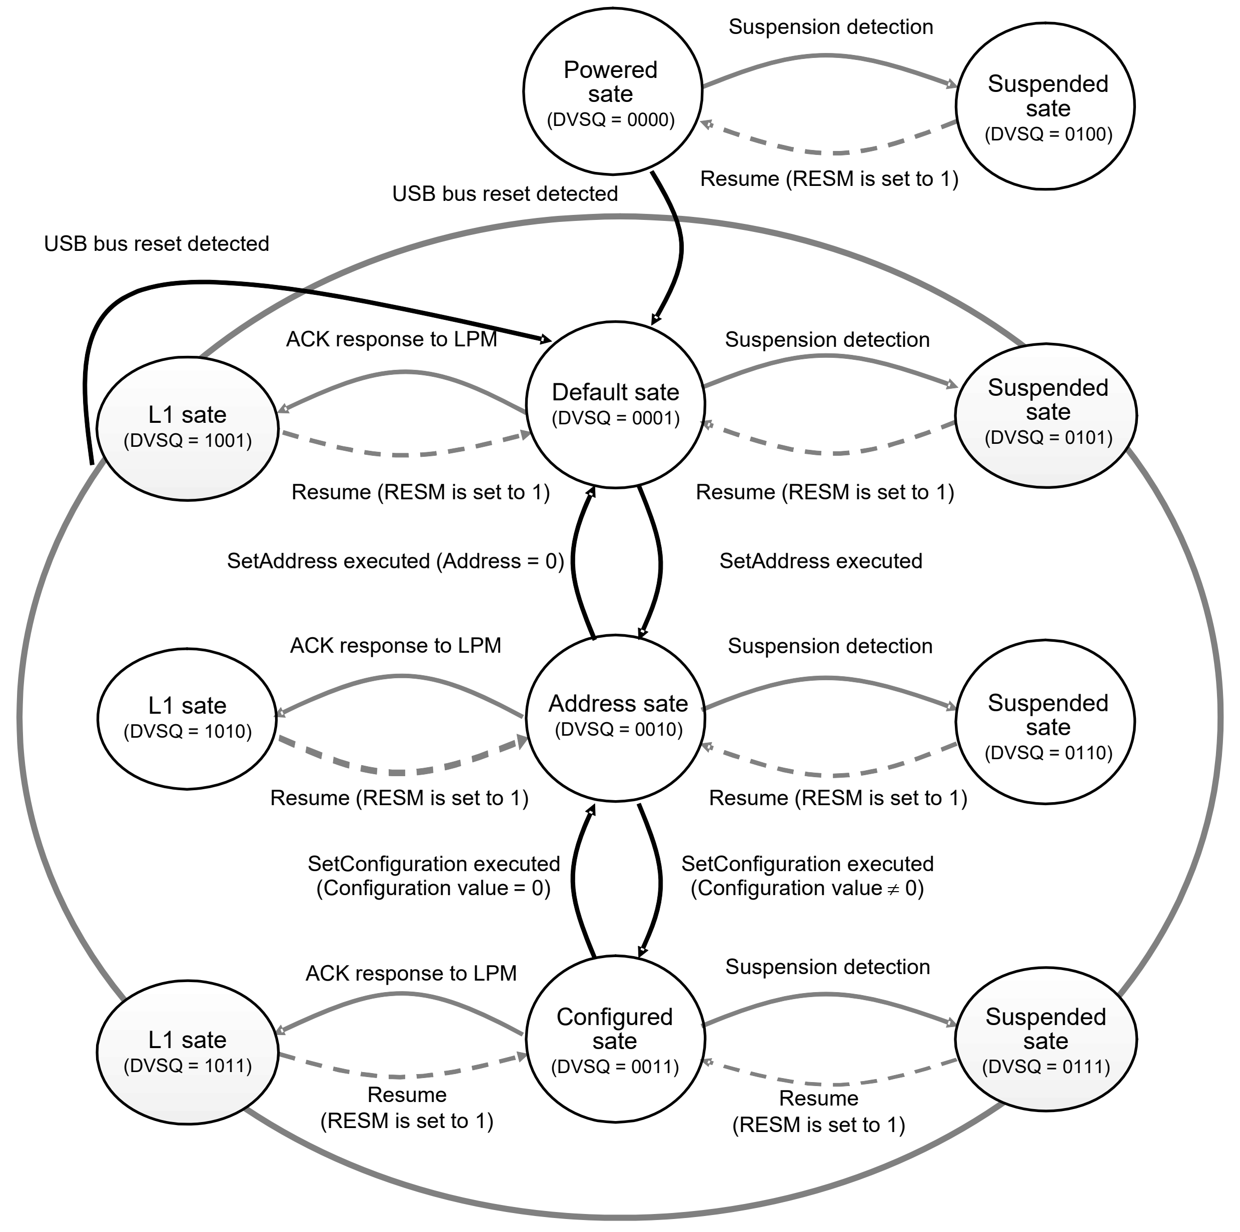
Figure 33.7 Timing of BEMP interrupt generation in device controller mode

33.3.6.4 Device state transition interrupt (device controller mode)

Figure 33.8 shows a diagram of the USBHS device state transitions. The USBHS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the PL1CTRL.DVSQ[3:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBHS controls device states, and device state transition interrupts can be generated, only in device controller mode.



Note: For a transition, indicated by a solid line, the DVST bit is set to 1. For a resume, indicated by a dashed line, the RESM bit is set to 1.

Figure 33.8 Device state transitions

33.3.6.5 Control transfer stage transition interrupt (device controller mode)

Figure 33.9 shows a diagram of the control transfer stage transitions of the USBHS. The USBHS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. When an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

(1) Control read transfer errors

- An OUT token or PING token is received but no data is transferred in response to the IN token at the data stage
- An IN token is received at the status stage
- A data packet with DATAPID = DATA0 is received at the status stage.

(2) Control write transfer errors

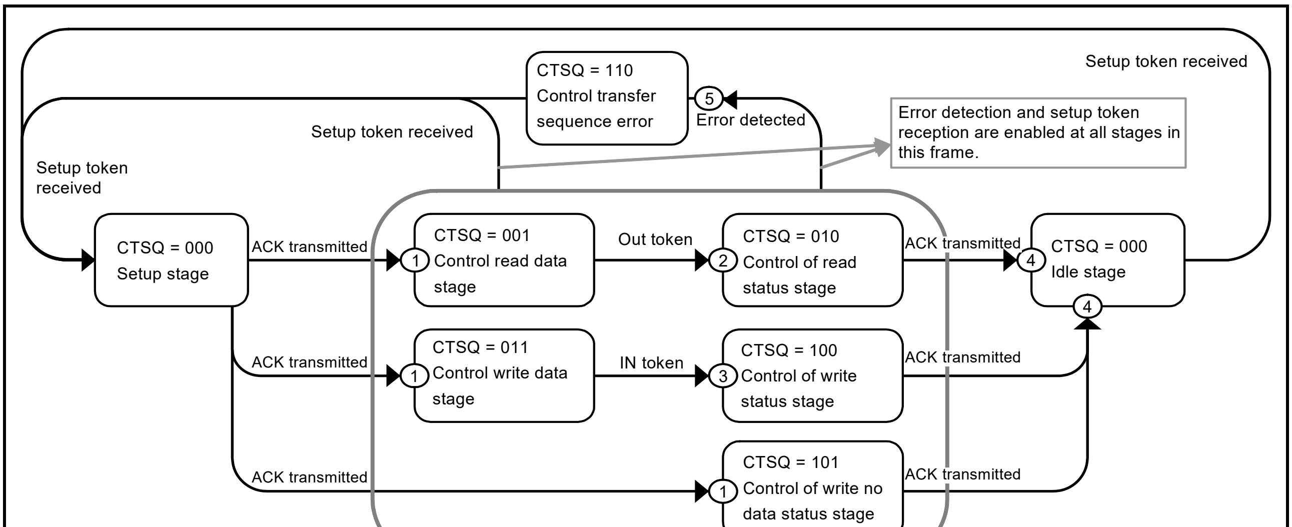
- An IN token is received but no ACK returned in response to the OUT token in the data stage
- A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
- An OUT token or PING token is received in the status stage.

(3) Control write no data transfer errors

- An OUT token or PING token is received at the status stage.

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT flag = 1), the CTSQ[2:0] = 110b value is saved until CTRT flag clears to 0, clearing the interrupt status. While CTSQ[2:0] bits = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBHS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.



Note:
CTRT interrupts
(1) Setup stage end
(2) Control read transfer status stage transition
(3) Control write transfer status stage transition
(4) Control transfer end
(5) Control transfer sequence error

Figure 33.9 Control transfer stage transitions

33.3.6.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBHS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

33.3.6.7 VBUS interrupt

When the USBHS_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBHS_VBUS pin can be checked in the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USBHS_VBUS pin level.

33.3.6.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device is in the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

33.3.6.9 OVRCR interrupt

An OVRCR interrupt is generated when the USBHS_OVRCURA or USBHS_OVRCURB pin level has changed. The levels of the USBHS_OVRCURA and USBHS_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

33.3.6.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected. It can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

33.3.6.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBHS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state.

33.3.6.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

33.3.6.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

33.3.6.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected in any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs.

33.3.6.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBHS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state.

33.3.6.16 PDDETINT interrupt

The USBHS sets the INTSTS1.PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value and generates the PDDETINT interrupt. When the PDDETINT interrupt is generated, use software to repeatedly read the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

33.3.6.17 LPMEND interrupt

When the LPM transaction ends because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag sets to 1 and the LPMEND interrupt is generated.

33.3.6.18 L1RSMEND interrupt

When performing resume processing when the USBHS has transitioned to the L1 state because an ACK is received in response to an LPM token, the USBHS sets the INTSTS1.L1RSMEND flag to 1 on completion of the resume processing.

33.3.7 Pipe Control

Table 33.22 lists the pipe settings for the USBHS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBHS provides 10 pipes for data transfer. Set up the pipes based on your system specifications.

Table 33.22 Pipe settings (1 of 2)

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE[1:0]	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	CNTMD	Selection of continuous transfer or discontinuous transfer	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Settable Set this number to a value other than 0000 when one or more pipes are used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
PIPEBUF	BUFSIZE	FIFO buffer size	DCP: Setting disabled (fixed to 256 bytes) Pipes 1 to 5: Settable up to 2 KB Pipes 6 to 9: Setting disabled (fixed to 64 bytes)
	BUFNMB	FIFO buffer number	DCP: Setting disabled (fixed to 0h-3h area) Pipes 1 to 5: Setting disabled (8h-87h area specifiable) Pipes 6 to 9: Setting disabled (fixed to 4h-7h area)
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Device select	Viewable only in host controller mode
	MXPS	Maximum packet size	Setting compliant with USB specification
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Setting disabled
	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode

Table 33.22 Pipe settings (2 of 2)

Register name	Bit name	Setting	Notes
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5
	SUREQ	Setup request	Settable only for the DCP and controlled in host controller mode
	SUREQCLR	SUREQ clear	Settable only for the DCP and controlled in host controller mode
	CSCLR	CSSTS clear	Controllable only in host controller mode
	CSSTS	Split status check	Viewable only in host controller mode
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in device controller mode
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clears the data toggle bit
	SQSET	Sequence set	Sets the data toggle bit
	SQMON	Sequence check	Monitors the data toggle bit
	PBUSY	PIPE busy check	-
	PID[1:0]	Response PID	-
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

33.3.7.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID[1:0] bits are 00b (NAK response)). Figure 33.10 shows pipe control register switching procedures when USB communication is enabled (PID[1:0] bits are 00b (BUF response)).

Do not change the following registers and bits when USB communication is enabled (PID[1:0] bits are 01b (BUF response)):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN
- Bits in DEVADDm (m = 0 to A).

To set the CSCLR bits and bits in DEVADDm (m = 0 to A), follow the procedures described in section 33.2, Register Descriptions.

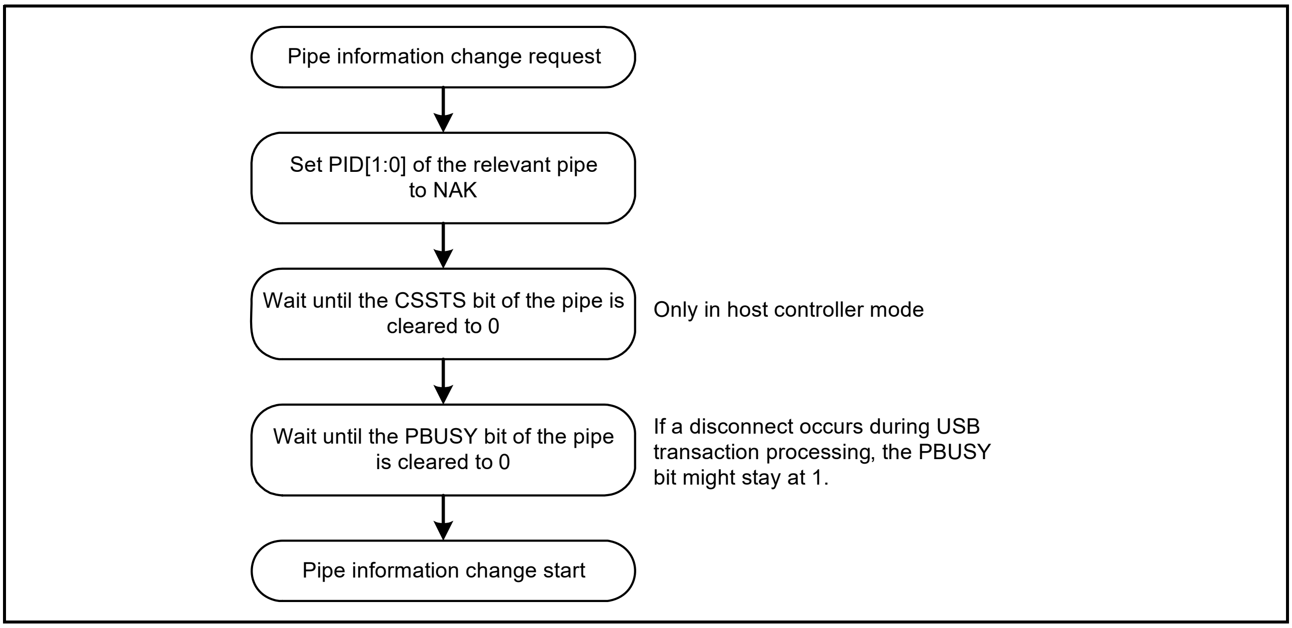


Figure 33.10 Procedure for changing pipe information when USB communication is enabled and PID[1:0] bits are 01b (BUF response)

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers while the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR and ACLRM bits.

To change pipe information, you must set the CURPIPE[3:0] bits to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit after the pipe information is changed.

33.3.7.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk transfer or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer.

33.3.7.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique.

33.3.7.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the MXPS bits in DCPMAXP and PIPEMAXP. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID[1:0] bits are set to 01b (BUF response)):

- DCP: Set to 64 for high-speed operation
- DCP: Set to 8, 16, 32, or 64 for full-speed operation
- Pipes 1 to 5: Set to 512 for high-speed bulk transfers
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for full-speed bulk transfers
- Pipes 1, 2: Set between 1 and 1024 for high-speed isochronous transfers
- Pipes 1, 2: Set between 1 and 1023 for full-speed isochronous transfers
- Pipes 6 to 9: Set between 1 and 64.

High-bandwidth interrupt transfers and isochronous transfers are not supported.

33.3.7.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBHS recognizes that the transfer has ended. Two transaction counters are provided. One is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read.

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared.

33.3.7.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBHS operation with different response PID settings.

(1) Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed.

Note: Use the SUREQ bit to execute setup transactions for the DCP.

(2) Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions.

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

(3) and (4) describe situations in which the USBHS writes to the PID[1:0] bits because of specific transaction results.

(3) Hardware response PID settings in host controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and issuing of tokens is automatically stopped:
    - When a non-isochronous transfer is performed and an NRDY interrupt is generated. For details, see section 33.3.6.2, NRDY interrupt.
    - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
    - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and issuing of tokens is automatically stopped:
    - When STALL is received in response to a transmitted token
    - When a received data packet exceeds the maximum packet size.

(4) Hardware response PID settings in device controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and a NAK response is returned to transactions:
    - When the setup token is received normally (DCP only)
    - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers.
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and a STALL response is returned to transactions:
    - When a received data packet exceeds the maximum packet size
    - When a control transfer sequence error is detected.

33.3.7.7 Data PID sequence bit

The USBHS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBHS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

33.3.7.8 Response PID = NAK function

The USBHS provides a function for disabling pipe operation (PID[1:0] bits are set to 00b (NAK response)) when the final data packet of a transaction is received. The USBHS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, software must enable the pipe again (PID[1:0] bits are set to 01b (BUF response)).

The response PID = NAK function can be used only for bulk transfers.

33.3.7.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode. During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

33.3.7.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next, enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK). Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

33.3.7.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (PID[1:0] bits are set to 00b (NAK response)). Next, enable pipe operation (PID[1:0] bits are set to 01b (BUF response)), on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (PID[1:0] bits are set to 00b (NAK response)) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

33.3.8 FIFO Buffer

The USBHS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBHS (SIE side).

33.3.8.1 Buffer status

Table 33.23 and Table 33.24 show the buffer status in the USBHS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 33.23 Buffer status indicated in the BSTS flag

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission is not complete. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 33.24 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

33.3.8.2 FIFO buffer clearing

Table 33.25 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using the BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 33.25 Buffer clearing methods

FIFO buffer clearing mode	Clearing the FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	• CFIFOCTR • DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid.	1: Mode valid 0: Mode invalid.

(1) Auto buffer clear mode function

The USBHS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

33.3.8.3 FIFO port functions

Table 33.26 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zero-length packet is received (DTLN[11:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[11:0] flags in the port control register.

Table 33.26 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW[1:0]	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE[3:0]	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN[11:0]	Checks the length of receive data

33.3.8.4 FIFO port selection

Table 33.27 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port selection register. After a pipe is selected, the software must check whether the written value can be correctly read from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBHS is modifying the pipe.) Next, the software checks that the FRDY flag in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW[1:0] bits in the port selection register. The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port selection register determines the direction.

Table 33.27 FIFO port access by pipe

Pipe	Access Method	Port that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

(1) REW bit

It is possible to temporarily stop access to a pipe being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port selection register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port selection register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with the REW bit set to 0, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

33.3.8.5 DMA/DTC transfers (D0FIFO and D1FIFO ports)

For pipes 1 to 9, the FIFO port can be accessed using the DMAC/DTC. When buffer access for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW[1:0] bits, and select the pipe targeted for the DMA/DTC transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

(1) DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBHS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 33.28 shows the packet reception and FIFO buffer clearing processing by software for each of the different settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA/DTC transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 33.28 Packet reception and FIFO buffer clearing processing by software

Buffer status when packet is received	**Register setting**			
	DCLRM = 0		**DCLRM = 1**	
	BFRE = 0	**BFRE = 1**	**BFRE = 0**	**BFRE = 1**
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

33.3.8.6 Allocating the FIFO buffer

Figure 33.11 shows an example of a memory map of the FIFO buffer. The FIFO buffer is an area shared by the USBHS and the control CPU of the application. There are two situations for the FIFO buffer: (1) access rights are given to the application (CPU side), and (2) access rights are given to the USBHS (SIE side).

An independent area is set for the FIFO buffer for each pipe. A memory area is determined by the first block number and the number of blocks (specified in the BUFNMB[7:0] and BUFSIZE[4:0] bits in PIPEBUF), where 64 bytes is regarded as one block. When the continuous transfer mode is selected in the CNTMD bit in PIPECFG, set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. When double buffering is selected in the DBLB bit in PIPECFG, twice the memory area specified in the BUFSIZE[4:0] bits in PIPEBUF is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) the FIFO buffer. Specify the number of the pipe to be allocated to the FIFO port in the CURPIPE[3:0] bits in C/DnFIFOSEL.

The FIFO buffer status of each pipe can be checked in the DCPCTR.BSTS, PIPEnCTR, and INBUFM bits. The FIFO port access rights can be checked in the FRDY flag in C/DnFIFOCTR.

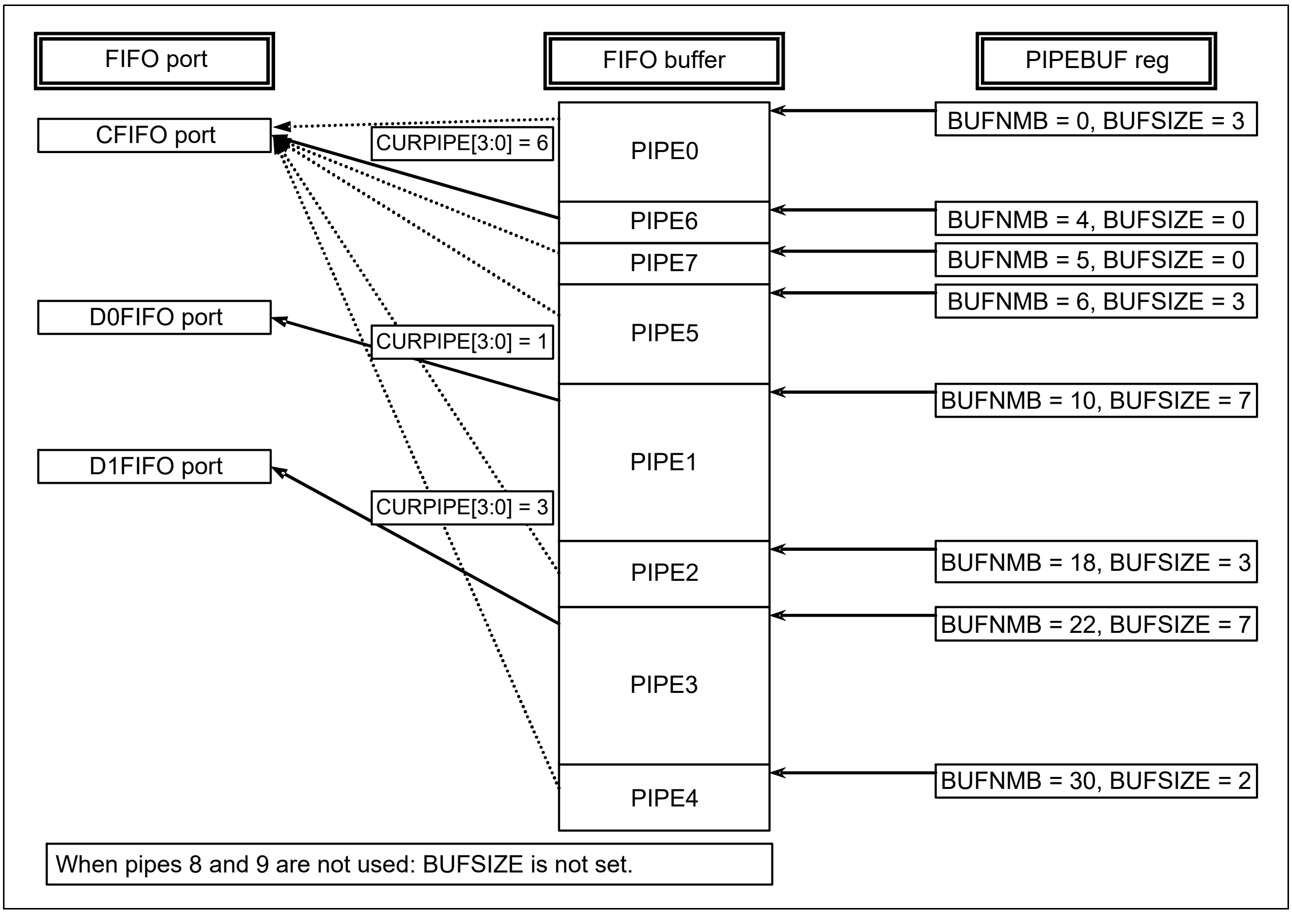

Figure 33.11 Example memory map of the FIFO buffer

33.3.9 Control Transfers Using the DCP

The Default Control Pipe (DCP) is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

33.3.9.1 Control transfers in host controller mode

(1) Setup stage

The USBREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the register and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in DEVADDm (m = 0 to A) corresponding to the specified USBAddress set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

The DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON flag.

(2) Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID to DATA1 in the DCPCTR.SQSET bit and set the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected using the BRDY or BEMP interrupt.

Data transfer of multiple packets is enabled in continuous transfer mode. However, when continuous transfer is specified in the receiving direction, the BRDY interrupt is not generated unless the buffer becomes full or a short packet is received (for 256 bytes or less, which is an integral multiple of the maximum packet size). If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer through the software to transmit a zero-length packet last.

(3) Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[11:0] flags after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

33.3.9.2 Control transfers in device controller mode

(1) Setup stage

The USBHS returns an ACK response to a normal setup packet for the USBHS. The USBHS operates in the setup stage as follows:

On receiving a new setup packet, the USBHS sets the following bits:

- Sets the INTSTS0.VALID flag to 1
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response)
- Sets the DCPCTR.CCPL bit to 0.

When the USBHS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID flag = 1, the PID[1:0] bits cannot be set to 01b (BUF response), and the data stage cannot be terminated.

Using the VALID flag function, the USBHS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBHS automatically detects the direction bit (bmRequestType bit 8) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and no-data control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBHS, see Figure 33.9.

(2) Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

In high-speed control write transfers, a NYET handshake response is returned based on the FIFO buffer status.

(3) Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).

After this setting is made, the USBHS automatically executes the status stage based on the data transfer direction determined at the setup stage. The status stage is executed as follows:

- For control read transfers:
  The USBHS receives a zero-length packet from the USB host and transmits an ACK response
- For control write transfer and no data control transfer:
  The USBHS transmits a zero-length packet and receives an ACK response from the USB host.

(4) Control transfer auto response function

The USBHS automatically responds to a normal SET_ADDRESS request. If the SET_ADDRESS request contains any of the following errors, a response must be returned by software.

- When bmRequestType is not 00h: except control write transfer
- When wIndex is not 00h: request error
- When wLength is not 00h: except no data control transfer
- When wValue is larger than 7Fh: request error
- When PL1CTRL.DVSQ[3:0] flags are 0011b (Configured): control transfer of device state error

A response by the corresponding software is required to all requests other than SET_ADDRESS.

33.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (setting of single buffer/double buffer or continuous/discontinuous transfer mode) is configurable for bulk transfers. The FIFO buffer size can be set up to 2 KB. The USBHS manages the FIFO buffer state and automatically responds to the PING packet and the NYET handshake.

33.3.10.1 PING packet control in host controller mode

In the OUT direction, a PING packet is automatically transmitted by the USBHS. The USBHS starts communication in the transmitting direction beginning with the PING packet. When it receives an ACK handshake in response to the PING packet, the USBHS transmits an OUT packet. The USBHS returns to the PING transmission state on receiving a NAK or NYET response during an OUT transaction. The procedure is as follows:

Starting OUT data transmission
→ (1) Transmit PING packet
(2) Receive NAK handshake
(3) Transmit PING packet
(4) Receive ACK handshake
(5) Transmit OUT data packet
(6) Receive ACK handshake
(7) Transmit OUT data packet
:
(8) Receive NAK/NYET handshake

The USBHS returns to the PING packet transmission state when a hardware reset is issued, the NYET or NAK handshake is received, the sequence toggle bit is cleared (SQCLR), or the buffer clear bit (ACLRM) is set.

33.3.10.2 NYET handshake control in device controller mode

Table 33.29 lists responses to received tokens during bulk and control transfers. The USBHS returns a NYET response when an available area for only one packet is left in the FIFO buffer when the USBHS has received an OUT token during a bulk or control transfer. When the USBHS receives a short packet, however, it returns an ACK response instead of NYET even when this condition occurs.

Table 33.29 Responses to received tokens

PID[1:0] bit setting	FIFO buffer state	Received token	Response	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	When OUT token is received, data packet is received.*1
	RCV-BRDY	OUT	NYET	Data packet is received*2
	RCV-BRDY	OUT (Short)	ACK	Data packet is received*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	Data packet is transmitted
	TRN-NRDY	IN	NAK	—

Note 1. RCV-BRDY: An available area for two packets is left in the FIFO buffer when an OUT token or a PING token is received.
Note 2. RCV-BRDY: An available area for only one packet is left in the FIFO buffer when an OUT token is received.
RCV-NRDY: No available area is left in the FIFO buffer when a PING token is received.
TRN-BRDY: The FIFO buffer contains transmit data when an IN token is received.
TRN-NRDY: The FIFO buffer contains no transmit data when an IN token is received.

33.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBHS performs interrupt transfers based on the timing dictated by the host controller. In the interrupt transfer, the USBHS ignores PING packets (no response) and does not transmit the NYET handshake, but returns an ACK, NAK, or STALL response.

In host controller mode, the software can set the timing for issuing tokens using the interval counter. The USBHS does not issue a PING token but issues an OUT token, including for transfers in the OUT direction.

The USBHS does not support high-bandwidth interrupt transfers.

33.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBHS issues interrupt transfer tokens based on this interval.

(1) Initializing the counter

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the IITV[2:0] bits
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBHS tries to execute the transaction in the next interval.

- When the PID[1:0] bits are set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT)

direction.

33.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBHS does not support high-bandwidth isochronous transfers but provides the following functions for isochronous transfers:

- Notification of isochronous transfer error
- Interval counter (specified in the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified in the PIPEPERI.IFIS bit)
- SOF pulse output function.

33.3.12.1 Error detection in isochronous transfers

The USBHS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 33.30 and Table 33.31 show the priority order for errors detected by the USBHS and the associated interrupts.

(1) PID errors

- The PID value of the received packet is invalid.

(2) CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal.

(3) Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size.

(4) Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction.

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction.

(5) Interval error

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer.

Table 33.30 Error detection for token transmission and reception (1 of 2)

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
3	Overrun or underrun error	An NRDY interrupt is generated to set the OVRN flag to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to the OUT token.

Table 33.30 Error detection for token transmission and reception (2 of 2)

4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 33.31 Error detection for data packet reception

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupt is generated. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes.
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes.

33.3.12.2 DATA PID

The USBHS does not support high-bandwidth transfers. In device controller mode, the USBHS responds as follows to a received PID:

(1) IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted.

(2) OUT direction (full-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored.

(3) OUT direction (high-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Received normally as data packet PID
- mDATA: Received normally as data packet PID.

33.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables functions as shown in Table 33.32. In host controller mode, the USBHS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 33.32 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer

The interval count is performed when an SOF is received or for complemented SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2IITV (μ) frames.

(1) Counter initialization in device controller mode

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the PIPEPERI.IITV[2:0] bits
- FIFO buffer initialization using the ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under either of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token, with the PID[1:0] bits set to 01b (BUF response)
- An SOF is received after data is received in response to an OUT token, with PID[1:0] bits set to 01b (BUF response).

The interval counter is not initialized under the following conditions:

- When the PID[1:0] bits are set to NAK or STALL
  This does not stop the interval timer. The USBHS attempts the transaction in the next interval.
- USB bus reset and USB suspension
  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBHS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBHS issues a token for a selected pipe once every 2^{IITV} frames.

The USBHS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to 01b (BUF response) by software.

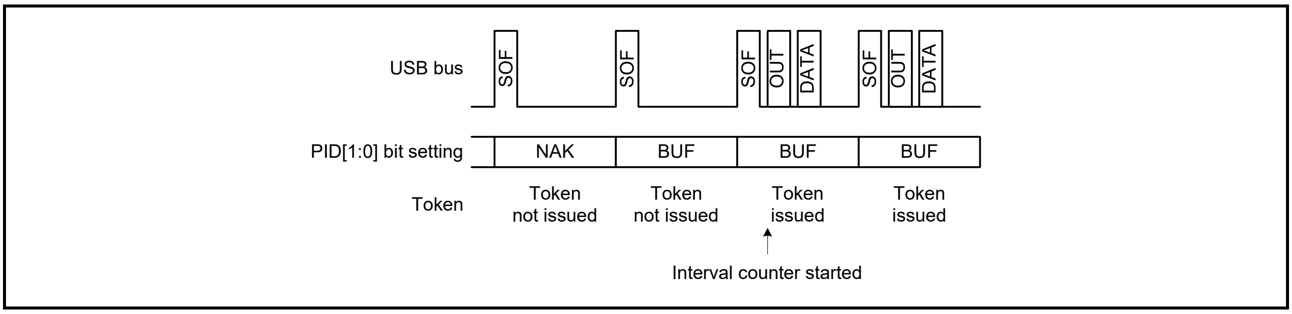

Figure 33.12 Token issuance when IITV[2:0] = 0

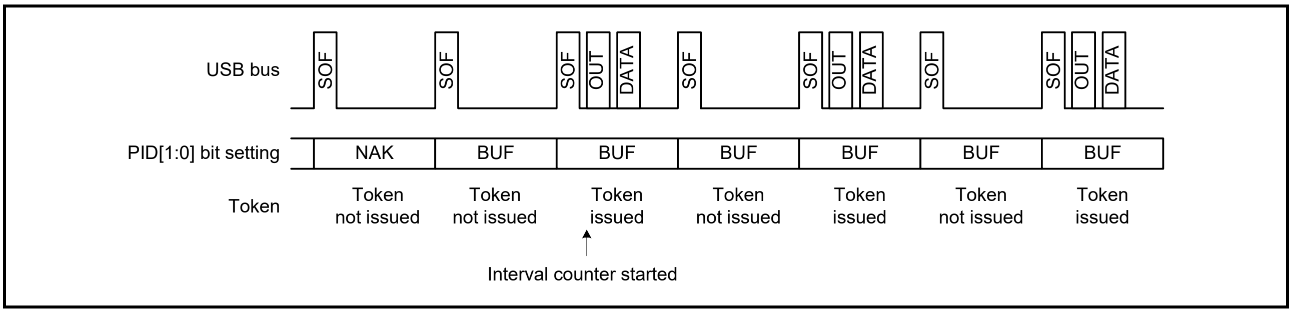

Figure 33.13 Token issuance when IITV[2:0] = 1

When the selected pipe is set for isochronous transfers, the USBHS carries out the following operation in addition to controlling the token issuance interval. The USBHS issues a token even when the NRDY interrupt generation condition is satisfied.

(a) When the selected pipe is for isochronous IN transfers

The USBHS generates an NRDY interrupt when the USBHS issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).

(b) When the selected pipe is for isochronous OUT transfers

The USBHS sets the OVRN flag to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, because the CPU or DMA/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the MCU is reset
  This initializes the IITV[2:0] bits
- When the PIPEnCTR.ACLRM bit is set to 1 by software.

(3) Interval counting and transfer control in device controller mode

(a) When the selected pipe is for isochronous OUT transfers

The USBHS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBHS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal complementation allows the interrupt to be generated when the SOF packet is received. However, when the IITV[2:0] bits are set to a value other than 0, the USBHS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to 00b (NAK response) by software after starting the interval timer, the USBHS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
  The interval counting starts when the PID[1:0] bits of the selected pipe are changed to BUF
- When the IITV[2:0] bits ≠ 0:
  The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to 01b (BUF response).

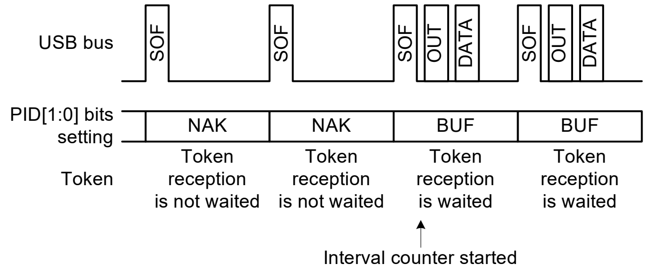

Figure 33.14 Relationship between frames and expected token reception when IITV[2:0] = 0

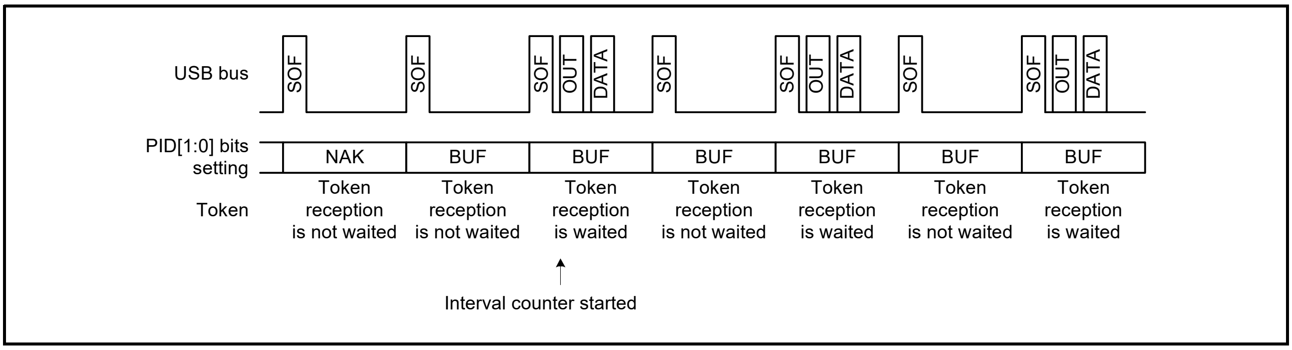

Figure 33.15 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

(b) When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When the IFIS bit is cleared to 0, the USBHS transmits a data packet in response to a received IN token, regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBHS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBHS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal complementation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBHS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBHS detects a USB bus reset.

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBHS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer in which data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 33.16 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 0 (every frame).

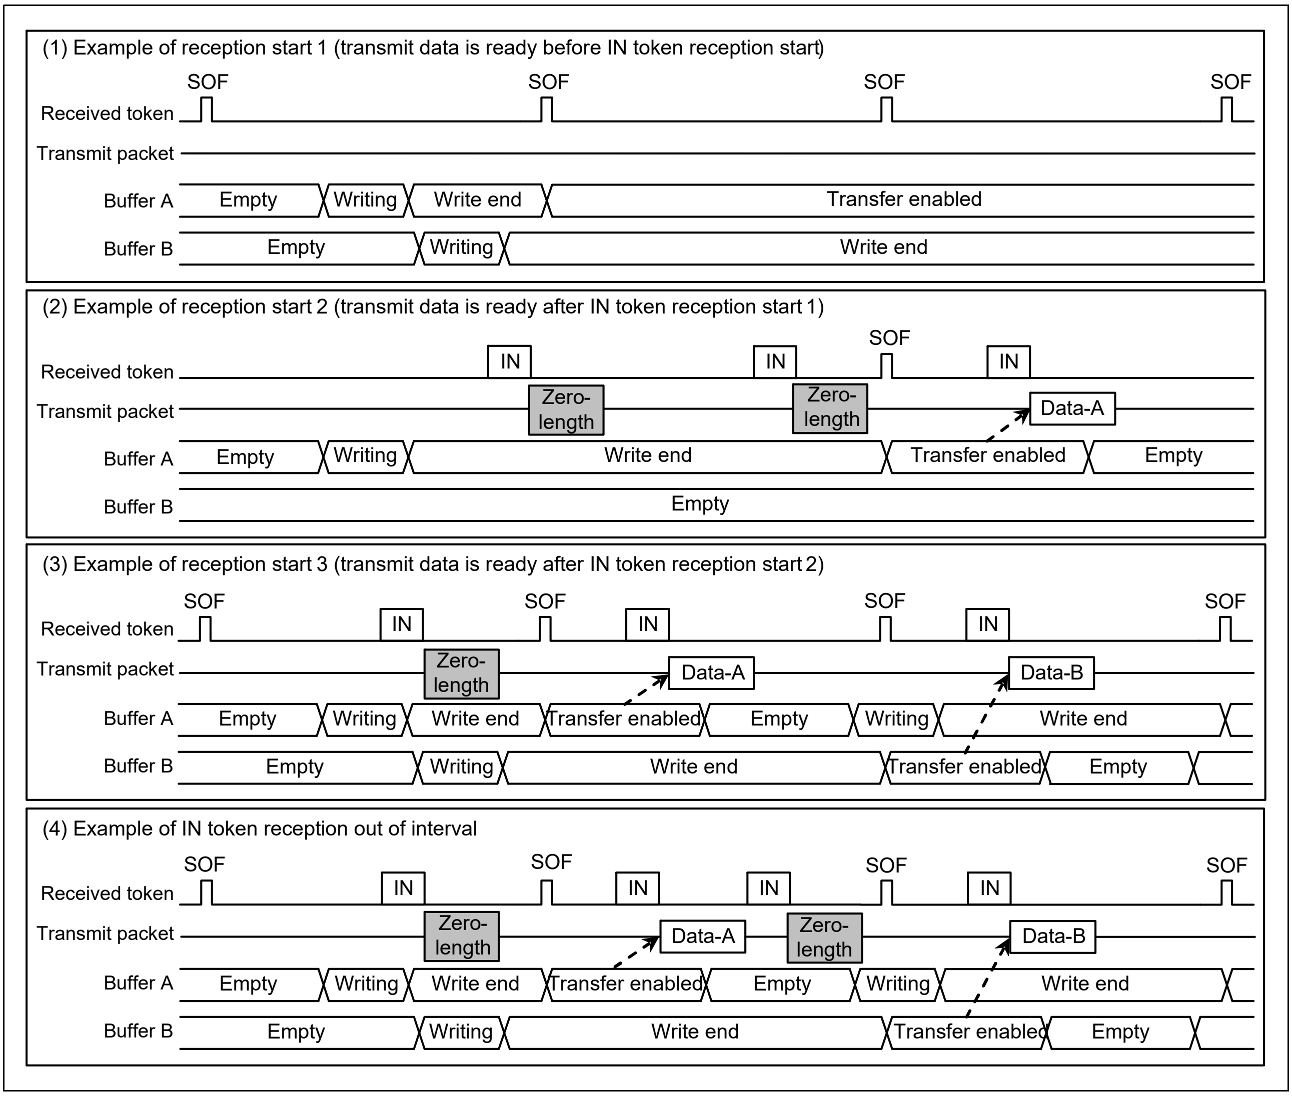

Figure 33.16 Example data setup operation

(5) Isochronous transfer transmit buffer flush in device controller mode

In device controller mode during isochronous data transmission, if the USBHS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV[2:0] = 0:
  The buffer flush operation starts from the first frame after the pipe is enabled
- When IITV[2:0] ≠ 0:
  The buffer flush operation starts after the first normal transaction.

Figure 33.17 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBHS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

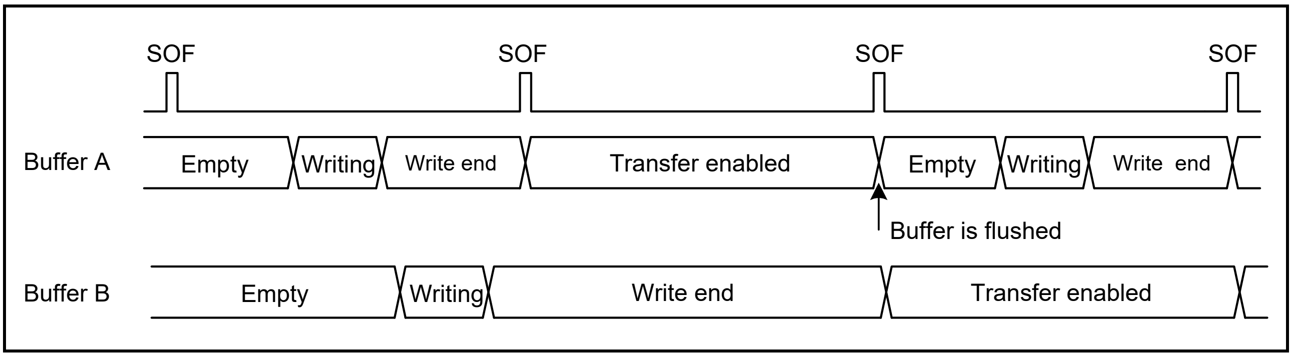

Figure 33.17 Example buffer flush operation

Figure 33.18 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing ①, and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs.
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs.

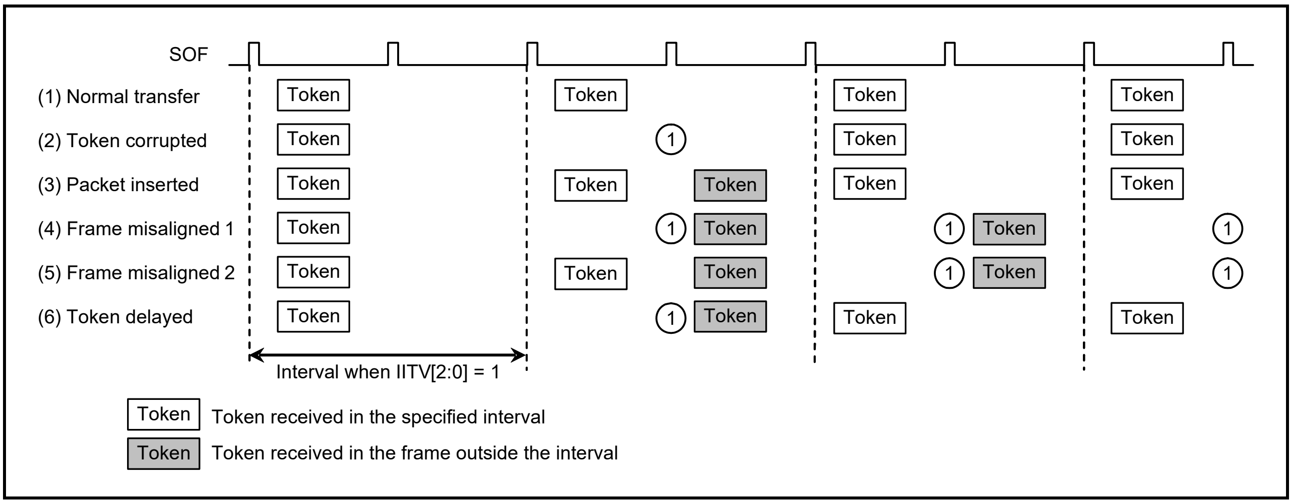

Figure 33.18 Example interval error occurrence when PIPEPERI.IITV[2:0] = 1

33.3.13 SOF Complementation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms in full-speed mode or 125 µs in high-speed mode because the SOF packet is missing or corrupted, the USBHS complements the SOF. SOF complementation begins when the SYSCFG.USBE and LPSTS.SUSPENDM bits are set to 1 and an SOF packet is received. The complementation function is initialized under the following conditions:

- Power-on reset
- USB bus reset

- Suspend state detection.

The SOF complementation function operates as follows:

- The frame interval (125 µs or 1 ms) is determined by the reset handshake protocol result
- The complementation function is not activated until an SOF packet is received
- When the first SOF packet is received, complementation is performed by counting 125 µs or 1 ms on the 48-MHz internal clock
- When the second or subsequent SOF packets are received, complementation is performed at the previous reception interval
- Complementation is not performed in the Suspend state or on reception of a USB bus reset. During high-speed operation, complementation continues for 3 ms from the last packet on transition to the Suspend state.

The USBHS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF complementation if the SOF packet is missing:

- Updating of the frame number and micro frame number
- SOFR interrupt and micro-SOF lock
- SOF pulse output
- Isochronous transfer interval count.

If an SOF packet is missing during full-speed operation, the FFRMNUM.FRNM[10:0] flags are not updated. If a micro-SOF packet is missing during high-speed operation, the URMNUM.UFRNM[2:0] bits are updated.

However, if a micro-SOF packet is missing while the UFRNM[2:0] bits are set to 000b, the FRNM bits are not updated. In this case, even if a subsequent micro-SOF packet with a value other than UFRNM[2:0] bits = 000b is received successfully while UFRNM[2:0] bits are set to the value other than 000b, the FRNM bits are not updated.

33.3.14 Pipe Schedule

33.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBHS generates transactions under the conditions as shown in Table 33.33.

Table 33.33 Conditions for generating transactions

	Conditions for generation				
Transaction	**DIR**	**PID[1:0]**	**IITV0**	**Buffer state**	**SUREQ**
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	—*1	Receive area exists	—*1
	OUT	BUF	—*1	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

33.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBHS. After the USBHS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:
   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers:
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:
   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

33.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission, and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

33.3.15 Battery charging detection processing

The USBHS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

This section describes operations required in device and host controller modes.

33.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBHS supports both methods as follows:
   - Software processing
     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBHS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL.VDPSRCE and IDMSINKE bits are then both set to 1, enabling the VDP_SRC and IMP_SINK circuits, respectively, to start primary detection processing.
   - Hardware processing
     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the BCCTRL.IDPSRCE bit is set to 1, enabling the IDP_SRC circuit, to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the BCCTRL.IDPSRCE bit to 0, disabling the IDP_SRC circuit, and set both the BCCTRL.VDPSRCE and IDMSINKE bits to 1, enabling the VDP_SRC and IDM_SINK circuits, respectively, to start primary detection processing. The VDPSRCE and IDMSINKE bits must be set to 1 simultaneously.
2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.*1
3. To start secondary detection processing, clear both the BCCTRL.VDPSRCE and IDMSINKE bits to 0, disabling the VDP_SRC and IDM_SINK circuits, respectively. Next, set both the BCCTRL.VDMSRCE and IDPSINKE bits to 1, enabling the VDM_SRC and IDP_SINK circuits, respectively.

4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.PDDETSTS flag. A value of 1 indicates that secondary detection processing is complete.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D- line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 33.19 illustrates this processing flow.

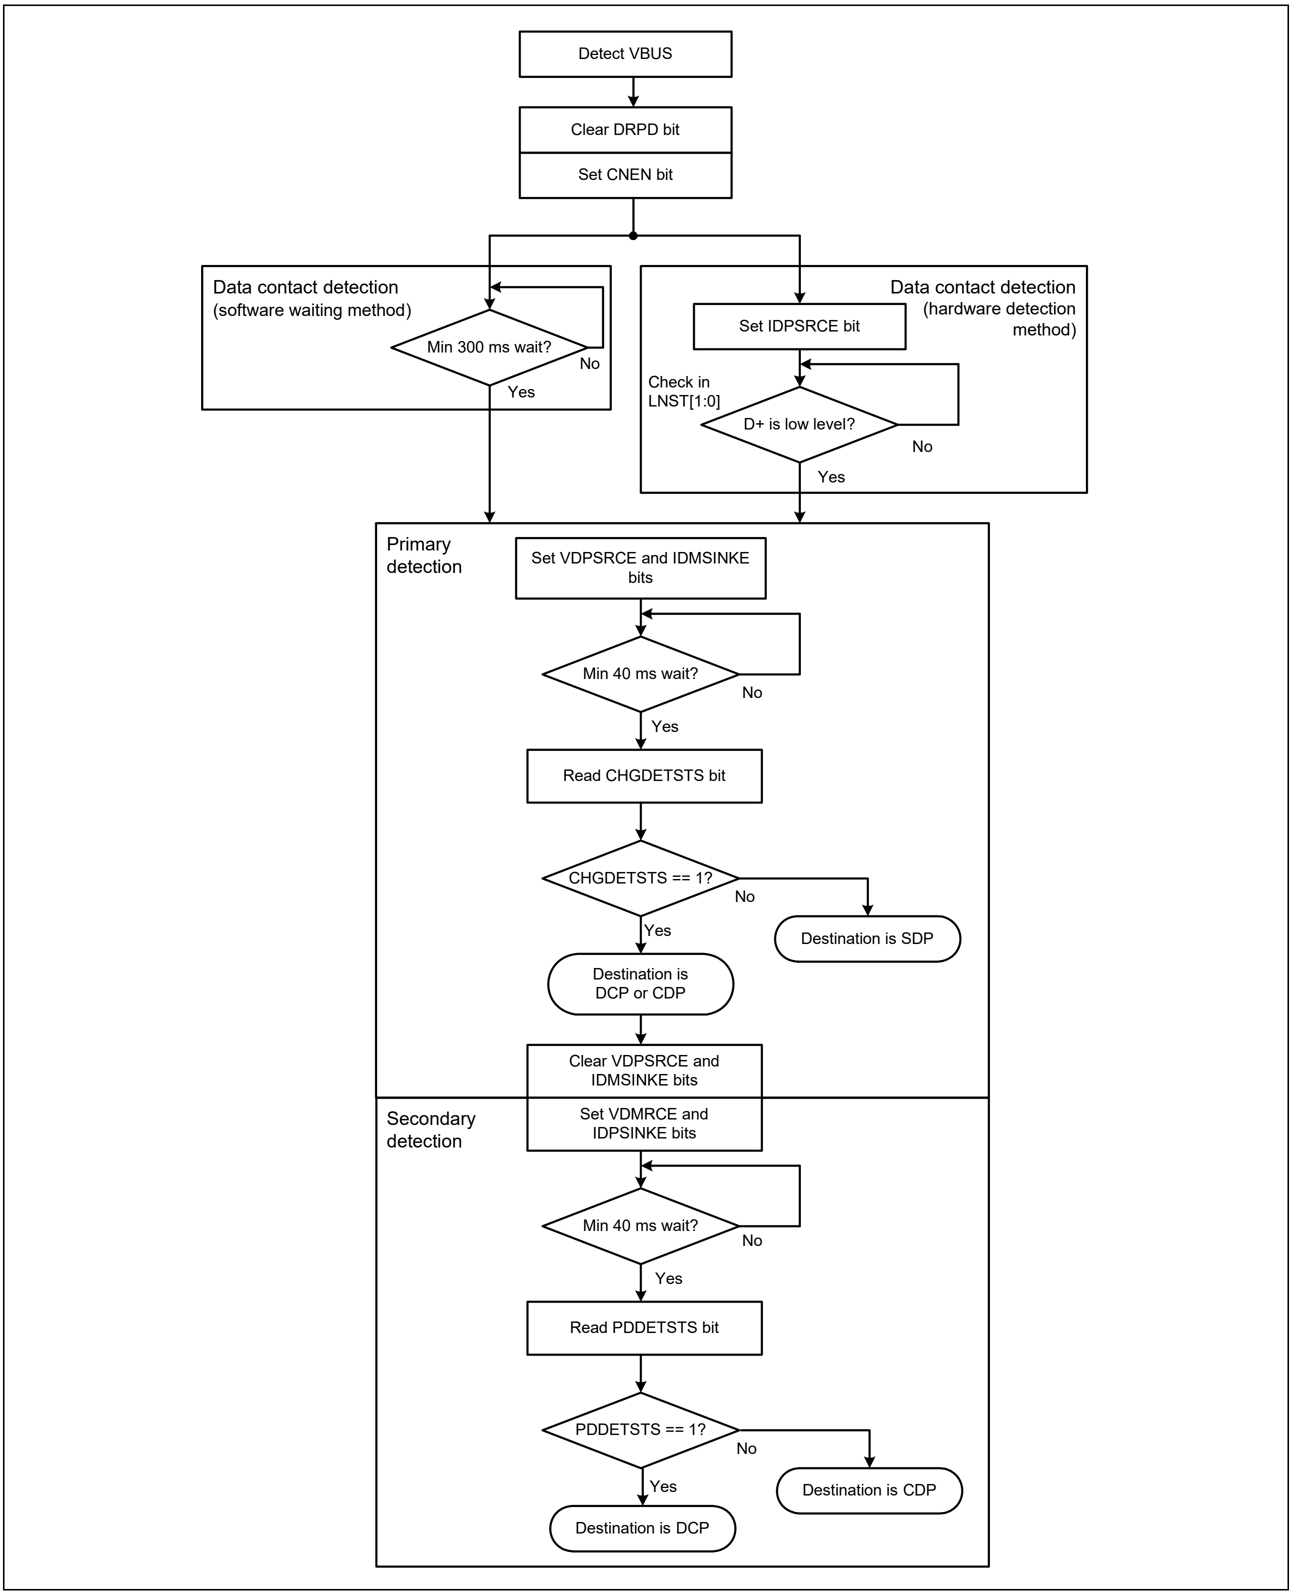

Figure 33.19 Processing flow as portable device

33.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBHS supports the following two primary detection methods:

- When the hardware has a portable device detection function

- When the hardware does not have the function or the function is present but not used.

Figure 33.20 and Figure 33.21 show the processing flows for these methods.

(1) When the hardware has a portable device detection function

a. Start driving the USBHS_VBUS input pin.

b. Set the BCCTRL.IDMSINKE bit to 1 to enable the portable device detection circuit.

c. Monitor the portable device detection signal and start driving the D-line when the level of the portable device detection signal is high*1.

d. Stop driving the D-line when the portable device detection signal is at the low level*1.

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal (EUH_CPDDET), and the current level can be obtained by reading the PDDETSTS flag.

(2) When the hardware does not have a portable device detection function or the function is not used

Software handles the timing of steps a. and b.

a. After a disconnect is detected, start driving the D-line within 200 ms.

b. After a connect is detected, stop driving the D-line within 10 ms.

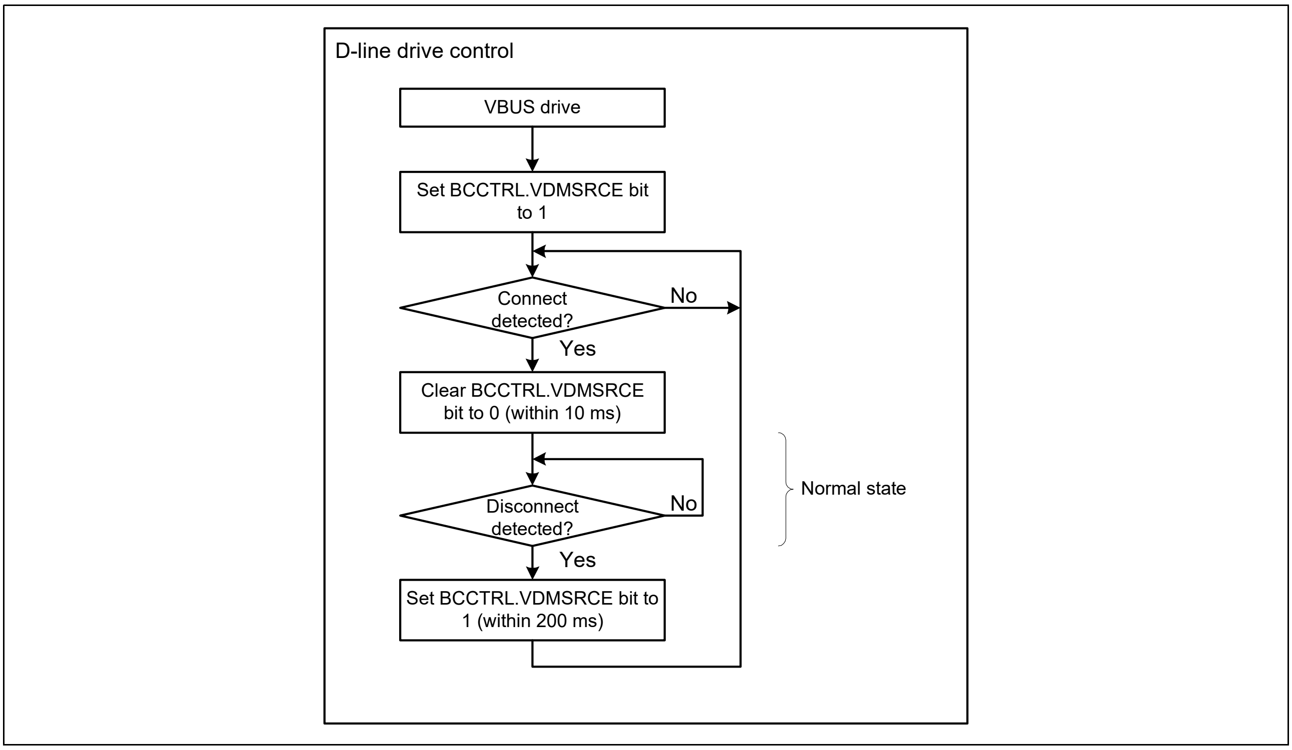

Figure 33.20 Processing flow as charging downstream port without hardware portable device detection function or when function is not used

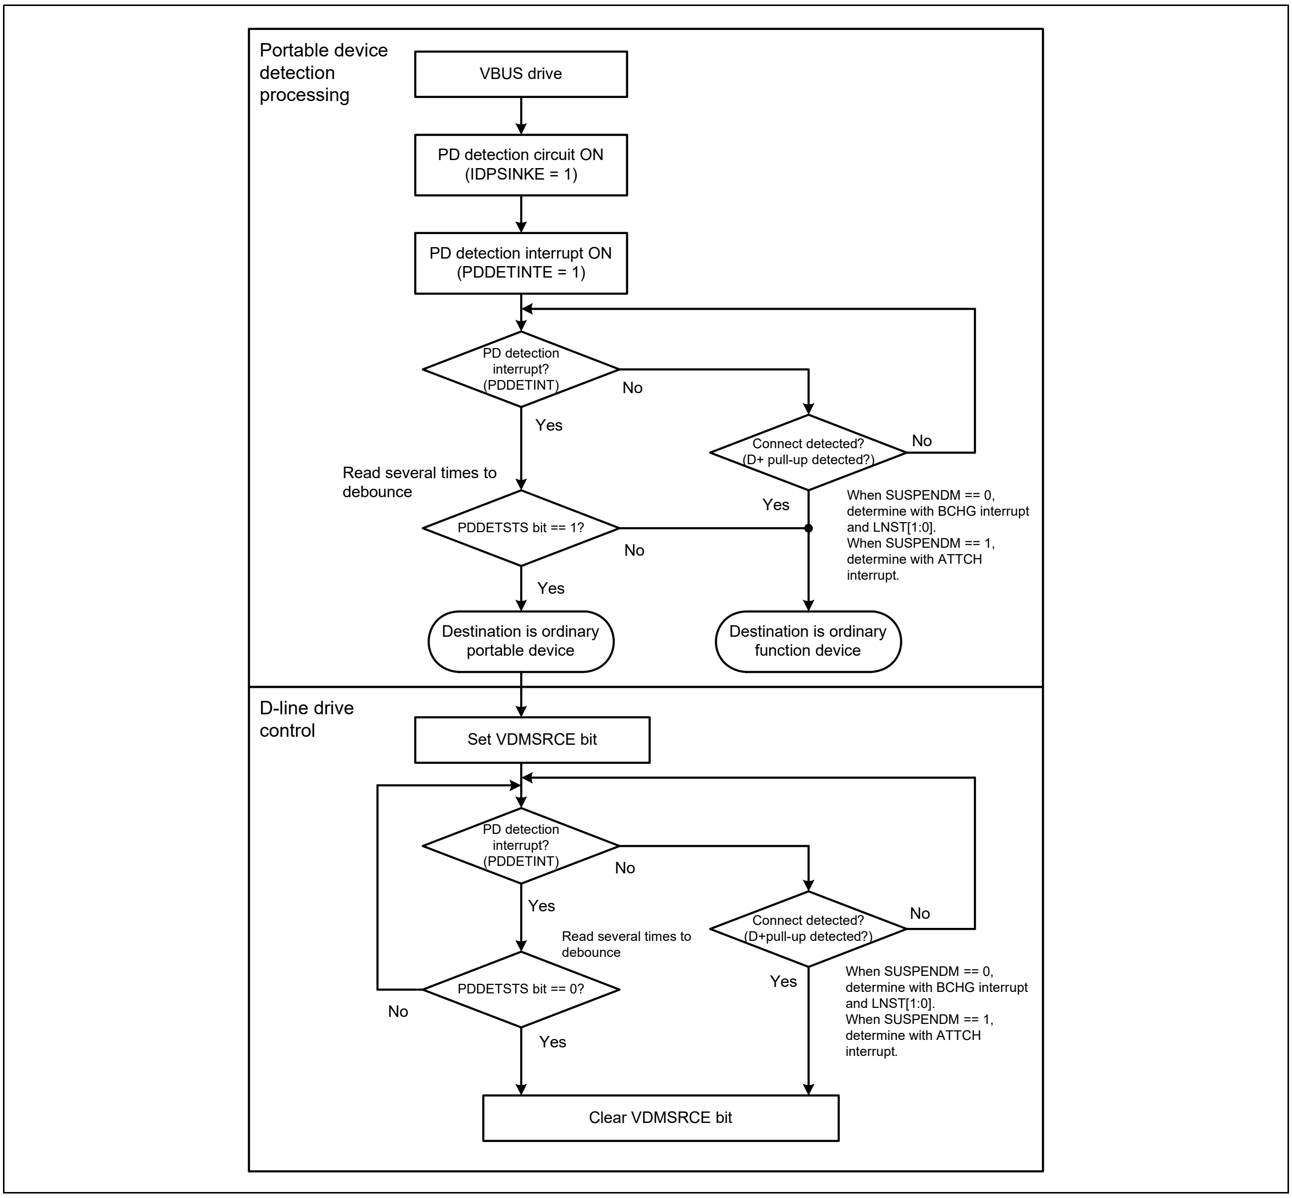

Figure 33.21 Processing flow as charging downstream port with hardware portable device detection function

33.3.16 Link Power Management Processing

The Link Power Management standard defines the existing Suspend state as the L2 state and also defines the L1 state as a state that allows transition and return with lower latency than the L2 state (Suspend). Table 33.34 provides a comparison between the L2 (Suspend) and L1 states.

Table 33.34 Comparison between L2 (Suspend) state and L1 state (1 of 2)

Parameter	L1 state	L2 (Suspend) state
Transition	LPM transaction	Idle for 3 ms
Return caused by host	Host: Minimum drive period (75 µs to 1.175 ms) can be specified by the host. Function: 10-µs K drive	Host: Minimum 20-ms K drive Function: 10-ms K drive

Table 33.34 Comparison between L2 (Suspend) state and L1 state (2 of 2)

Parameter	L1 state	L2 (Suspend) state
Return caused by function	Device: 50-μs K drive Function: 60- to 990-μs K drive Device: 10-μs K drive	Function: 1- to 15-ms K drive Host: Minimum 20-ms K drive Function: 10-ms K drive
Signaling	Low- and full-speed idle	Low- and full-speed idle

33.3.16.1 Processing in device controller mode

(1) Descriptor contents

In device controller mode, the USBHS must return its descriptor on receiving the GetDescriptor command.

Change the content of the descriptor to be returned depending on whether the transition to and return from the L1 state corresponds to the processing for the LPM transaction. The following table shows the relationship between LPM correspondence and the descriptor.

Table 33.35 Relationship between LPM correspondence and descriptor

Correspondence with LPM	bcdUSB field	USB2.0 extension descriptor		Response to received LPM request	Notes
		Provided/ not provided	Value of LPM bit		
Does not correspond	0200h	Not provided	—	No response	Normal operation when the LPM is not supported
	0201h	Provided	0	STALL	Setting for clear non-correspondence to LPM. In this case, a STALL response must be returned.
Corresponds	0201h	Provided	1	ACK or NYET	Normal operation when the LPM is supported

Declare whether to correspond to the transition to and return from L1 in the LPM bit in the USB 2.0 extension descriptor. To provide the USB2.0 extension descriptor, the bcdUSB field of the device descriptor must be set to a value of 0201h or larger.

When the LPM is not supported, the USB2.0 extension descriptor is not provided and the bcdUSB field value must be 0200h. If an LPM token is received in this case, it must be ignored. It is also possible to set the bcdUSB field value to 0201h and the LPM bit in the USB2.0 extension descriptor to 0 (LPM tokens not supported). In this case, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set the bcdUSB field value to 0201h and set the LPM bit in the USB 2.0 extension descriptor to 1 (LPM tokens supported). This allows acknowledgment when returning a NYET or ACK response to the LPM token.

(2) Processing during LPM token reception

Transition to and return from the L1 state in device controller mode is as follows:

a. When the USBHS receives an LPM token from the host, the L1RESPEN, L1RESPMD[1:0], and L1NEGOMD settings in PL1CTRL1 determine whether a response packet is sent or the token is ignored and, if a response is to be sent, whether it is an ACK, NYET, or STALL packet.

b. If an ACK response to the LPM token is sent and the host does not transmit another LPM token in 8 μs, the USBHS enters the L1 state. The USBHS handles detection of the newly transmitted packet and the transition to the L1 state. The DVST interrupt can be used to detect the transition.

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line in the K-state:
  The function device detects the K-state and starts processing the return from the L1 state in response to an

RESM interrupt request

- When the function device outputs a remote wakeup signal:
  If the software on the function device sets the DVSTCTR0.WKUP bit to 1, it sends a remote wakeup signal to the host.

The software clears the DVSTCTR0.WKUP bit to 0 on returning from the L2 (Suspend) state, and the USBHS clears the DVSTCTR0.WKUP bit to 0 for return from the L1 state.

(3) HIRD field value negotiation function

The HIRD field value included in the LPM token indicates the host K-drive period on return from the L1 state. The HIRD field value can be adjusted according to the requirements of the target system. For example, a small HIRD field value is better for systems focusing on higher transfer efficiency, while a large HIRD field value is better for systems focusing on low power consumption.

Based on the L1NEGOMD and HIRDTHR[3:0] settings in PL1CTRL1, an ACK response is returned when the received HIRD field value is in the expected range, and otherwise a NYET response is returned, requesting the host to change the HIRD field value.

Note: This HIRD field value negotiation function at the host must also support negotiation processing.

33.3.16.2 Processing in host controller mode

(1) Processing during LPM token transmission

Transition to and return from the L1 state in host controller mode is as follows:

a. When the HL1CTRL.L1REQ bit is set to 1, an LPM token is sent to the function device from the host device.

b. If an ACK response is received from the function device, a transition to the L1 state starts within 10 µs and is complete within 50 µs. If a transaction error is detected, another LPM token is transmitted within 8 µs. Retransmission can proceed up to two times. The USBHS handles all of this processing.

c. Two types of processing can return the USBHS from the L1 state:

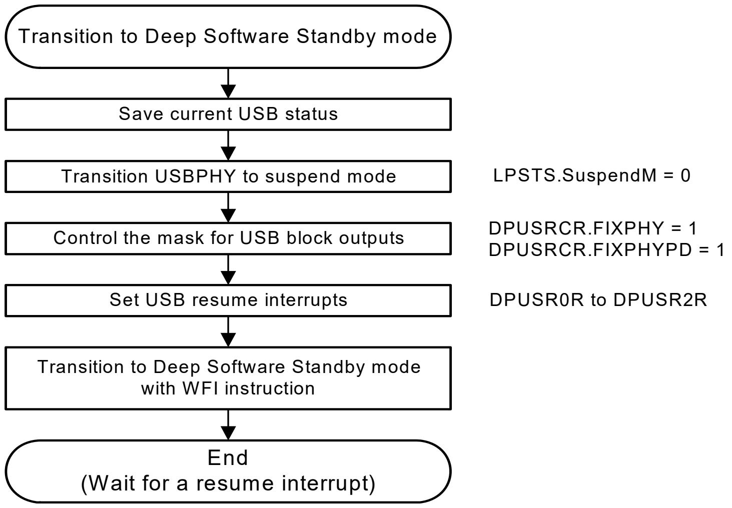
- When the host drives the D-line for the K state:
  When the DVSTCTR0.RESUME bit is set to 1, the host device starts driving the D-line for the K-state and starts processing the return
- When the function device generates a remote wakeup signal:
  When the host device detects a remote wakeup signal from the function device, it sets the DVSTCTR0.RESUME bit to 1 and starts driving the D-line for the K-state.

Unlike when returning from the Suspend (L2) state, the USBHS clears the DVSTCTR0.RESUME bit to 0. After clearing the RESUME bit, it sets the DVSTCTR0.UACT bit to 1 and issues an L1RSMEND interrupt request.

33.3.17 Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 33.22 shows the flow for setting the USBHS when entering Deep Software Standby mode from either host or device controller mode. Figure 33.23 and Figure 33.24 show the flows for setting the USBHS when canceling Deep Software Standby mode from host controller mode. Figure 33.25 shows the flow for setting the USBHS when canceling Deep Software Standby mode from device controller mode.



Note: When connected to an external device, transition to Deep Software Standby mode is enabled only on USB Suspend.

Note: Never invoke Deep Software Standby mode in the following cases:
- In an L1 Suspend status with the USB-LPM protocol.
- When remote wakeup is enabled in host controller mode.

Figure 33.22 USBHS setup flow for transition to Deep Software Standby mode as a host or device controller

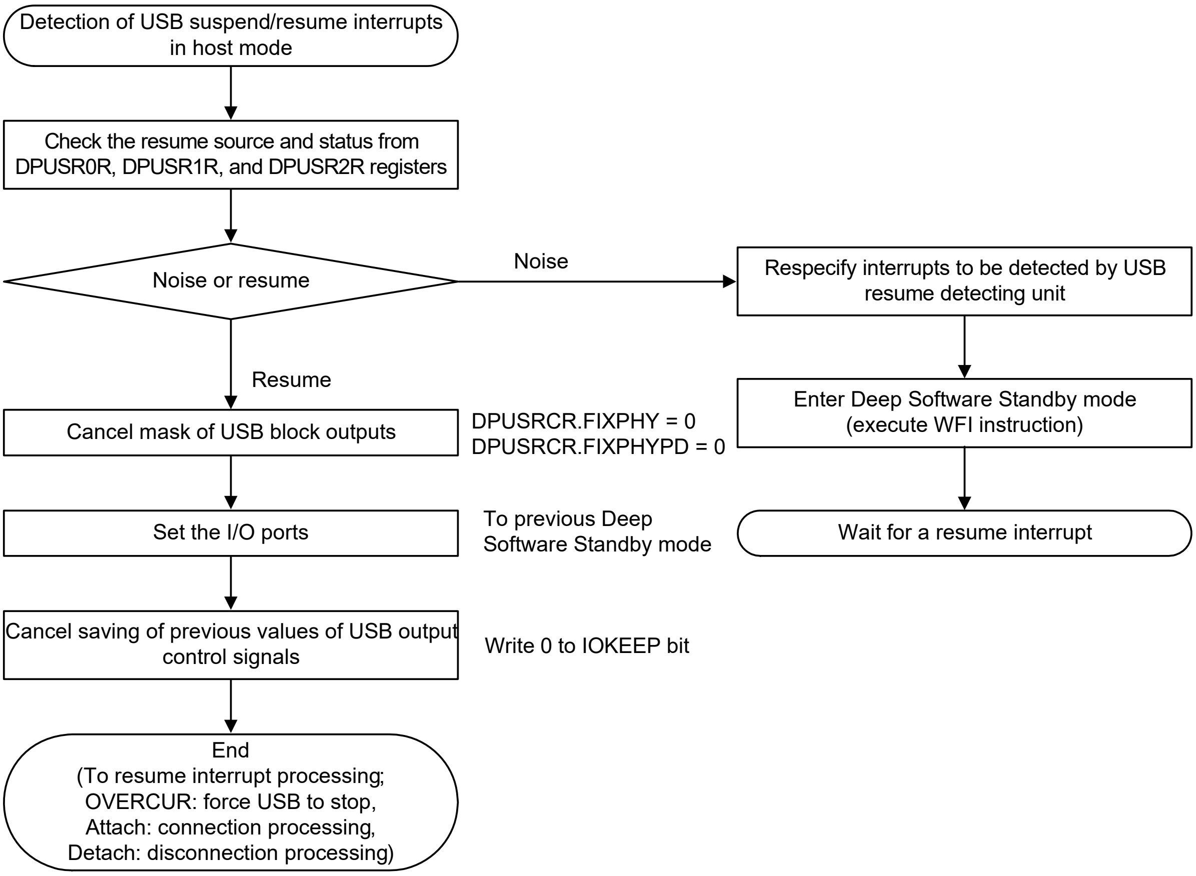


Figure 33.23 USBHS setup flow for canceling Deep Software Standby mode as a host controller (1)

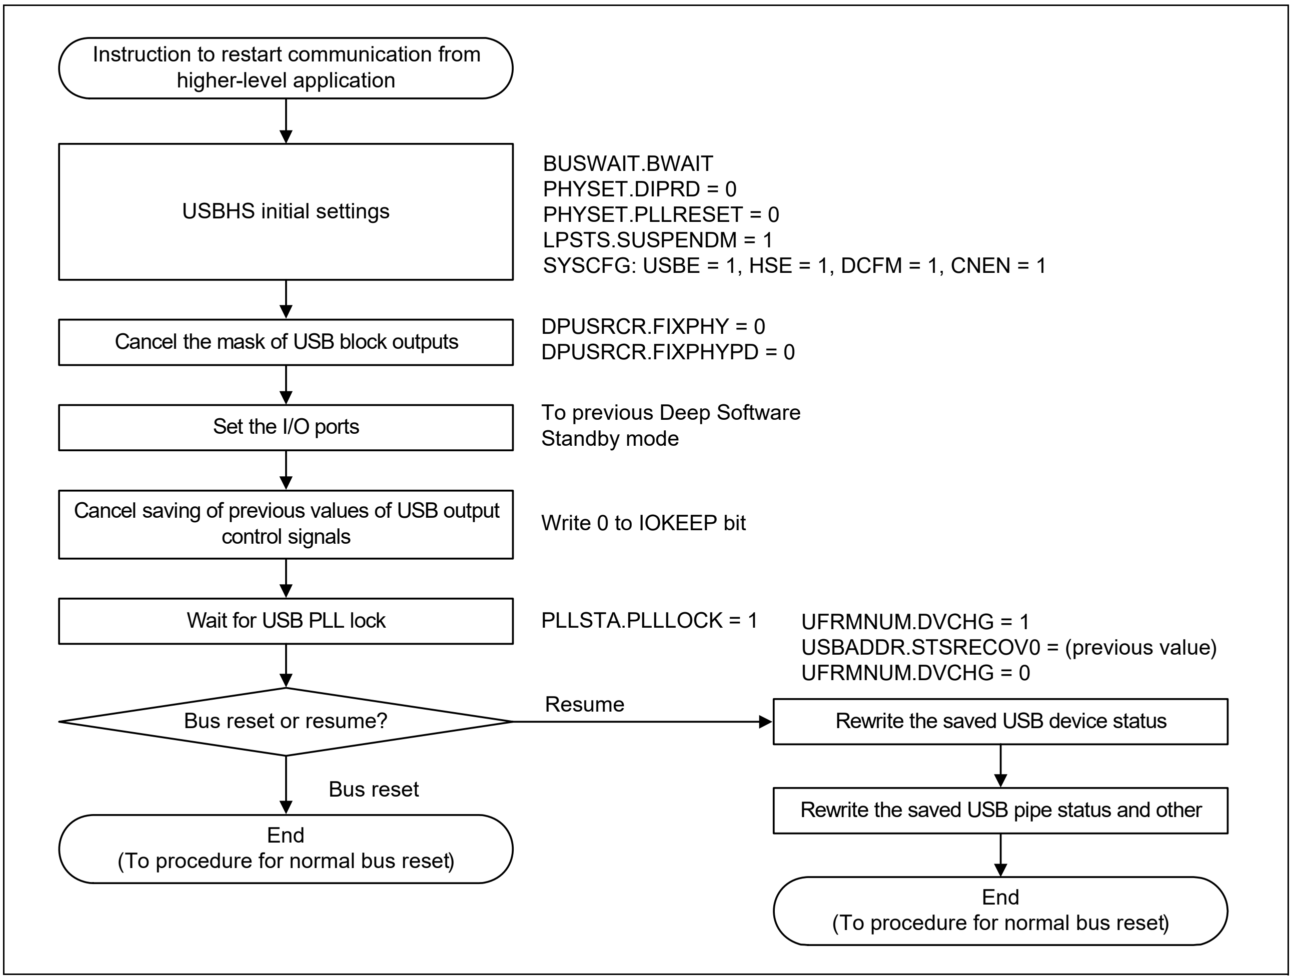

Figure 33.24 USBHS setup flow for canceling Deep Software Standby mode as a host controller (2)

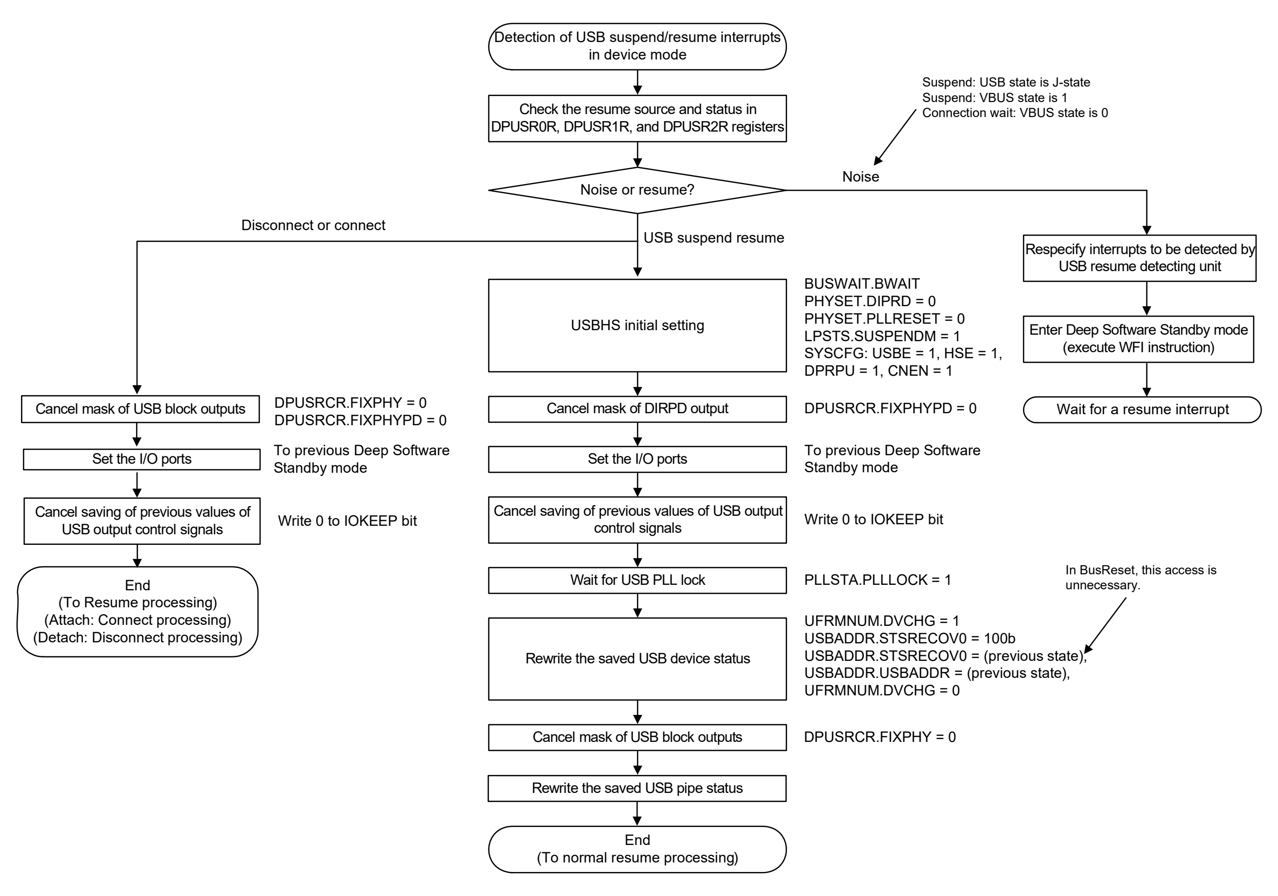

Note: In BusReset return, the write to the STSRECOV0 bit must be within 2.5 µS of USBHS-PHY PLL oscillation start.

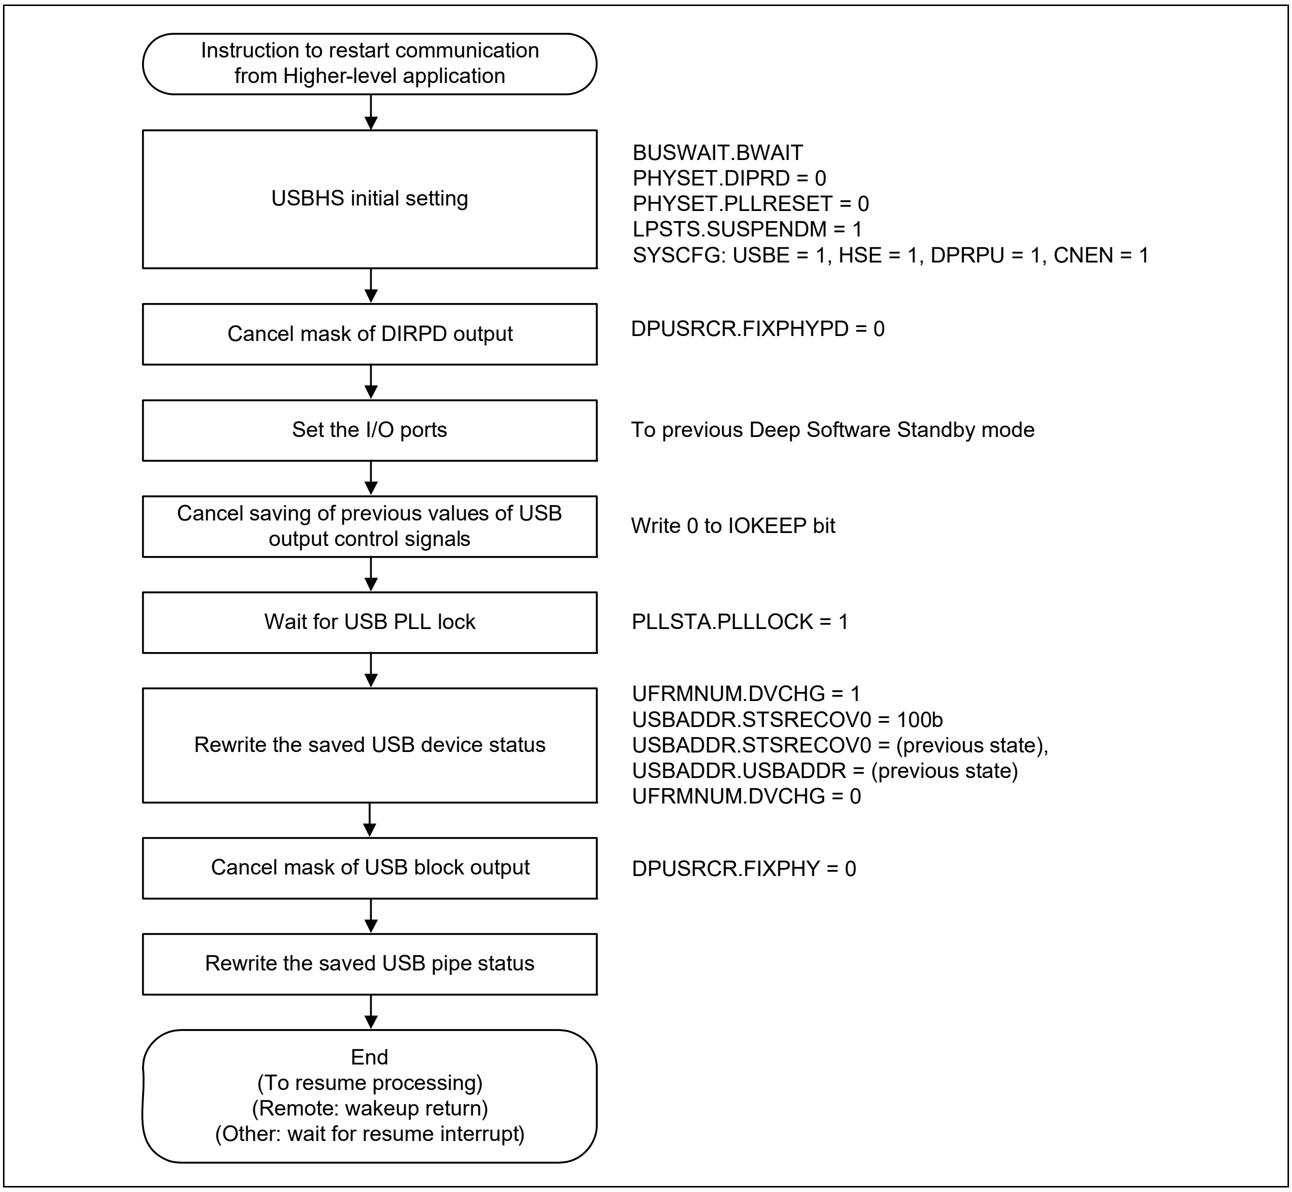

Figure 33.26 USBHS setup flow for canceling Deep Software Standby mode as a device controller (2)

33.3.18 Example External Connection Circuits

Figure 33.27 shows an example OTG connection in a self-powered system. The USBHS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU and SYSCFG.DRPD bits. In device controller mode, the pull-up resistor of USB data line is disabled if SYSCFG.DPRPU bit is set to 0 while communicating with the USB host. The USBHS can use this to notify the USB host of a device disconnect.

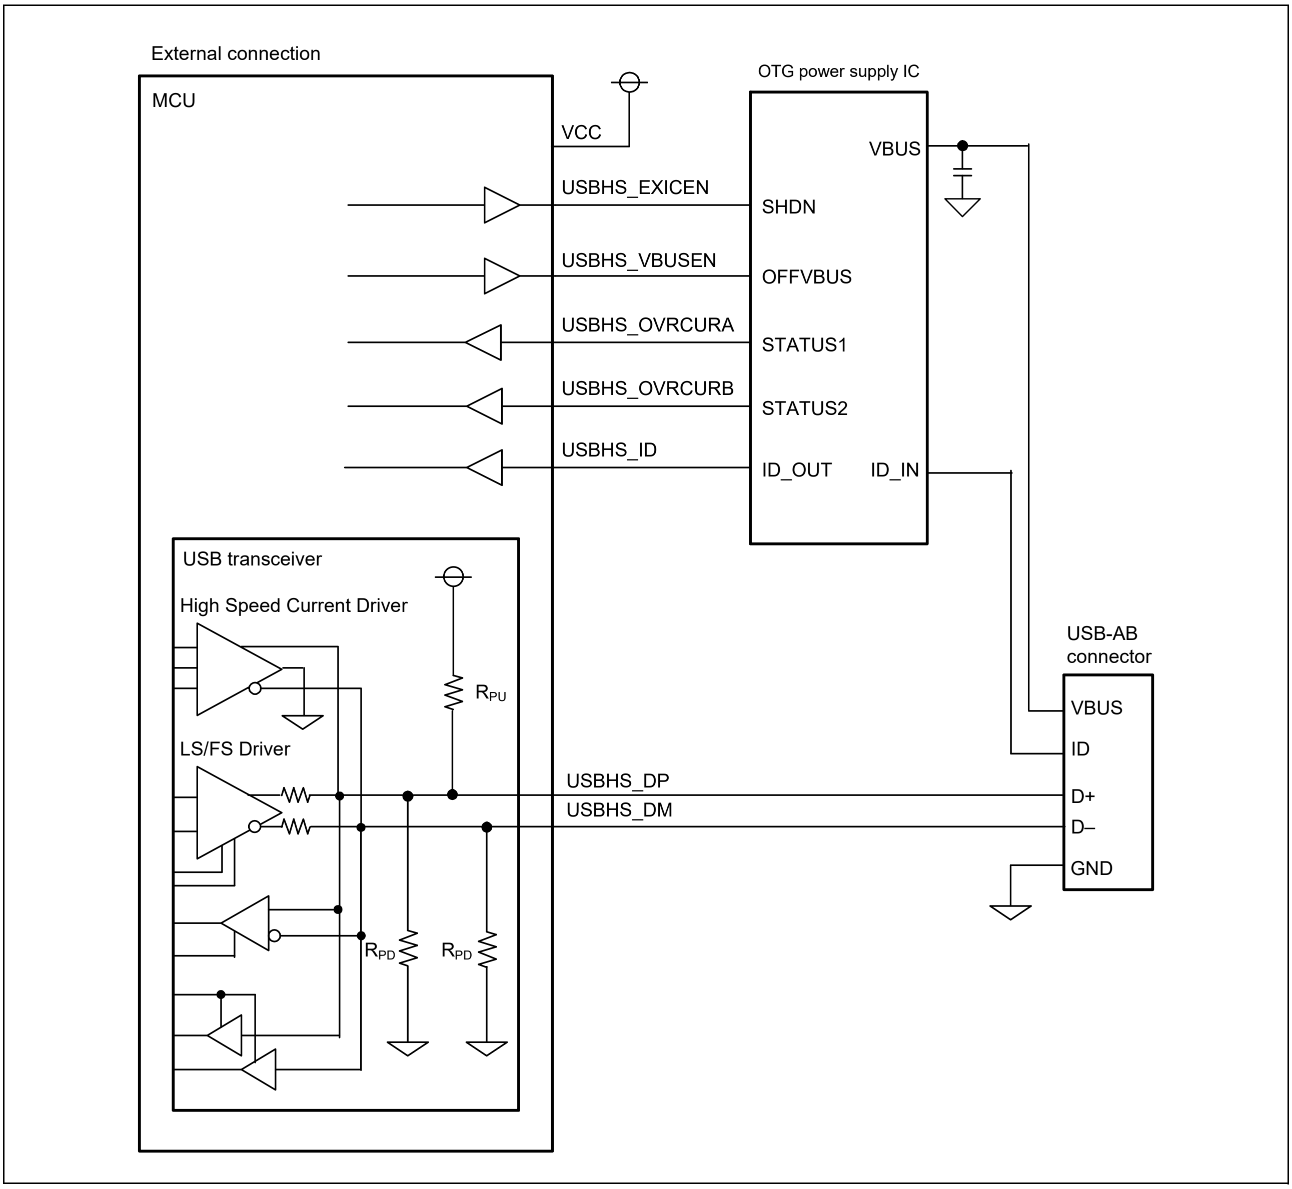

Figure 33.27 Example OTG connection in a self-powered system

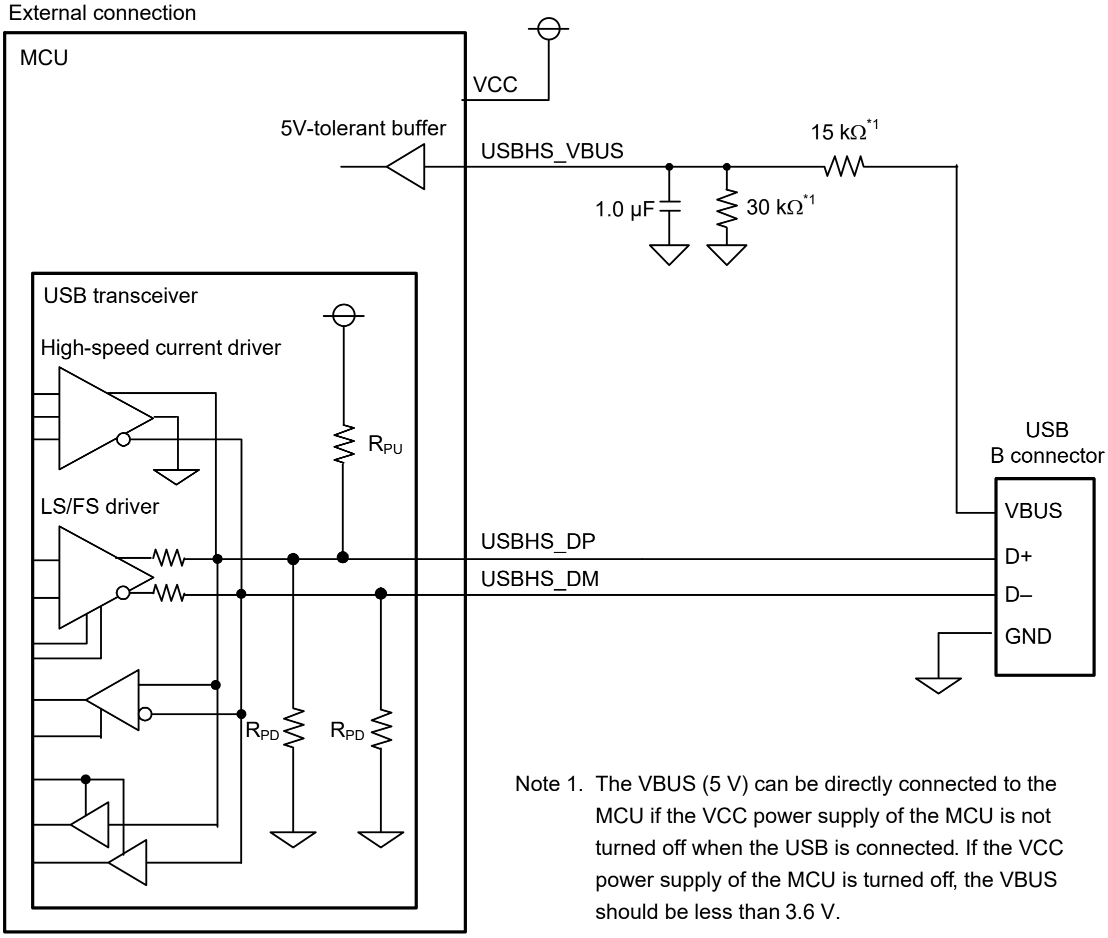
Figure 33.28 shows an example USB device connection in a self-powered system.



Note 1. The VBUS (5 V) can be directly connected to the MCU if the VCC power supply of the MCU is not turned off when the USB is connected. If the VCC power supply of the MCU is turned off, the VBUS should be less than 3.6 V.

33.4 Usage Notes

33.4.1 Settings for the Module-Stop Function

USBHS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. After releasing module stop, make settings required to activate the PHY circuit, including the input system clock frequency setting, and then clear the PHYSET.DIRPD bit to 0. For details, see section 11, Low Power Modes.

33.4.2 Setup for Transitioning to Deep Software Standby Mode

Before transitioning to Deep Software Standby mode, clear the DVSTCTR0.VBUSEN bit to 0.

33.4.3 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels Software Standby is changed in Software Standby mode.

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

33.4.4 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR ports are set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

34. Serial Communications Interface (SCI)

34.1 Overview

The Serial Communications Interface (SCI) is configurable to five asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Smart card interface.

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. Each SCI has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

Table 34.1 lists the SCI specifications, Figure 34.1 shows a block diagram of SCI channel n, and Table 34.2 lists the I/O pins by mode.

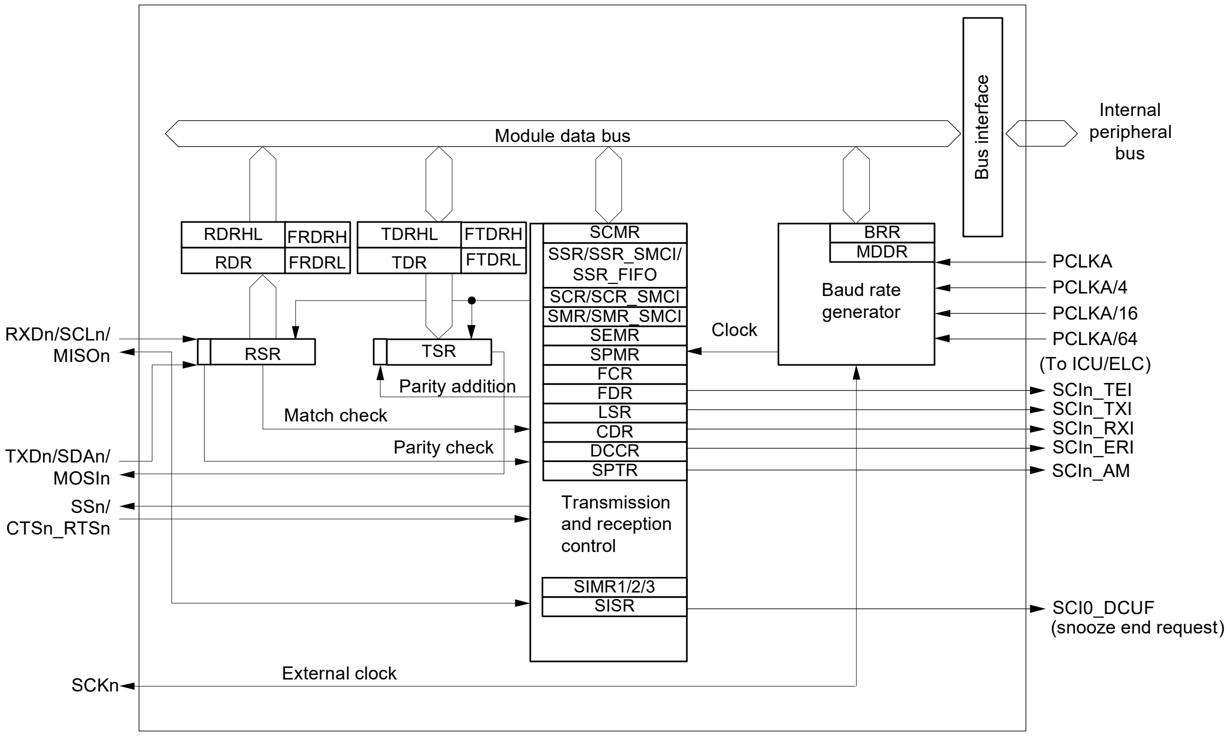
Table 34.1 SCI specifications (1 of 2)

Parameter	Specifications
Serial communication modes	• Asynchronous • Clock synchronous • Smart card interface • Simple IIC • Simple SPI.
Transfer speed	Bit rate specifiable with the on-chip baud rate generator
Full-duplex communications	• Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
I/O pins	See Table 34.2
Data transfer	Selectable as LSB-first or MSB-first transfer
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, and address match Completion of generation of a start condition, restart condition, or stop condition (for simple IIC mode)
Module-stop function	Module-stop state can be set for each channel
Snooze end request	SCI0 address mismatch (SCI0_DCUF)

Table 34.1 SCI specifications (2 of 2)

Parameter		Specifications
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, and framing errors
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
	Address match	Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register
	Address non-match (SCI0 only) receive data	Snooze end request can be issued upon detecting a non-match between the received data and the value in the compare match register
	Start-bit detection	Selectable to low level or falling edge detection
	Break detection	Breaks from framing errors detectable by reading from SPTR register
	Clock source	Selectable to internal or external clock
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communications function	Serial communication enabled among multiple processors
	Noise cancellation	Digital noise filters included on signal paths from the RXDn pin inputs
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
Smart card interface mode	Error processing	Error signal can be automatically transmitted upon detecting a parity error during reception
		Data can be automatically retransmitted upon receiving an error signal during transmission
	Data type	Both direct and inverse convention supported
Simple IIC mode	Transfer format	I^{2}C bus format (MSB-first only)
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps
	Noise cancellation	The signal paths from input on the SCLn and SDAn pins incorporate digital noise filters, and provide an adjustable interval for noise cancellation
Simple SPI mode	Data length	8 bits
	Error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	SS input pin function	High impedance state can be invoked on the output pins by driving the SSn pin high
	Clock settings	Configurable among four clock phase and clock polarity settings
Bit rate modulation function		Error reduction through correction of outputs from the on-chip baud rate generator
Event link function		Error event output for receive error or error signal detection (SCIn_ERI, n = 0 to 9)
		Receive data full event output (SCIn_RXI, n = 0 to 9)*1
		Transmit data empty event output (SCIn_TXI, n = 0 to 9)*1
		Transmit end event output (SCIn_TEI, n = 0 to 9)*1
		Address match event output (SCIn_AM, n = 0 to 9)

Note 1. Using this event link function is prohibited when FIFO operation is selected in asynchronous mode.



RSR: Receive Shift Register
RDR: Receive Data Register
TSR: Transmit Shift Register
TDR: Transmit Data Register
SMR/SMR_SMCI: Serial Mode Register
SCR/SCR_SMCI: Serial Control Register
SSR/SSR_SMCI/SSR_FIFO: Serial Status Register
SCMR: Smart Card Mode Register
BRR: Bit Rate Register
MDDR: Modulation Duty Register
SEMR: Serial Extended Mode Register
SPMR: SPI Mode Register
SIMR1/2/3: IIC Mode Register 1/2/3
SISR: IIC Status Register

RDRHL: Receive 9-Bit Data Register
FRDRH/L: Receive FIFO Data Register
TDRHL: Transmit 9-Bit Data Register
FTDRH/L: Transmit FIFO Data Register
FCR: FIFO Control Register
FDR: FIFO Data Count Register
LSR: Line Status Register
CDR: Compare Match Data Register
DCCR: Data Compare Match Control Register
SPTR: Serial Port Register

34.2 Register Descriptions

34.2.1 Receive Shift Register (RSR)

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, it is automatically transferred to the RDR register, RDRHL register, or receive FIFO. The RSR register cannot be directly accessed by the CPU.

34.2.2 Receive Data Register (RDR)

Address(es): SCI0.RDR 4007 0005h, SCI1.RDR 4007 0025h, SCI2.RDR 4007 0045h, SCI3.RDR 4007 0065h, SCI4.RDR 4007 0085h, SCI5.RDR 4007 00A5h, SCI6.RDR 4007 00C5h, SCI7.RDR 4007 00E5h, SCI8.RDR 4007 0105h, SCI9.RDR 4007 0125h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

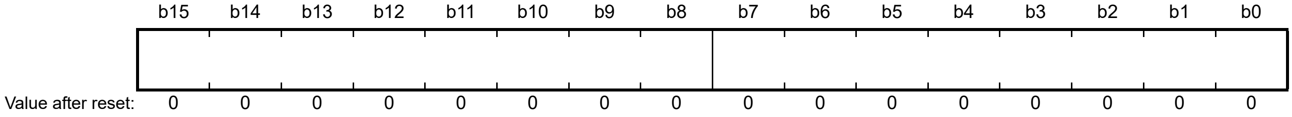
RDR is an 8-bit register that stores receive data. When one frame of serial data is received, it is transferred from the RSR register to the RDR register, and the RSR register can receive more data. Because RSR and RDR function as a double buffer in this way, continuous receive operations can be performed.

Read the RDR register only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before the receive data is read from the RDR register, an overrun error occurs. The RDR register cannot be written to by the CPU.

34.2.3 Receive 9-Bit Data Register (RDRHL)

Address(es): SCI0.RDRHL 4007 0010h, SCI1.RDRHL 4007 0030h, SCI2.RDRHL 4007 0050h, SCI3.RDRHL 4007 0070h, SCI4.RDRHL 4007 0090h, SCI5.RDRHL 4007 00B0h, SCI6.RDRHL 4007 00D0h, SCI7.RDRHL 4007 00F0h, SCI8.RDRHL 4007 0110h, SCI9.RDRHL 4007 0130h



RDRHL is a 16-bit register that stores receive data. Use the RDRHL register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are a shadow register of RDR, so access to the RDRHL register affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDRHL register, allowing the RSR register to receive more data.

The RSR and RDRHL registers have a double-buffered construction to enable continuous reception. The RDRHL register must be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from the RDRHL register.

The CPU cannot write to the RDRHL register. Bits [15:9] are fixed to 0. These bits are read as 0. The write value should be 0.

34.2.4 Receive FIFO Data Register H, L, HL (FRDRH, FRDRL, FRDRHL)

Receive FIFO Data Register H (FRDRH)

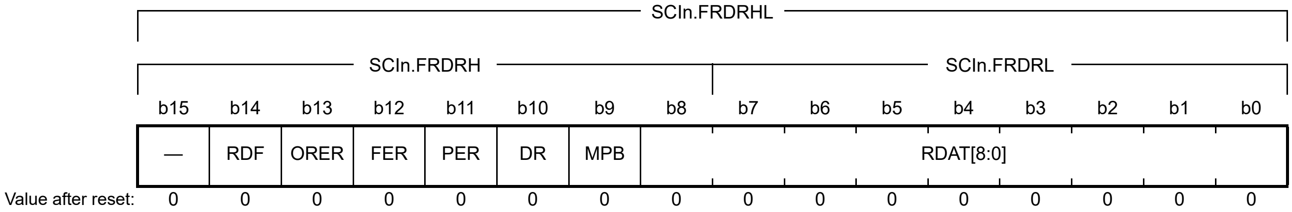
Address(es): SCI0.FRDRH 4007 0010h, SCI1.FRDRH 4007 0030h, SCI2.FRDRH 4007 0050h, SCI3.FRDRH 4007 0070h, SCI4.FRDRH 4007 0090h, SCI5.FRDRH 4007 00B0h, SCI6.FRDRH 4007 00D0h, SCI7.FRDRH 4007 00F0h, SCI8.FRDRH 4007 0110h, SCI9.FRDRH 4007 0130h

Receive FIFO Data Register L (FRDRL)

Address(es): SCI0.FRDRL 4007 0011h, SCI1.FRDRL 4007 0031h, SCI2.FRDRL 4007 0051h, SCI3.FRDRL 4007 0071h, SCI4.FRDRL 4007 0091h, SCI5.FRDRL 4007 00B1h, SCI6.FRDRL 4007 00D1h, SCI7.FRDRL 4007 00F1h, SCI8.FRDRL 4007 0111h, SCI9.FRDRL 4007 0131h

Receive FIFO Data Register HL (FRDRHL)

Address(es): SCI0.FRDRHL 4007 0010h, SCI1.FRDRHL 4007 0030h, SCI2.FRDRHL 4007 0050h, SCI3.FRDRHL 4007 0070h, SCI4.FRDRHL 4007 0090h, SCI5.FRDRHL 4007 00B0h, SCI6.FRDRHL 4007 00D0h, SCI7.FRDRHL 4007 00F0h, SCI8.FRDRHL 4007 0110h, SCI9.FRDRHL 4007 0130h



Bit	Symbol	Bit name	Description	R/W
b8 to b0	RDAT[8:0]	Serial Receive Data	Valid only in asynchronous mode, including multi-processor mode, and clock synchronous mode, and with FIFO selected. Stores the serial receive data.	R
b9	MPB	Multi-Processor Bit Flag	Stores the value of the multi-processor bit in the serial receive data (RDAT[8:0]): 0: Data transmission cycle 1: ID transmission cycle. Valid only in asynchronous mode with SMR.MP = 1, and with FIFO selected.	R

Bit	Symbol	Bit name	Description	R/W
b10	DR	Receive Data Ready Flag	This flag is the same as SSR_FIFO.DR: 0: Receiving is in progress, or no received data remains in the FRDRH and FRDRL registers after successfully completed reception 1: Next receive data is not received for a period after successfully completed reception.	R*1
b11	PER	Parity Error Flag	0: No parity error occurred in the first data of FRDRH and FRDRL 1: Parity error occurred in the first data of FRDRH and FRDRL.	R
b12	FER	Framing Error Flag	0: No framing error occurred in the first data of FRDRH and FRDRL 1: Framing error occurred in the first data of FRDRH and FRDRL.	R
b13	ORER	Overrun Error Flag	This flag is the same as SSR_FIFO.ORER: 0: No overrun error occurred 1: Overrun error occurred.	R*1
b14	RDF	Receive FIFO Data Full Flag	This flag is the same as SSR_FIFO.RDF: 0: The amount of receive data written in FRDRH and FRDRL is less than the specified receive triggering number 1: The amount of receive data written in FRDRH and FRDRL is equal to or greater than the specified receive triggering number.	R*1
b15	—	Reserved	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

34.2.5 Transmit Data Register (TDR)

Address(es): SCI0.TDR 4007 0003h, SCI1.TDR 4007 0023h, SCI2.TDR 4007 0043h, SCI3.TDR 4007 0063h,
SCI4.TDR 4007 0083h, SCI5.TDR 4007 00A3h, SCI6.TDR 4007 00C3h, SCI7.TDR 4007 00E3h,
SCI8.TDR 4007 0103h, SCI9.TDR 4007 0123h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn_TXI).

34.2.6 Transmit 9-Bit Data Register (TDRHL)

Address(es): SCI0.TDRHL 4007 000Eh, SCI1.TDRHL 4007 002Eh, SCI2.TDRHL 4007 004Eh, SCI3.TDRHL 4007 006Eh,
SCI4.TDRHL 4007 008Eh, SCI5.TDRHL 4007 00AEh, SCI6.TDRHL 4007 00CEh, SCI7.TDRHL 4007 00EEh,
SCI8.TDRHL 4007 010Eh, SCI9.TDRHL 4007 012Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

TDRHL is a 16-bit register that stores transmit data. Use the TDRHL register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are a shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL register is transferred to the TSR register and transmission is started.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation is continued by transferring the data from the TDRHL register to the TSR register.

The CPU can read from and write to the TDRHL register. Bits [15:9] in the TDRHL register are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to the TDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

34.2.7 Transmit FIFO Data Register H, L, HL (FTDRH, FTDRL, FTDRHL)

Transmit FIFO Data Register H (FTDRH)

Address(es): SCI0.FTDRH 4007 000Eh, SCI1.FTDRH 4007 002Eh, SCI2.FTDRH 4007 004Eh, SCI3.FTDRH 4007 006Eh, SCI4.FTDRH 4007 008Eh, SCI5.FTDRH 4007 00AEh, SCI6.FTDRH 4007 00CEh, SCI7.FTDRH 4007 00EEh, SCI8.FTDRH 4007 010Eh, SCI9.FTDRH 4007 012Eh

Transmit FIFO Data Register L (FTDRL)

Address(es): SCI0.FTDRL 4007 000Fh, SCI1.FTDRL 4007 002Fh, SCI2.FTDRL 4007 004Fh, SCI3.FTDRL 4007 006Fh, SCI4.FTDRL 4007 008Fh, SCI5.FTDRL 4007 00AFh, SCI6.FTDRL 4007 00CFh, SCI7.FTDRL 4007 00EFh, SCI8.FTDRL 4007 010Fh, SCI9.FTDRL 4007 012Fh

Transmit FIFO Data Register HL (FTDRHL)

Address(es): SCI0.FTDRHL 4007 000Eh, SCI1.FTDRHL 4007 002Eh, SCI2.FTDRHL 4007 004Eh, SCI3.FTDRHL 4007 006Eh, SCI4.FTDRHL 4007 008Eh, SCI5.FTDRHL 4007 00AEh, SCI6.FTDRHL 4007 00CEh, SCI7.FTDRHL 4007 00EEh, SCI8.FTDRHL 4007 010Eh, SCI9.FTDRHL 4007 012Eh

	SCIn.FTDRHL															
	SCIn.FTDRH								SCIn.FTDRL							
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b8 to b0	TDAT[8:0]	Serial Transmit Data	Valid only in asynchronous mode, including multi-processor mode, and clock synchronous mode, and with FIFO selected. Specifies the serial transmit data.	W
b9	MPBT	Multi-Processor Transfer Bit Flag	Specifies the multi-processor bit in the transmission frame: 0: Data transmission cycle 1: ID transmission cycle. Valid only in asynchronous mode and SMR.MP = 1, and with FIFO selected.	W
b15 to b10	—	Reserved	The write value should be 1.	W

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDRL registers.

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

34.2.8 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to the TSR register, and then sends the data to the TXDn pin. The CPU cannot directly access the TSR register.

34.2.9 Serial Mode Register (SMR) for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI0.SMR 4007 0000h, SCI1.SMR 4007 0020h, SCI2.SMR 4007 0040h, SCI3.SMR 4007 0060h, SCI4.SMR 4007 0080h, SCI5.SMR 4007 00A0h, SCI6.SMR 4007 00C0h, SCI7.SMR 4007 00E0h, SCI8.SMR 4007 0100h, SCI9.SMR 4007 0120h

	b7	b6	b5	b4	b3	b2	b1	b0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLKA clock (n = 0)*1 0 1: PCLKA/4 clock (n = 1)*1 1 0: PCLKA/16 clock (n = 2)*1 1 1: PCLKA/64 clock (n = 3).*1	R/W*4
b2	MP	Multi-Processor Mode	Valid only in asynchronous mode: 0: Disable multi-processor communications function 1: Enable multi-processor communications function.	R/W*4
b3	STOP	Stop Bit Length	Valid only in asynchronous mode: 0: 1 stop bit 1: 2 stop bits.	R/W*4
b4	PM	Parity Mode	Valid only when the PE bit is 1: 0: Even parity 1: Odd parity.	R/W*4
b5	PE	Parity Enable	Valid only in asynchronous mode: • When transmitting: 0: Do not add parity bit 1: Add parity bit. • When receiving: 0: Do not check parity bit 1: Check parity bit.	R/W*4
b6	CHR	Character Length	Selects the transmit/receive character length in combination with the SCMR.CHR1 bit: CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length.*3 Valid only in asynchronous mode.*2	R/W*4
b7	CM	Communication Mode	0: Asynchronous mode or simple IIC mode 1: Clock synchronous mode or simple SPI mode.	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register. See section 34.2.17, Bit Rate Register (BRR).
Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.
Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 34.2.17, Bit Rate Register (BRR).

MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multi-processor mode.

PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

CM bit (Communication Mode)

The CM bit selects the communication mode:

- Asynchronous mode or simple IIC mode
- Clock synchronous mode or simple SPI mode.

34.2.10 Serial Mode Register for Smart Card Interface Mode (SMR_SMCI) (SCMR.SMIF = 1)

Address(es): SCI0.SMR_SMCI 4007 0000h, SCI1.SMR_SMCI 4007 0020h, SCI2.SMR_SMCI 4007 0040h, SCI3.SMR_SMCI 4007 0060h, SCI4.SMR_SMCI 4007 0080h, SCI5.SMR_SMCI 4007 00A0h, SCI6.SMR_SMCI 4007 00C0h, SCI7.SMR_SMCI 4007 00E0h, SCI8.SMR_SMCI 4007 0100h, SCI9.SMR_SMCI 4007 0120h

	b7	b6	b5	b4	b3	b2	b1	b0
	GM	BLK	PE	PM	BCP[1:0]		CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1 b0 0 0: PCLKA clock (n = 0)*1 0 1: PCLKA/4 clock (n = 1)*1 1 0: PCLKA/16 clock (n = 2)*1 1 1: PCLKA/64 clock (n = 3).*1	R/W*2
b3, b2	BCP[1:0]	Base Clock Pulse	Selects the number of base clock cycles in combination with the SCMR.BCP2 bit. Table 34.3 lists the combinations of the SCMR.BCP2 and SMR.BCP[1:0] bits.	R/W*2
b4	PM	Parity Mode	Valid only when the PE bit is 1: 0: Even parity 1: Odd parity.	R/W*2
b5	PE	Parity Enable	When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.	R/W*2
b6	BLK	Block Transfer Mode	0: Non-block transfer mode operation 1: Block transfer mode operation.	R/W*2
b7	GM	GSM Mode	0: Non-GSM mode operation 1: GSM mode operation.	R/W*2

Note 1. n is the decimal notation of the value of n in the BRR register. See section 34.2.17, Bit Rate Register (BRR).
Note 2. Writable only when SCR_SMCI.TE = 0 and SCR_SMCI.RE = 0 (both serial transmission and reception are disabled).

The SMR_SMCI register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bit (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 34.2.17, Bit Rate Register (BRR).

BCP[1:0] bits (Base Clock Pulse)

The BCP[1:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set these bits in combination with the SCMR.BCP2 bit.

For details, see section 34.6.4, Receive Data Sampling Timing and Reception Margin.

Table 34.3 Combinations of SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period
0	00	93 clock cycles (S = 93)*1
0	01	128 clock cycles (S = 128)*1
0	10	186 clock cycles (S = 186)*1
0	11	512 clock cycles (S = 512)*1
1	00	32 clock cycles (S = 32)*1 (initial value)
1	01	64 clock cycles (S = 64)*1
1	10	372 clock cycles (S = 372)*1
1	11	256 clock cycles (S = 256)*1

Note 1. See section 34.2.17, Bit Rate Register (BRR).

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 34.6.2, Data Format (Except in Block Transfer Mode).

PE bit (Parity Enable)

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 enables block transfer mode operation. For details, see section 34.6.3, Block Transfer Mode.

GM bit (GSM Mode)

Setting the GM bit to 1 enables GSM mode operation. In GSM mode, the SSR_SMCI.TEND flag set timing is moved forward to 11.0 ETUs (elementary time unit = 1-bit transfer time) from the start bit, and clock output control is added. For details, see section 34.6.6, Serial Data Transmission (Except in Block Transfer Mode) and section 34.6.8, Clock Output Control.

34.2.11 Serial Control Register (SCR) for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Address(es): SCI0.SCR 4007 0002h, SCI1.SCR 4007 0022h, SCI2.SCR 4007 0042h, SCI3.SCR 4007 0062h,
SCI4.SCR 4007 0082h, SCI5.SCR 4007 00A2h, SCI6.SCR 4007 00C2h, SCI7.SCR 4007 00E2h,
SCI8.SCR 4007 0102h, SCI9.SCR 4007 0122h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• Asynchronous mode: b1 b0 0 0: On-chip baud rate generator The SCKn pin is available for use as an I/O port based on the I/O port settings 0 1: On-chip baud rate generator A clock with the same frequency as the bit rate is output from the SCKn pin 1 x: External clock Input a clock with a frequency 16 times the bit rate from the SCKn pin when the SEMR.ABCS bit is 0. Input a clock signal with a frequency eight times the bit rate when the SEMR.ABCS bit is 1. • Clock synchronous mode: b1 b0 0 x: Internal clock The SCKn pin functions as the clock output pin 1 x: External clock. The SCKn pin functions as the clock input pin.	R/W*1
b2	TEIE	Transmit End Interrupt Enable	0: Disable SCIn_TEI interrupt requests 1: Enable SCIn_TEI interrupt requests.	R/W
b3	MPIE	Multi-Processor Interrupt Enable	Valid in asynchronous mode when SMR.MP = 1: 0: Non-multi processor reception 1: When data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags RDRF, ORER, and FER in SSR to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi processor reception is resumed.	R/W*3
b4	RE	Receive Enable	0: Disable serial reception 1: Enable serial reception.	R/W*2
b5	TE	Transmit Enable	0: Disable serial transmission 1: Enable serial transmission.	R/W*2
b6	RIE	Receive Interrupt Enable	0: Disable SCIn_RXI and SCIn_ERI interrupt requests 1: Enable SCIn_RXI and SCIn_ERI interrupt requests.	R/W
b7	TIE	Transmit Interrupt Enable	0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests.	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.

Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.

The SCR register controls operation and clock source selection for transmission and reception.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, and FER in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi processor reception resumes. For details, see section 34.4, Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically cleared to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0. Set the TIE bit to 1 while the TE bit is 1. The SCIn_TXI interrupt occurs after TE and TIE bits are set to 1 simultaneously, before transfer starts.

34.2.12 Serial Control Register for Smart Card Interface Mode (SCR_SMCI) (SCMR.SMIF = 1)

Address(es): SCI0.SCR_SMCI 4007 0002h, SCI1.SCR_SMCI 4007 0022h, SCI2.SCR_SMCI 4007 0042h, SCI3.SCR_SMCI 4007 0062h, SCI4.SCR_SMCI 4007 0082h, SCI5.SCR_SMCI 4007 00A2h, SCI6.SCR_SMCI 4007 00C2h, SCI7.SCR_SMCI 4007 00E2h, SCI8.SCR_SMCI 4007 0102h, SCI9.SCR_SMCI 4007 0122h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	• When SMR_SMCI.GM = 0: b1 b0 0 0: Disable output The SCKn pin is available for use as an I/O port if set up in the I/O port settings 0 1: Output clock 1 x: Setting prohibited. • When SMR_SMCI.GM = 1: b1 b0 0 0: Fix output low x 1: Output clock 1 0: Fix output high.	R/W*1
b2	TEIE	Transmit End Interrupt Enable	Set this bit to 0 in smart card interface mode	R/W
b3	MPIE	Multi-Processor Interrupt Enable	Set this bit to 0 in smart card interface mode	R/W
b4	RE	Receive Enable	0: Disable serial reception 1: Enable serial reception.	R/W*2
b5	TE	Transmit Enable	0: Disable serial transmission 1: Enable serial transmission.	R/W*2
b6	RIE	Receive Interrupt Enable	0: Disable SCIn_RXI and SCIn_ERI interrupt requests 1: Enable SCIn_RXI and SCIn_ERI interrupt requests.	R/W
b7	TIE	Transmit Interrupt Enable	0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests.	R/W

x: Don't care

Note 1. Writable only when TE = 0 and RE = 0.

Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written to TE and RE.

The SCR_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see section 34.10, Interrupt Sources.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits control the clock output from the SCKn pin. In GSM mode, clock output can be dynamically switched. For details, see section 34.6.8, Clock Output Control.

TEIE bit (Transmit End Interrupt Enable)

Set the TEIE bit to 0 in smart card interface mode.

MPIE bit (Multi-Processor Interrupt Enable)

Set the MPIE bit to 0 in smart card interface mode.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit. Set the reception format in the SMR_SMCI register before setting the RE bit to 1.

If reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in SSR_SMCI are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission. When the TE bit is set to 1, serial transmission is started by writing transmit data to TDR. Set the transmission format in the SMR_SMCI register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR_SMCI register, and then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0. Set the TIE bit to 1 while the TE bit is 1. The SCIn_TXI interrupt occurs after TE and TIE bits are set to 1 simultaneously, before transfer starts.

34.2.13 Serial Status Register (SSR) for Non-Smart Card Interface and Non-FIFO Mode (SCMR.SMIF = 0 and FCR.FM = 0)

Address(es): SCI0.SSR 4007 0004h, SCI1.SSR 4007 0024h, SCI2.SSR 4007 0044h, SCI3.SSR 4007 0064h, SCI4.SSR 4007 0084h, SCI5.SSR 4007 00A4h, SCI6.SSR 4007 00C4h, SCI7.SSR 4007 00E4h, SCI8.SSR 4007 0104h, SCI9.SSR 4007 0124h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	Sets the value of the multi-processor bit in the transmission frame: 0: Data transmission cycle 1: ID transmission cycle.	R/W
b1	MPB	Multi-Processor	Value of the multi-processor bit in the reception frame: 0: Data transmission cycle 1: ID transmission cycle.	R
b2	TEND	Transmit End Flag	0: A character is being transmitted 1: Character transfer is complete.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: Parity error occurred.	R/(W)*1
b4	FER	Framing Error Flag	0: No framing error occurred 1: Framing error occurred.	R/(W)*1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: Overrun error occurred.	R/(W)*1
b6	RDRF	Receive Data Full Flag	0: No received data in RDR register 1: Received data in RDR register.	R/(W)*1
b7	TDRE	Transmit Data Empty Flag	0: Transmit data in TDR register 1: No transmit data in TDR register.	R/(W)*1

Note 1. Only 0 can be written to clear the flag after reading 1.

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after 1 is read while the SCR.TE bit is 1.

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to the PER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to the RDRF flag after 1 is read
- When data is read from the RDR register.

Note: Do not clear RDRF flag by accessing RDRF bit in the SSR register unless communication is aborted.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register.

[Clearing conditions]

- When 0 is written to the TDRE flag after 1 is read
- When the SCR.TE bit is 1 and data is written to the TDR register.

Note: Do not clear TDRE flag by accessing TDRE bit in the SSR register unless communication is aborted.

34.2.14 Serial Status Register for Non-Smart Card Interface and FIFO Mode (SSR_FIFO) (SCMR.SMIF = 0 and FCR.FM = 1)

Address(es): SCI0.SSR_FIFO 4007 0004h, SCI1.SSR_FIFO 4007 0024h, SCI2.SSR_FIFO 4007 0044h, SCI3.SSR_FIFO 4007 0064h, SCI4.SSR_FIFO 4007 0084h, SCI5.SSR_FIFO 4007 00A4h, SCI6.SSR_FIFO 4007 00C4h, SCI7.SSR_FIFO 4007 00E4h, SCI8.SSR_FIFO 4007 0104h, SCI9.SSR_FIFO 4007 0124h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDFE	RDF	ORER	FER	PER	TEND	—	DR
Value after reset:	1	0	0	0	0	0	x	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	DR	Receive Data Ready Flag	0: Receiving is in progress, or no received data remains in FRDRHL after successfully completed reception (receive FIFO empty) 1: Next receive data is not received for a period after normal receiving is complete, when the amount of data stored in the FIFO is equal to or less than the receive triggering number.	R/(W)*1
b1	—	Reserved	The read value is undefined. The write value should be 1.	R/W

Bit	Symbol	Bit name	Description	R/W
b2	TEND	Transmit End Flag	0: A character is being transmitted 1: Character transfer is complete.	R/(W)*1
b3	PER	Parity Error Flag	0: No parity error occurred 1: Parity error occurred.	R/(W)*1

b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: Overrun error occurred.	R/(W)*1
b6	RDF	Receive FIFO Data Full Flag	0: The amount of receive data written in FRDRHL is less than the specified receive triggering number 1: The amount of receive data written in FRDRHL is equal to or greater than the specified receive triggering number.	R/(W)*1
b7	TDFE	Transmit FIFO Data Empty Flag	0: The amount of transmit data written in FTDRHL exceeds the specified transmit triggering number 1: The amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number.	R/(W)*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_FIFO register provides the SCI with FIFO mode status flags.

DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 ETUs (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 ETUs*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1.

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.
The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL while the SCR.TE bit is 1
- When 0 is written to the TEND flag after 1 is read while the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1.

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to the PER flag after 1 is read.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to the FER flag after 1 is read.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,*1 and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to the RDF flag after 1 is read
- When FRDRHL is read by the DMAC or DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF flag is set to 0. After that, when the amount of data stored in the FRDRHL register is equal to or greater than the RTRG value, RDF is set to 1 after 1

PCLKA.

Note: Do not clear RDF flags by accessing RDF bit in the SSR register before reading receive data unless communication is aborted.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number.*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC or DMAC is activated
- When 0 is written to the TDFE flag after reading 1 is read.
The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLKA.

Note: Do not clear TDFE flags by accessing TDFE bit in the SSR register before writing transmit data unless communication is aborted.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.

34.2.15 Serial Status Register for Smart Card Interface Mode (SSR_SMCI) (SCMR.SMIF = 1)

Address(es): SCI0.SSR_SMCI 4007 0004h, SCI1.SSR_SMCI 4007 0024h, SCI2.SSR_SMCI 4007 0044h, SCI3.SSR_SMCI 4007 0064h, SCI4.SSR_SMCI 4007 0084h, SCI5.SSR_SMCI 4007 00A4h, SCI6.SSR_SMCI 4007 00C4h, SCI7.SSR_SMCI 4007 00E4h, SCI8.SSR_SMCI 4007 0104h, SCI9.SSR_SMCI 4007 0124h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Bit name	Description	R/W
b0	MPBT	Multi-Processor Bit Transfer	Set this bit to 0 in smart card interface mode	R/W
b1	MPB	Multi-Processor	Set this bit to 0 in smart card interface mode	R
b2	TEND	Transmit End Flag	0: A character is being transmitted 1: Character transfer is complete.	R
b3	PER	Parity Error Flag	0: No parity error occurred 1: Parity error occurred.	R/(W)*
b4	ERS	Error Signal Status Flag	0: No low error signal response 1: Low error signal response occurred.	R/(W)*1
b5	ORER	Overrun Error Flag	0: No overrun error occurred 1: Overrun error occurred.	R/(W)*1
b6	RDRF	Receive Data Full Flag	0: No received data in RDR register 1: Received data in RDR register.	R/(W)*1

Bit	Symbol	Bit name	Description	R/W
b7	TDRE	Transmit Data Empty Flag	0: Transmit data in TDR register 1: No transmit data in TDR register.	R/(W)*1

Note 1. Only 0 can be written, to clear the flag after 1 is read.

The SSR_SMCI register provides the SCI with smart card interface mode status flags.

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit = 0 (serial transmission is disabled).
  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 0, 11.0 ETUs after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 1, 11.0 ETUs after the start of transmission.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR_SMCI.TE bit is 1
- When 0 is written to the TDRE flag after 1 is read while the SCR_SMCI.TE bit is 1.

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to the PER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

- When 0 is written to the ERS flag after 1 is read.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register.

The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to the ORER flag after 1 is read. After writing 0 to this flag, read it to verify that its value is 0.

When the RE bit in SCR_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to the RDRF flag after 1 is read
- When data is read from the RDR register.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit is 0
- When data is transmitted from the TDR register to the TSR register.

[Clearing conditions]

- When 0 is written to the TDRE flag after 1 is read
- When the SCR_SMCI.TE bit is 1 and data is written to the TDR register.

Note: Do not clear TDRE flags by accessing TDRE bit in the SSR register unless communication is aborted.

34.2.16 Smart Card Mode Register (SCMR)

Address(es): SCI0.SCMR 4007 0006h, SCI1.SCMR 4007 0026h, SCI2.SCMR 4007 0046h, SCI3.SCMR 4007 0066h, SCI4.SCMR 4007 0086h, SCI5.SCMR 4007 00A6h, SCI6.SCMR 4007 00C6h, SCI7.SCMR 4007 00E6h, SCI8.SCMR 4007 0106h, SCI9.SCMR 4007 0126h

	b7	b6	b5	b4	b3	b2	b1	b0
	BCP2	—	—	CHR1	SDIR	SINV	—	SMIF
Value after reset:	1	1	1	1	0	0	1	0

Bit	Symbol	Bit name	Description	R/W
b0	SMIF	Smart Card Interface Mode Select	0: Non-smart card interface mode (asynchronous mode, clock synchronous mode, simple SPI mode, or simple IIC mode) 1: Smart card interface mode.	R/W*1
b1	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b2	SINV	Transmitted/Received Data Invert	0: TDR register contents are transmitted as they are. Receive data is stored as received in the RDR register. 1: TDR register contents are inverted before transmission. Receive data is stored in inverted form in the RDR register. The SINV bit can be used in the following modes: • Smart card interface mode • Asynchronous mode (including multi-processor mode) • Clock synchronous mode • Simple SPI mode. Set the SINV bit to 0 for operation in simple IIC mode.	R/W*1

Bit	Symbol	Bit name	Description	R/W
b3	SDIR	Transmitted/Received Data Transfer Direction	0: Transfer LSB-first 1: Transfer MSB-first. The SDIR bit can be used in the following modes: • Smart card interface mode • Asynchronous mode (including multi-processor mode) • Clock synchronous mode • Simple SPI mode. Set the SDIR bit to 1 for operation in simple IIC mode.	R/W*[1]
b4	CHR1	Character Length 1	Valid only in asynchronous mode.*[2] Selects the transmit/receive character length in combination with the SMR.CHR bit: CHR1 CHR 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length.*[3]	R/W*[1]
b6, b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b7	BCP2	Base Clock Pulse 2	Selects the number of base clock cycles in combination with the SMR_SMCI.BCP[1:0] bits. Table 34.4 lists the combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits.	R/W*[1]

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode.

SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR_SMCI.

CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR_SMCI.BCP[1:0] bits.

Table 34.4 Combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits (1 of 2)

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period
0	00	93 clock cycles (S = 93)*[1]
0	01	128 clock cycles (S = 128)*[1]
0	10	186 clock cycles (S = 186)*[1]
0	11	512 clock cycles (S = 512)*[1]
1	00	32 clock cycles (S = 32)*[1] (Initial Value)

Table 34.4 Combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits (2 of 2)

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period
1	01	64 clock cycles (S = 64)*1
1	10	372 clock cycles (S = 372)*1
1	11	256 clock cycles (S = 256)*1

Note 1. See section 34.2.17, Bit Rate Register (BRR).

34.2.17 Bit Rate Register (BRR)

Address(es): SCI0.BRR 4007 0001h, SCI1.BRR 4007 0021h, SCI2.BRR 4007 0041h, SCI3.BRR 4007 0061h, SCI4.BRR 4007 0081h, SCI5.BRR 4007 00A1h, SCI6.BRR 4007 00C1h, SCI7.BRR 4007 00E1h, SCI8.BRR 4007 0101h, SCI9.BRR 4007 0121h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 34.5 shows the relationship between the setting (N) in the BRR and the bit rate (B) for asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is FFh. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

Table 34.5 Relationship between N setting in BRR and bit rate B

	SEMR settings				
Mode	BGDM bit	ABCS bit	ABCSE bit	BRR setting	Error
Asynchronous, multi-processor transfer	0	0	0	$N = \frac{PCLKA \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 64 \times 2^{2n-1} \times (N + 1)} - 1\} \times 100$
	1	0	0	$N = \frac{PCLKA \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 32 \times 2^{2n-1} \times (N + 1)} - 1\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLKA \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 16 \times 2^{2n-1} \times (N + 1)} - 1\} \times 100$
	Don’t care	Don’t care	1	$N = \frac{PCLKA \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 12 \times 2^{2n-1} \times (N + 1)} - 1\} \times 100$
Clock synchronous, simple SPI				$N = \frac{PCLKA \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	-
Smart card interface				$N = \frac{PCLKA \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times S \times 2^{2n+1} \times (N + 1)} -1\} \times 100$
Simple IIC*1				$N = \frac{PCLKA \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	-

B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator ($0 \leq N \leq 255$)
PCLKA: Operating frequency (MHz)

n and S: Determined by the SMR/SMR_SMCI and SCMR register settings as listed in Table 34.7 and Table 34.8.

Note 1. Adjust the bit rate so that the widths of high and low level of the SCL output in simple IIC mode satisfy the I²C bus standard.

Table 34.6 Calculating widths of SCL high and low levels

Mode	SCL	Formula (result in seconds)
IIC	Width at high level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLKA \times 10^6}$
	Width at low level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLKA \times 10^6}$

Table 34.7 Clock source settings

SMR or SMR_SMCI.CKS[1:0] bit setting		
CKS[1:0] bits	Clock source	n
0 0	PCLKA clock	0
0 1	PCLKA/4 clock	1
1 0	PCLKA/16 clock	2
1 1	PCLKA/64 clock	3

Table 34.8 Base clock settings in smart card interface mode

SCMR.BCP2 bit setting	SMR_SMCI.BCP[1:0] bit setting		
BCP2 bit	BCP[1:0] bits	Base clock cycles for 1-bit period	S
0	0 0	93 clock cycles	93
0	0 1	128 clock cycles	128
0	1 0	186 clock cycles	186
0	1 1	512 clock cycles	512
1	0 0	32 clock cycles	32
1	0 1	64 clock cycles	64
1	1 0	372 clock cycles	372
1	1 1	256 clock cycles	256

Table 34.9 and Table 34.10 list examples of BRR (N) settings in asynchronous mode. Table 34.11 lists the maximum bit rate settable for each operating frequency. Table 34.15 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 34.6.4, Receive Data Sampling Timing and Reception Margin. Table 34.12 and Table 34.14 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 34.16. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 34.9 Examples of BRR settings for different bit rates in asynchronous mode (1) (1 of 2)

Note: In this example, SEMR.ABCS = 0, SEMR.ABCSE = 0, and SEMR.BGDM = 0.
When either the ABCS or BGDM bit is set to 1, the bit rate doubles.
When both ABCS and BGDM are set to 1, the bit rate increases four times.

10 M															0	0*1					0	2

Space: Setting prohibited.

—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 00h and SMR.CKS[1:0] = 00b) is not available.

Table 34.14 Maximum bit rate with external clock input in clock synchronous and simple SPI modes (1 of 2)

400 k	0	3	1.12/1.28*1	0	4	1.17/1.33	0	8	1.05/1.20

Note 1. The minimum value of low width is smaller than 1.3 μs which is the standard value of fast mode. The setting values are the same as in Table 34.17.

34.2.18 Modulation Duty Register (MDDR)

Address(es): SCI0.MDDR 4007 0012h, SCI1.MDDR 4007 0032h, SCI2.MDDR 4007 0052h, SCI3.MDDR 4007 0072h, SCI4.MDDR 4007 0092h, SCI5.MDDR 4007 00B2h, SCI6.MDDR 4007 00D2h, SCI7.MDDR 4007 00F2h, SCI8.MDDR 4007 0112h, SCI9.MDDR 4007 0132h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The MDDR register corrects the bit rate adjusted by the BRR register.

When the SEMR.BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in the MDDR register (M/256). Table 34.19 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of the MDDR register is FFh. Bit [7] in this register is fixed to 1. The CPU can read the MDDR register, but the MDDR register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

Table 34.19 Relationship between MDDR setting (M) and bit rate (B) when bit rate modulation function is used

	SEMR settings				
Mode	**BGDM bit**	**ABCS bit**	**ABCSE bit**	**BRR setting**	**Error**
Asynchronous, multi-processor transfer	0	0	0	$N = \frac{PCLKA \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	1	0	0	$N = \frac{PCLKA \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLKA \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
	Don’t care	Don’t care	1	$N = \frac{PCLKA \times 10^6}{12 \times 2^{2n-1} \times (256/M) \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times 12 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\} \times 100$
Clock synchronous, simple SPI*1				$N = \frac{PCLKA \times 10^6}{8 \times 2^{2n-1} \times (256/M) \times B} - 1$	—
Smart card interface				$N = \frac{PCLKA \times 10^6}{S \times 2^{2n+1} \times (256/M) \times B} - 1$	$\text{Error (\%)} = \{\frac{PCLKA \times 10^6}{B \times S \times 2^{2n+1} \times (256/M) \times (N+1)} - 1\} \times 100$
Simple IIC*2				$N = \frac{PCLKA \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	—

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 255)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLKA: Operating frequency (MHz)
n and S: Determined by the SMR/SMR_SMCI and SCMR register settings as listed in Table 34.7 and Table 34.8 in section 34, Bit Rate Register (BRR).

Note 1. Do not use this function in clock synchronous mode or in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).
Note 2. Adjust the bit rate so that the widths of high and low level of the SCL output in simple IIC mode satisfy the I2C bus standard.

Table 34.20 and Table 34.21 list examples of N settings in BRR and M settings in MDDR in asynchronous mode.

Table 34.20 Examples of BRR and MDDR settings for multiple bit rates in asynchronous mode (1)

	50					60					120				
	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)	n	N	M	BGDM bit	Error (%)
230400	0	3	151	0	0.00	0	10	173	1	-0.01	0	10	173	0	-0.01
460800	0	1	151	0	0.00	0	6	220	1	-0.09	0	10	173	1	-0.09

Note 1. In this example, the ABCS and ABCSE bits in the SEMR register are 0.
SEMR.BRME = 0 (M = 256) disables the bit rate modulation function.

34.2.19 Serial Extended Mode Register (SEMR)

Address(es): SCI0.SEMR 4007 0007h, SCI1.SEMR 4007 0027h, SCI2.SEMR 4007 0047h, SCI3.SEMR 4007 0067h, SCI4.SEMR 4007 0087h, SCI5.SEMR 4007 00A7h, SCI6.SEMR 4007 00C7h, SCI7.SEMR 4007 00E7h, SCI8.SEMR 4007 0107h, SCI9.SEMR 4007 0127h

	b7	b6	b5	b4	b3	b2	b1	b0
	RXDESEL	BGDM	NFEN	ABCS	ABCSE	BRME	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	BRME	Bit Rate Modulation Enable	0: Disable bit rate modulation function 1: Enable bit rate modulation function.	R/W[*1]
b3	ABCSE	Asynchronous Mode Extended Base Clock Select 1	Valid only in asynchronous mode with SCR.CKE[1] = 0: 0: Clock cycles for 1-bit period determined by combination of the BGDM and ABCS bits in the SEMR register 1: Baud rate is 6 base clock cycles for 1-bit period.	R/W[*1]
b4	ABCS	Asynchronous Mode Base Clock Select	Valid only in asynchronous mode: 0: Select 16 base clock cycles for 1-bit period 1: Select 8 base clock cycles for 1-bit period.	R/W[*1]
b5	NFEN	Digital Noise Filter Function Enable	• In asynchronous mode: 0: Disable noise cancellation function for RXDn input signal 1: Enable noise cancellation function for RXDn input signal. • In simple IIC mode: 0: Disable noise cancellation function for SCLn and SDAn input signals 1: Enable noise cancellation function for SCLn and SDAn input signals. The NFEN bit must be 0 in all other modes.	R/W[*1]
b6	BGDM	Baud Rate Generator Double-Speed Mode Select	Valid only in asynchronous mode with SCR.CKE[1] = 0. 0: Output clock from baud rate generator with single frequency 1: Output clock from baud rate generator with double frequency.	R/W[*1]
b7	RXDESEL	Asynchronous Start Bit Edge Detection Select	Valid only in asynchronous mode: 0: Detect low level on RXDn pin as start bit 1: Detect falling edge of RXDn pin as start bit.	R/W[*1]

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0. Set this bit to 0 except in asynchronous mode.

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period. Set this bit to 0 except in asynchronous mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple IIC mode.

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0). The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDSEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

34.2.20 Noise Filter Setting Register (SNFR)

Address(es): SCI0.SNFR 4007 0008h, SCI1.SNFR 4007 0028h, SCI2.SNFR 4007 0048h, SCI3.SNFR 4007 0068h, SCI4.SNFR 4007 0088h, SCI5.SNFR 4007 00A8h, SCI6.SNFR 4007 00C8h, SCI7.SNFR 4007 00E8h, SCI8.SNFR 4007 0108h, SCI9.SNFR 4007 0128h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	NFCS[2:0]	Noise Filter Clock Select	In asynchronous mode, selects the standard setting for the base clock: b2 b0 0 0 0: Use clock signal divided by 1 with noise filter. In simple IIC mode, selects the standard settings for the clock source of the on-chip baud rate generator selected in the SMR.CKS[1:0] bits: b2 b0 0 0 1: Use clock signal divided by 1 with noise filter 0 1 0: Use clock signal divided by 2 with noise filter 0 1 1: Use clock signal divided by 4 with noise filter 1 0 0: Use clock signal divided by 8 with noise filter. Other settings are prohibited.	R/W*1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR_SMCI are 0 (serial reception and transmission disabled).

The SNFR register sets the digital noise filter clock.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple IIC mode, set the bits to a value in the range from 001b to 100b.

34.2.21 IIC Mode Register 1 (SIMR1)

Address(es): SCI0.SIMR1 4007 0009h, SCI1.SIMR1 4007 0029h, SCI2.SIMR1 4007 0049h, SCI3.SIMR1 4007 0069h, SCI4.SIMR1 4007 0089h, SCI5.SIMR1 4007 00A9h, SCI6.SIMR1 4007 00C9h, SCI7.SIMR1 4007 00E9h, SCI8.SIMR1 4007 0109h, SCI9.SIMR1 4007 0129h

	b7	b6	b5	b4	b3	b2	b1	b0
	IICDL[4:0]					—	—	IICM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	IICM	Simple IIC Mode Select	SMIF IICM 0 0: Asynchronous mode (including multi-processor mode), clock synchronous mode, or simple SPI mode 0 1: Simple IIC mode 1 0: Smart card interface mode 1 1: Setting prohibited.	R/W*1
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7 to b3	IICDL[4:0]	SDA Delay Output Select	SDA signal output delay in cycles of the clock signal from the on-chip baud rate generator: b7 b3 0 0 0 0 0: No output delay 0 0 0 0 1: 0 to 1 cycle 0 0 0 1 0: 1 to 2 cycles 0 0 0 1 1: 2 to 3 cycles 0 0 1 0 0: 3 to 4 cycles 0 0 1 0 1: 4 to 5 cycles : 1 1 1 1 0: 29 to 30 cycles 1 1 1 1 1: 30 to 31 cycles.	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

SIMR1 selects simple IIC mode and the number of delay stages for the SDAn output.

IICM bit (Simple IIC Mode Select)

In combination with the SCMR.SMIF bit, the IICM bit selects the operating mode.

IICDL[4:0] bits (SDA Delay Output Select)

The IICDL[4:0] bits specify an output delay on the SDAn pin relative to the falling edge of the output on the SCLn pin.

The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLKA by the divisor set in SMR.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator. Set these bits to 00000b unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

34.2.22 IIC Mode Register 2 (SIMR2)

Address(es): SCI0.SIMR2 4007 000Ah, SCI1.SIMR2 4007 002Ah, SCI2.SIMR2 4007 004Ah, SCI3.SIMR2 4007 006Ah, SCI4.SIMR2 4007 008Ah, SCI5.SIMR2 4007 00AAh, SCI6.SIMR2 4007 00CAh, SCI7.SIMR2 4007 00EAh, SCI8.SIMR2 4007 010Ah, SCI9.SIMR2 4007 012Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	IICACKT	—	—	—	IICCSC	IICINTM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	IICINTM	IIC Interrupt Mode Select	0: Use ACK/NACK interrupts 1: Use reception and transmission interrupts.	R/W*1
b1	IICCSC	Clock Synchronization	0: Do not synchronize with clock signal 1: Synchronize with clock signal.	R/W*1
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	IICACKT	ACK Transmission Data	0: ACK transmission 1: NACK transmission and ACK/NACK reception.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

SIMR2 selects how reception and transmission are controlled in simple IIC mode.

IICINTM bit (IIC Interrupt Mode Select)

The IICINTM bit selects the sources of interrupt requests in simple IIC mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCL clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCL clock signal is not synchronized if the IICCSC bit is 0. The SCL clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

34.2.23 IIC Mode Register 3 (SIMR3)

Address(es): SCI0.SIMR3 4007 000Bh, SCI1.SIMR3 4007 002Bh, SCI2.SIMR3 4007 004Bh, SCI3.SIMR3 4007 006Bh, SCI4.SIMR3 4007 008Bh, SCI5.SIMR3 4007 00ABh, SCI6.SIMR3 4007 00CBh, SCI7.SIMR3 4007 00EBh, SCI8.SIMR3 4007 010Bh, SCI9.SIMR3 4007 012Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	IICSCLS[1:0]		IICSDAS[1:0]		IICSTIF	IICSTPREQ	IICRSTAREQ	IICSTAREQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	IICSTAREQ	Start Condition Generation	0: Do not generate start condition 1: Generate start condition.*1, *3, *5, *6	R/W
b1	IICRSTAREQ	Restart Condition Generation	0: Do not generate restart condition 1: Generate restart condition.*2, *3, *5, *6	R/W

Bit	Symbol	Bit name	Description	R/W
b2	IICSTPREQ	Stop Condition Generation	0: Do not generate stop condition 1: Generate stop condition.*2, *3, *5, *6	R/W
b3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag	0: No requests are being made for generating conditions, or a condition is being generated 1: Generation of start, restart, or stop condition is complete. When 0 is written to IICSTIF, it is cleared to 0.*4	R/W*4
b5, b4	IICSDAS[1:0]	SDA Output Select	b5 b4 0 0: Output serial data 0 1: Generate start, restart, or stop condition 1 0: Output low on SDAn pin 1 1: Drive SDAn pin to high-impedance state.	R/W
b7, b6	IICSCLS[1:0]	SCL Output Select	b7 b6 0 0: Output serial clock 0 1: Generate start, restart, or stop condition 1 0: Output low on SCLn pin 1 1: Drive SCLn pin to high-impedance state.	R/W

Note 1. Only generate a start condition after checking the bus state and confirming that the bus is free.
Note 2. Generate a restart or stop condition after checking the bus state and confirming that the bus is busy.
Note 3. Do not set more than one of the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Write only 0. When 1 is written, the value is ignored.
Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDA Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value.

IICSCLS[1:0] bits (SCL Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSCLS[1:0] and IICSDAS[1:0] to the same value.

34.2.24 IIC Status Register (SISR)

Address(es): SCI0.SISR 4007 000Ch, SCI1.SISR 4007 002Ch, SCI2.SISR 4007 004Ch, SCI3.SISR 4007 006Ch, SCI4.SISR 4007 008Ch, SCI5.SISR 4007 00ACh, SCI6.SISR 4007 00CCh, SCI7.SISR 4007 00ECh, SCI8.SISR 4007 010Ch, SCI9.SISR 4007 012Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IICACKR
Value after reset:	0	0	x	x	0	x	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	IICACKR	ACK Reception Data Flag	0: ACK received 1: NACK received.	R
b1	—	Reserved	This bit is read as 0.	R
b2	—	Reserved	The read value is undefined.	R
b3	—	Reserved	This bit is read as 0.	R
b5, b4	—	Reserved	The read value is undefined.	R
b7, b6	—	Reserved	These bits are read as 0.	R

SISR monitors the state in simple IIC mode.

IICACKR flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from the IICACKR flag. The IICACKR flag is updated on the rising edge of the SCLn clock for the received ACK/NACK bit.

34.2.25 SPI Mode Register (SPMR)

Address(es): SCI0.SPMR 4007 000Dh, SCI1.SPMR 4007 002Dh, SCI2.SPMR 4007 004Dh, SCI3.SCI3 4007 006Dh, SCI4.SPMR 4007 008Dh, SCI5.SPMR 4007 00ADh, SCI6.SPMR 4007 00CDh, SCI7.SCI7 4007 00EDh, SCI8.SPMR 4007 010Dh, SCI9.SPMR 4007 012Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	CKPH	CKPOL	—	MFF	—	MSS	CTSE	SSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SSE	SSn Pin Function Enable	0: Disable SSn pin function 1: Enable SSn pin function.	R/W*1
b1	CTSE	CTS Enable	0: Disable CTS function (enable RTS output function) 1: Enable CTS function.	R/W*1
b2	MSS	Master Slave Select	0: Transmit through TXDn pin and receive through RXDn pin (master mode) 1: Receive through TXDn pin and transmit through RXDn pin (slave mode).	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	MFF	Mode Fault Flag	0: No mode fault error 1: Mode fault error.	R/W*2
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	CKPOL	Clock Polarity Select	0: Do not invert clock polarity 1: Invert clock polarity.	R/W*1
b7	CKPH	Clock Phase Select	0: Do not delay clock 1: Delay clock.	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

Note 2. Only 0 can be written to this bit, to clear the flag.

The SPMR register selects settings for simple SPI mode.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin. Set this bit to 0 in modes other than simple SPI mode.

MFF flag (Mode Fault Flag)

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 34.70 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 34.70 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

34.2.26 FIFO Control Register (FCR)

Address(es): SCI0.FCR 4007 0014h, SCI1.FCR 4007 0034h, SCI2.FCR 4007 0054h, SCI3.FCR 4007 0074h, SCI4.FCR 4007 0094h, SCI5.FCR 4007 00B4h, SCI6.FCR 4007 00D4h, SCI7.FCR 4007 00F4h, SCI8.FCR 4007 0114h, SCI9.FCR 4007 0134h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RSTRG[3:0]				RTRG[3:0]				TTRG[3:0]				DRES	TFRST	RFRST	FM
Value after reset:	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	FM	FIFO Mode Select	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode: 0: Non-FIFO mode. Selects TDR/RDR or TDRHL/RDRHL for communication. 1: FIFO mode. Selects FTDRHL/FRDRHL for communication.	R/W*1
b1	RFRST	Receive FIFO Data Register Reset	Valid only when FCR.FM = 1: 0: Do not reset FRDRHL 1: Reset FRDRHL.	R/W
b2	TFRST	Transmit FIFO Data Register Reset	Valid only when FCR.FM = 1: 0: Do not reset FTDRHL 1: Reset FTDRHL.	R/W
b3	DRES	Receive Data Ready Error Select Bit	Selects the interrupt requested when detecting receive data ready: 0: Receive data full interrupt (SCIn_RXI) 1: Receive error interrupt (SCIn_ERI).	R/W
b7 to b4	TTRG[3:0]	Transmit FIFO Data Trigger Number	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode: 0000: Trigger number 0 : 1111: Trigger number 15.	R/W
b11 to b8	RTRG[3:0]	Receive FIFO Data Trigger Number	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode: 0000: Trigger number 0 : 1111: Trigger number 15.	R/W
b15 to b12	RSTRG[3:0]	RTS Output Active Trigger Number Select	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1, SPMR.CTSE = 0, and SPMR.SSE = 0: 0000: Trigger number 0 : 1111: Trigger number 15.	R/W

Note 1. Writable only when TE = 0 and RE = 0.

FCR selects FIFO mode, resets FTDRHL and FRDRHL, selects the FIFO data trigger number for transmission or reception, and selects the RTS output active trigger number.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLKA.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLKA.

DRES bit (Receive Data Ready Error Select Bit)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request. When starting DMAC or DTC and reading from the FRDRH and FRDRL registers, set the DRES bit to 1.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

RTRG[3:0] bits (Receive FIFO Data Trigger Number)

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn_RXI interrupt does not occur.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

34.2.27 FIFO Data Count Register (FDR)

Address(es): SCI0.FDR 4007 0016h, SCI1.FDR 4007 0036h, SCI2.FDR 4007 0056h, SCI3.FDR 4007 0076h,
SCI4.FDR 4007 0096h, SCI5.FDR 4007 00B6h, SCI6.FDR 4007 00D6h, SCI7.FDR 4007 00F6h,
SCI8.FDR 4007 0116h, SCI9.FDR 4007 0136h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	T[4:0]					—	—	—	R[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	R[4:0]	Receive FIFO Data Count	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1. Indicates the amount of receive data stored in FRDRHL.	R
b7 to b5	—	Reserved	These bits are read as 0.	R

Bit	Symbol	Bit name	Description	R/W
b12 to b8	T[4:0]	Transmit FIFO Data Count	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1. Indicates the amount of non-transmitted data stored in FTDRHL.	R
b15 to b13	—	Reserved	These bits are read as 0.	R

The FDR register indicates the amount of data stored in FRDRHL and FTDRHL.

R[4:0] bits (Receive FIFO Data Count)

The R[4:0] bits indicate the amount of receive data stored in FRDRHL. 00h means no receive data, and 10h means that the maximum received data is stored in FRDRHL.

T[4:0] bits (Transmit FIFO Data Count)

The T[4:0] bits indicate the amount of non-transmitted data stored in FTDRHL. 00h means no transmit data, and 10h means that all (maximum amount) of the data to be transmitted is stored in FTDRHL.

34.2.28 Line Status Register (LSR)

Address(es): SCI0.LSR 4007 0018h, SCI1.LSR 4007 0038h, SCI2.LSR 4007 0058h, SCI3.LSR 4007 0078h,
SCI4.LSR 4007 0098h, SCI5.LSR 4007 00B8h, SCI6.LSR 4007 00D8h, SCI7.LSR 4007 00F8h,
SCI8.LSR 4007 0118h, SCI9.LSR 4007 0138h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PNUM[4:0]					—	FNUM[4:0]					—	ORER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ORER	Overrun Error Flag	Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, and when FIFO is selected: 0: No overrun error occurred 1: Overrun error occurred.	R*[1]
b1	—	Reserved	This bit is read as 0.	R
b6 to b2	FNUM[4:0]	Framing Error Count	Indicates the amount of data with a framing error in the receive data stored in FRDRHL.	R
b7	—	Reserved	This bit is read as 0.	R
b12 to b8	PNUM[4:0]	Parity Error Count	Indicates the amount of data with a parity error in the receive data stored in FRDRHL.	R
b15 to b13	—	Reserved	These bits are read as 0.	R

Note 1. Write 0 to SSR_FIFO.ORER to clear the flag.

The LSR register indicates the receive error status.

ORER bit (Overrun Error Flag)

The ORER bit reflects the value in SSR_FIFO.ORER.

FNUM[4:0] bits (Framing Error Count)

The FNUM[4:0] value indicates the amount of data with a framing error stored in the FRDRHL register.

PNUM[4:0] bits (Parity Error Count)

The PNUM[4:0] value indicates the amount of data with a parity error stored in the FRDRHL register.

34.2.29 Compare Match Data Register (CDR)

Address(es): SCI0.CDR 4007 001Ah, SCI1.CDR 4007 003Ah, SCI2.CDR 4007 005Ah, SCI3.CDR 4007 007Ah, SCI4.CDR 4007 009Ah, SCI5.CDR 4007 00BAh, SCI6.CDR 4007 00DAh, SCI7.CDR 4007 00FAh, SCI8.CDR 4007 011Ah, SCI9.CDR 4007 013Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPD[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b8 to b0	CMPD[8:0]	Compare Match Data	Holds compare data pattern for address match wakeup function.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The CDR register sets the compare data for the address match function.

CMPD[8:0] bits (Compare Match Data)

The CMPD[8:0] bits set the data to be compared to receive data for the address match function, when the address match function is enabled (DCCR.DCME = 1).

Three bit lengths are available:

- CMPD[6:0] with 7-bit length
- CMPD[7:0] with 8-bit length
- CMPD[8:0] with 9-bit length.

34.2.30 Data Compare Match Control Register (DCCR)

Address(es): SCI0.DCCR 4007 0013h, SCI1.DCCR 4007 0033h, SCI2.DCCR 4007 0053h, SCI3.DCCR 4007 0073h, SCI4.DCCR 4007 0093h, SCI5.DCCR 4007 00B3h, SCI6.DCCR 4007 00D3h, SCI7.DCCR 4007 00F3h, SCI8.DCCR 4007 0113h, SCI9.DCCR 4007 0133h

	b7	b6	b5	b4	b3	b2	b1	b0
	DCME	IDSEL	—	DFER	DPER	—	—	DCMF
Value after reset:	0	1	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	DCMF	Data Compare Match Flag	0: Not matched 1: Matched.	R/(W)*1
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b3	DPER	Data Compare Match Parity Error Flag	0: No parity error occurred 1: Parity error occurred.	R/(W)*1
b4	DFER	Data Compare Match Framing Error Flag	0: No framing error occurred 1: Framing error occurred.	R/(W)*1
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	IDSEL	ID Frame Select	Valid only in asynchronous mode, including multi-processor mode: 0: Always compare data regardless of the MPB bit value 1: Only compare data when MPB bit = 1 (ID frame).	R/W
b7	DCME	Data Compare Match Enable	Valid only in asynchronous mode, including multi-processor mode: 0: Disable address match function 1: Enable address match function.	R/W

Note 1. Only 0 can be written, to clear the flag after reading 1.

The DCCR register controls the address match function.

DCMF flag (Data Compare Match Flag)

The DCMF flag indicates that the SCI detected a receive data match with the comparison data (CDR.CMPD).

[Setting condition]

- On match of the comparison data (CDR.CMPD) with the receive data when DCCR.DCME = 1.

[Clearing condition]

- When 0 is written after 1 is read from DCMF.

Clearing the SCR.RE bit to 0 does not affect the DCMF flag, which retains its previous value.

DPER flag (Data Compare Match Parity Error Flag)

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

[Clearing conditions]

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

DFER flag (Data Compare Match Framing Error Flag)

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in receive mode without data compare match function. See section 34.3.6, Address Match (Receive Data Match Detection) Function.

The write value must be 0 for all modes other than asynchronous mode.

34.2.31 Serial Port Register (SPTR)

Address(es): SCI0.SPTR 4007 001Ch, SCI1.SPTR 4007 003Ch, SCI2.SPTR 4007 005Ch, SCI3.SPTR 4007 007Ch, SCI4.SPTR 4007 009Ch, SCI5.SPTR 4007 00BCh, SCI6.SPTR 4007 00DCh, SCI7.SPTR 4007 00FCh, SCI8.SPTR 4007 011Ch, SCI9.SPTR 4007 013Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPB2IO	SPB2DT	RXDMON
Value after reset:	0	0	0	0	0	0	1	1

Bit	Symbol	Bit name	Description	R/W
b0	RXDMON	Serial Input Data Monitor	Indicates the state of the RXDn pin: 0: RXDn pin is low 1: RXDn pin is high.	R
b1	SPB2DT	Serial Port Break Data Select	Selects the output level of the TXDn pin when SCR.TE = 0: 0: Output low level on TXDn pin 1: Output high level on TXDn pin.	R/W
b2	SPB2IO	Serial Port Break I/O	Selects whether the value of SPB2DT is output to TXDn pin: 0: Do not output value of SPB2DT bit on TXDn pin 1: Output value of SPB2DT bit on TXDn pin.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission pin (TXDn pin) status.

This register can only be used in asynchronous mode.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in Table 34.22.

Table 34.22 TXDn pin status

Value of SCR.TE	Value of SPTR.SPB2IO	Value of SPTR.SPB2DT	TXDn pin status
0	0	x	Hi-Z (initial value)
0	1	0	Low level output
0	1	1	High level output
1	x	x	Serial transmit data is output

x: Don't care.

Note: Use the SPTR register in asynchronous mode only. Using this register in any other mode is not guaranteed.

34.3 Operation in Asynchronous Mode

Figure 34.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is held in the mark state (high level) when not communicating.

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

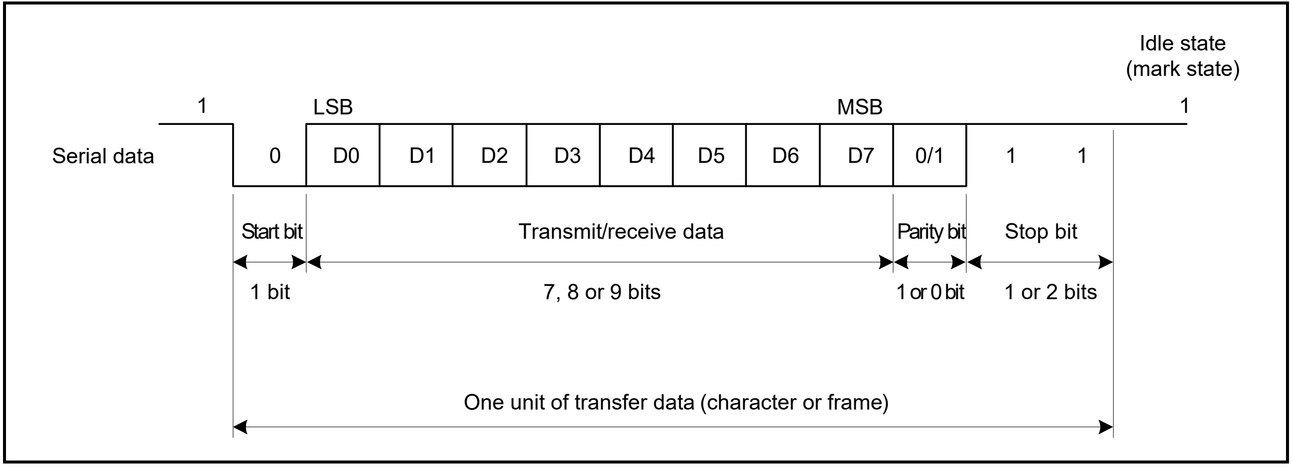

Figure 34.2 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

34.3.1 Serial Data Transfer Format

Table 34.23 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected with the SMR and SCMR register settings. For details on the multi-processor function, see section 34.4, Multi-Processor Communication Function.

Table 34.23 Serial transfer formats in asynchronous mode (1 of 2)

SCMR setting	SMR setting				Serial transfer format and frame length
CHR1	CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	S 9-bit data STOP
0	0	0	0	1	S 9-bit data STOP STOP
0	0	1	0	0	S 9-bit data P STOP
0	0	1	0	1	S 9-bit data P STOP STOP
1	0	0	0	0	S 8-bit data STOP
1	0	0	0	1	S 8-bit data STOP STOP

Table 34.23 Serial transfer formats in asynchronous mode (2 of 2)

SCMR setting	SMR setting				Serial transfer format and frame length												
CHR1	CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12	13
1	0	1	0	0	S	8-bit data								P	STOP		
1	0	1	0	1	S	8-bit data								P	STOP	STOP	
1	1	0	0	0	S	7-bit data							STOP				
1	1	0	0	1	S	7-bit data							STOP	STOP			
1	1	1	0	0	S	7-bit data							P	STOP			
1	1	1	0	1	S	7-bit data							P	STOP	STOP		
0	0	—	1	0	S	9-bit data									MPB	STOP	
0	0	—	1	1	S	9-bit data									MPB	STOP	STOP
1	0	—	1	0	S	8-bit data								MPB	STOP		
1	0	—	1	1	S	8-bit data								MPB	STOP	STOP	
1	1	—	1	0	S	7-bit data							MPB	STOP			
1	1	—	1	1	S	7-bit data							MPB	STOP	STOP		

S: Start bit
STOP: Stop bit
P: Parity bit

MPB: Multi-processor bit

34.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs synchronization.

Because receive data is sampled on the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 34.3. The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)\, F - \frac{\left| D - 0.5 \right|}{N} (1 + F) \right| \times 100\ [\%] \cdots \text{Formula (1)}$$

M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0. N = 8 when SEMR.ABCS = 1. N = 6 when SEMR.ABCSE = 1.)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\%$$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.
When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

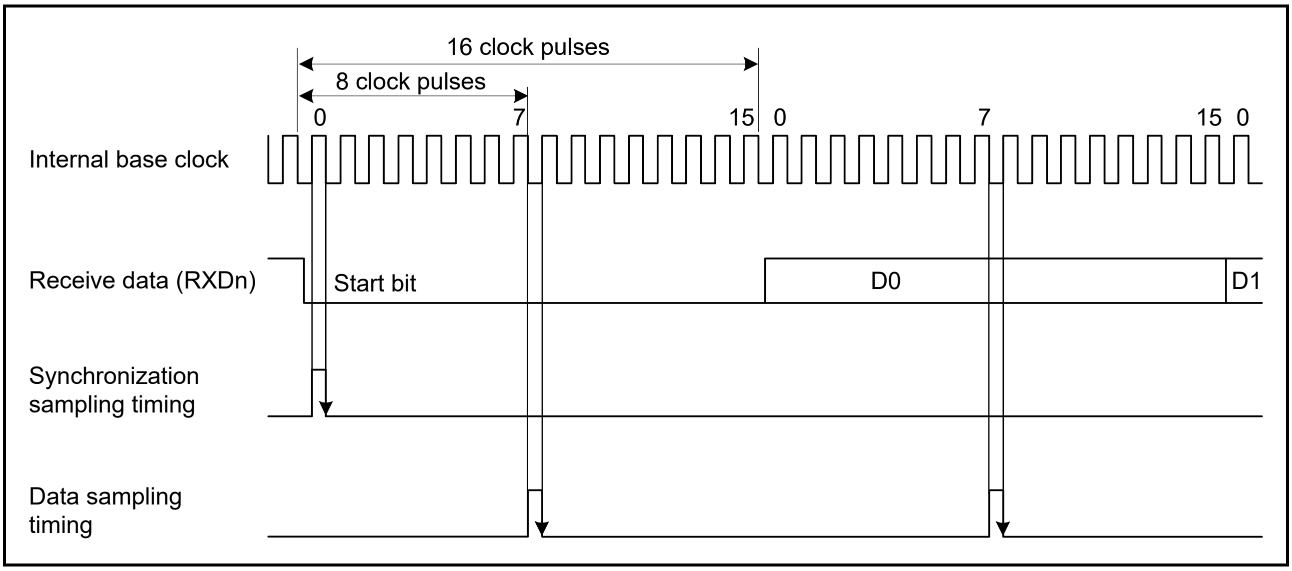

Figure 34.3 Receive data sampling timing in asynchronous mode

34.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 34.4.

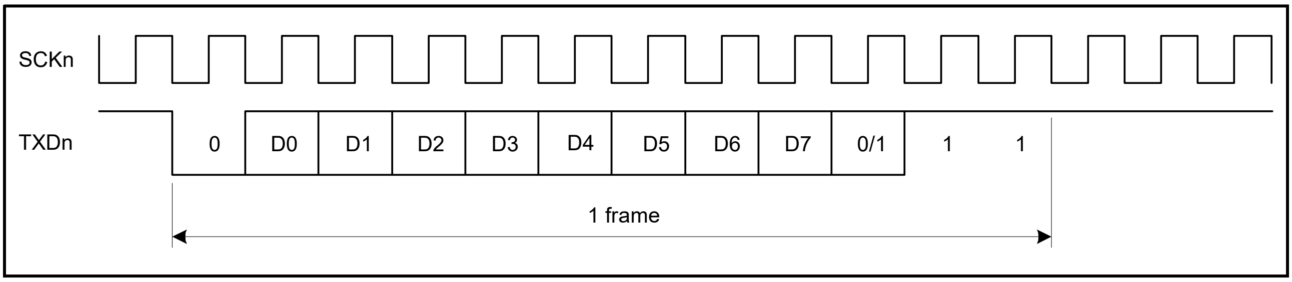

Figure 34.4 **Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1**

34.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0. When the SEMR.ABCSE bit is set to 1, the number of basic clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SMER.ABCSE = 0.

As shown by Formula (1) in section 34.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit in SEMR is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

34.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low-level output]

(a) Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read
- The ORER, FER, and PER flags in the SSR register are all 0.

(b) FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit is 1
- The amount of receive data written in FRDRHL is equal to or less than the specified receive triggering number
- The ORER bit in the SSR_FIFO register (ORER in FRDRH) is 0.

[Condition for high-level output]

(a Non-FIFO selected

- The conditions for low-level output are not satisfied
- When reception is terminated with SCR.RE = 0 without reading the RDR register after reception is complete, RTS remains high. At this time, read the SCR register for dummy values after writing 0 to SCR.RE.

(b) FIFO selected

- The conditions for low-level output are not satisfied.

34.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1*4, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD*3) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a mismatch.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data. Until SCI detects a match between the comparison data (CDR.CMPD*3) and the receive data, the received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

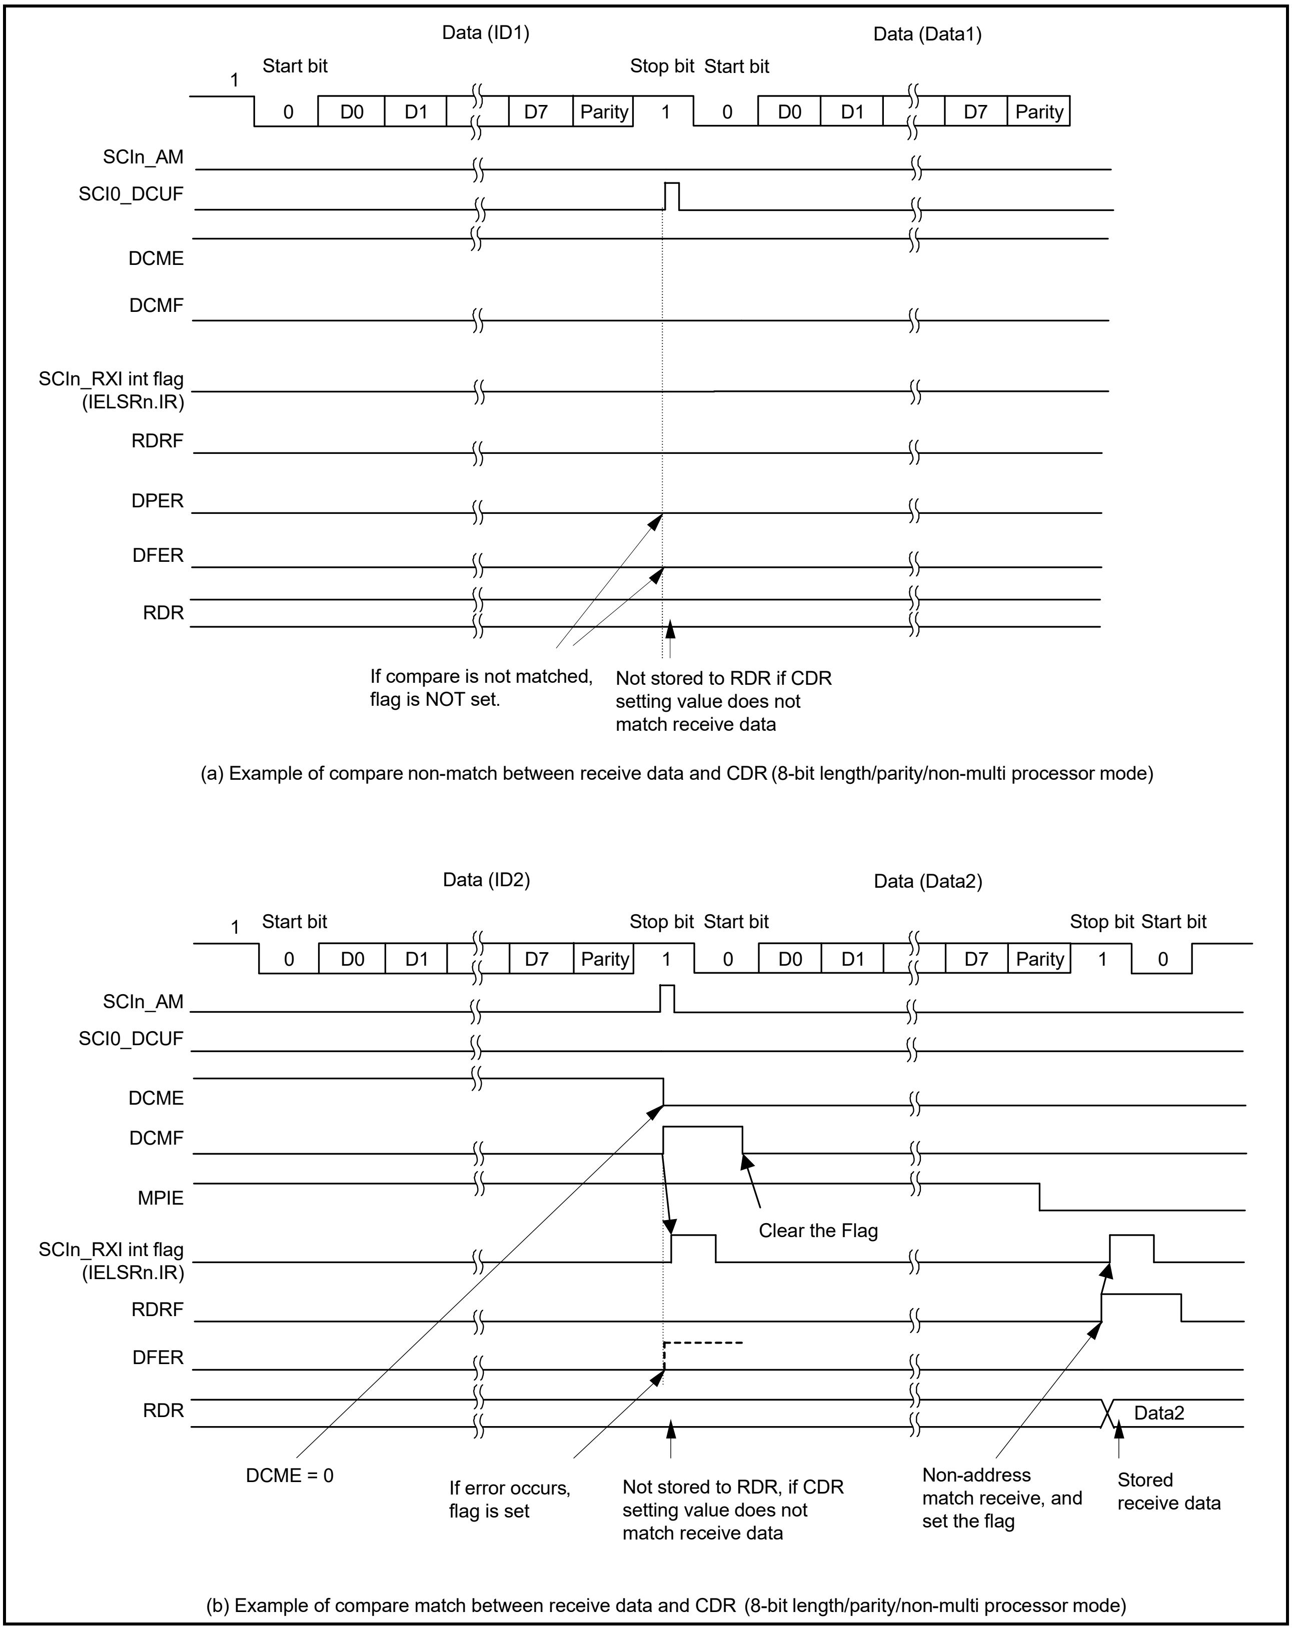
If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER bit is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER bit is set to 1. The compared receive data is not stored in the RDR register*1, and SSR.RDRF remains 0.*2

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 34.5 and Figure 34.6.

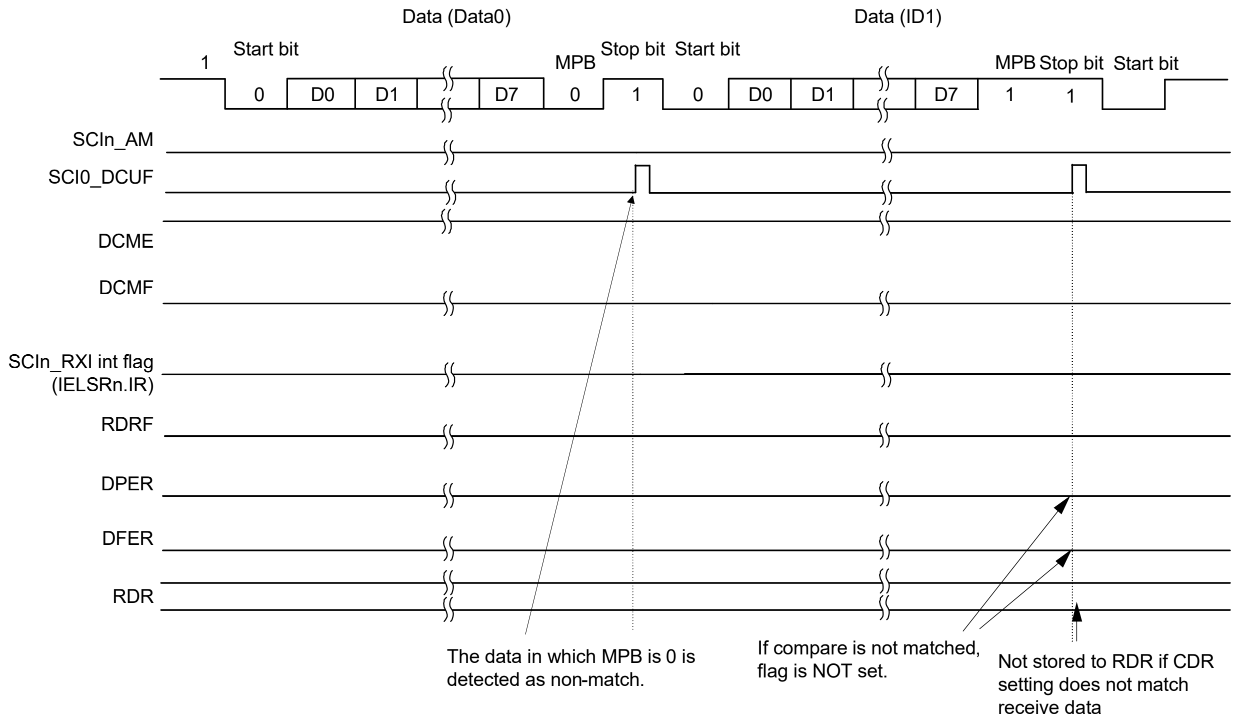
Note 1. When FCR.FM = 1, this refers to the FRDRHL register.
Note 2. When FCR.FM = 1, this refers to the SSR_FIFO.RDF flag.
Note 3. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.
Note 4. Set the DCCR.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.



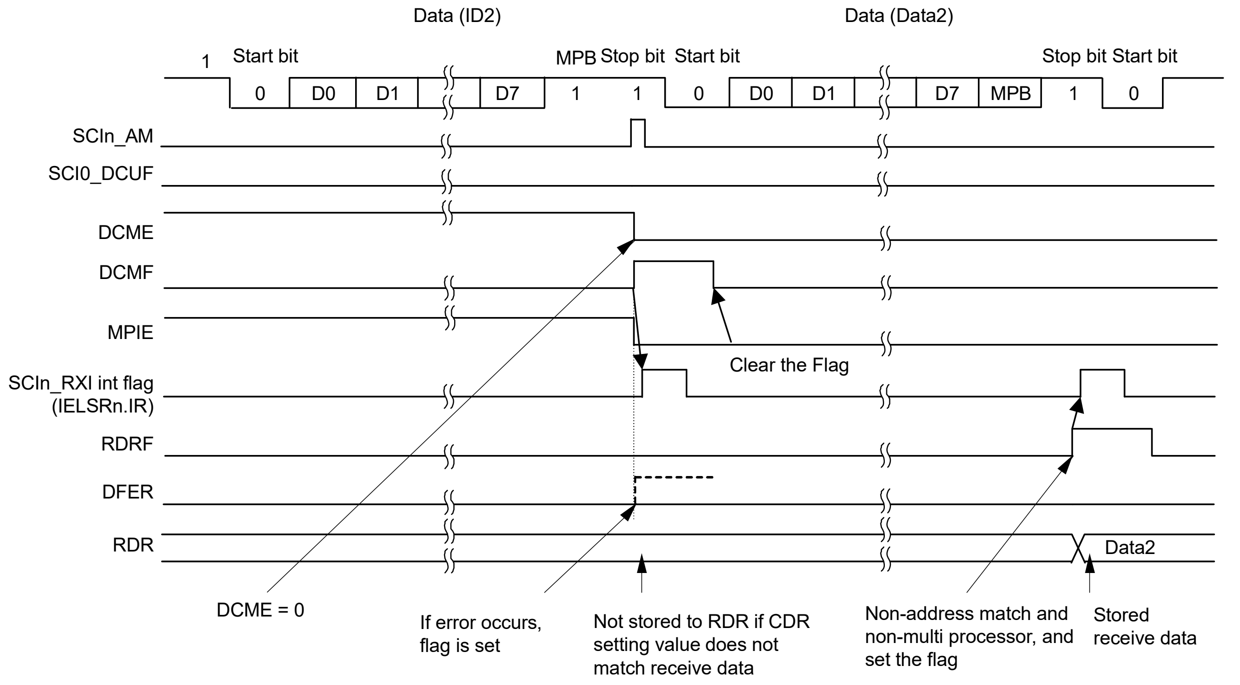
(a) Example of compare non-match between receive data and CDR (8-bit length/parity/non-multi processor mode)

(b) Example of compare match between receive data and CDR (8-bit length/parity/non-multi processor mode)

Figure 34.5 **Example of address match (1) non-multi processor mode**



(a) Example of compare non-match between receive data and CDR (8-bit length/IDSEL = 1/multi-processor mode)



(b) Example of compare match between receive data and CDR (8-bit length/IDSEL = 1/multi-processor mode)

Figure 34.6 Example of address match (2) multi-processor mode

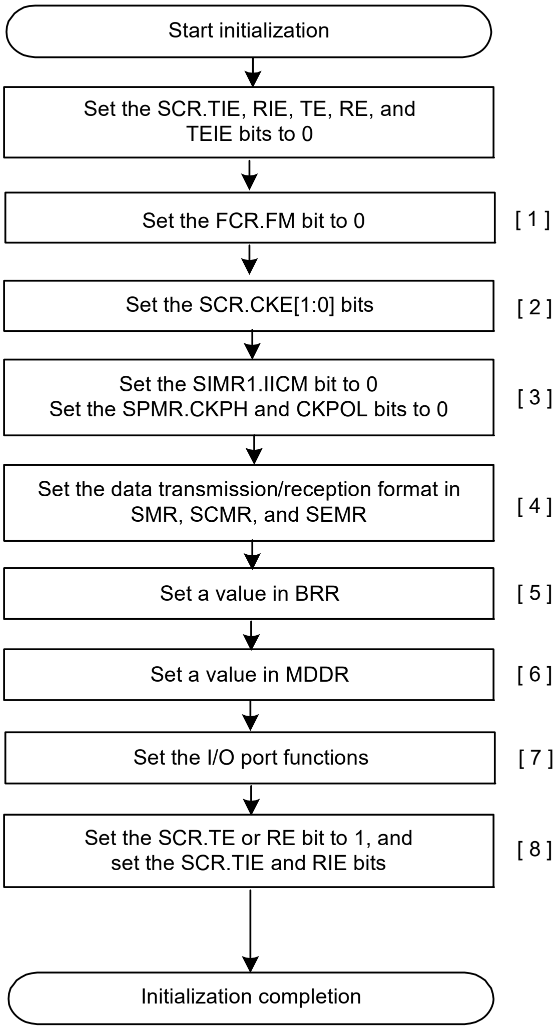
34.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Figure 34.7 and Figure 34.8. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: When the SCR.RE bit is set to 0, the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO, and the RDR and RDRHL registers are not initialized. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.



[1] Set the FCR.FM bit to 0.

[2] Set the clock selection in SCR.
When the clock output is selected in asynchronous mode, the clock is output immediately after SCR settings are made.

[3] Set the SIMR1.IICM bit to 0.
Set the SPMR.CKPH and CKPOL bits to 0.
Step [3] can be skipped if the values have not been changed from the initial values.

[4] Set data transmission/reception format in SMR, SCMR, and SEMR.

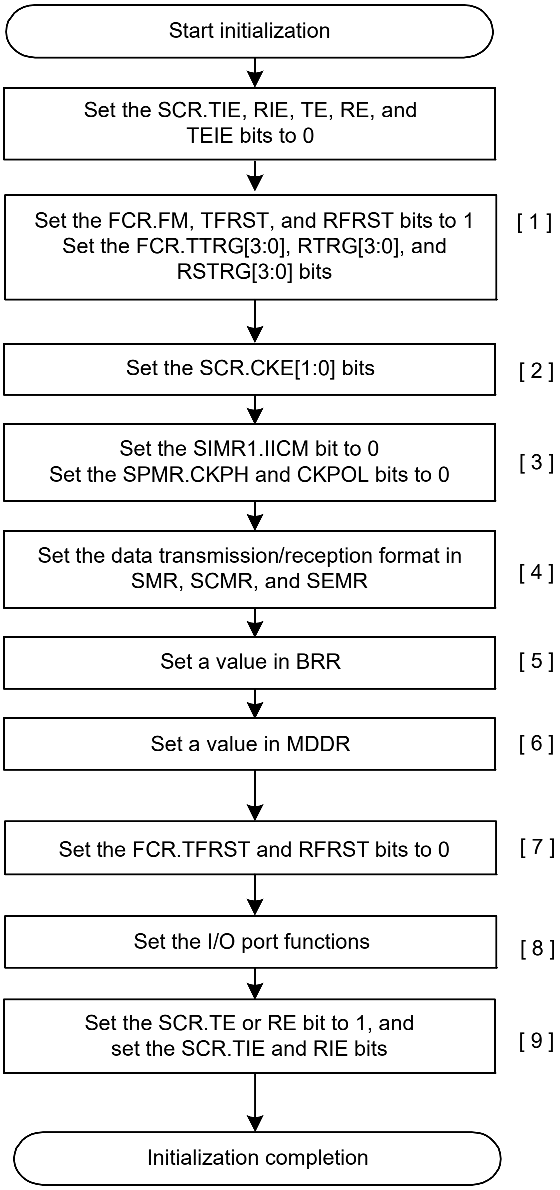
[5] Write a value corresponding to the bit rate to BRR.
This step is not necessary if an external clock is used.

[6] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.

[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Figure 34.7 Example flow of SCI initialization in asynchronous mode with non-FIFO selected



[1] Set the FCR.FM, TFRST, and RFRST bits to 1 (FIFO mode enabled, transmit/receive FIFOs empty). Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.

[2] Set the clock selection in SCR. When the clock output is selected in asynchronous mode, the clock is output immediately after SCR settings are made.

[3] Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits to 0. Step [3] can be skipped if the values have not been changed from the initial values.

[4] Set data transmission/reception format in SMR, SCMR, and SEMR.

[5] Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.

[6] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.

[7] Set the FCR.TFRST and RFRST bits to 0.

[8] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[9] Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits. Setting the TE and RE bits allows TXDn and RXDn to be used.

Figure 34.8 Example flow of SCI initialization in asynchronous mode with FIFO selected

34.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 34.9, Figure 34.10, and Figure 34.11 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level for one frame (preamble) is output to TXD.

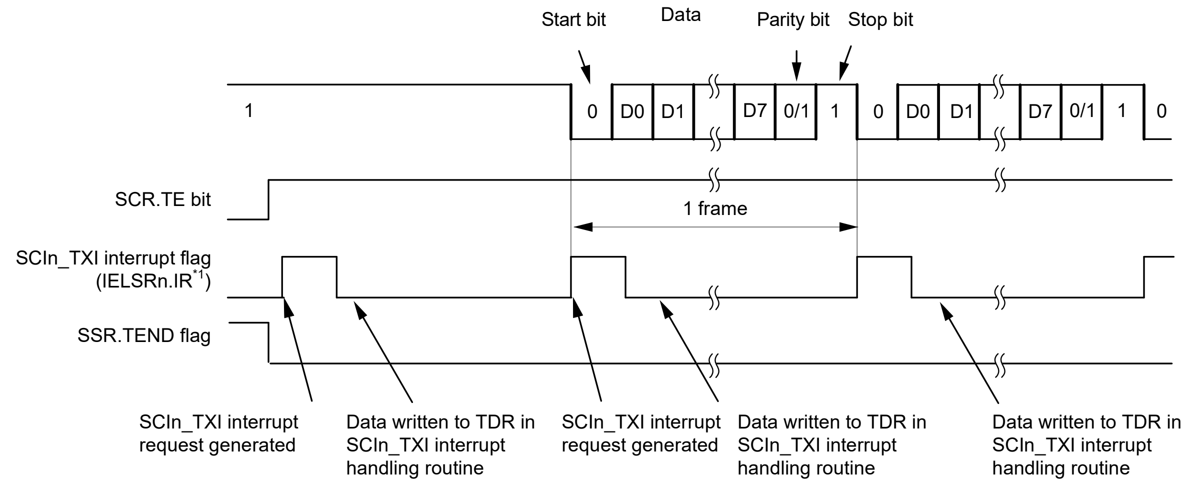
1. The SCI transfers data from the TDR^{*1} register to the TSR register when data is written to TDR^{*1} in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR^{*1} register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR^{*1} register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is

complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR*1 register from the handling routine for SCIn_TXI requests.

3. Data is sent from the TXDn pin in the following order:
    - Start bit
    - Transmit data
    - Parity bit or multi-processor bit (can be omitted depending on the format)
    - Stop bit.
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR*1 register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

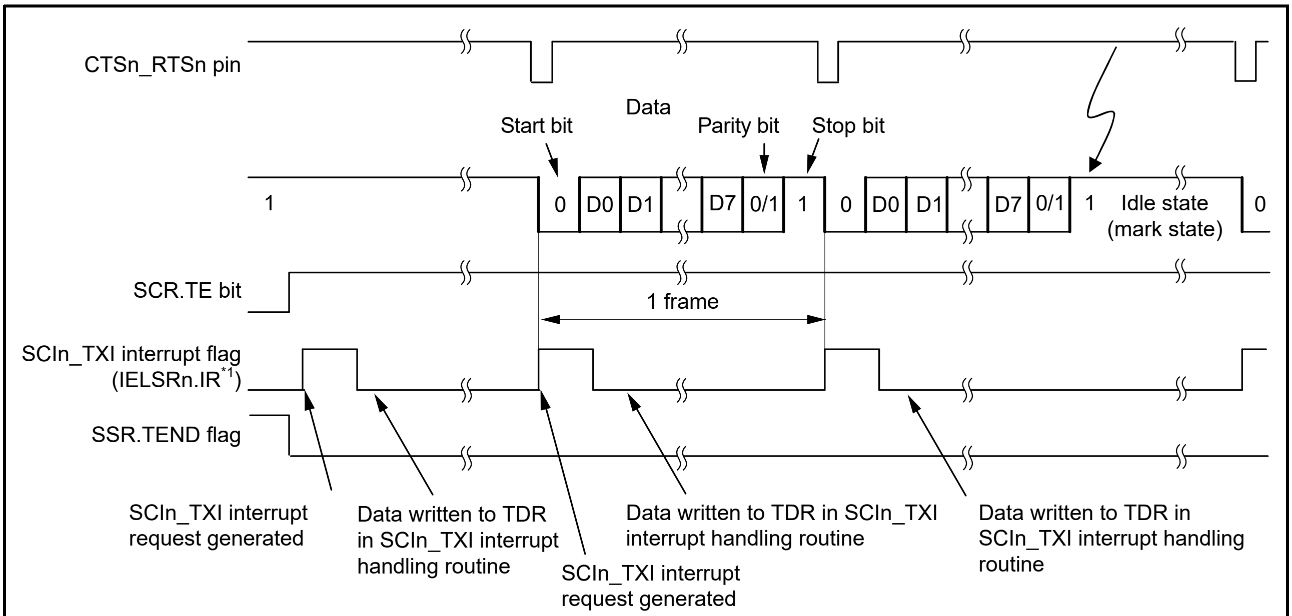
Note 1. Only write data to the TDRHL register when 9-bit data length is selected.

Figure 34.9, Figure 34.10, and Figure 34.11 show examples of serial transmission in asynchronous mode.



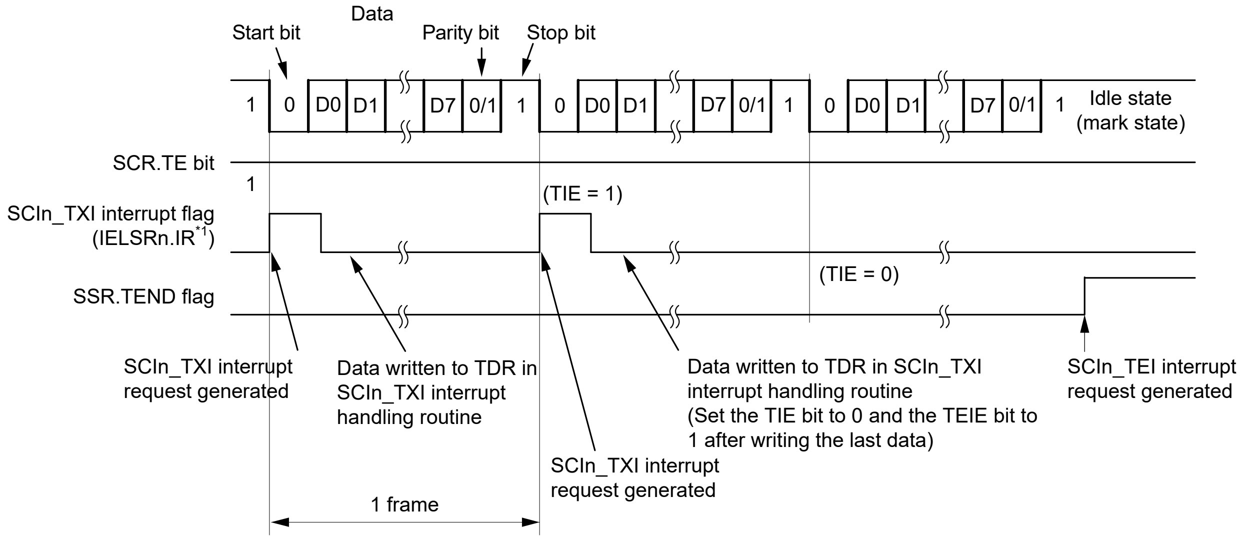
Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.9 Example operation for serial transmission in asynchronous mode (1) with 8-bit data, parity bit, 1 stop bit, CTS function not used, and at the beginning of transmission



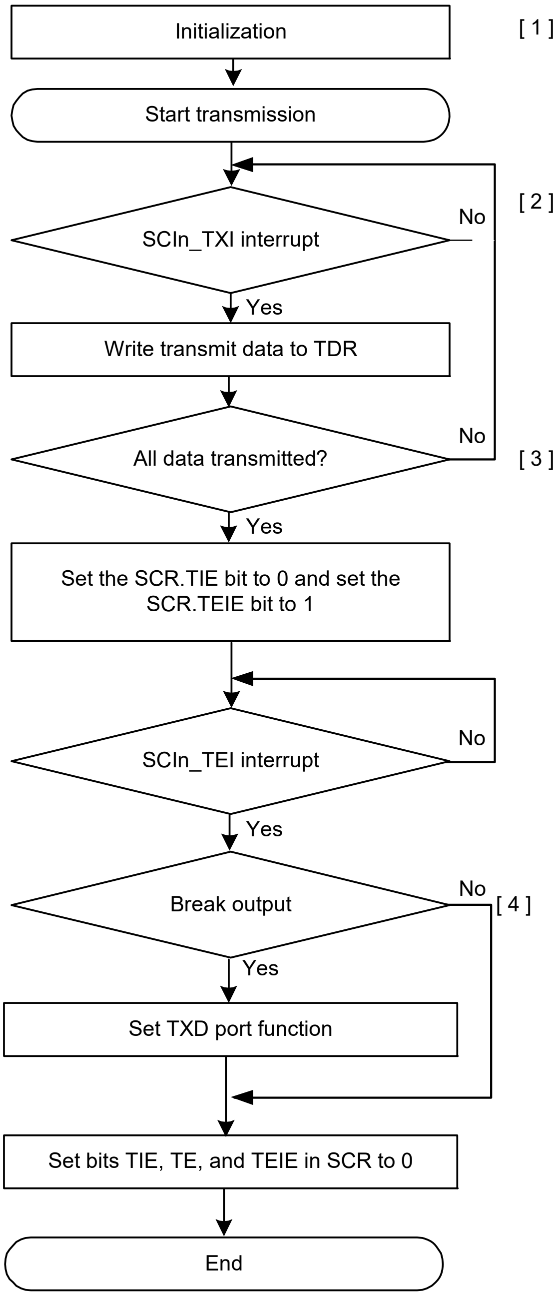
Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.10 Example operation for serial transmission in asynchronous mode (2) with 8-bit data, parity bit, one stop bit, CTS function used, and at the beginning of transmission



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.11 Example operation for serial transmission in asynchronous mode (3) with 8-bit data, parity bit, one stop bit, CTS function not used, and from the middle of transmission until transmission completion



[1] SCI Initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a Frame (preamble), and transmission is enabled.

[2] Transmit data write to TDR by an SCIn_TXI interrupt request. When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated. Write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR once using an SCIn_TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXDn, pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note: The TDR register becomes the TDRHL register when 9-bit data length is selected.

Figure 34.12 Example flow of serial transmission in asynchronous mode with non-FIFO selected

(2) FIFO selected

Figure 34.13 shows an example of a data format that is written to FTDRH and FTDRL in asynchronous mode.

Data corresponding to the data length is set to FTDRH and FTDRL. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

Data Length	Register Setting		Transmit data in FTDRH, FTDRL															
			FTDRHL															
			FTDRH								FTDRL							
	SCMR. CHR1	SMR. CHR	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	—	—	—	—	—	—	—	—	7-bit transmit data						
8 bits	1	1	—	—	—	—	—	—	—	—	8-bit transmit data							
9 bits	0	Don't care	—	—	—	—	—	—	—	9-bit transmit data								

—: Invalid. The write value should be 0.

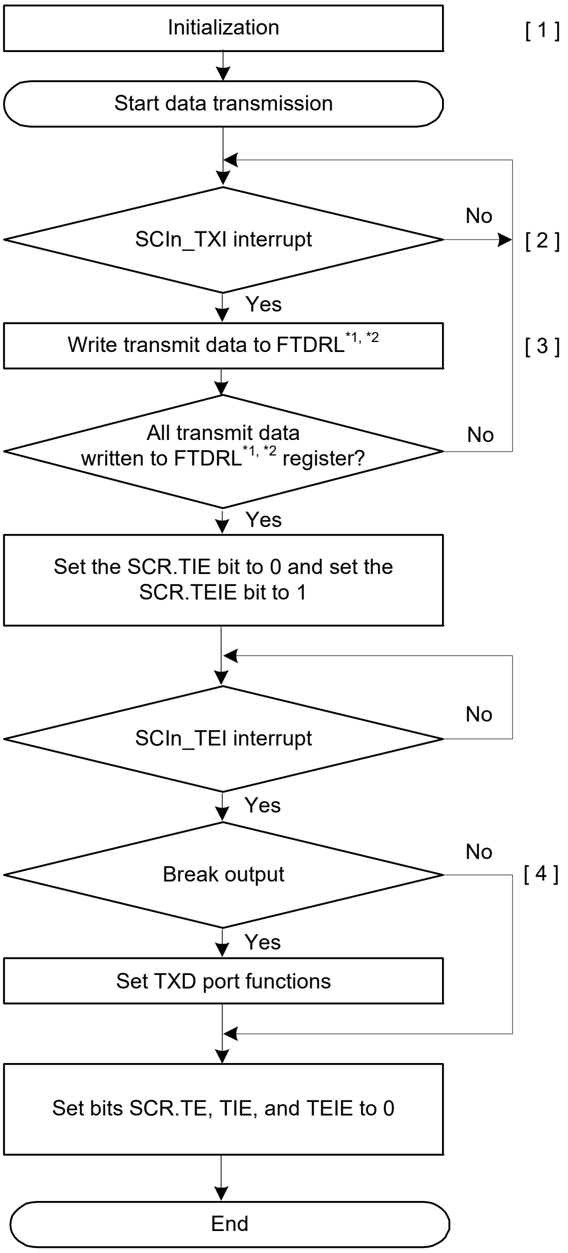
Figure 34.13 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXD for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1 *2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
    - Start bit
    - Transmit data
    - Parity bit or multi-processor bit (can be omitted depending on the format)
    - Stop bit.
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

Figure 34.14 shows an example flow of serial transmission in asynchronous mode with FIFO selected.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame (preamble), and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1, *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data).
Transmit data can also be written to FTDRL by activating the DMAC or DTC. When writing the data to FTDRL by DMAC or DTC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXDn pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.

Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

Figure 34.14 Example flow of serial transmission in asynchronous mode with FIFO selected

34.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

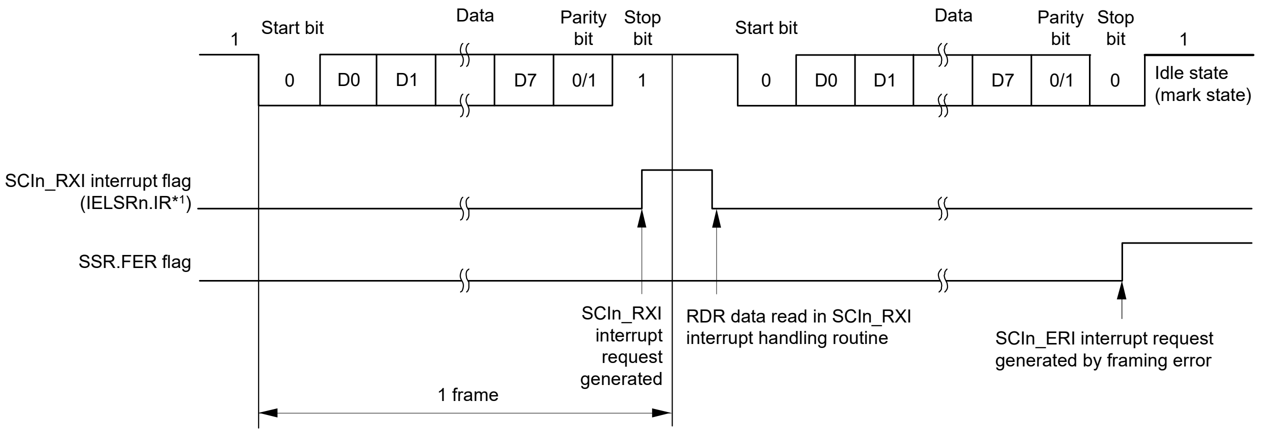
Figure 34.15 and Figure 34.16 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*1 register.

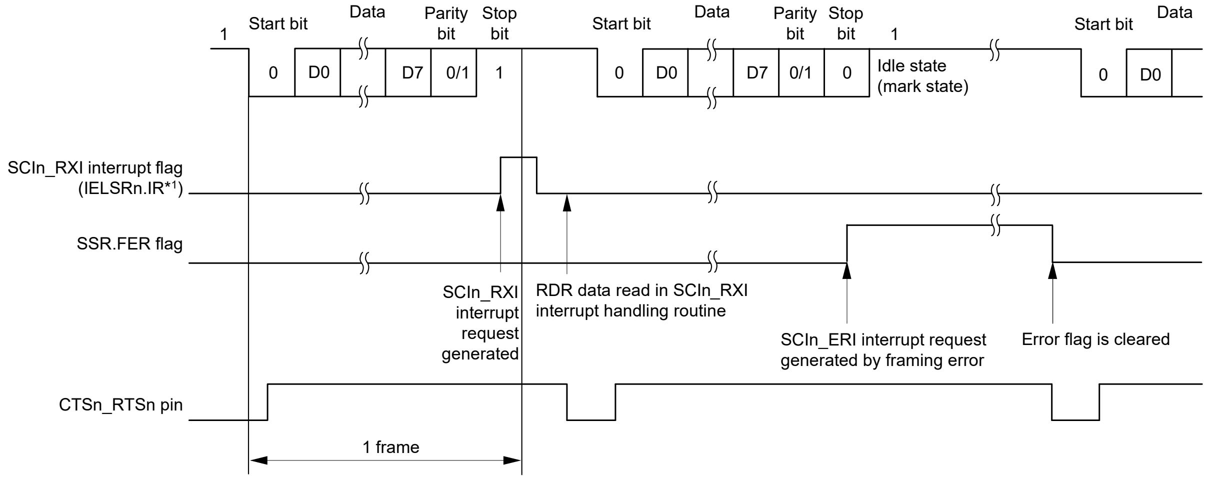
4. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR*1 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.15 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.16 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

Table 34.24 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

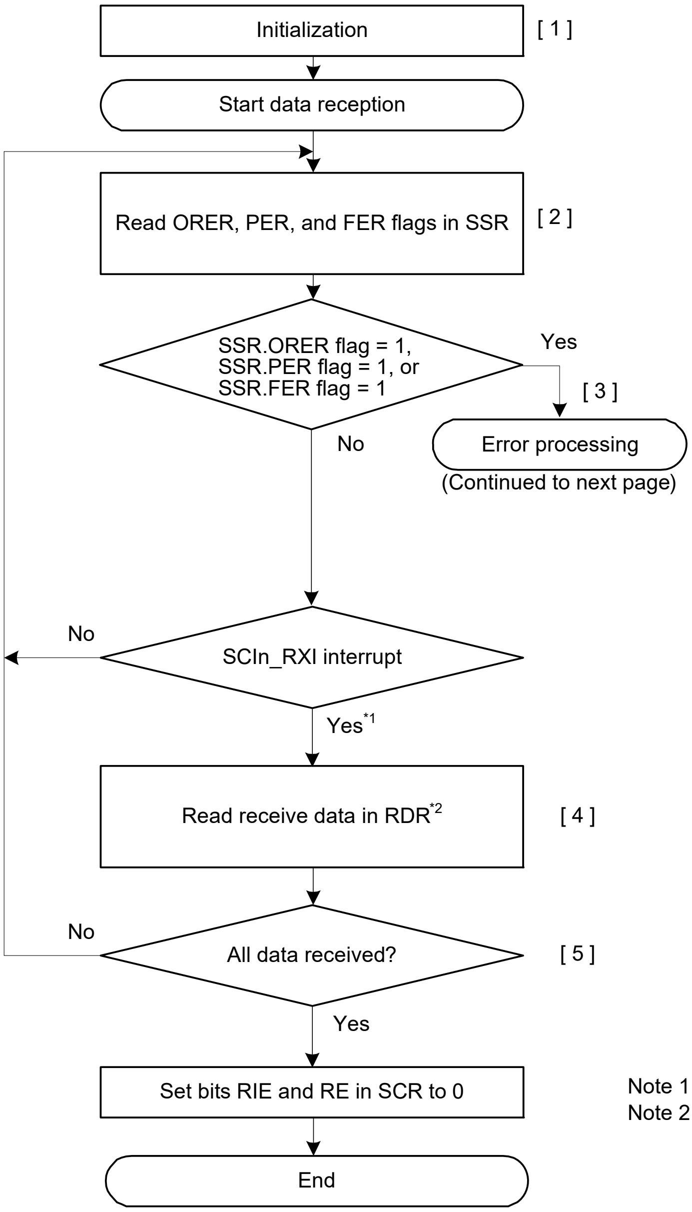
If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 34.17 and Figure 34.18 show example flows of serial data reception.

Table 34.24 Flags in SSR Status Register and receive data handling

Flags in the SSR Status Register				
ORER	**FER**	**PER**	**Receive data**	**Receive error type**
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. An error is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, always set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once in the SCIn_RXI interrupt handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the stop bit of a frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 34.17 Example flow of serial reception in asynchronous mode with non-FIFO selected (1)

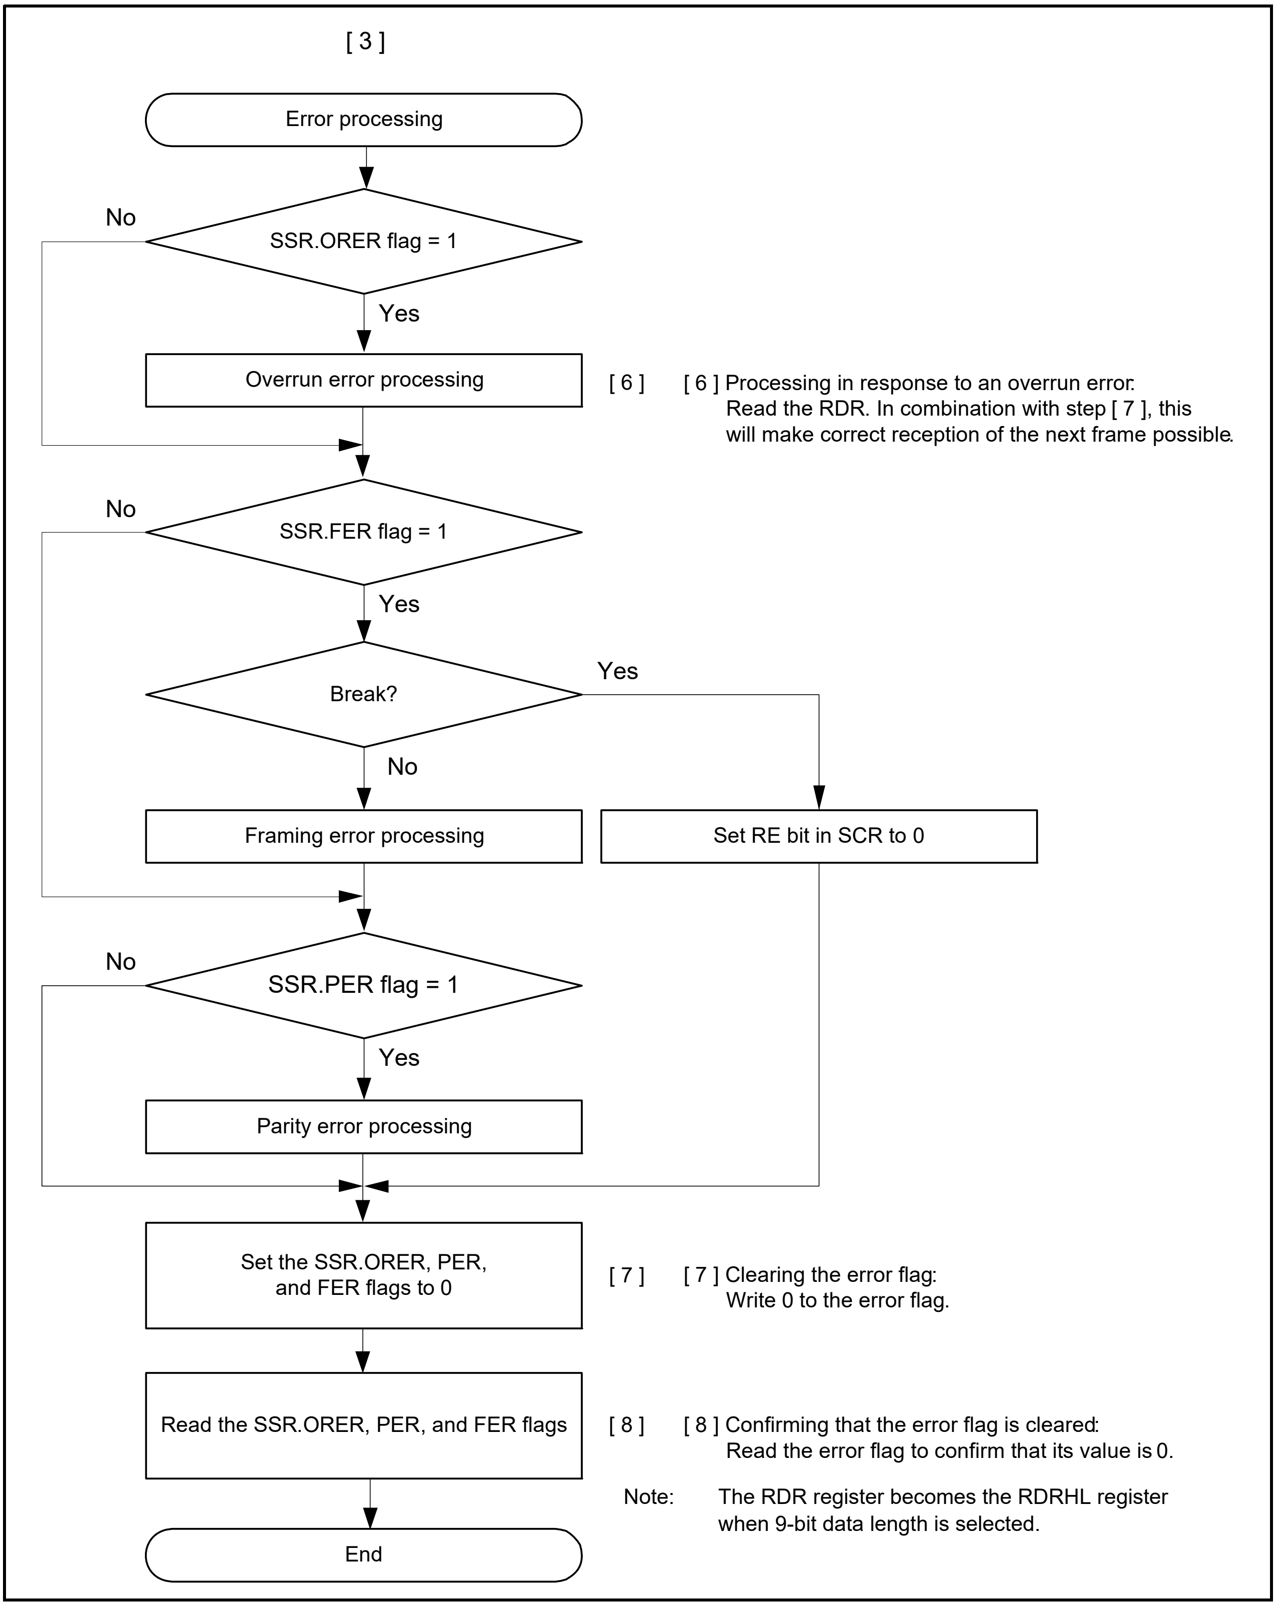


Figure 34.18 Example flow of serial reception in asynchronous mode with non-FIFO selected (2)

(2) FIFO selected

Figure 34.19 shows an example of a data format that is written to FRDRH and FRDRL in asynchronous mode.

In asynchronous mode, 0 is written to the MPB flag in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads

FRDRL, the SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The RDF, ORER, and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

Data Length	Register Setting		Receive data in FRDRH, FRDRL															
			FRDRHL															
			FRDRH								FRDRL							
	SCMR. CHR1	SMR. CHR	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	RDF	ORER	FER	PER	DR	0	0	0	7-bit receive data						
8 bits	1	1	—	RDF	ORER	FER	PER	DR	0	0	8-bit receive data							
9 bits	0	Don't care	—	RDF	ORER	FER	PER	DR	0	9-bit receive data								

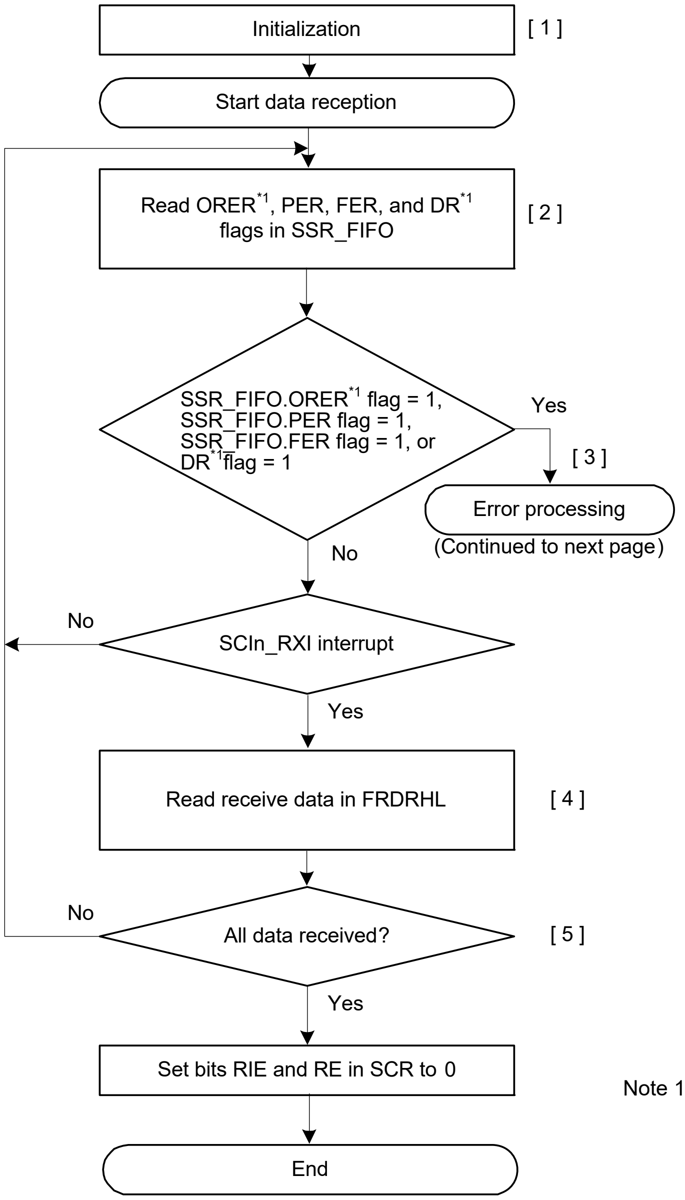
Note: 0 is always read for MPB flag (FRDRH[1]).
When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7].
When data length is 8 bits, 0 is always read for FRDRH[0].
FRDRH[7] bit is read as an indefinite value.

Figure 34.19 Data format stored in FRDRH and FRDRL with FIFO selected

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register, and checks the parity bit and stop bit.
3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*1 register.
4. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*1 register. If the RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*1 register. If the RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
6. After a framing error is detected and when SCI detects that the continuous receive data is for one frame, reception stops.
7. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 ETUs from the last stop bit in asynchronous mode, the SSR_FIFO.DR bit is set to 1. When the RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.
8. When reception finishes successfully, receive data is transferred to the FRDRL*1 register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL*2 register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL*3 is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 2. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

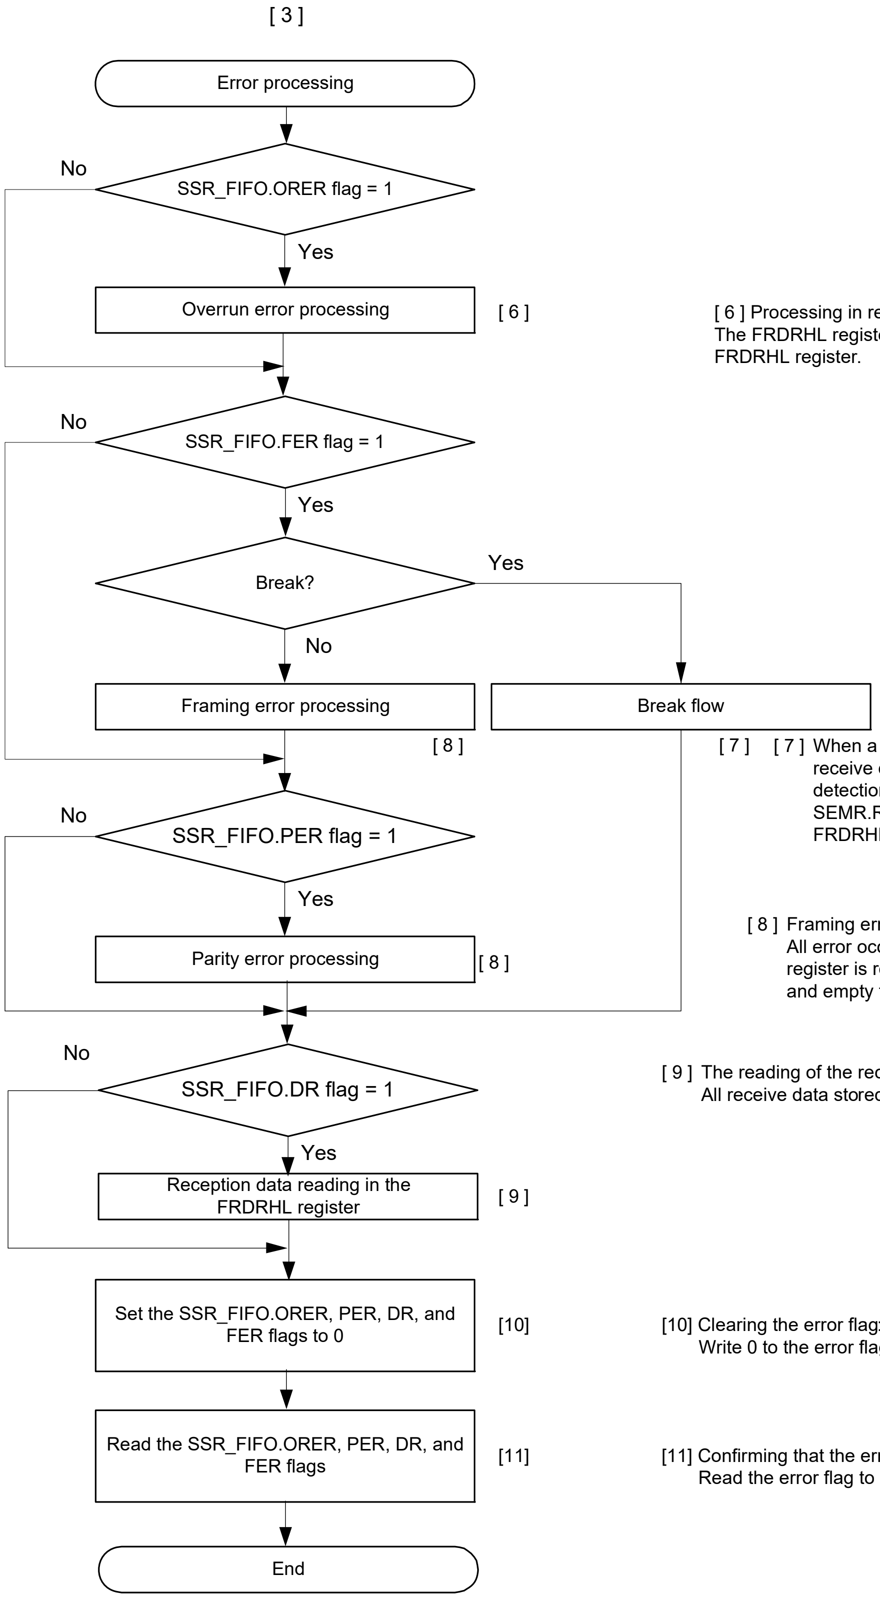
[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON bit. An error is identified by reading the ORER^{*1}, PER, DR^{*1}, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER^{*1} flag to 0. Reception cannot be resumed if ORER^{*1} flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR^{*1} = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF and DR flags to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

Figure 34.20 Example flow of serial reception in asynchronous mode with FIFO selected (1)



[6] Processing in response to an overrun error.
The FRDRHL register is read and a space is made in the FRDRHL register.

[7] When a break is detected, transfer of the receive data to FRDRHL stops after the detection. When the break ends at SEMR.RXDESEL = 0, the last stored data of FRDRHL is break error frame (All 0 data).

[8] Framing error processing / parity error processing:
All error occurrence data stored in the FRDRHL register is read. (Or write 1 to the FCR.RFRST bit and empty the FRDRHL register.)

[9] The reading of the receive data (when FCR.DRES is 1):
All receive data stored in the FRDRHL register is read.

[10] Clearing the error flag:
Write 0 to the error flag.

[11] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Figure 34.21 Example flow of serial reception in asynchronous mode with FIFO selected (2)

34.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle.

Figure 34.22 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register.

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to non-multi processor reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi processor asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in non-multi processor asynchronous mode.

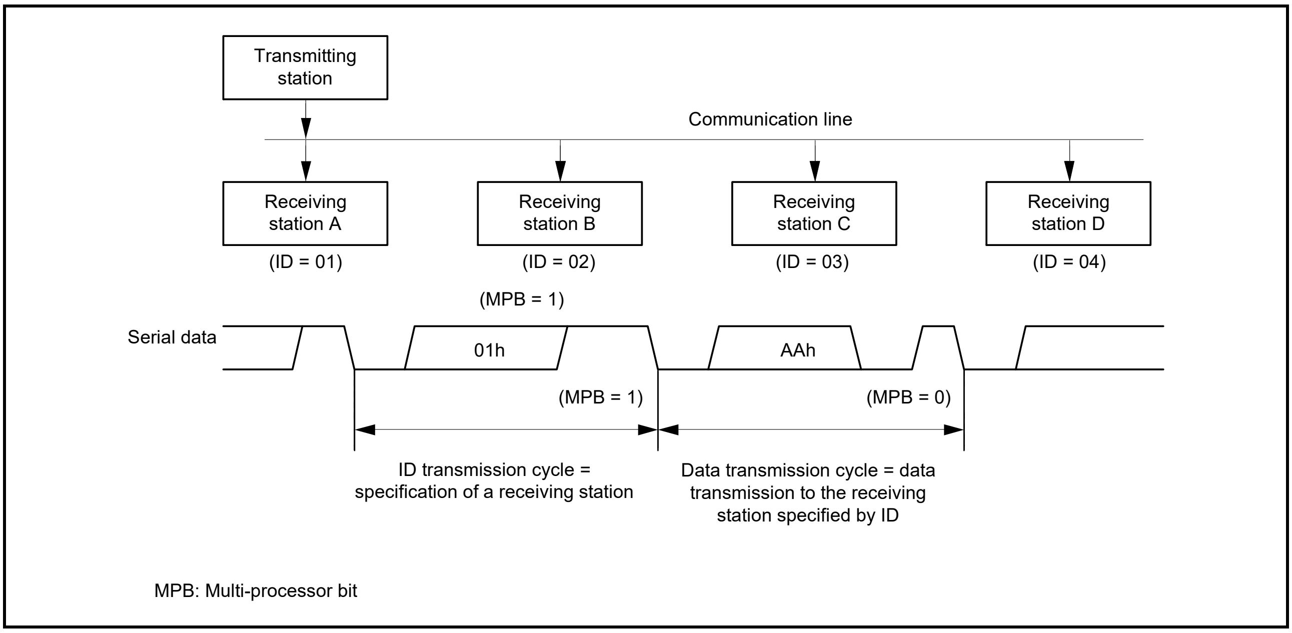


Figure 34.22 Example of communication using multi-processor format with transmission of data AAh to receiving station A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FRDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register.

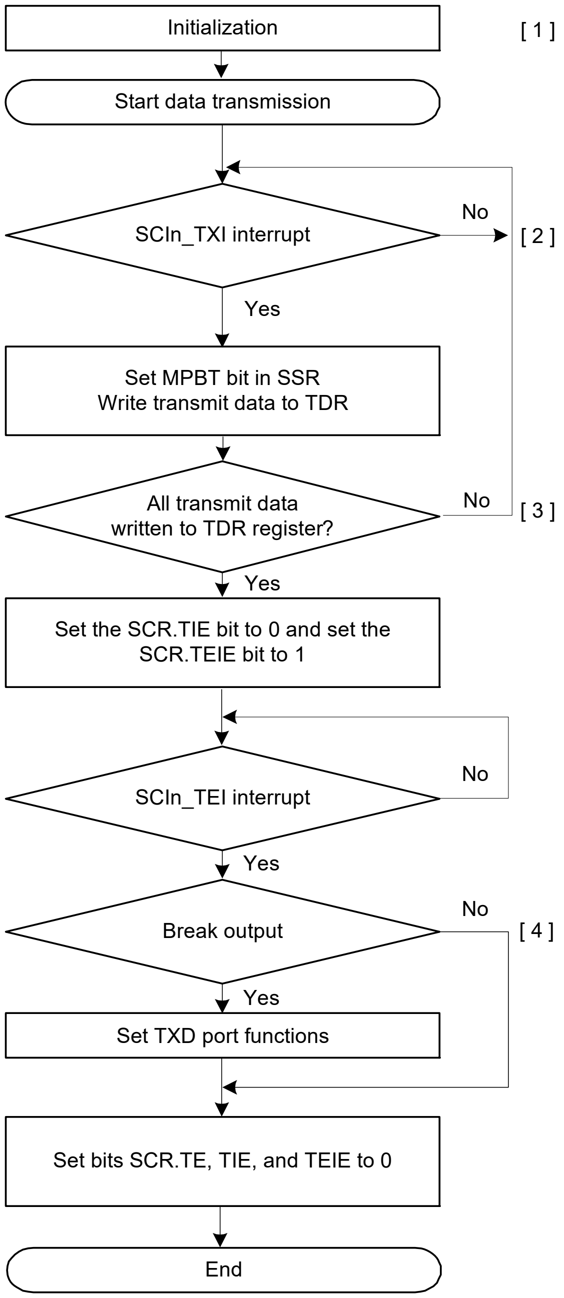
When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FRDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to non-multi processor reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi processor asynchronous mode with non-FIFO selected.

34.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 34.23 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Set the MPBT bit in SSR to 0 or 1, and write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using an SCIn_TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXDn pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Figure 34.23 Example flow of multi-processor serial transmission with non-FIFO selected

(2) FIFO selected

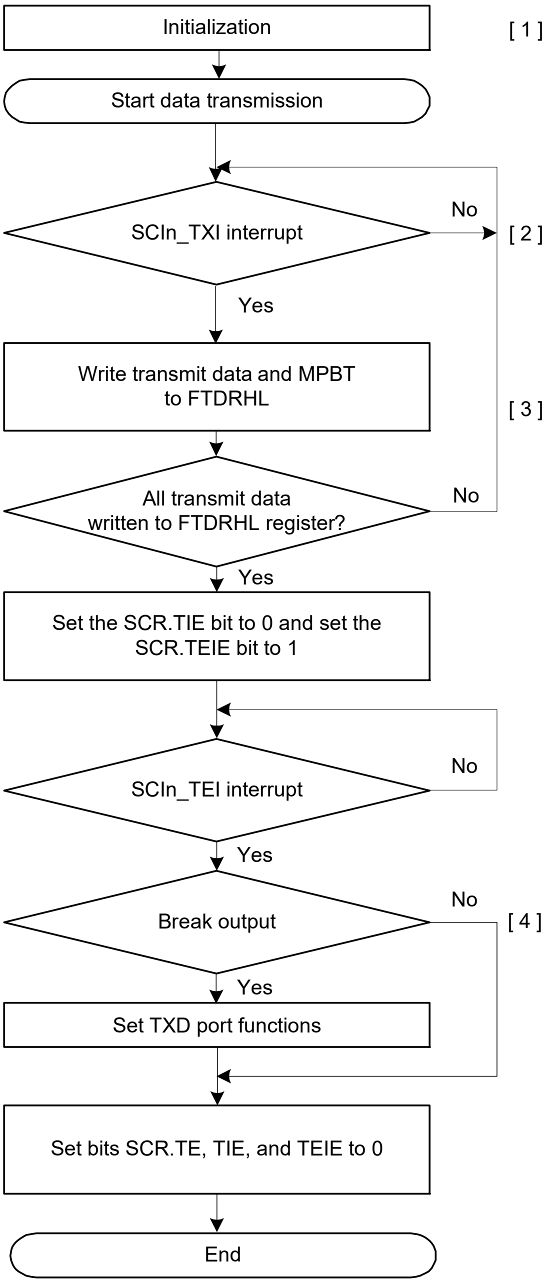
Figure 34.24 shows an example of data format that is written to FTDRH and FTDRL in multi-processor mode. The FTDRH.MPBT bit is set to 1. Data is set to FTDRH and FTDRL with the correct data length. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

Data Length	Register Setting		Transmit data in FTDRH, FTDRL															
			FTDRHL															
			FTDRH								FTDRL							
	SCMR. CHR1	SMR. CHR	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	—	—	—	—	—	MPBT	—	—	7-bit transmit data						
8 bits	1	1	—	—	—	—	—	—	MPBT	—	8-bit transmit data							
9 bits	0	Don’t care	—	—	—	—	—	—	MPBT	9-bit transmit data								

—: Invalid. The write value should be 0.

Figure 34.24 Data format written to FTDRH and FTDRL in multi-processor mode with FIFO selected

Figure 34.25 shows an example flow of multi-processor data transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the FTDRH.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode with non-FIFO selected.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRHL by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRHL to TSR, when the quantity of receive data written in FTDRHL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data and MPBT to FTDRHL once using an SCIn_TXI interrupt request. Transmit data can also be written to FTDRHL by activating the DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRHL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXDn pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

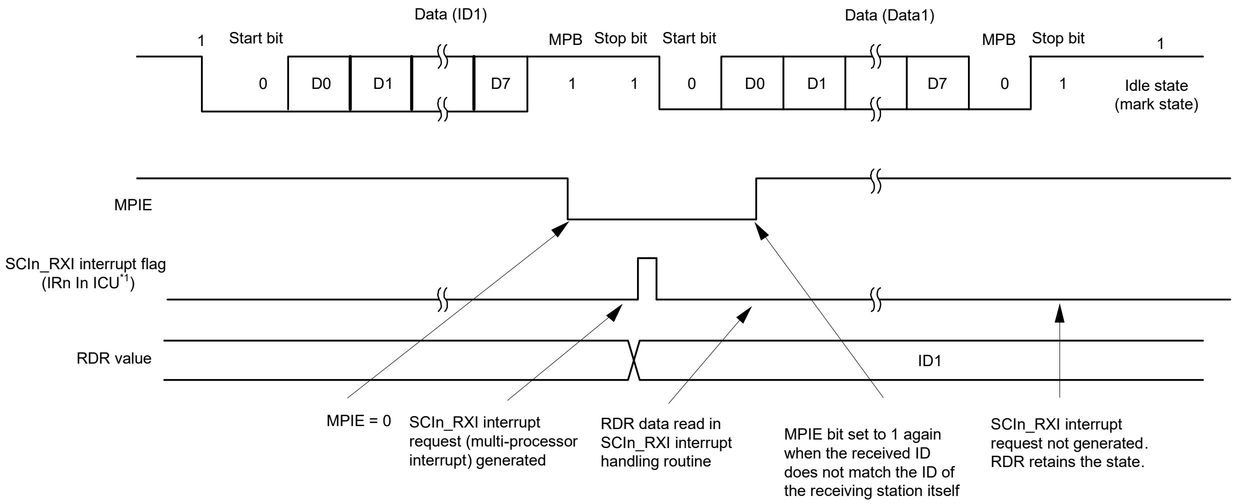
Figure 34.25 Example flow of serial transmission in multi-processor mode with FIFO selected

34.4.2 Multi-Processor Serial Data Reception

(1) Non-FIFO selected

Figure 34.27 and Figure 34.28 are example flows of multi-processor data reception. When the SCR.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRHL register when 9-bit data length is selected), and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode.

Figure 34.26 shows an example operation for data reception.



MPIE = 0

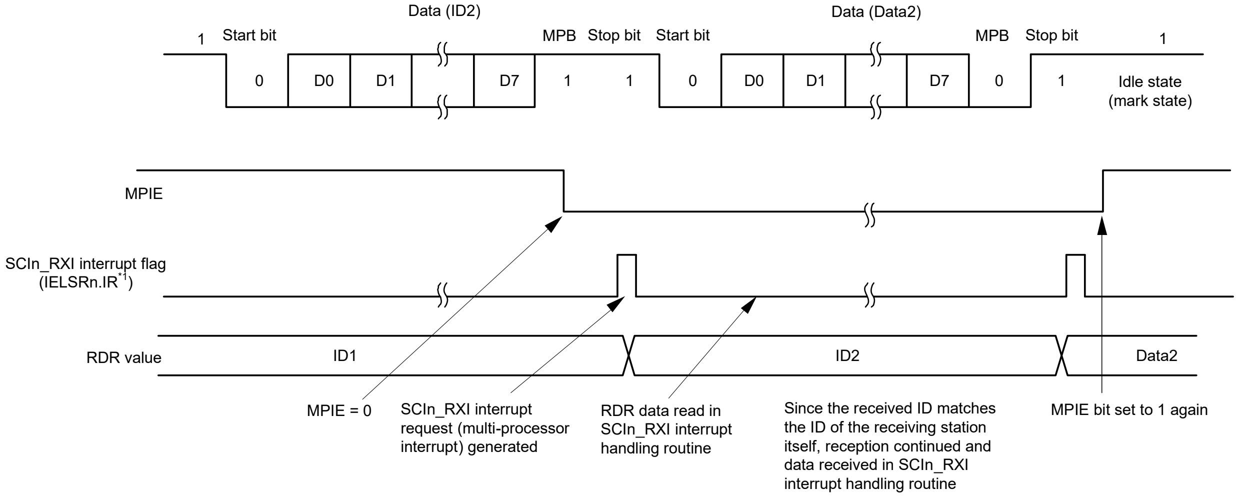
SCIn_RXI interrupt request (multi-processor interrupt) generated

RDR data read in SCIn_RXI interrupt handling routine

MPIE bit set to 1 again when the received ID does not match the ID of the receiving station itself

SCIn_RXI interrupt request not generated. RDR retains the state.

(a) When the received ID does not match the ID of the receiving station itself



MPIE = 0

SCIn_RXI interrupt request (multi-processor interrupt) generated

RDR data read in SCIn_RXI interrupt handling routine

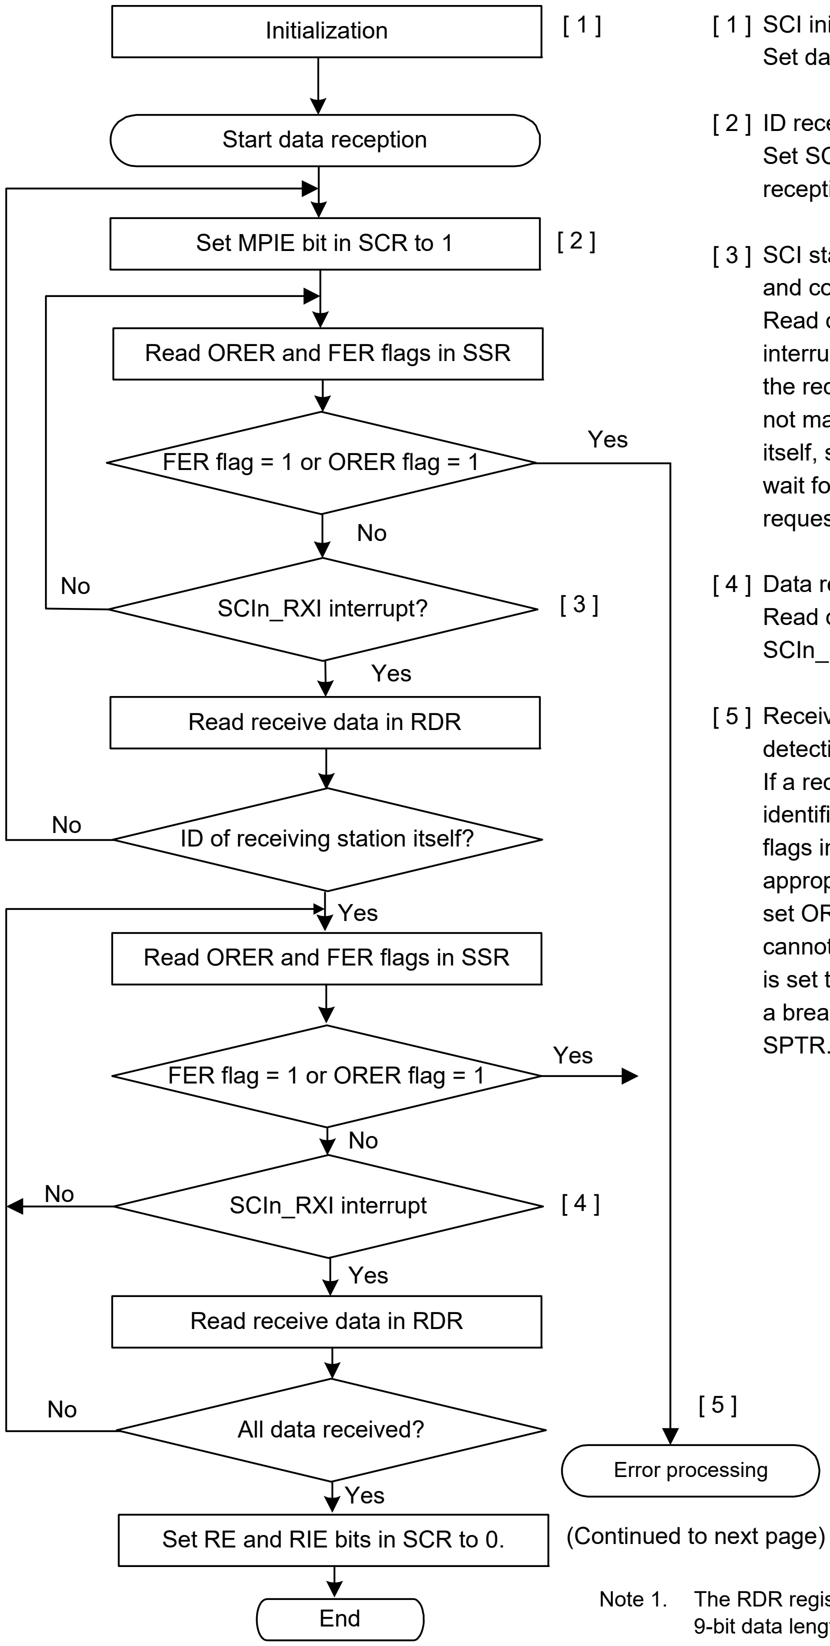
Since the received ID matches the ID of the receiving station itself, reception continued and data received in SCIn_RXI interrupt handling routine

MPIE bit set to 1 again

(b) When the received ID matches the ID of the receiving station itself

Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.26 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit



[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set SCR.MPIE bit to 1 and wait for ID reception.

[3] SCI status confirmation and reception and comparison of ID:
Read data in RDR[*1] at the first SCIn_RXI interrupt and compare it with the ID of the receiving station itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another SCIn_RXI interrupt request.

[4] Data reception at an SCIn_RXI interrupt:
Read data in RDR[*1] once in the SCIn_RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in SSR. After performing the appropriate error processing, be sure to set ORER and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading SPTR.RXDMON bit.

(Continued to next page)

Note 1. The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 34.27 Example flow of multi-processor serial reception with non-FIFO selected (1)

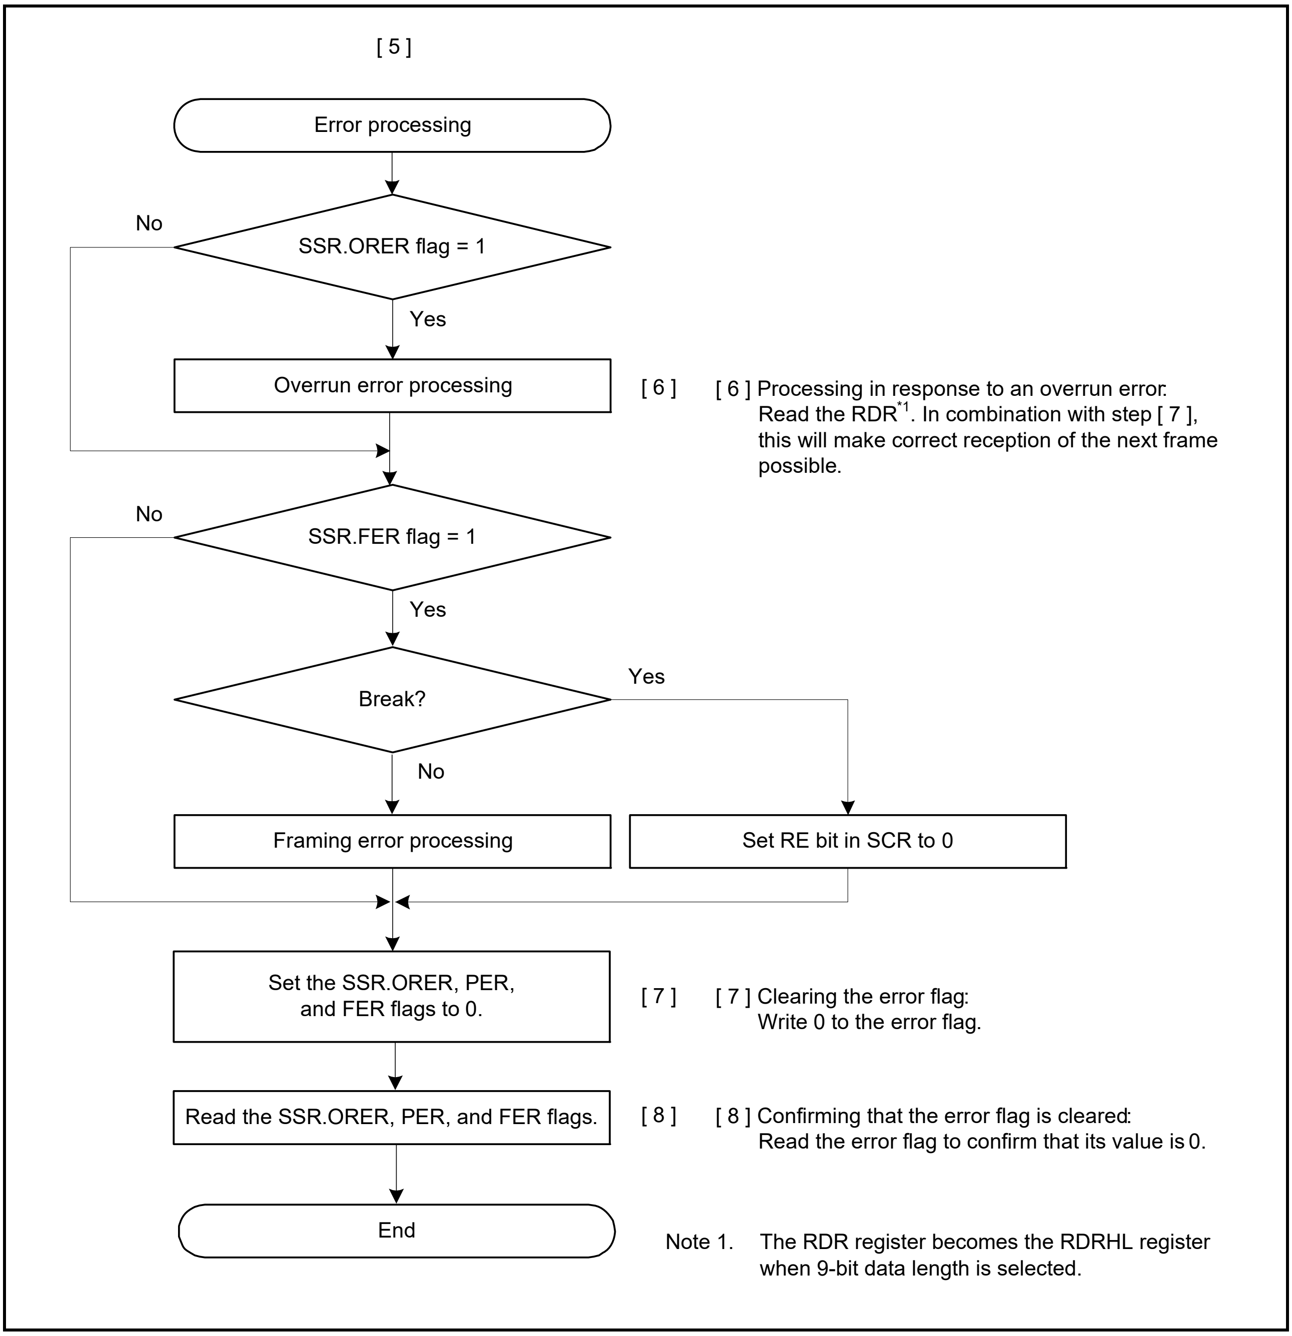


Figure 34.28 Example flow of multi-processor serial reception with non-FIFO selected (2)

(2) FIFO selected

Figure 34.29 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB flag. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

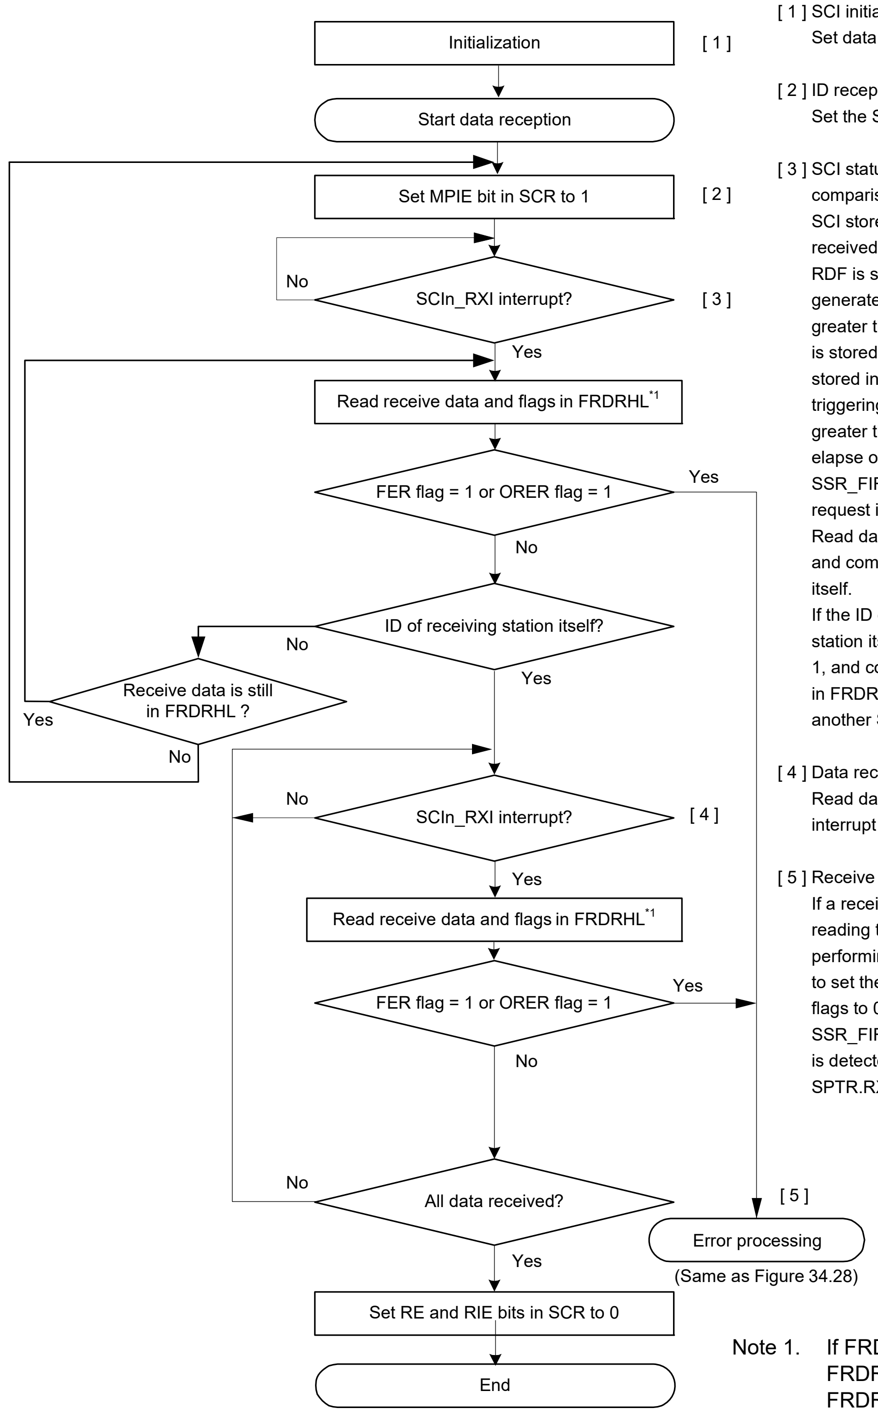
Data Length	Register Setting		Receive data in FRDRH, FRDRL															
			FRDRHL															
			FRDRH								FRDRL							
	SCMR. CHR1	SMR. CHR	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	RDF	ORER	FER	0	DR	MPB	0	0	7-bit receive data						
8 bits	1	1	—	RDF	ORER	FER	0	DR	MPB	0	8-bit receive data							
9 bits	0	Don't care	—	RDF	ORER	FER	0	DR	MPB	9-bit receive data								

Note: When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]
When data length is 8 bits, 0 is always read for FRDRH[0]
FRDRH[7] bit is read as an indefinite value.

Figure 34.29 Data format stored in FRDRH and FRDRL in multi-processor mode with FIFO selected

Figure 34.30 shows an example flow of multi-processor data reception with FIFO selected. When the SCR.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the FRDRHL register. The SCR.MPIE bit is automatically cleared and non-multi processor reception continues.

If a framing error occurs and the SSR_FIFO.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in asynchronous mode with non-FIFO selected.



[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set the SCR.MPIE bit to 1 and wait for ID reception.

[3] SCI status confirmation and reception and comparison of ID:
SCI stores first data (MPB = 1) and subsequent received data in FRDRHL.
RDF is set to 1 and an SCIn_RXI interrupt request is generated when a quantity of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL. When the quantity of data stored in FRDRHL falls the specified receive triggering number and received data is equal to or greater than 1, and no next data is received after the elapse of 15 ETUs from the last stop bit, SSR_FIFO.DR is set to 1. An SCIn_RXI interrupt request is generated when FCR.DRES bit is 0.
Read data in FRDRHL at the first SCIn_RXI interrupt, and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, the SCI reads until the data with MPB = 1, and compares next ID. If it is no data with MPB = 1 in FRDRHL, set the MPIE bit to 1 again and wait for another SCIn_RXI interrupt request.

[4] Data reception at an SCIn_RXI interrupt:
Read data in FRDRHL once in the SCIn_RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading the ORER and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the SSR_FIFO.ORER and SSR_FIFO.FER flags to 0. Reception cannot be resumed if the SSR_FIFO.ORER flag is set to 1. When framing error is detected, a break can be detected by reading the SPTR.RXDMON bit.

Note 1. If FRDRH and FRDRL are used instead of FRDRHL, read in order from FRDRH to FRDRL.

Figure 34.30 Example flow of serial reception in multi-processor mode with FIFO selected

34.5 Operation in Clock Synchronous Mode

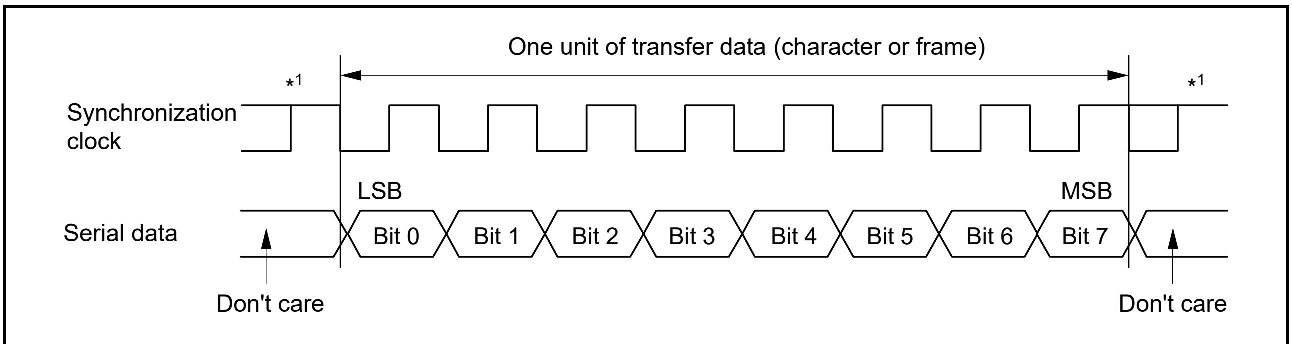
Figure 34.31 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 00h and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 00h and SMR.CKS[1:0] = 00b) is not available.



Note 1. Holds a high level except during continuous transfer.

Figure 34.31 Data format in clock synchronous serial communications with LSB-first order

34.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 && SPMR.CKPOL = 0) or (SPMR.CKPH = 1 && SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 && SPMR.CKPOL = 1) or (SPMR.CKPH = 1 && SPMR.CKPOL = 0).

34.5.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication becomes possible. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

(a) Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- When serial communication is enabled
- There is no received data available to be read when the SCR.RE bit is 1
- Data is available for transmission in the TSR register when SCR.TE bit is 1
- The SSR.ORER flag is 0.

(b) FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- When serial communication is enabled
- The amount of receive data written in FRDRHL is less than the specified CTSn_RTSn output triggering number when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0.

[Condition for high output]

(a) Non-FIFO selected

- The conditions for low output are not satisfied
- When reception is terminated with SCR.RE = 0 without reading the RDR register after reception is complete, RTS remains high. At this time, read the SCR register for dummy values after writing 0 to SCR.RE.

(b) FIFO selected

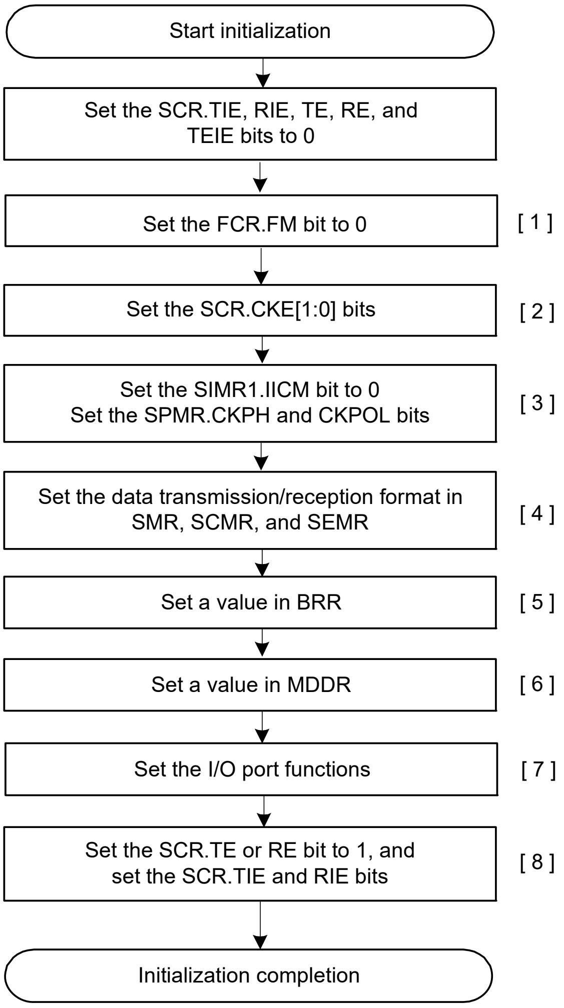
- The conditions for low output are not satisfied.

34.5.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 00h to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in 34.5.2 CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor the RDR and RDRHL register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.



[1] Set the FCR.FM bit to 0.

[2] Set the clock selection in SCR.

[3] Set the SIMR1.IICM bit to 0.
Set the SPMR.CKPH and CKPOL bits.
Step [3] can be skipped if the values have not been changed from the initial values.

[4] Set data transmission/reception format in SMR, SCMR, and SEMR.

[5] Write a value corresponding to the bit rate to BRR.
This step is not necessary if an external clock is used.

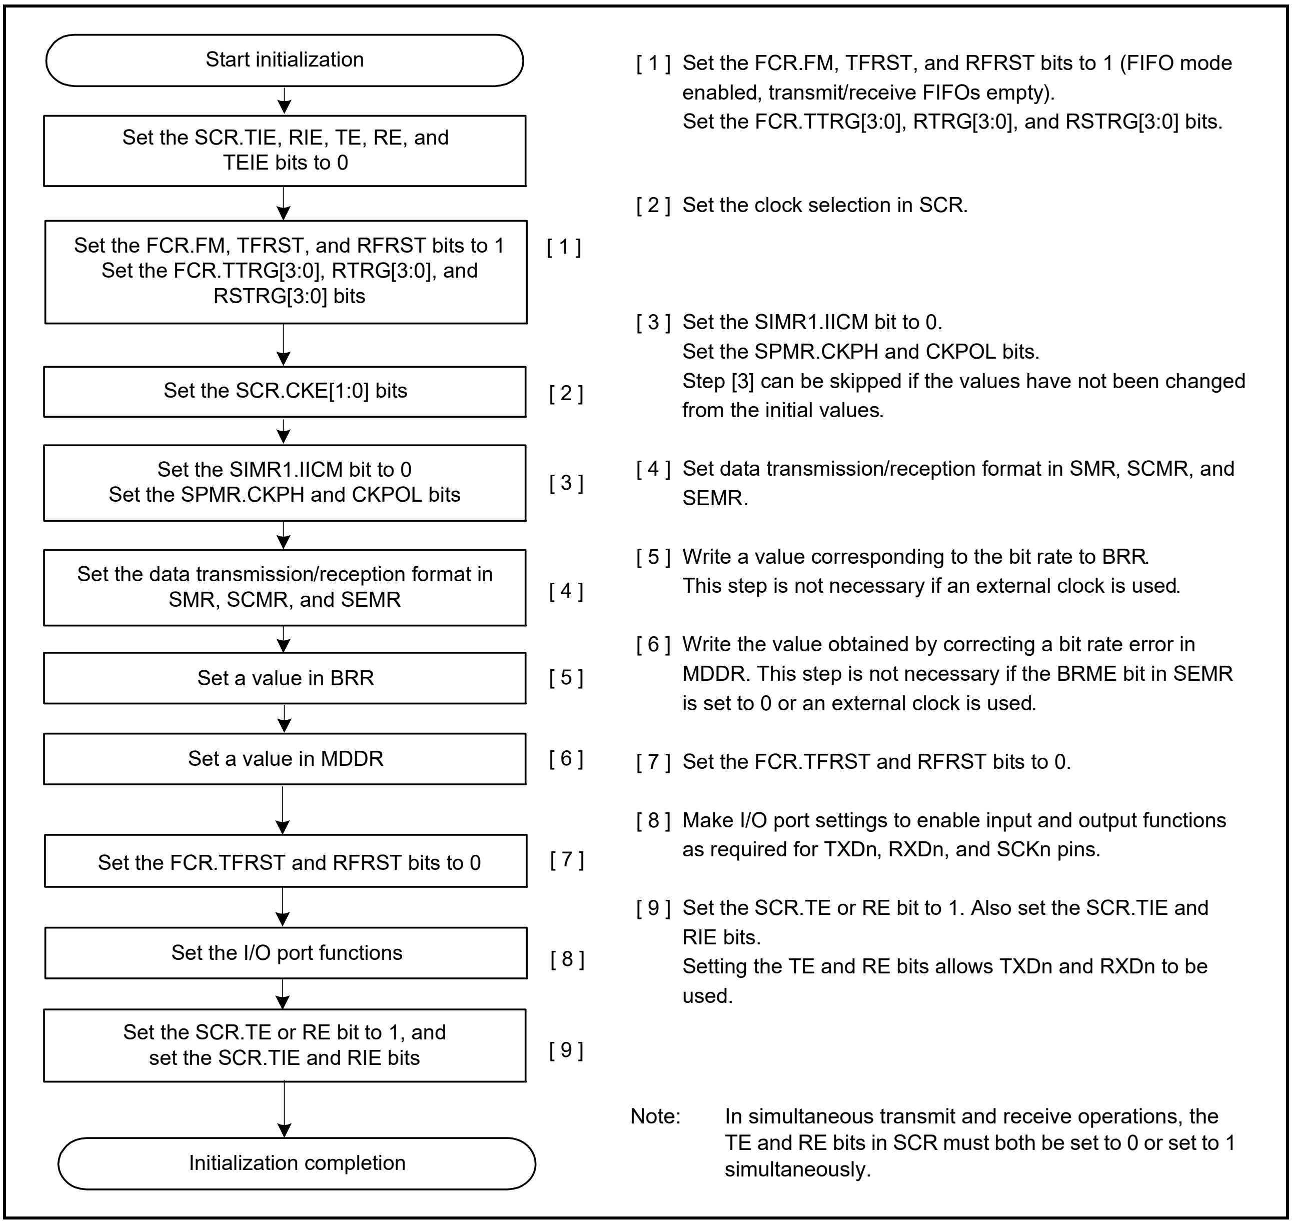
[6] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.

[7] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[8] Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously.

Figure 34.32 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected



[1] Set the FCR.FM, TFRST, and RFRST bits to 1 (FIFO mode enabled, transmit/receive FIFOs empty).
Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.

[2] Set the clock selection in SCR.

[3] Set the SIMR1.IICM bit to 0.
Set the SPMR.CKPH and CKPOL bits.
Step [3] can be skipped if the values have not been changed from the initial values.

[4] Set data transmission/reception format in SMR, SCMR, and SEMR.

[5] Write a value corresponding to the bit rate to BRR.
This step is not necessary if an external clock is used.

[6] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.

[7] Set the FCR.TFRST and RFRST bits to 0.

[8] Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.

[9] Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits.
Setting the TE and RE bits allows TXDn and RXDn to be used.

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously.

Figure 34.33 Example flow of SCI initialization in clock synchronous mode with FIFO selected

34.5.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 34.34, Figure 34.35, and Figure 34.36 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

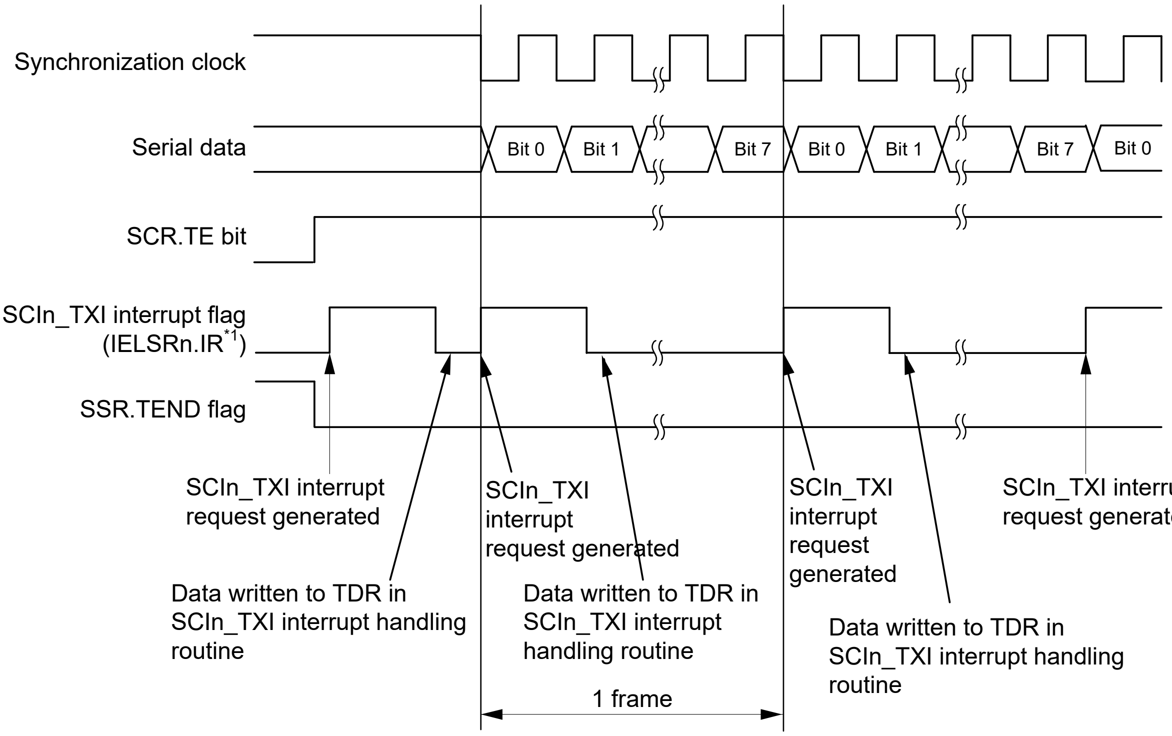
1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.

3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 34.34, Figure 34.35, and Figure 34.36 show examples of serial data transmission.

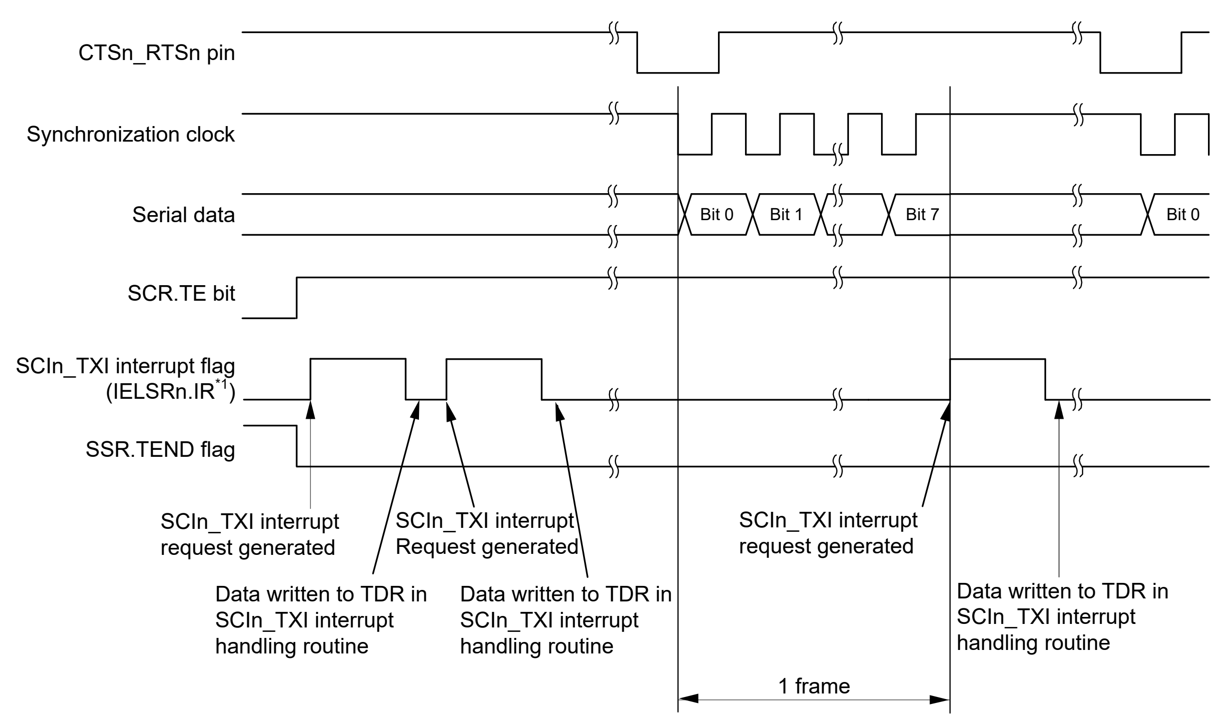
Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.



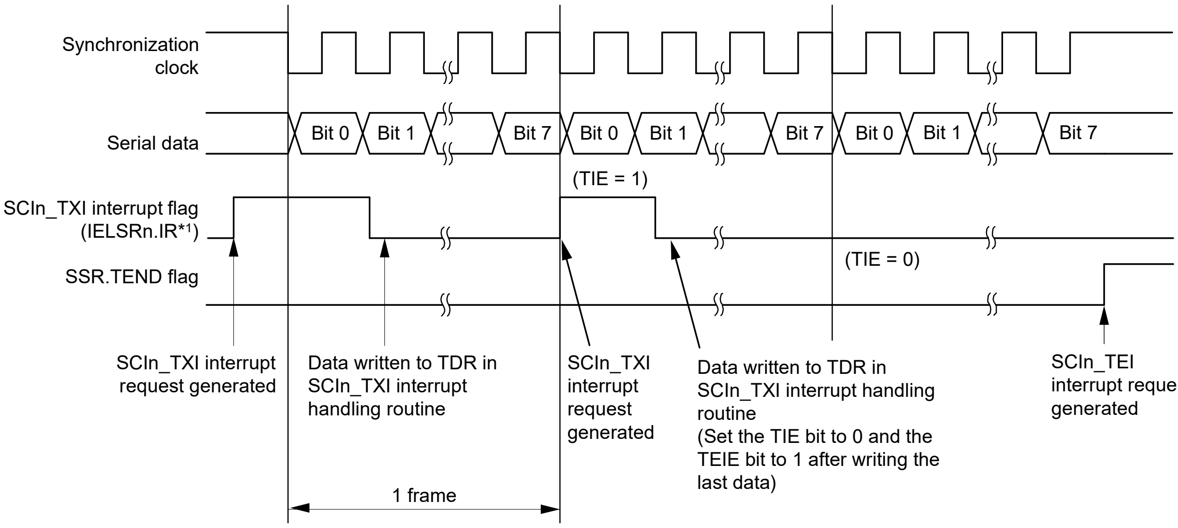
Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.34 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission



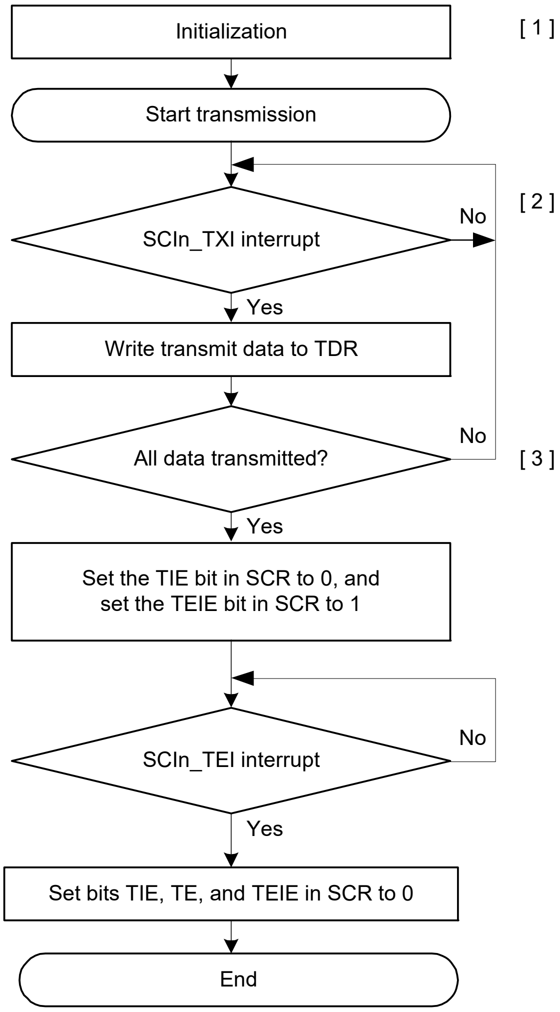
Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.35 Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.36 Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion



[1] SCI initialization:
Set data transmission.

[2] Write transmit data to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR on accepting a transmit data empty interrupt (SCIn_TXI) request.
Transmit data can also be written to TDR by activating the DMAC or DTC by the SCIn_TXI interrupt request.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 34.37 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

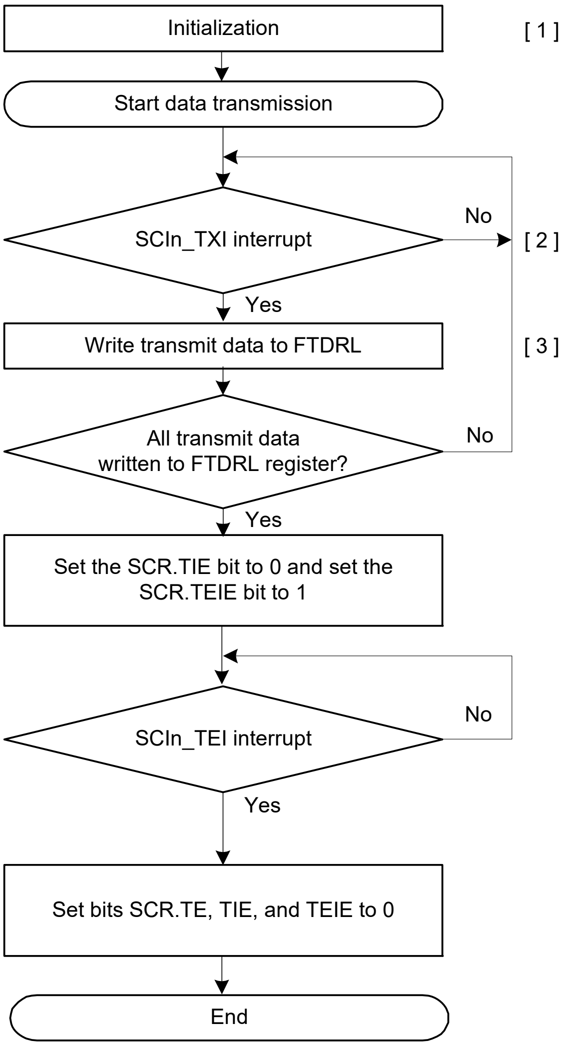
Figure 34.38 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.

3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.
5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRL by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data has finished.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCK pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 34.38 Example flow of serial transmission in clock synchronous mode with FIFO selected

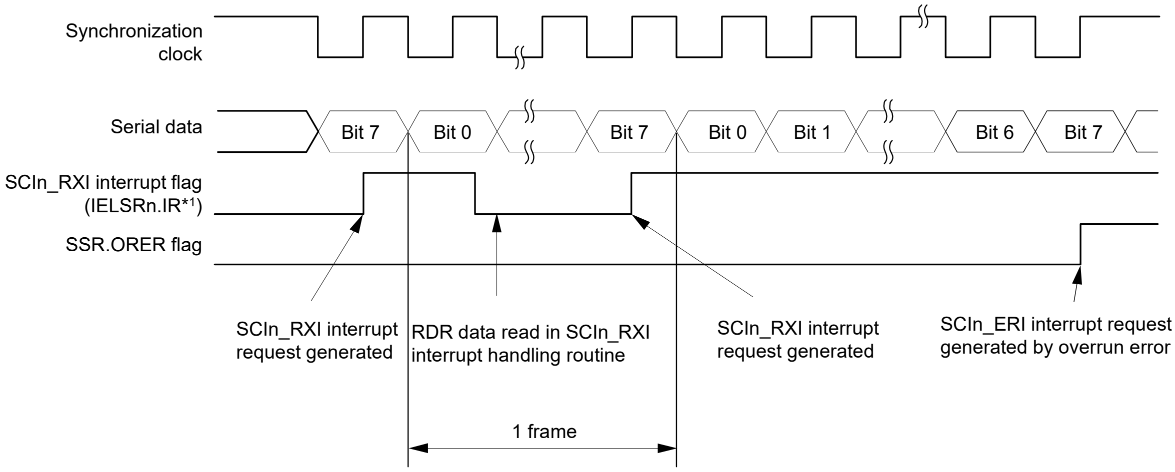
34.5.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 34.39 and Figure 34.40 show examples of SCI operation for serial reception in clock synchronous mode.

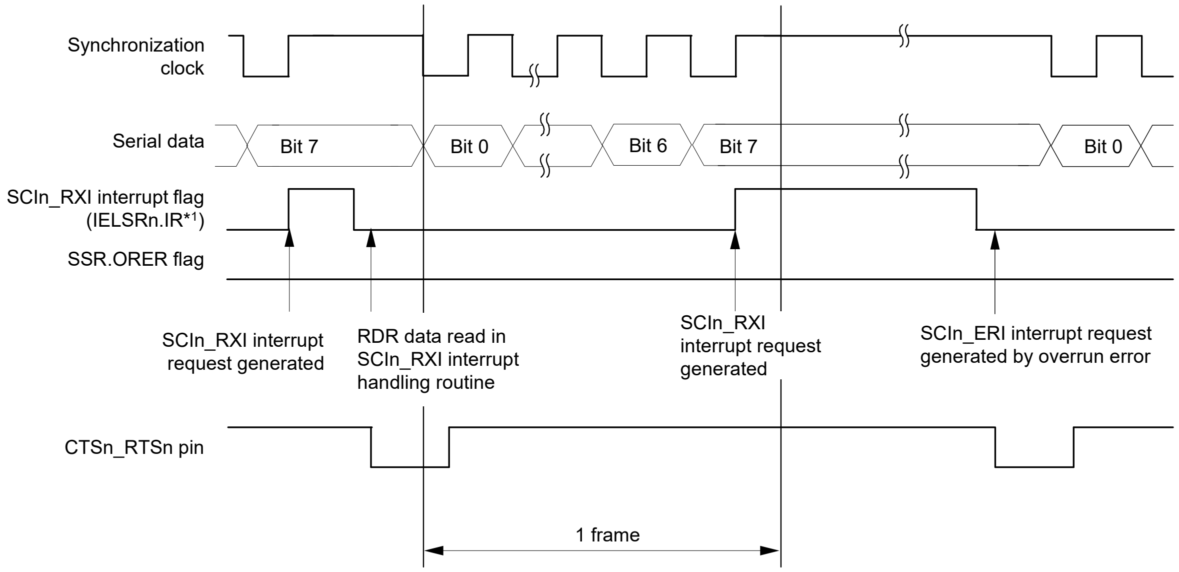
In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER bit is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.39 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used

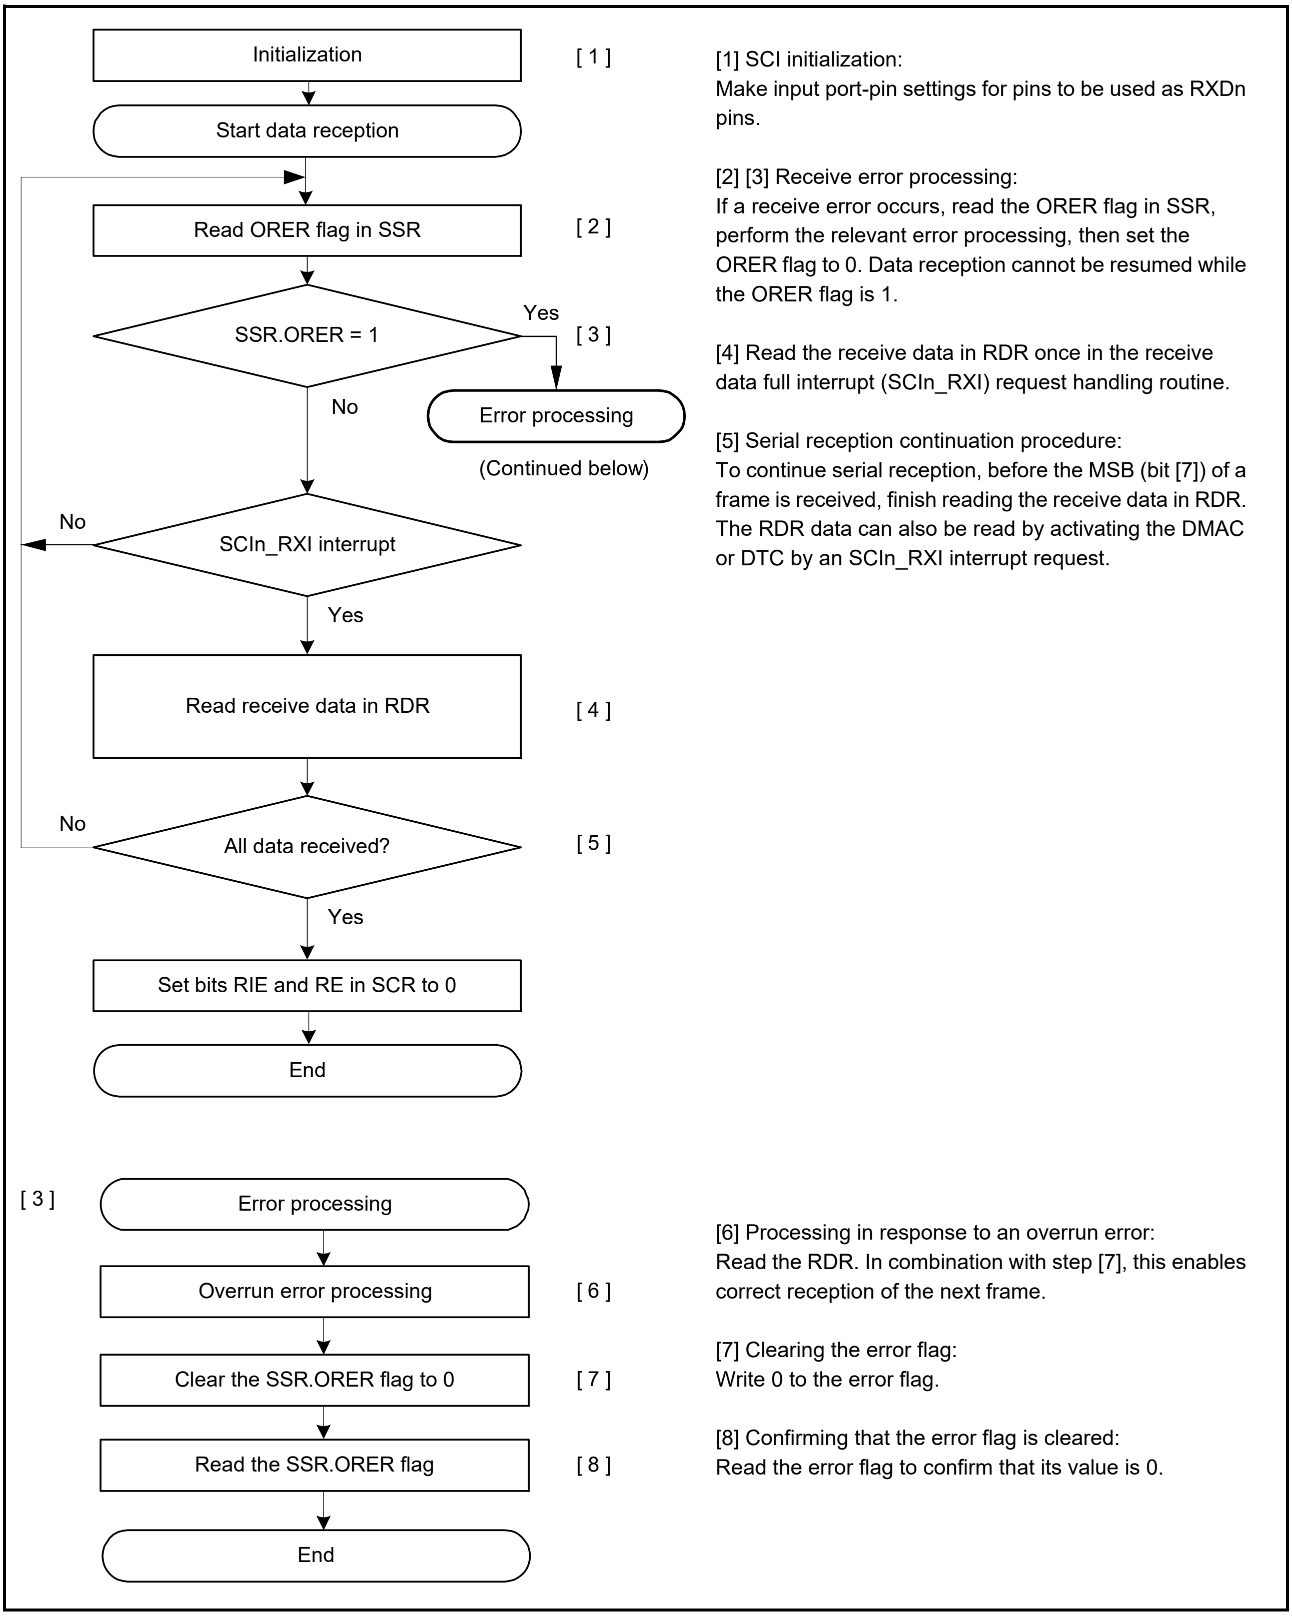


Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.40 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER bits in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

Figure 34.41 shows an example flow of serial data reception.



[1] SCI initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Read the receive data in RDR once in the receive data full interrupt (SCIn_RXI) request handling routine.

[5] Serial reception continuation procedure:
To continue serial reception, before the MSB (bit [7]) of a frame is received, finish reading the receive data in RDR. The RDR data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request.

[6] Processing in response to an overrun error:
Read the RDR. In combination with step [7], this enables correct reception of the next frame.

[7] Clearing the error flag:
Write 0 to the error flag.

[8] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Figure 34.41 Example flow of serial reception in clock synchronous mode with non-FIFO selected

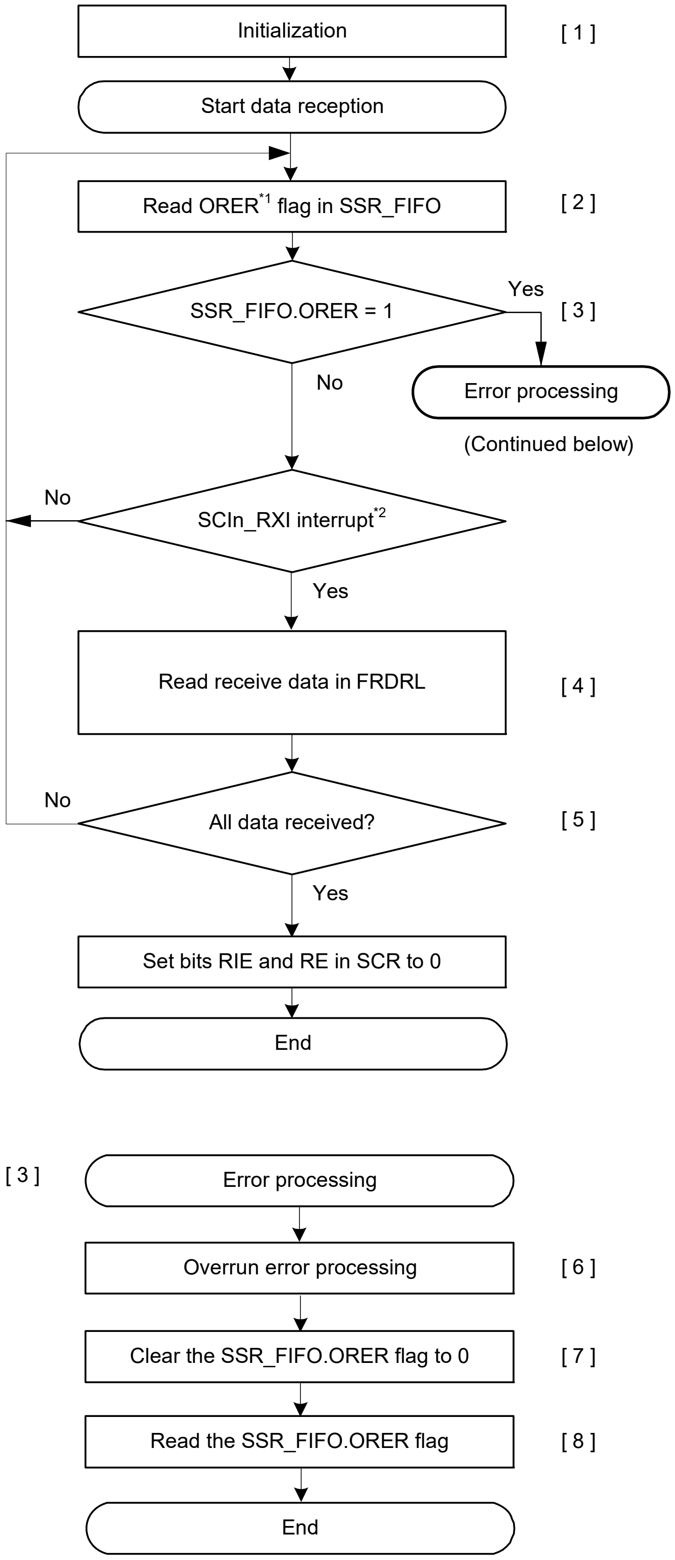
(2) FIFO selected

Figure 34.42 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR_FIFO.ORER bit is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL*[1] register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL*[1] register. The RDF bit is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL*[2] in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the RTS trigger number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.



[1] SCI initialization:
Make input port-pin settings for pins to be used as RXDn pins.

[2] [3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] The receive data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[5] Serial reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. The FRDRL data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request. The RDF flag is cleared automatically in this case. Do not write to the RDF flag.

[6] Processing in response to an overrun error:
Read the FRDRL. In combination with step [7], this enables correct reception of the next frame.

[7] Clearing the error flag:
Write 0 to the error flag.

[8] Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Note 1. It can also be read from FRDRH.ORER. However, to clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.

Note 2. It should be all receive data and is an integer times the FIFO triggering number.

Figure 34.42 Example flow of serial reception in clock synchronous mode with FIFO selected

34.5.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

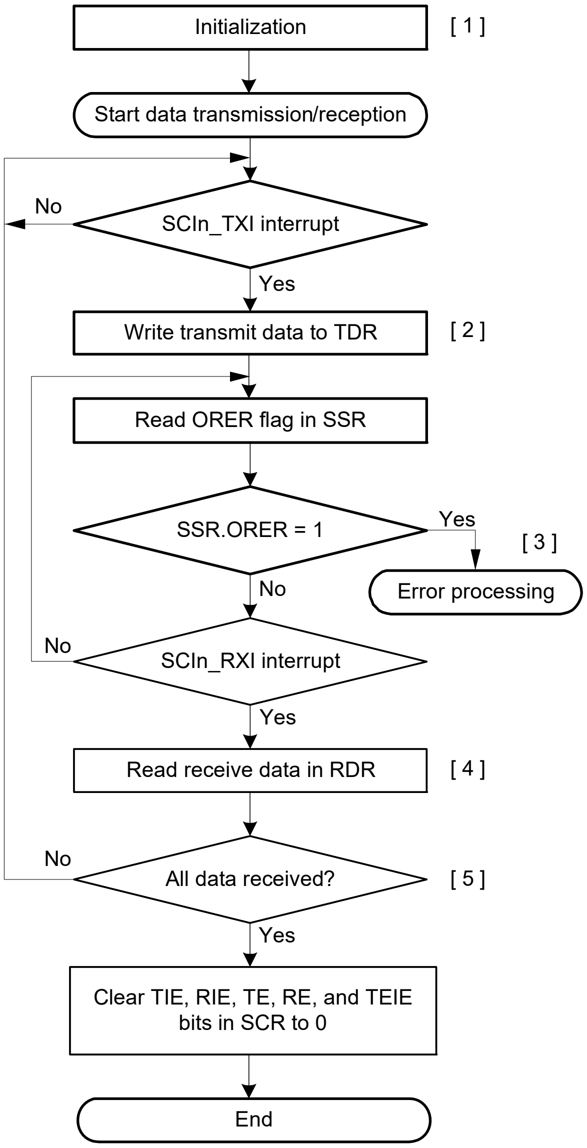
Figure 34.43 shows an example flow of simultaneous serial transmission and reception operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmission and reception operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to TDR once in the SCIn_TXI interrupt request handling routine.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in RDR once in the SCIn_RXI interrupt request handling routine.

[5] Serial transmission or reception continuation procedure:
To continue serial transmission and reception, before the MSB (bit [7]) of the current frame is received, finish reading the receive data in RDR by the SCIn_RXI interrupt. Also, before the MSB (bit [7]) of the current frame is transmitted, write data to TDR by the SCIn_TXI interrupt.
Transmit data can also be written to TDR by activating the DMAC or DTC by a transmit data empty interrupt (SCIn_TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (SCIn_RXI) request.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first set the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, then set TIE, RIE, TE, and RE bits to 1 simultaneously.

Figure 34.43 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 34.44 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

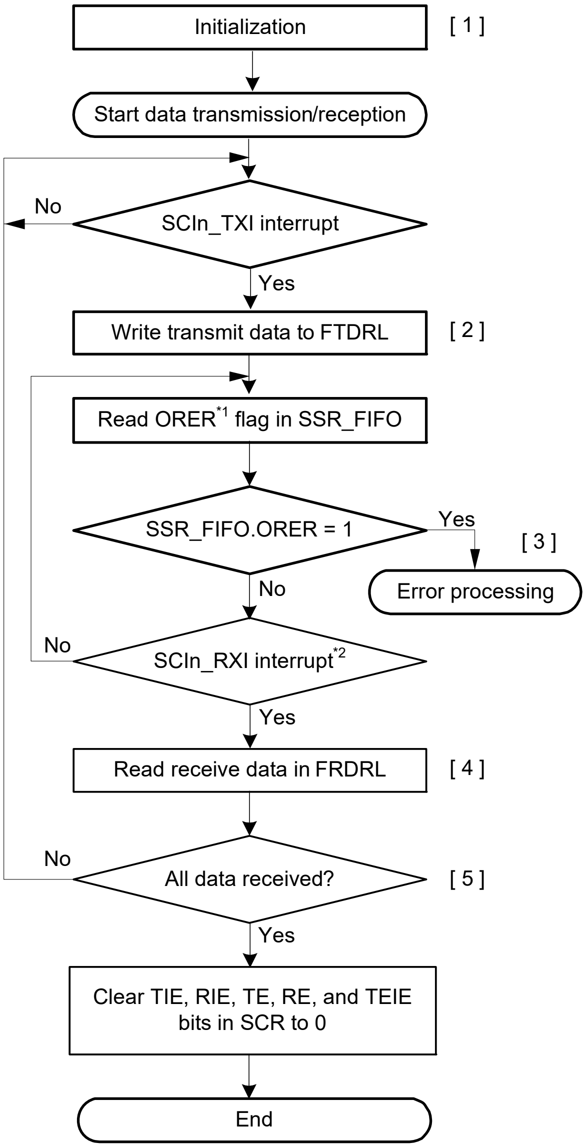
To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the SSR_FIFO.TEND flag is set to 1.
2. Initialize the SCR register, then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.

2. Set the RIE and RE bits to 0, then check that the receive error flag ORER in SSR_FIFO is 0.
3. Set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to FTDRL in the SCIn_TXI Interrupt request handling routine. The amount of transmit data it is possible to write in is 16 minus the amount of stored transmit FIFO data.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot be resumed while the ORER flag is 1.

[4] Reading receive data:
The receive data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[5] Serial transmission or reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data has finished, write the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0.
Transmit data can also be written to FTDRL by activating the DMAC or DTC by a transmit FIFO data empty interrupt (SCIn_TXI) request. Similarly, the FRDRL data can also be read by activating the DMAC or DTC by a receive FIFO data full interrupt (SCIn_RXI) request. The RDF and TDFE flags are cleared automatically in this case. Do not write to the RDF and TDFE flags.

Note 1. ORER can also read from FRDRH.ORER. To clear the ORER flag, write 0 to SSR_FIFO.ORER.
Note 2. The total receive data amount must be an integral multiple of the FIFO triggering number.

Figure 34.44 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

34.6 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

34.6.1 Example Connection

Figure 34.45 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 34.45, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

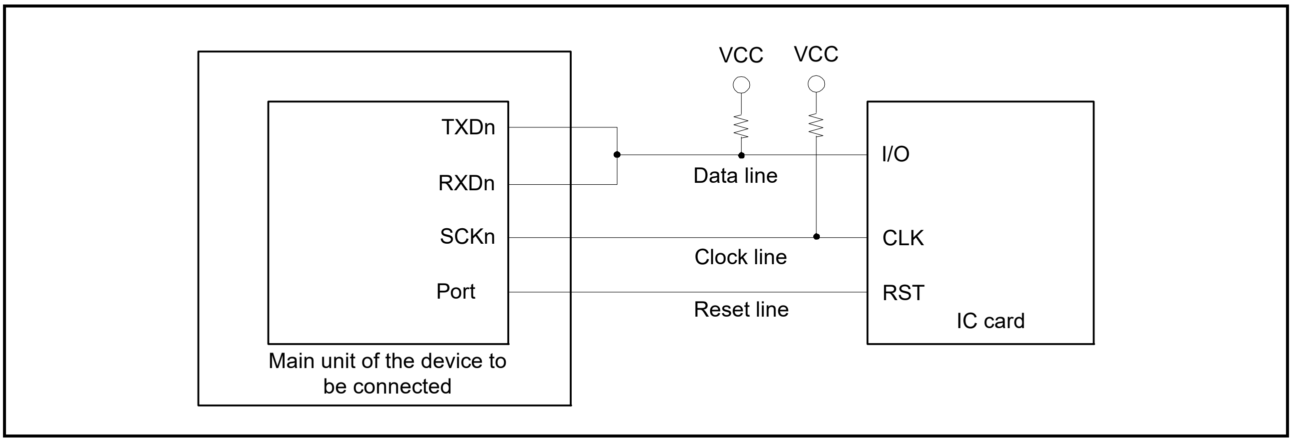


Figure 34.45 Example connection with a smart card (IC card)

34.6.2 Data Format (Except in Block Transfer Mode)

Figure 34.46 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode
- During transmission, at least 2 ETUs (elementary time unit — the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame
- If a parity error is detected during reception, a low error signal is output for 1 ETU after 10.5 ETUs elapse from the start bit
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 ETUs.

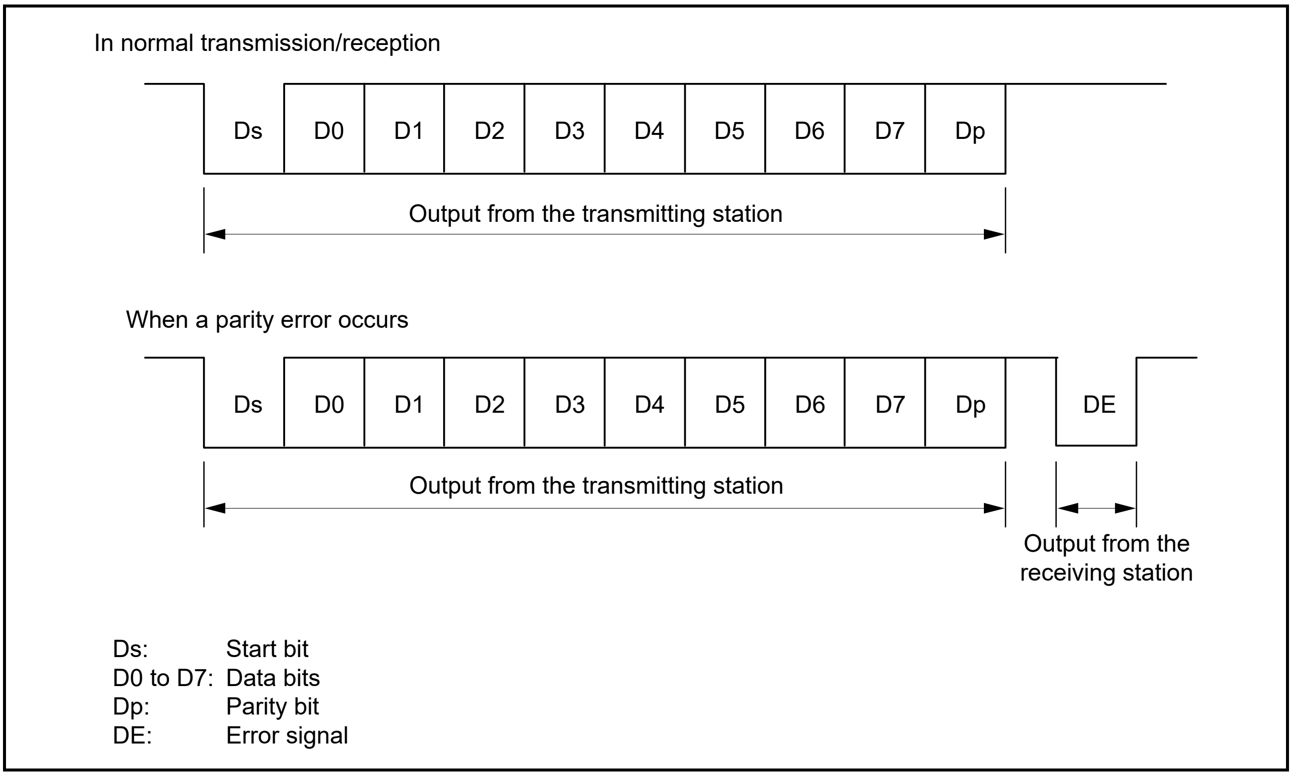

Figure 34.46 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 34.47. Therefore, data in the start character in the figure is 3Bh.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is required by the smart card standard.

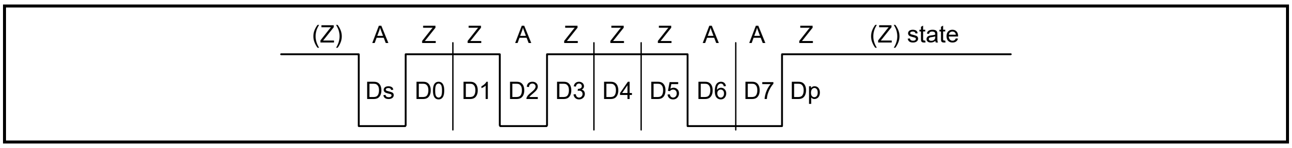

Figure 34.47 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 34.48. Therefore, data in the start character in the figure is 3Fh.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

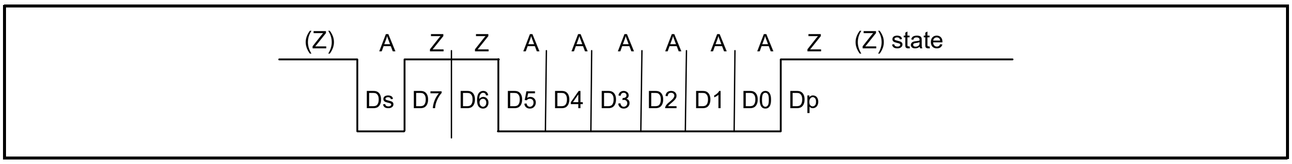

Figure 34.48 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

34.6.3 Block Transfer Mode

Block transfer mode differs from non-block transfer mode of smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER bit in SSR_SMCI is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 ETU is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 ETUs after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in non-block transfer mode of smart card interface mode, but the flag is read as 0 because no error signal is transferred.

34.6.4 Receive Data Sampling Timing and Reception Margin

Only the clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits.

For data reception, the falling edge of the start bit is sampled with the base clock to perform synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 34.49. The reception margin is determined by the following formula:

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\%$

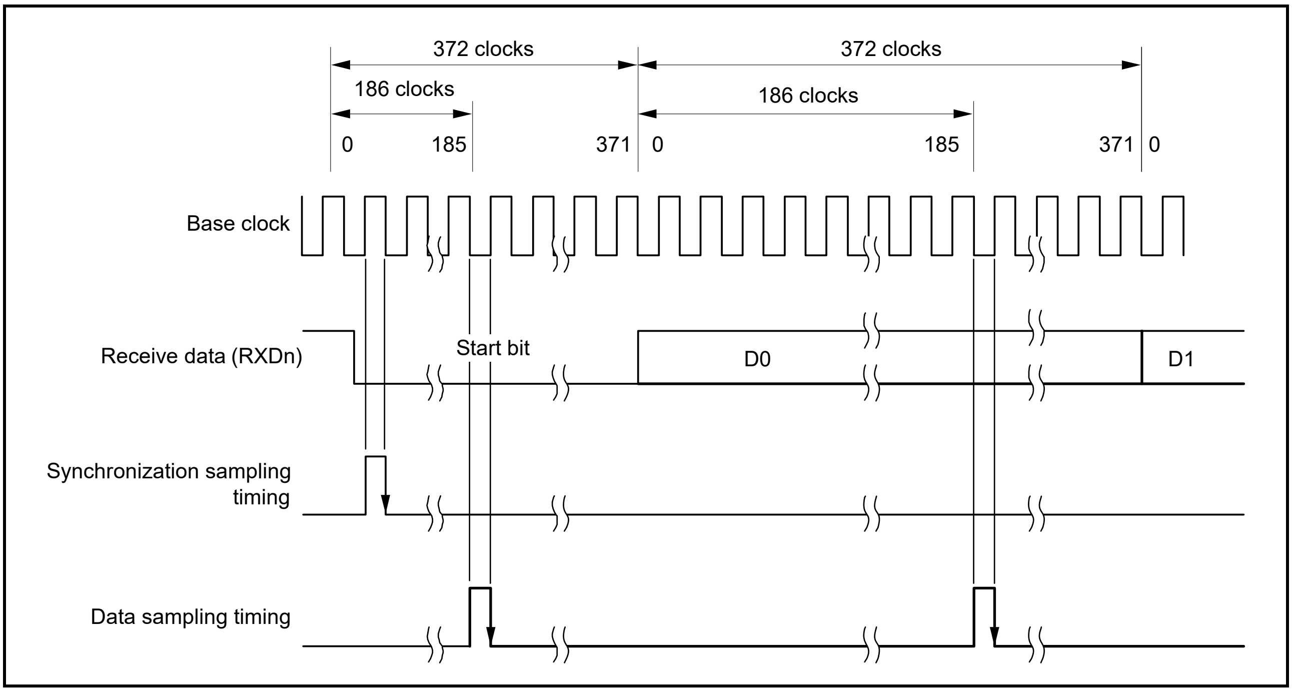

Figure 34.49 **Receive data sampling timing in smart card interface mode when clock frequency is 372 times the bit rate**

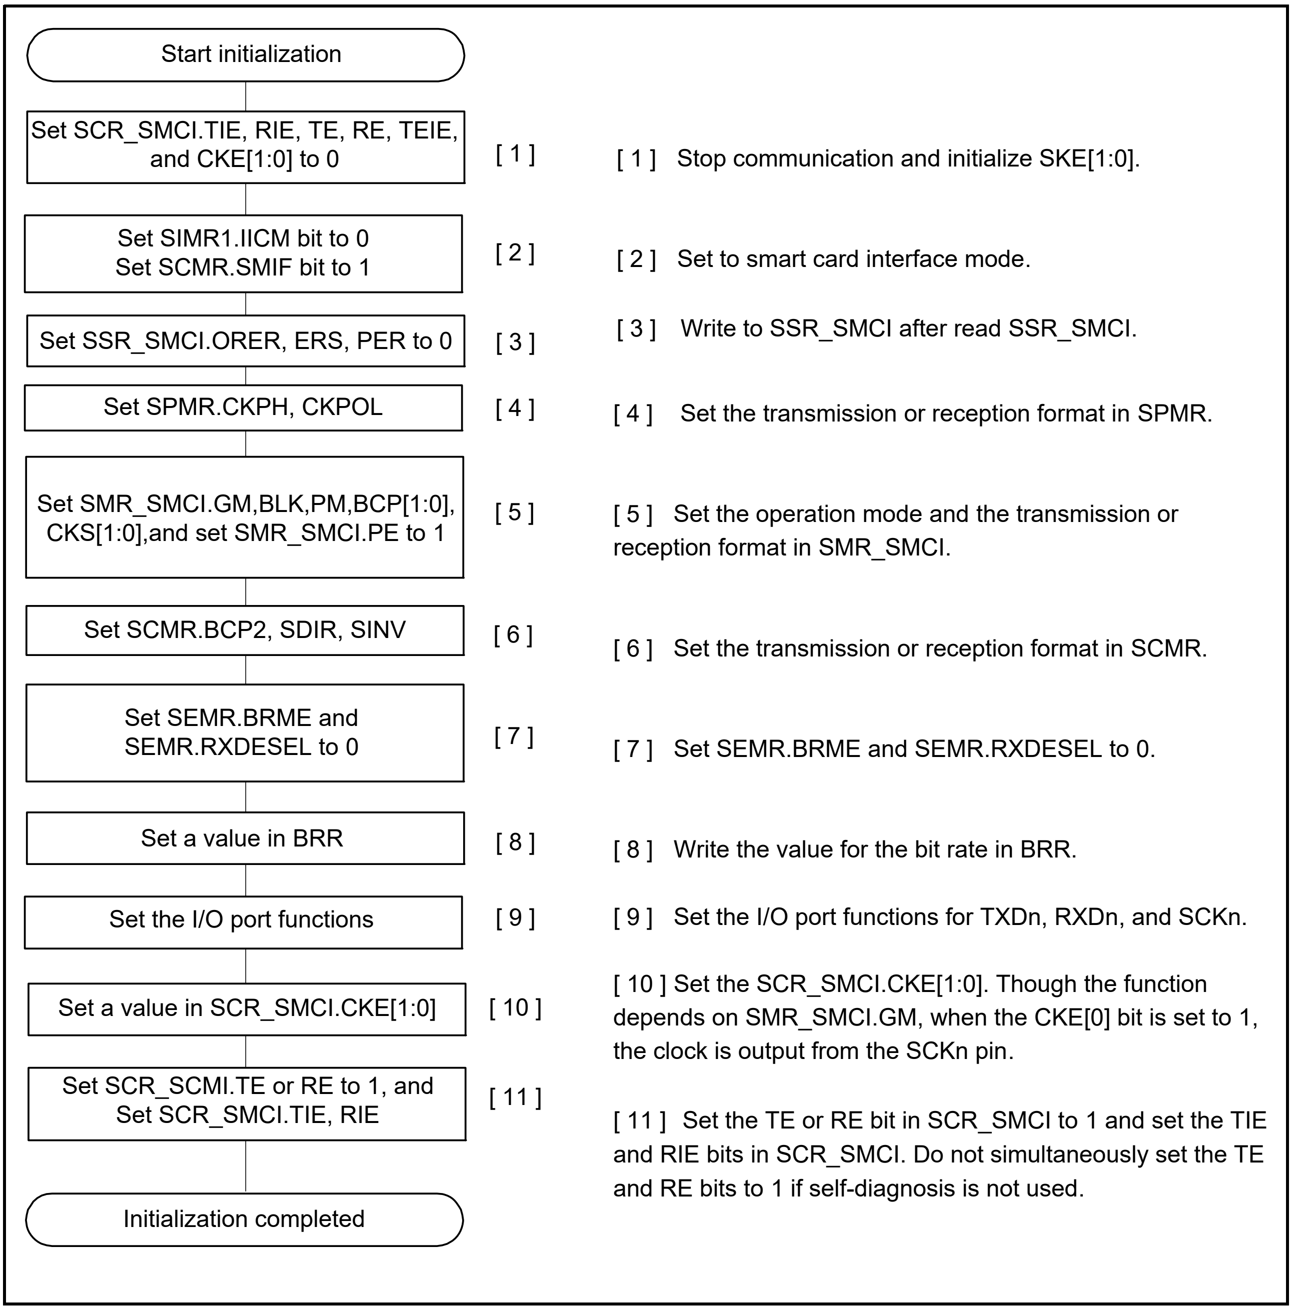
34.6.5 Initialization of the SCI

Before transmitting and receiving data, write the initial value 00h in the SCR_SMCI register and initialize the SCI following the example flow shown in Figure 34.50.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SSR_SMCI.TE = 1 and SSR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SSR_SMCI.TE = 0 and SSR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.



[1] Stop communication and initialize SKE[1:0].

[2] Set to smart card interface mode.

[3] Write to SSR_SMCI after read SSR_SMCI.

[4] Set the transmission or reception format in SPMR.

[5] Set the operation mode and the transmission or reception format in SMR_SMCI.

[6] Set the transmission or reception format in SCMR.

[7] Set SEMR.BRME and SEMR.RXDESEL to 0.

[8] Write the value for the bit rate in BRR.

[9] Set the I/O port functions for TXDn, RXDn, and SCKn.

[10] Set the SCR_SMCI.CKE[1:0]. Though the function depends on SMR_SMCI.GM, when the CKE[0] bit is set to 1, the clock is output from the SCKn pin.

[11] Set the TE or RE bit in SCR_SMCI to 1 and set the TIE and RIE bits in SCR_SMCI. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis is not used.

Figure 34.50 Example flow of SCI initialization in smart card interface mode

Figure 34.51 shows a timing diagram when data transmission is performed by transitioning to smart card interface mode according to the flow in Figure 34.50. Figure 34.51 shows when the GM bit in SMR_SMCI is set to 0. The timing in Figure 34.51 shows when the port is connected as SCKn pin and TXDn pin, the pins are Hi-Z because CKE[0] bit in SCR_SMCI is 0.

Start the clock output to the SCK pin by setting CKE[0] bit in SCR_SMCI to 1, then start data transmission by writing transmit data after setting TE bit in SCR_SMCI to 1. When the TE bit in SCR_SMCI changes from 0 to 1, there is a preamble period for one frame before data transmission starts. In smart card interface mode, the TXDn pin is Hi-Z during the preamble period. Pull-up or pull-down for the SCKn and TXDn pins is required outside the MCU.

In the smart card interface mode, even when the TE and RE bits in SCR_SMCI are 0, the clock is continuously output if the clock output setting is used.

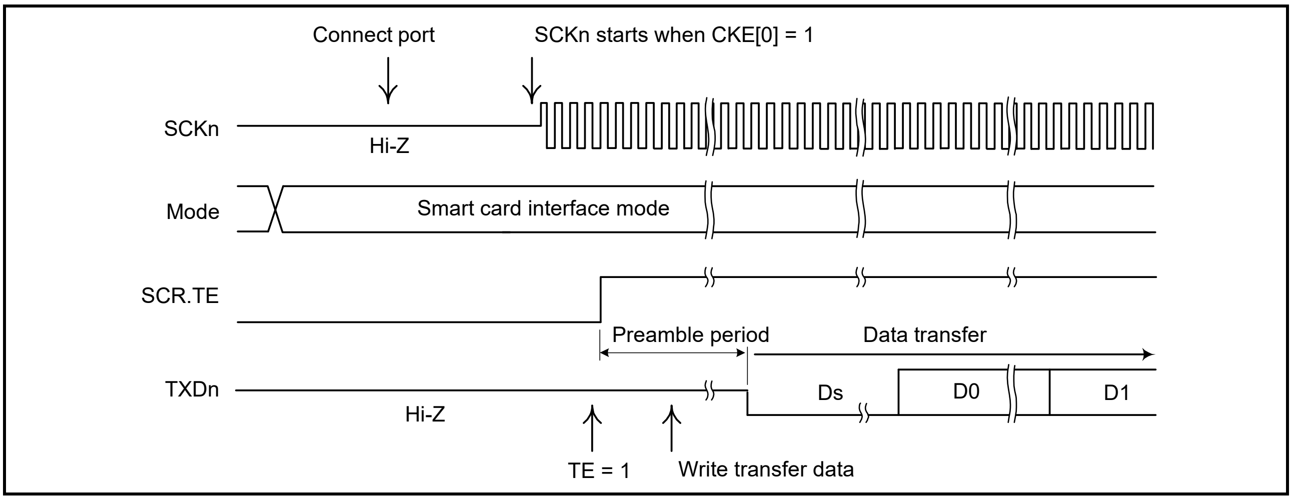


Figure 34.51 Example timing of data transmission in smart card interface mode

34.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 34.52 shows the data re-transfer operation during transmission.

- [1] indicates when an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
- [2] indicates for a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
- [3] indicates if no error signal is returned from the receiver, the ERS flag is not set to 1.
- [4] indicates the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 34.54 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, DMA Controller (DMAC) and section 18, Data Transfer Controller (DTC).

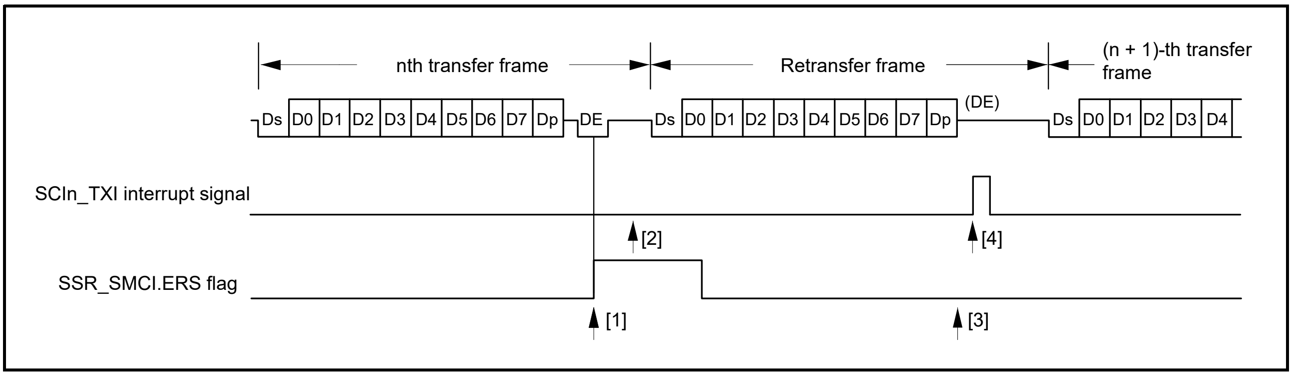

Figure 34.52 Data retransfer operation in SCI transmission mode

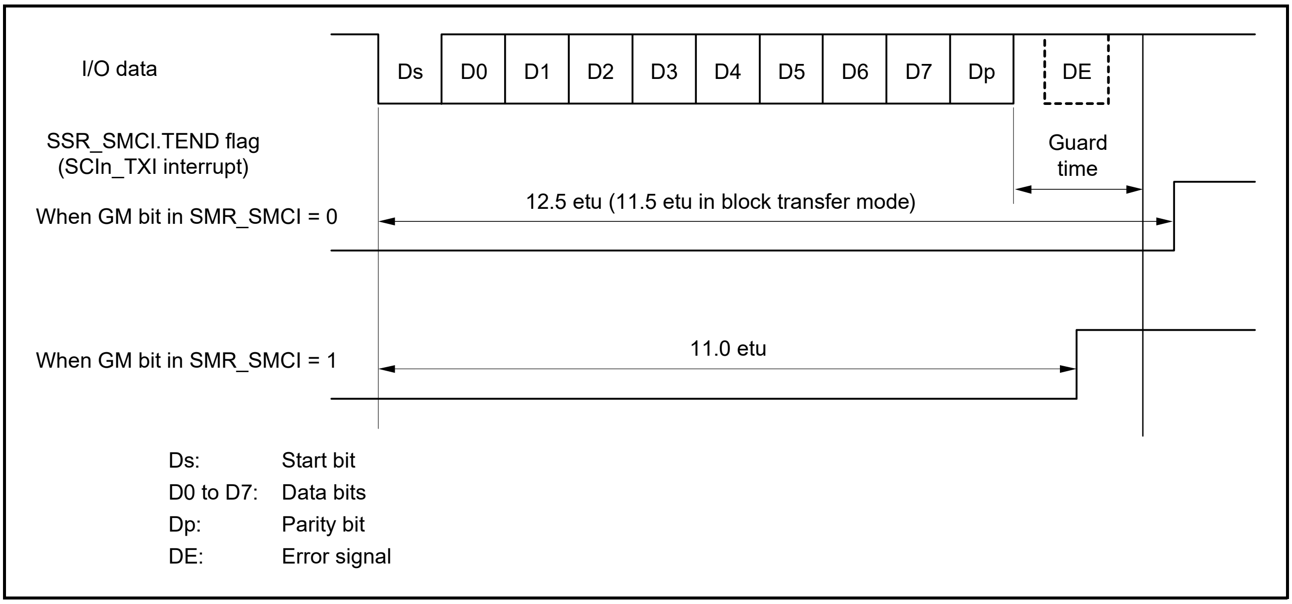
The SSR_SMCI.TEND flag is set at different timings depending on the SMR_SMCI.GM bit setting. Figure 34.53 shows the TEND flag generation timing.



Ds:	Start bit
D0 to D7:	Data bits
Dp:	Parity bit
DE:	Error signal

Figure 34.53 SSR.TEND flag generation timing during transmission

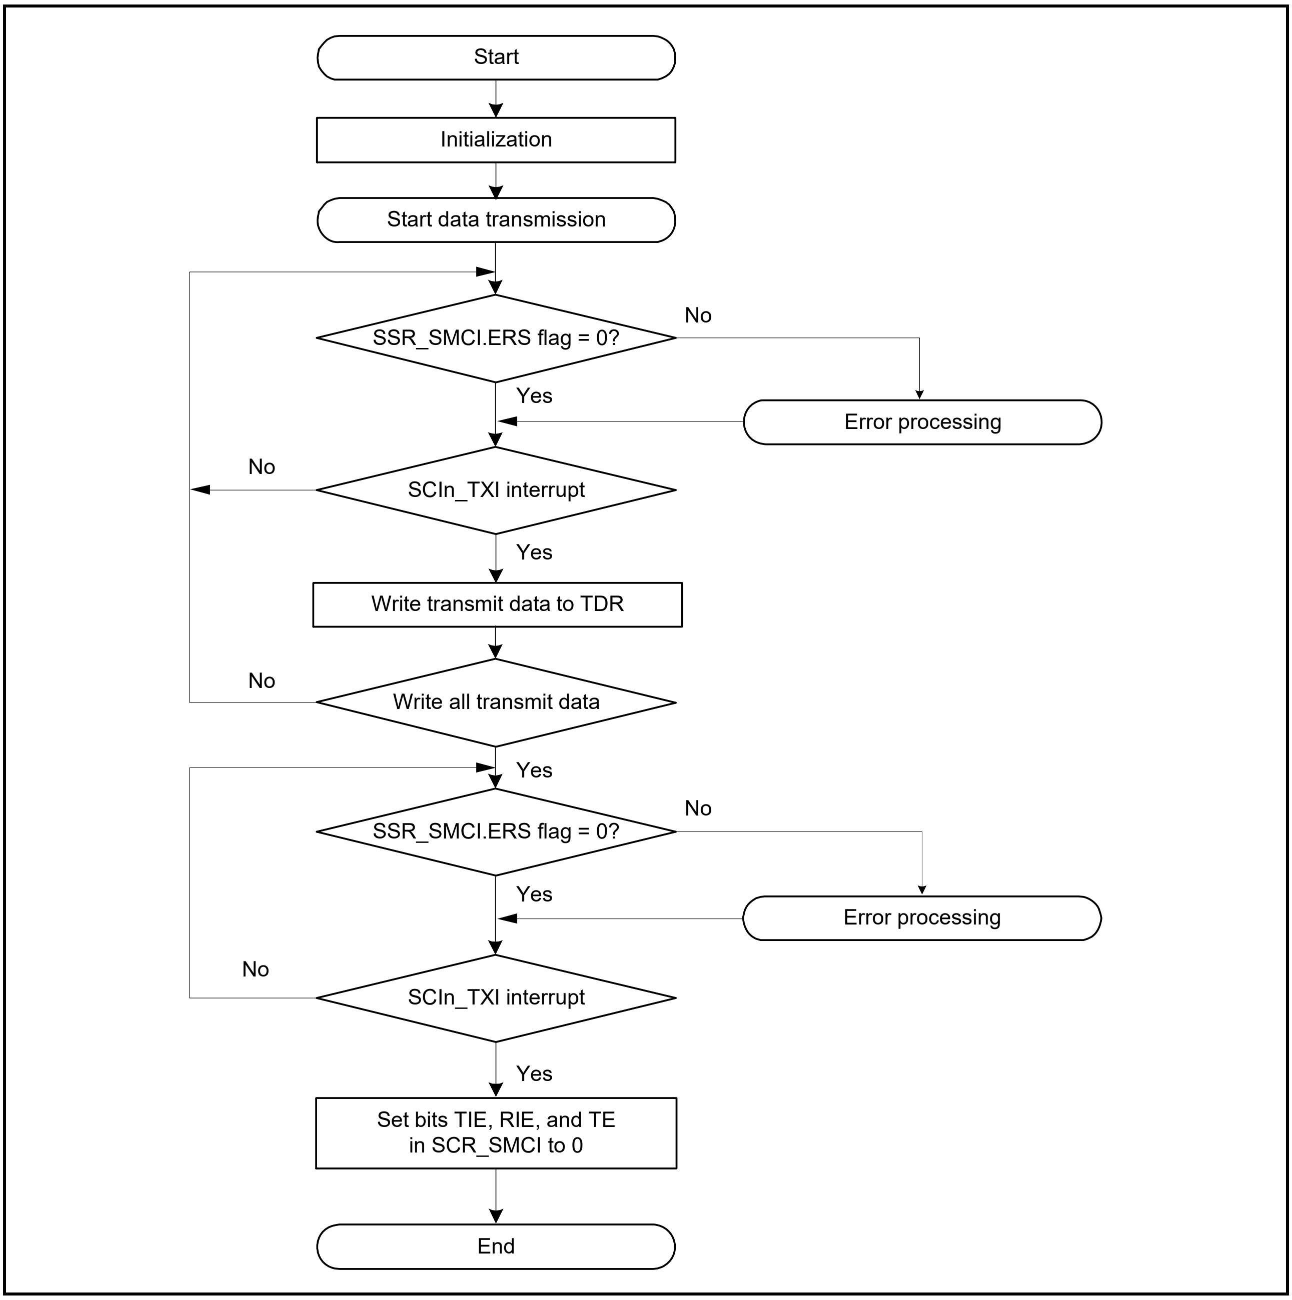


Figure 34.54 Example flow of smart card interface transmission

34.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 34.55 shows the data re-transfer operation in reception mode.

- [1] indicates if a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
- [2] indicates for a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
- [3] indicates when no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
- [4] indicates the data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 34.56 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 34.3.9, Serial Data Reception in Asynchronous Mode.

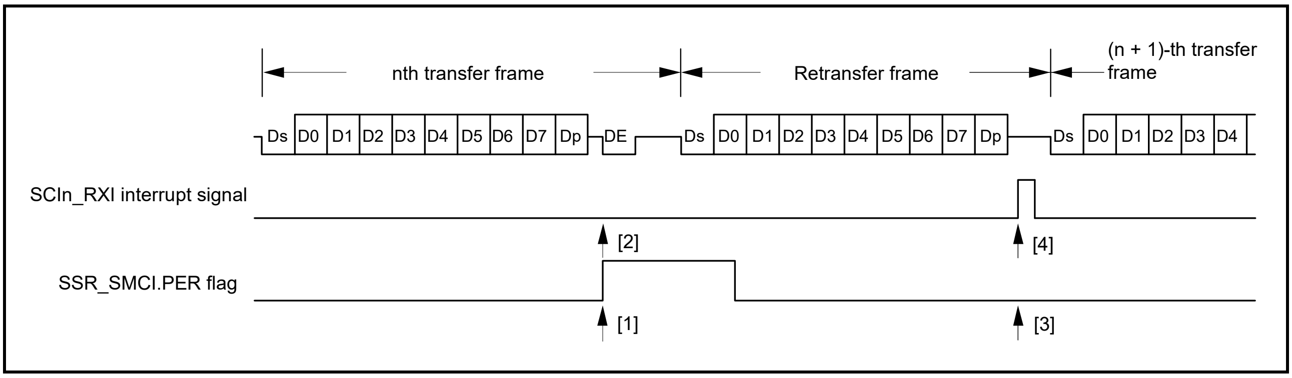

Figure 34.55 Data retransfer operation in SCI reception mode

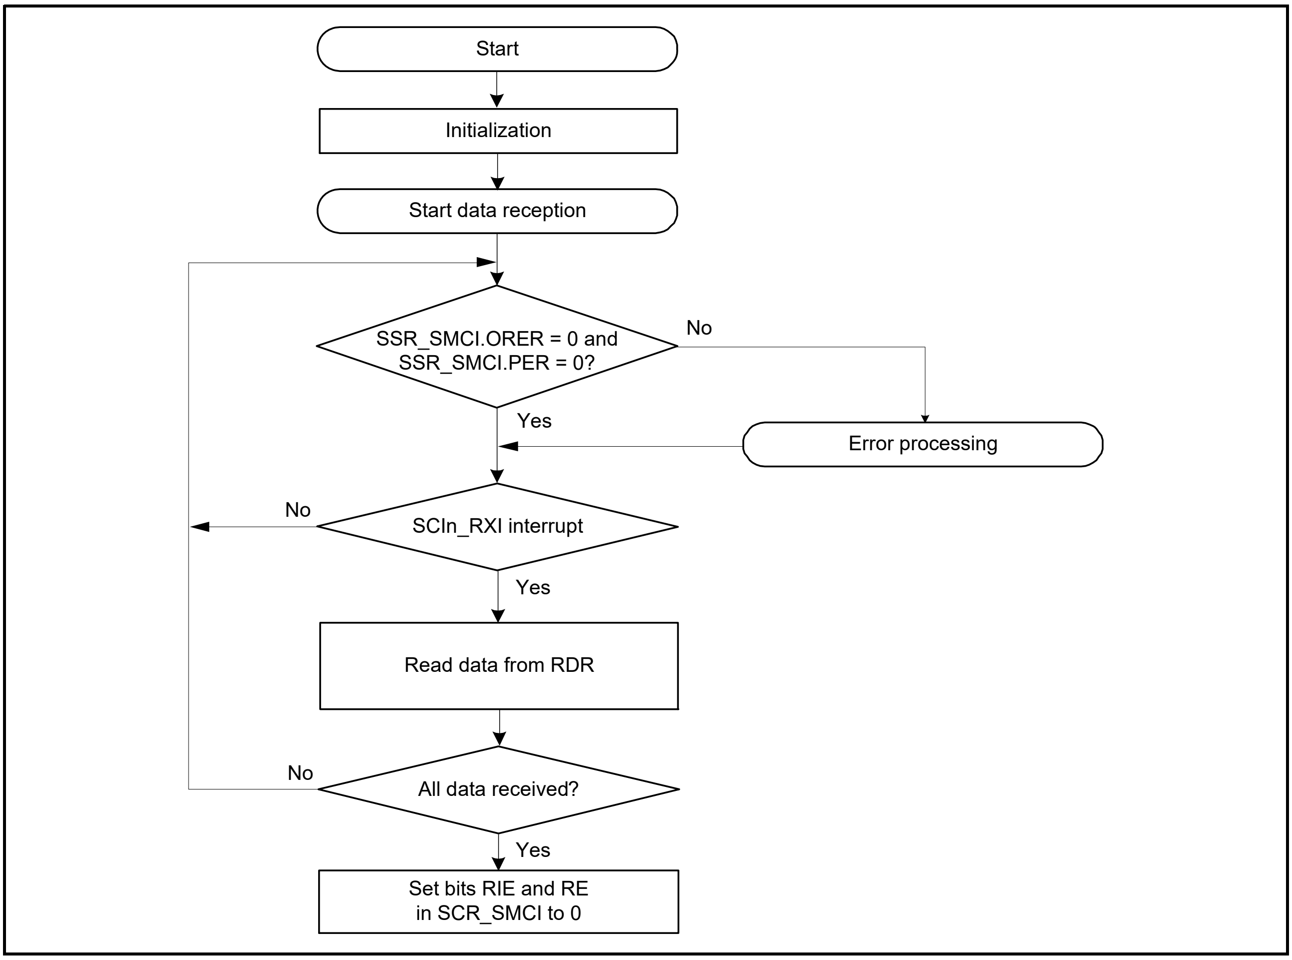

Figure 34.56 Example flow of smart card interface reception

34.6.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1: 0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 34.2.12, Serial Control Register for Smart Card Interface Mode (SCR_SMCI) (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 34.6.4, Receive Data Sampling Timing and Reception Margin is output.

Figure 34.57 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCK pin, so there is a possibility that pulses with an unintended width might be output from the SCK pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

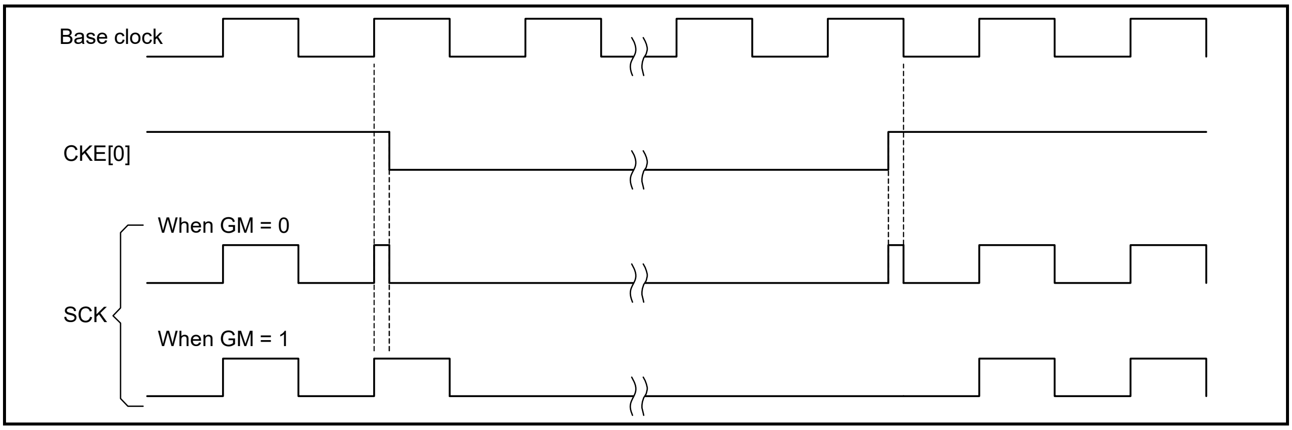

Figure 34.57 Clock output control

34.7 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 34.58 and Figure 34.59.

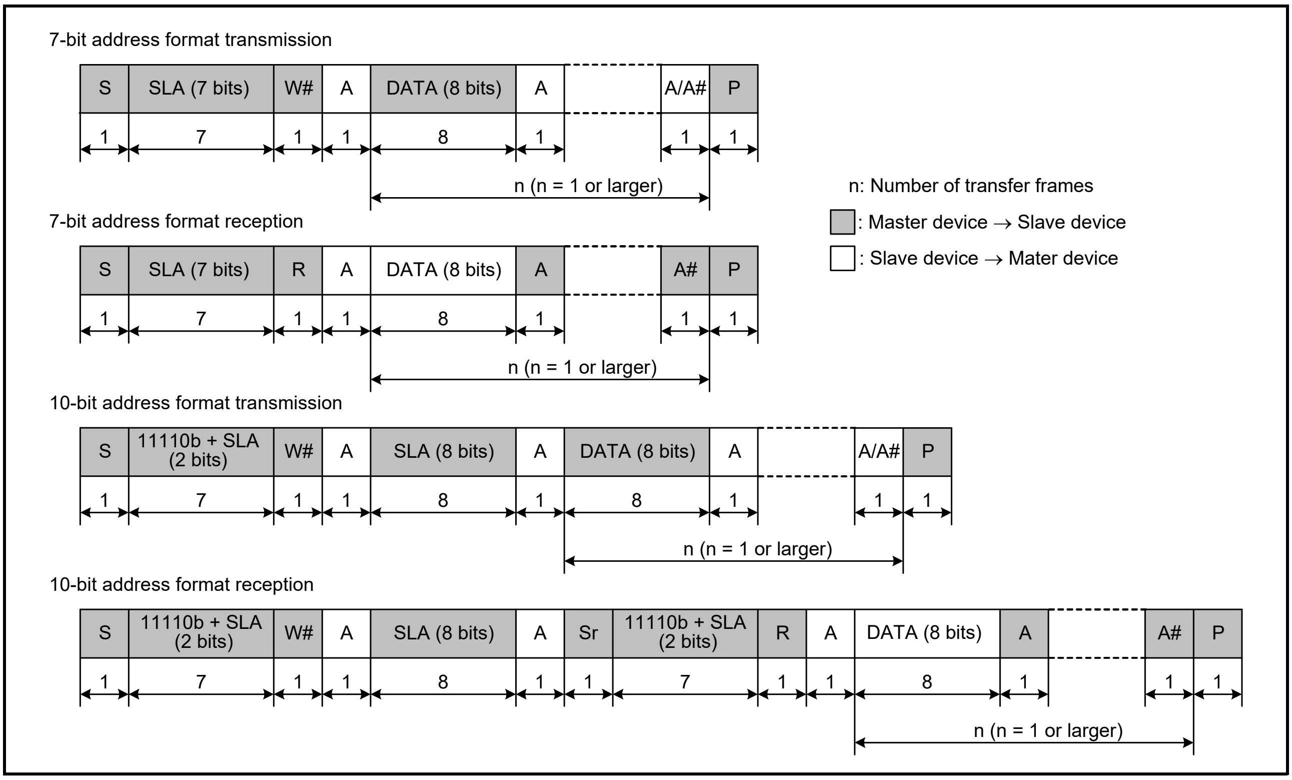

Figure 34.58 I^2C bus format

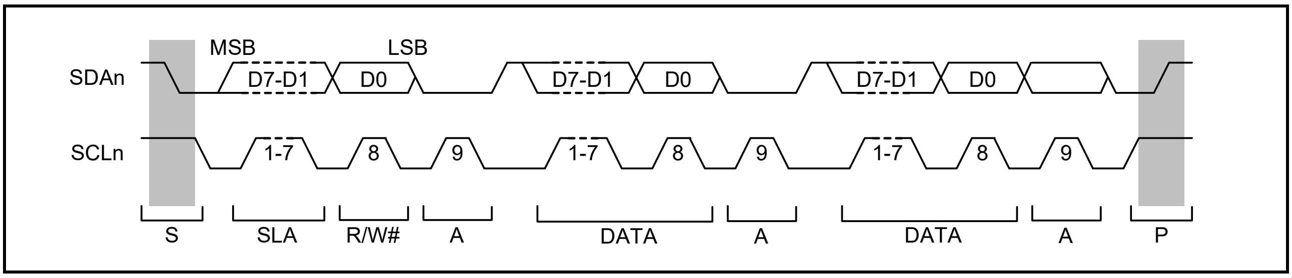

Figure 34.59 I2C bus timing when SLA is 7 bits

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high.

34.7.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output.

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output.

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting

- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output.

Figure 34.60 shows the timing of operations in the generation of start, restart, and stop conditions.

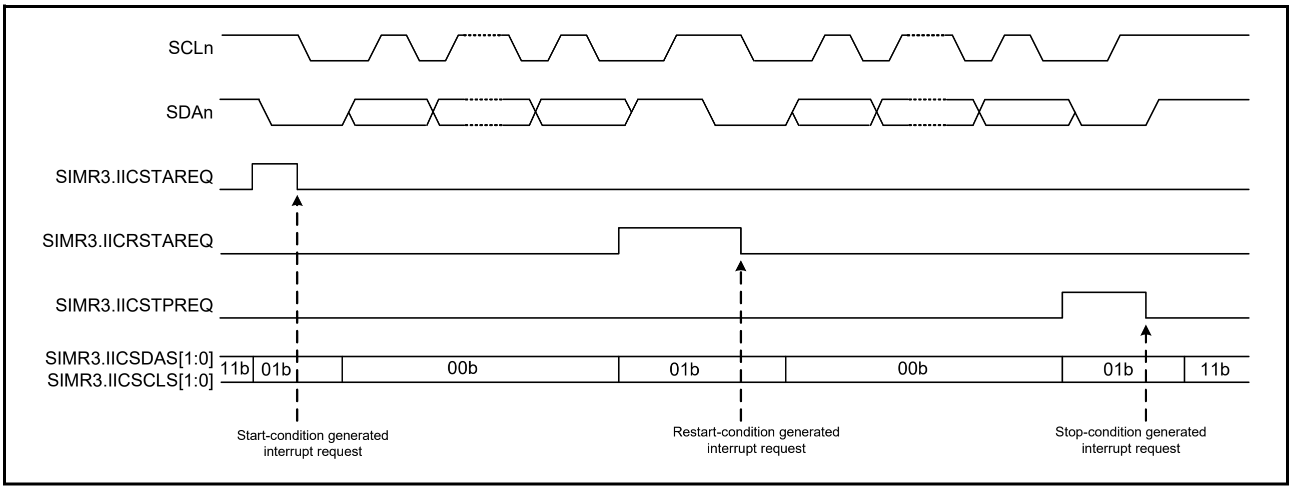

Figure 34.60 Timing of operations in generation of start, restart, and stop conditions

34.7.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLKA). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed. Figure 34.61 shows an example operation for synchronizing the clocks.

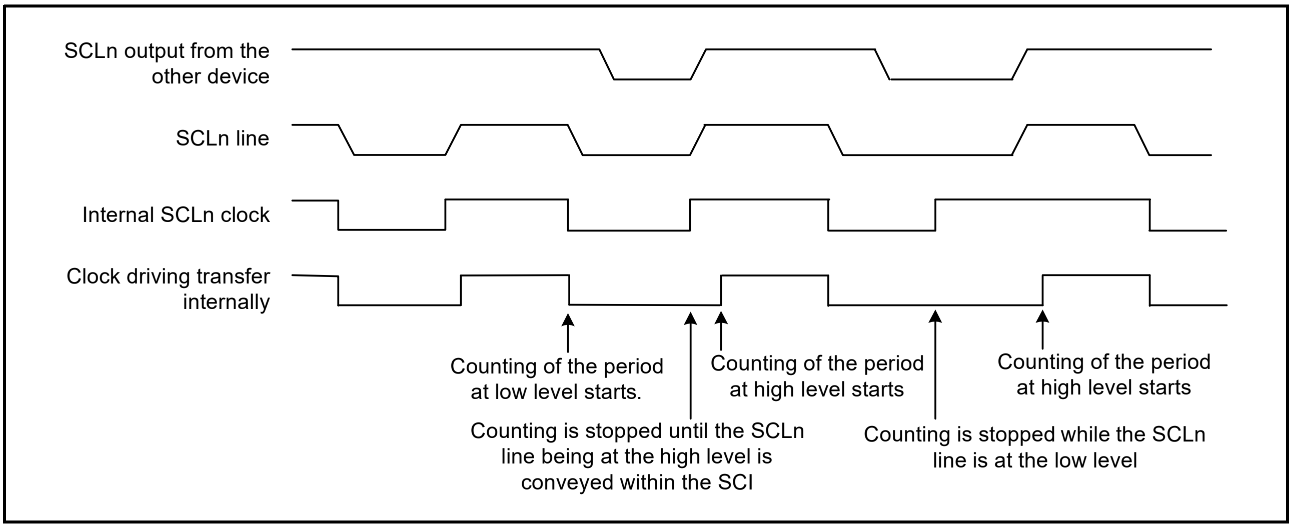

Figure 34.61 Example operations for clock synchronization

34.7.3 SDA Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLKA, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDA output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in standard mode and fast mode).

Figure 34.62 shows the timing of delays in SDA output.

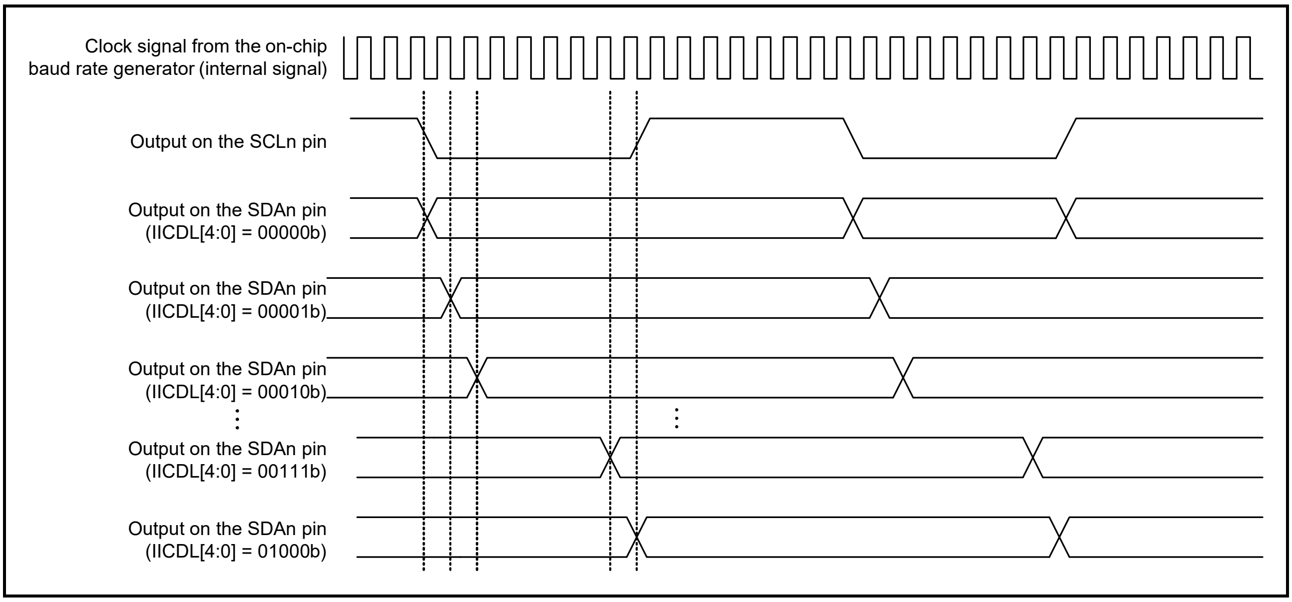

Figure 34.62 Timing of delays in SDA output

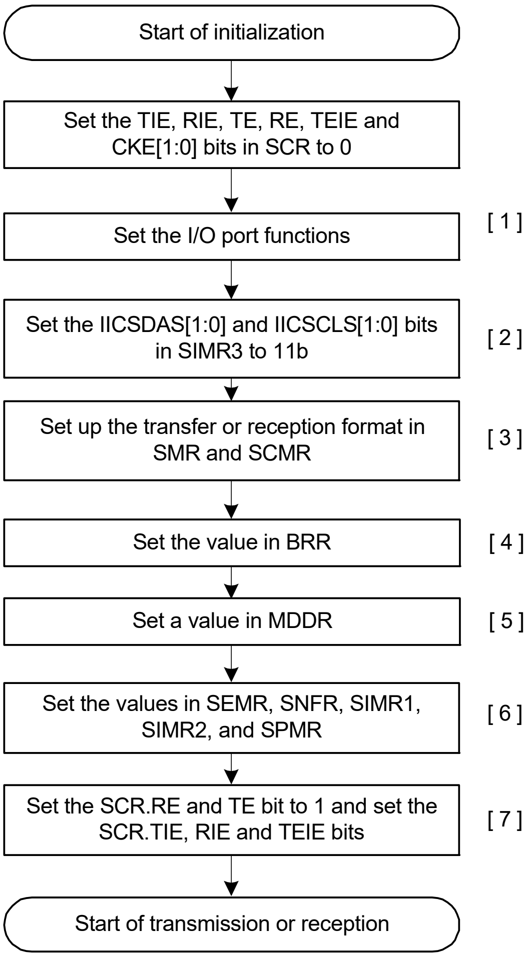
34.7.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 00h to SCR and initialize the interface following the example shown in Figure 34.63.

Always set SCR to its initial value before making any changes to the operating mode or transfer format.

In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.



[1] Make I/O port settings that allow use (on N-channel open-drain output pins) of the SCLn and SDAn pin functions.

[2] Place the SCLn and SDAn pins in the high-impedance state until a start condition is to be generated.

[3] Set the format for transmission and reception in SMR and SCMR.
In SMR, set the CKS[1:0] bits to the desired value and set the other bits to 0.
In SCMR, set the SDIR bit to 1 and the SINV and SMIF bits to 0.

[4] Write the value for the desired bit rate to BRR.

[5] Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is cleared to 0.

[6] Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR.
Set the NFEN and BRME bits in SEMR.
In SNFR, set the NFCS[2:0] bits.
In SIMR1, set the IICM bit to 1 and the IICDL[4:0] bits as required.
In SIMR2, set the IICACKT and IICCSC bits to 1 and the IICINTM bits as required.
In SPMR, set all the bits to 0.

[7] Set the RE and TE bits in the SCR to 1. Then, set the SCR.TIE, RIE, and TEIE bits (for transmission and when the SIMR2.IICINTM bit is 1, set the RIE bit to 0). Setting the TE and RE bits to 1 makes the SCLn and SDAn pin functions available.

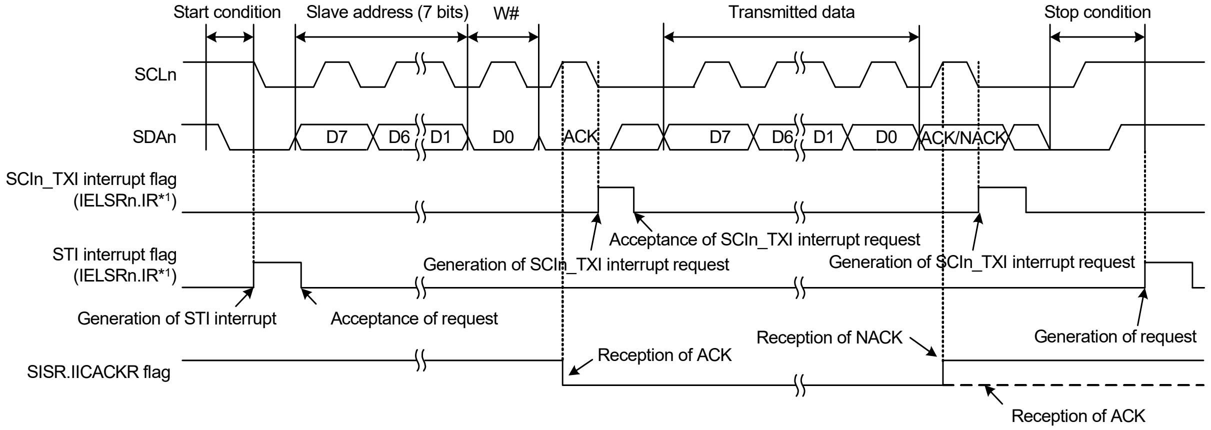
Figure 34.63 Example flow of SCI initialization in simple IIC mode

34.7.5 Operation in Master Transmission in Simple IIC Mode

Figure 34.64 and Figure 34.65 show examples of master transmission and Figure 34.66 shows an example flow of data transmission. The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled). See Table 34.29 for more information on the STI interrupt.

When 10-bit slave addresses are in use, steps [3] and [4] in Figure 34.66 are repeated twice.

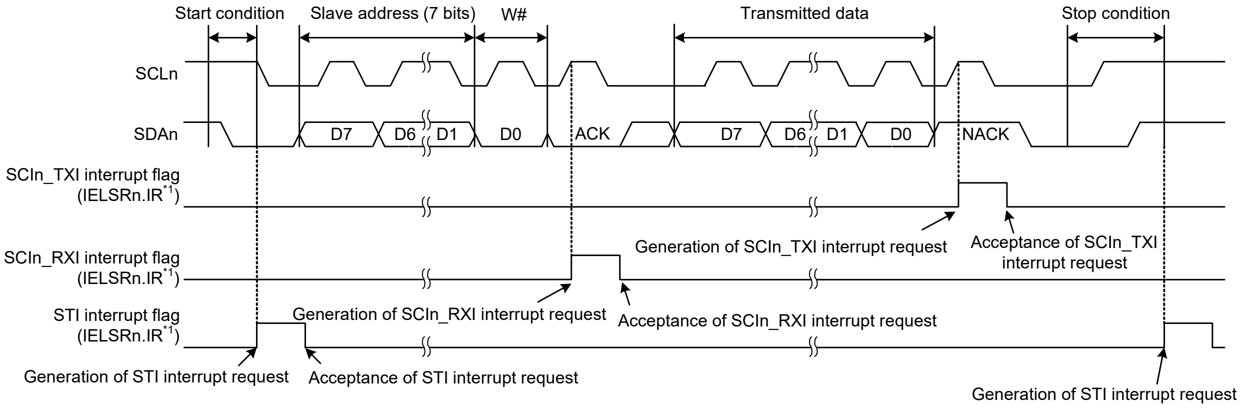
In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.64 **Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts**

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.65 **Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts**

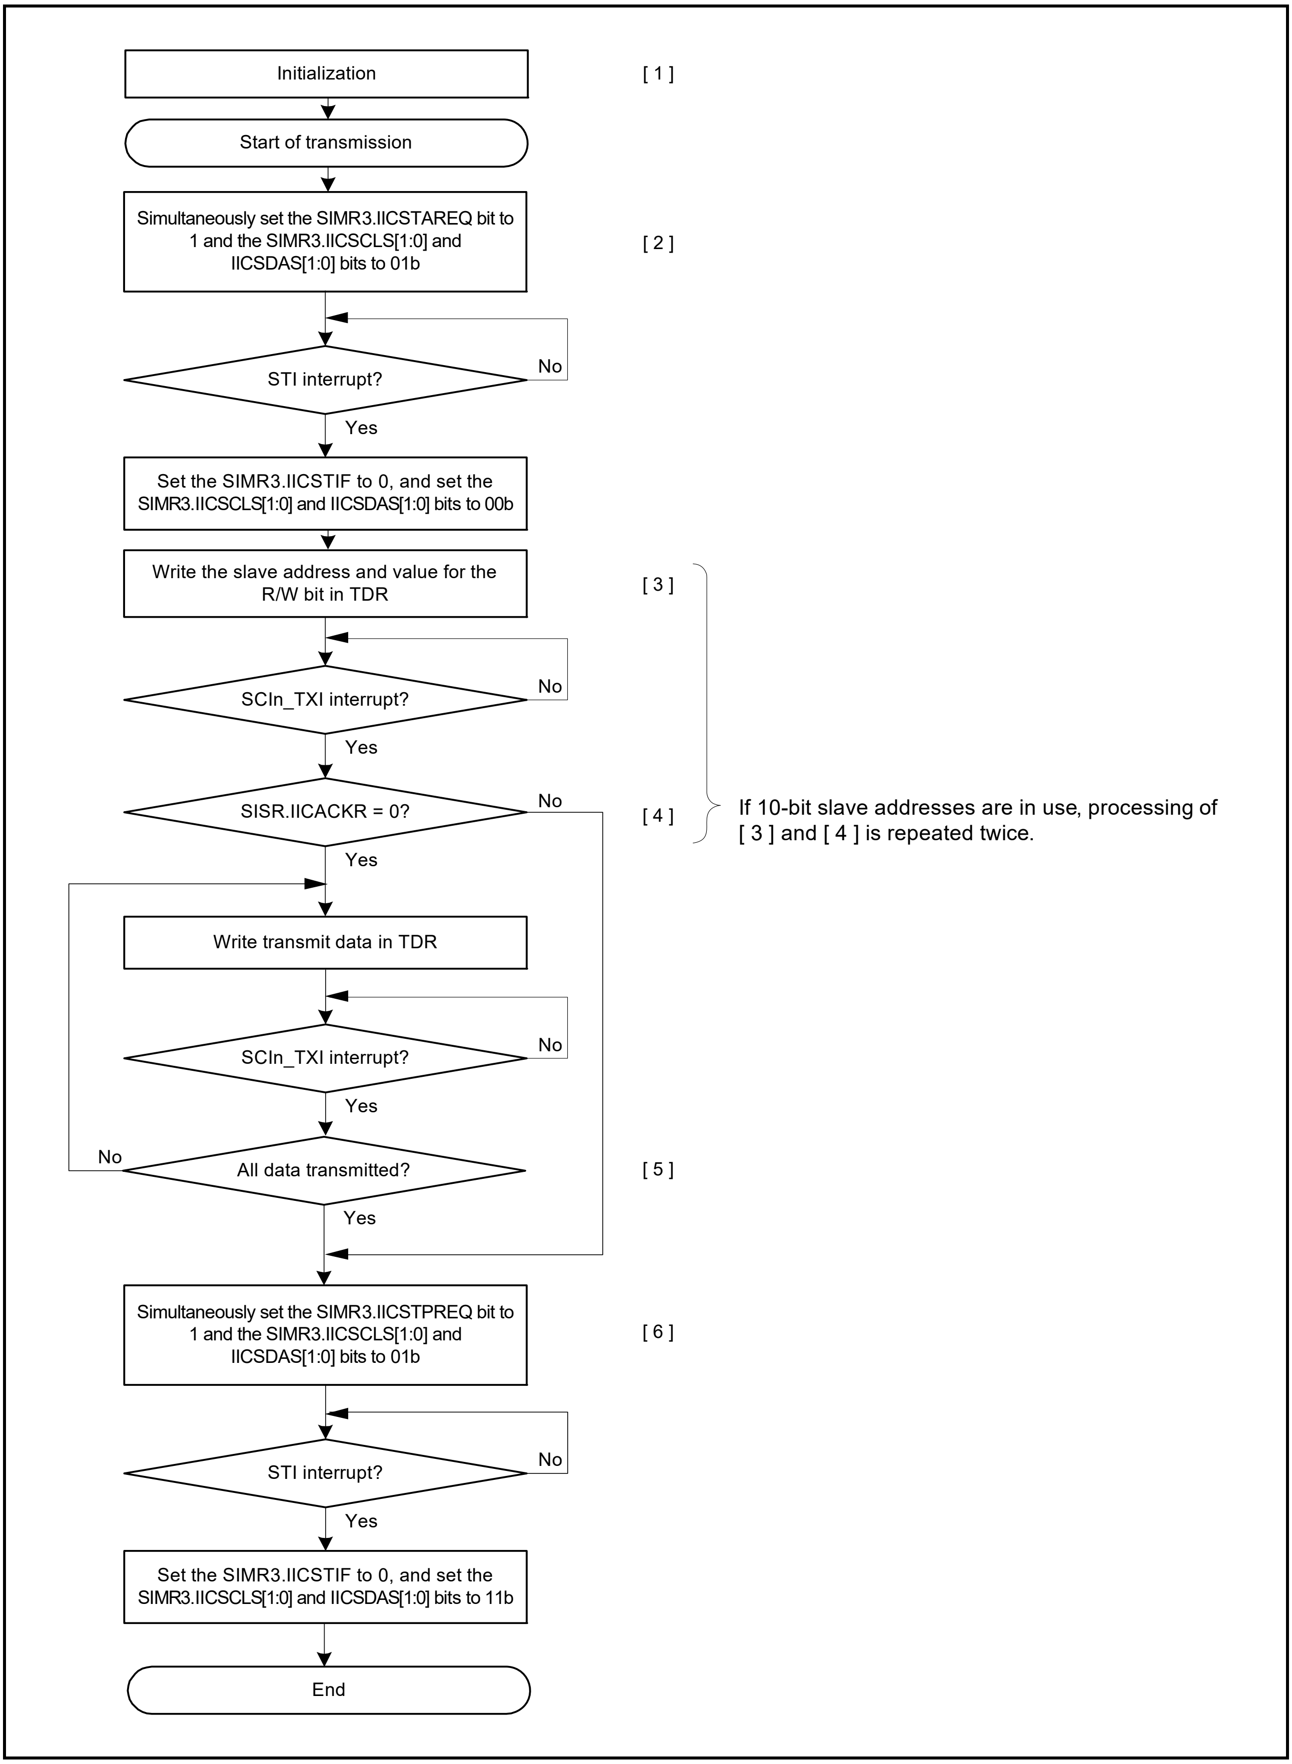


Figure 34.66 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts

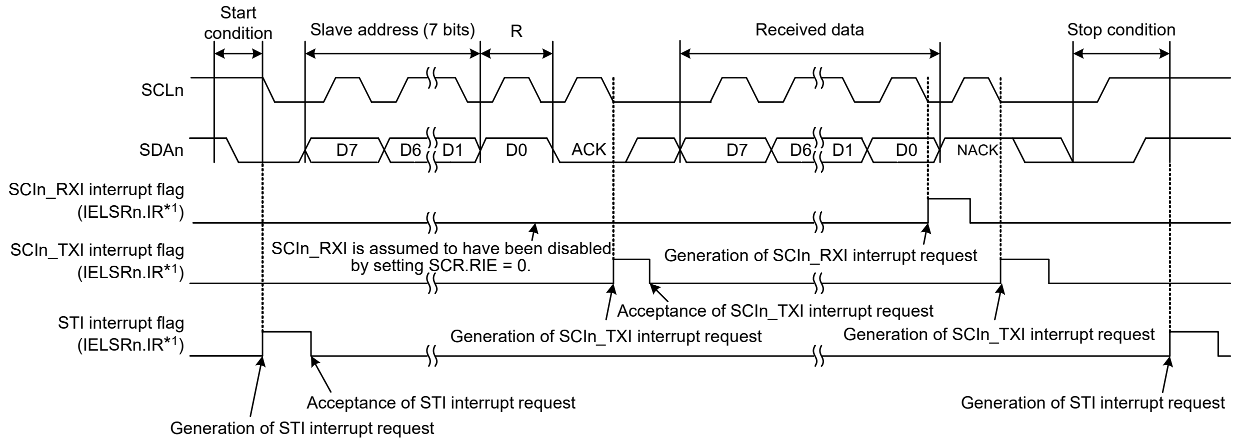
34.7.6 Master Reception in Simple IIC Mode

Figure 34.67 shows an example operation in simple IIC mode master reception and Figure 34.68 shows an example flow of master reception.

The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.67 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts

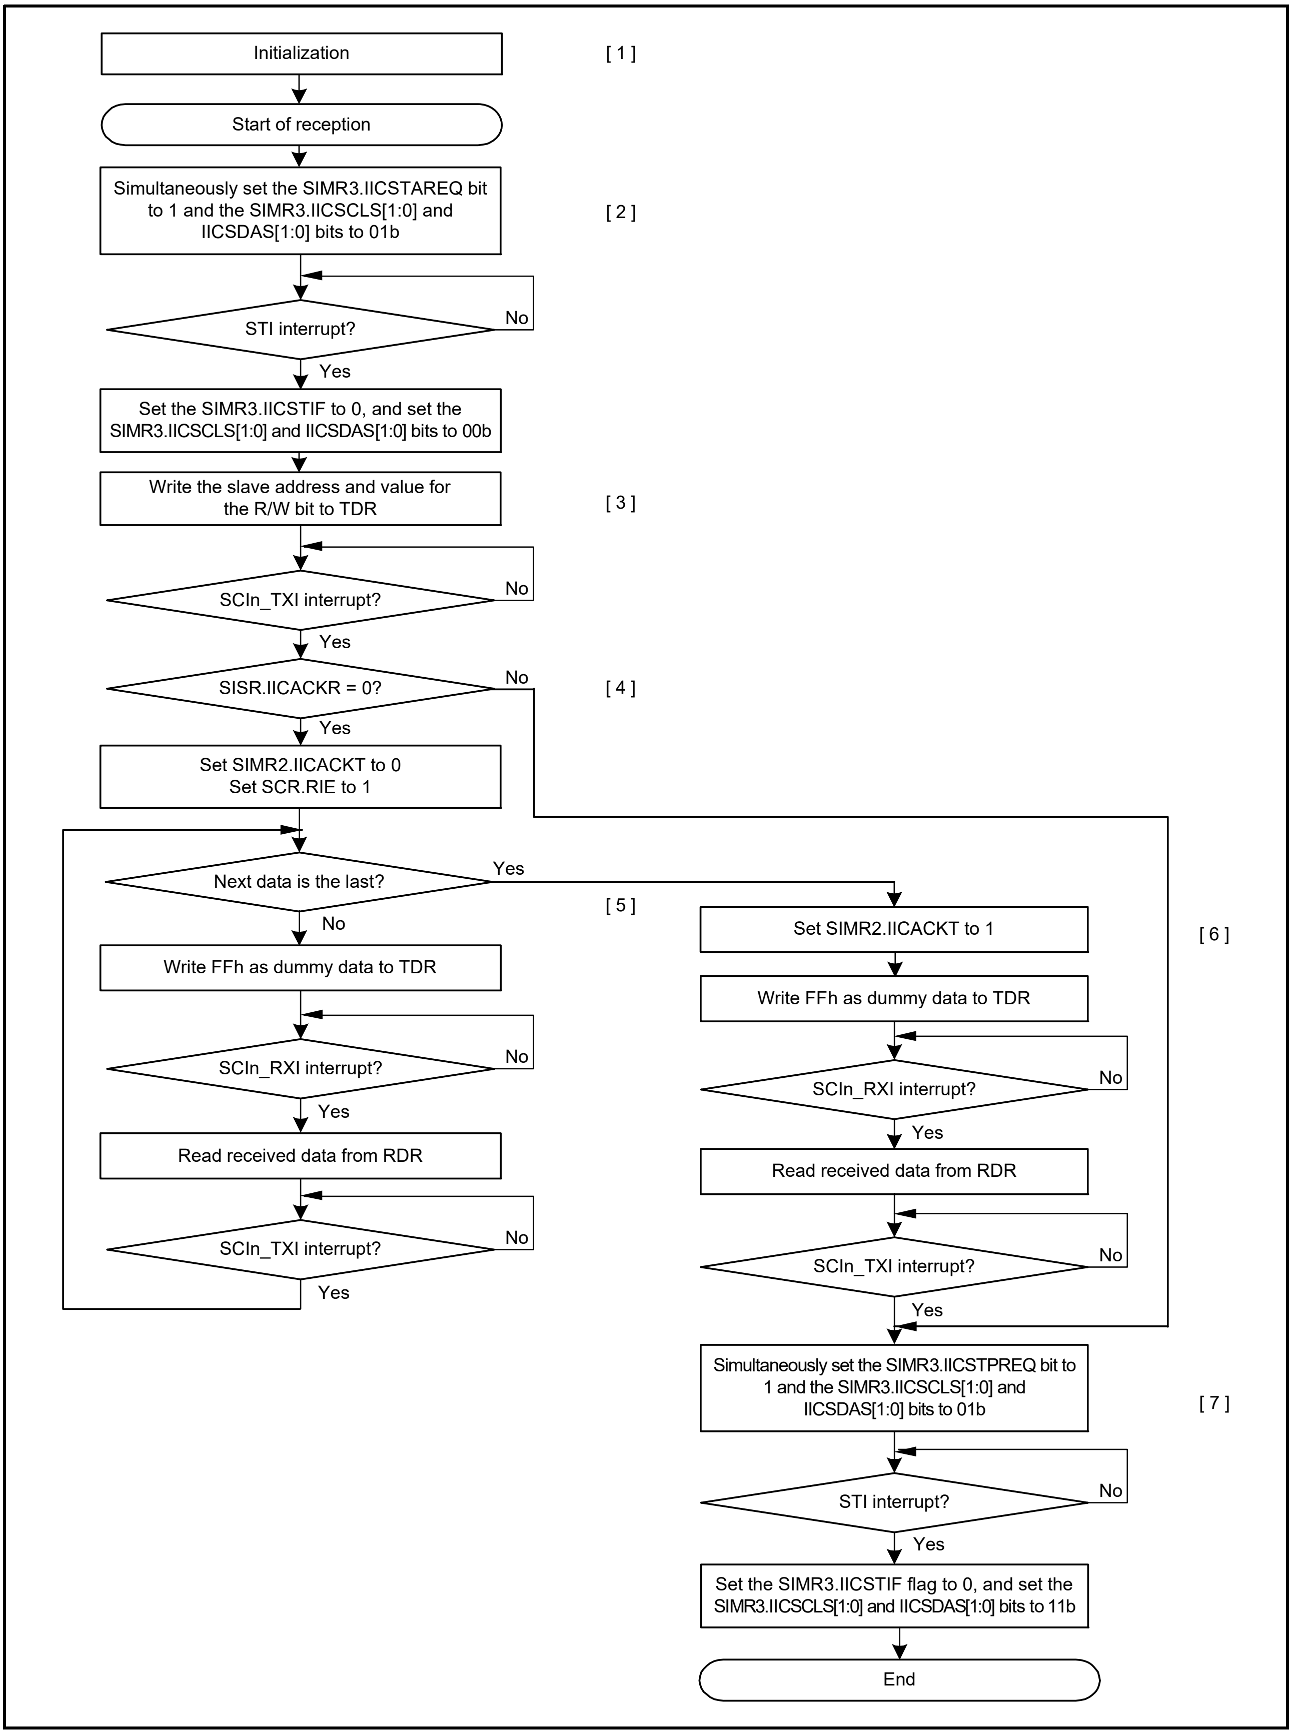


Figure 34.68 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts

34.8 Operation in Simple SPI Mode

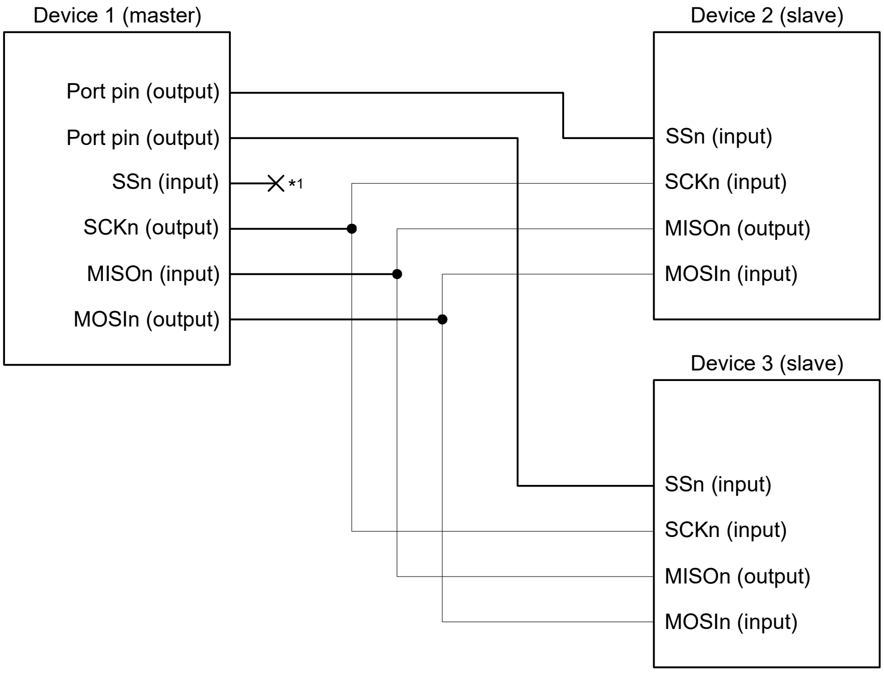
As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 places the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 34.69 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 34.69 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

34.8.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 34.25 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 34.25 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of TXDn pin	State of RXDn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin. Because the SSn pin function is not required, the pin is available for other purposes.

Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).

Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE and RE bits = 00b) in a multi-master configuration (SPMR.SSE = 1).

34.8.2 SS Function in Master Mode

Setting the SCR.CKE[1:0] bits to 00b and the SPMR.MSS bit to 0 selects master operation.

In single-master configurations (SPMR.SSE = 0), the SSn pin is not used, and so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and this indicates that transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. Additionally, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. Even if a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn pin outputs are placed in the high-impedance state after completion of the transfer. Use a general port pin to produce the SS output signal from the master.

34.8.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

34.8.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 34.70. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

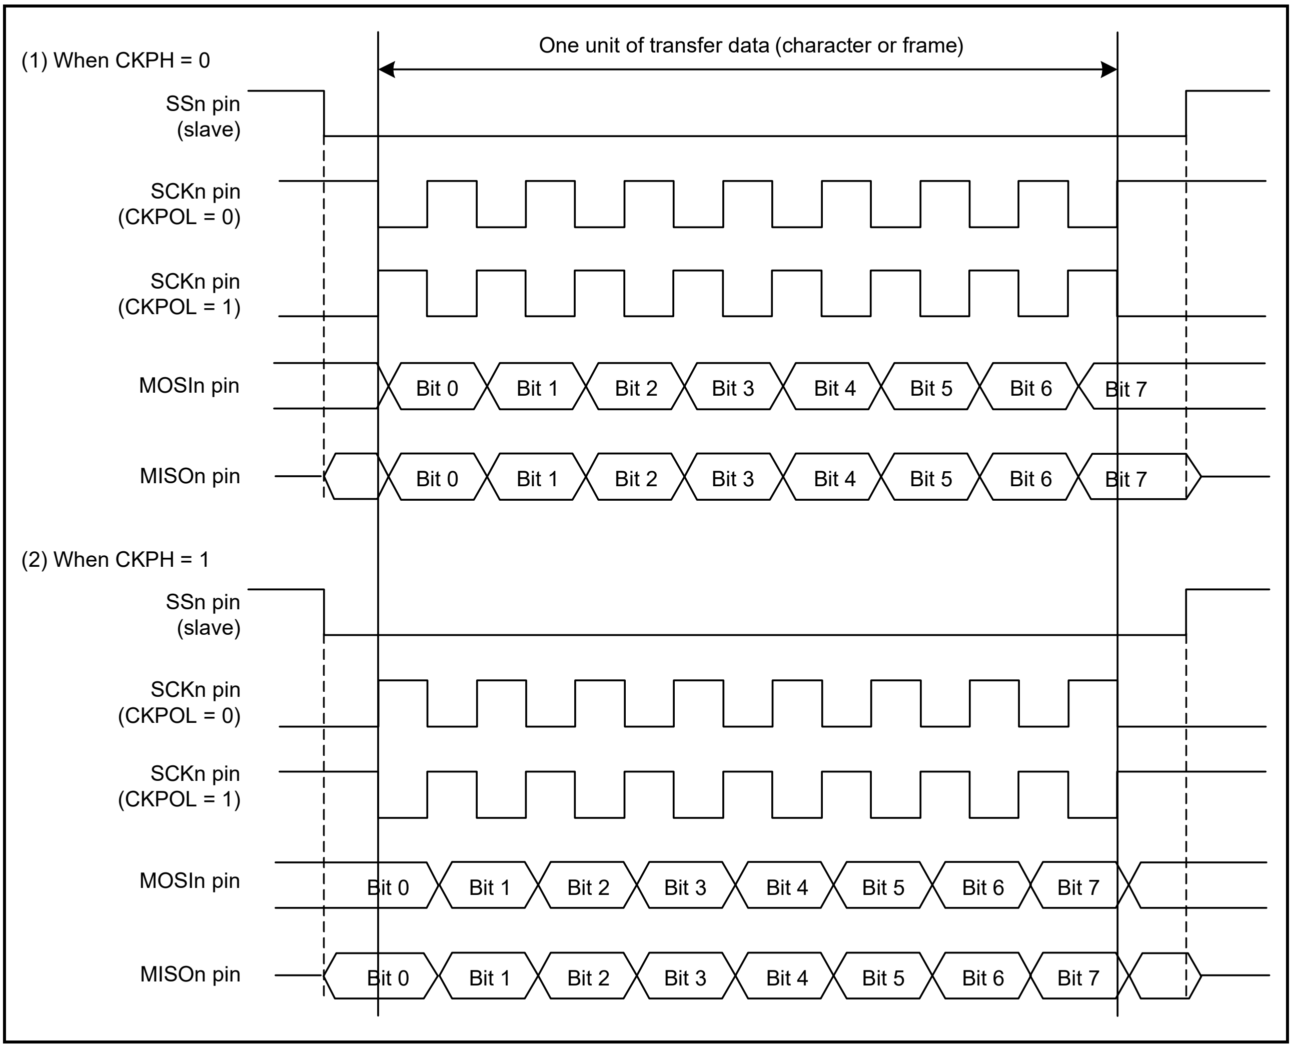


Figure 34.70 Relation between clock signal and transmit or receive data in simple SPI mode

34.8.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See Figure 34.32 for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note 1. Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.
Note 2. Changing the value of the TE bit from 1 to 0 or from 0 to 1 leads to the generation of a transmit data empty interrupt (SCIn_TXI) if the value of the SCR.TIE bit is 1.

34.8.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

34.9 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register when the PCLKA is selected in the CKS[1:0] bits in SMR/SMR_SMCI.

Figure 34.71 shows an example where the PCLKA is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

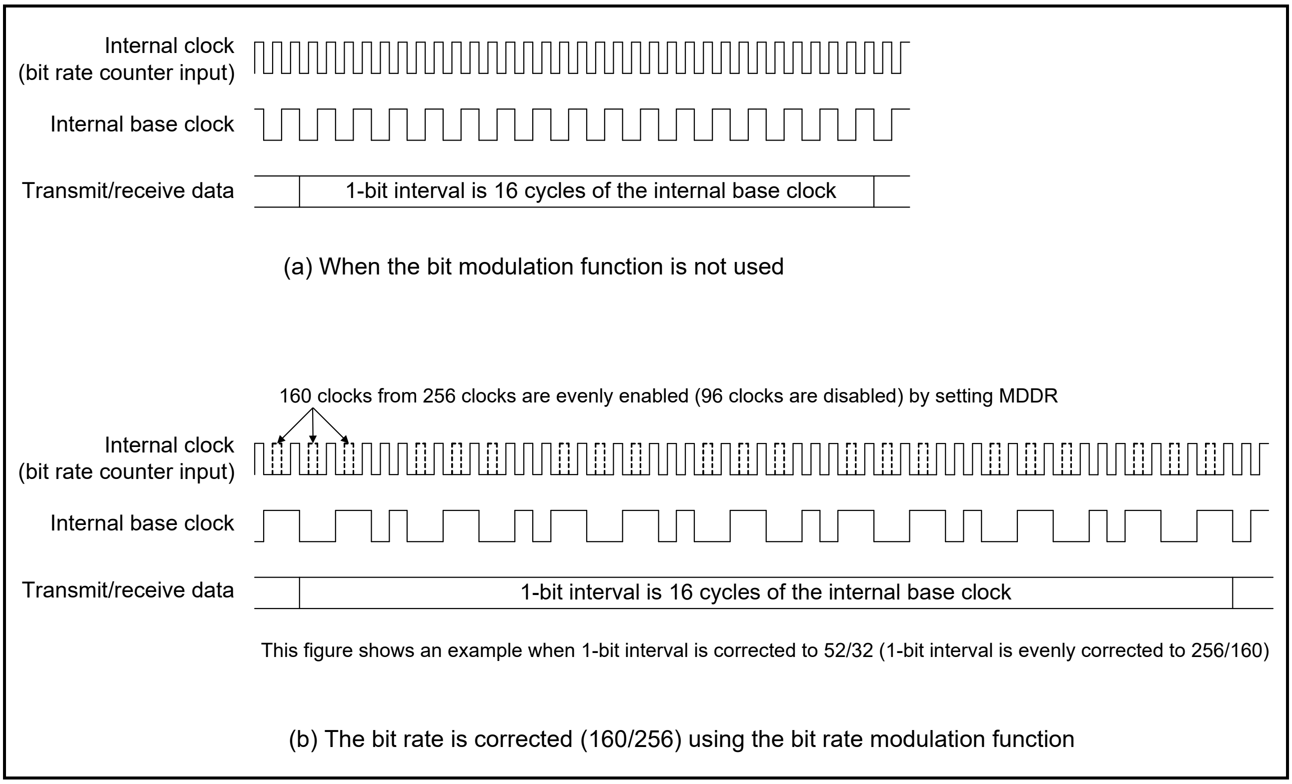

Figure 34.71 Example internal base clock when bit rate modulation function is used

34.10 Interrupt Sources

34.10.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (non-FIFO selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the Interrupt Controller Unit (ICU) is 1, the ICU does not output the interrupt request but retains it internally (with a capacity for retention of one request per source).

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

34.10.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO selected)

Even when an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is cleared to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

34.10.3 Interrupts in Asynchronous, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 34.26 lists interrupt sources in asynchronous mode, clock synchronous mode, and simple SPI mode. A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the ORER, FER, and PER flags in the SSR register to 1 while the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request. An SCIn_RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the SCIn_ERI interrupt request.

(2) FIFO selected

Table 34.27 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0 or by setting SCR.TIE to 1 when SCR.TE is 1.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

Note 1. When asynchronous mode and 9-bit data length are selected.

Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.

Table 34.26 SCI interrupt sources with non-FIFO selected (1 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_ERI	Receive error *1	ORER, FER, PER, DFER, DPER	RIE	Not possible	Not possible
SCIn_RXI	Receive data full	RDRF	RIE	Possible	Possible
	Address match	DCMF	RIE	Possible	Possible
SCIn_AM	Address match	DCMF	—	Possible	Possible

Table 34.26 SCI interrupt sources with non-FIFO selected (2 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_TXI	Transmit data empty	TDRE	TIE	Possible	Possible
SCIn_TEI	Transmit end	TEND	TEIE	Not possible	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

Table 34.27 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_ERI	Receive error*1	ORER, FER, PER, DFER, DPER	RIE	Not possible	Not possible
		DR (when FCR.DRES = 1)	RIE	Not possible	Not possible
SCIn_RXI	Receive data full	RDF	RIE	Possible	Possible
	Receive data ready	DR (when FCR.DRES = 0)	RIE	Possible	Possible
	Address match	DCMF	RIE	Possible	Possible
SCIn_AM	Address match	DCMF	—	Possible	Possible
SCIn_TXI	Transmit data empty	TDFE	TIE	Possible	Possible
SCIn_TEI	Transmit end	TEND	TEIE	Not possible	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

34.10.4 Interrupts in Smart Card Interface Mode

Table 34.28 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 34.28 SCI Interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_ERI	Receive error or error signal detection	ORER, FER, ERS	RIE	Not possible	Not possible
SCIn_RXI	Receive data full	RDRF	RIE	Possible	Possible
SCIn_TXI	Transmit end	TEND	TIE	Possible	Possible

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 17, DMA Controller (DMAC) and section 18, Data Transfer Controller (DTC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

34.10.5 Interrupts in Simple IIC Mode

Table 34.29 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 34.29 SCI interrupt sources

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC activation	DMAC activation
SCIn_RXI	Reception, ACK detection	—	RIE	Possible	Possible
SCIn_TXI	Transmission, NACK detection	—	TIE	Possible	Possible
STIn	Completion of generation of a start, restart, or stop condition	IICSTIF	TEIE	Not possible	Not possible

Note 1. Activation of the DTC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts).

34.11 Event Linking

By using interrupt request signals as event signals, the SCI can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 ETUs elapse when FIFO is selected and the FCR.DRES bit is 1.

(2) Receive data full event output

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode
- When the SIMR2.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used.

(a) Non-FIFO selected

- Indicates that received data is set in the Receive Data Register (RDR or RDRHL).

(b) FIFO selected

- Using this event output is prohibited.

(3) Transmit data empty event output

- Indicates that the SCR/SCR_SMCI.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode.

(a) Non-FIFO selected

- Indicates that transmit data is transferred from the Transmit Data Register (TDR or TDRHL) to the Transmit Shift Register (TSR).

(b) FIFO selected

- Using this event output is prohibited.

(4) Transmit end event output

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode
- When FIFO is selected, using this event output is prohibited.

(5) Address match event output

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

34.12 Address Mismatch Event Output (SCI0_DCUF)

SCI0_DCUF indicates the mismatch of comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only.

34.13 Noise Cancellation Function

Figure 34.72 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 the period of 1 transfer bit.

When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 the period of 1 transfer bit.

When SEMR.ABCSE = 1, the cycle is 1/6 the period of 1 transfer bit.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock for the noise cancellation function is selected in the SNFR.NFCS bit by dividing the baud rate generator source clock by 1, 2, 4, or 8.

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

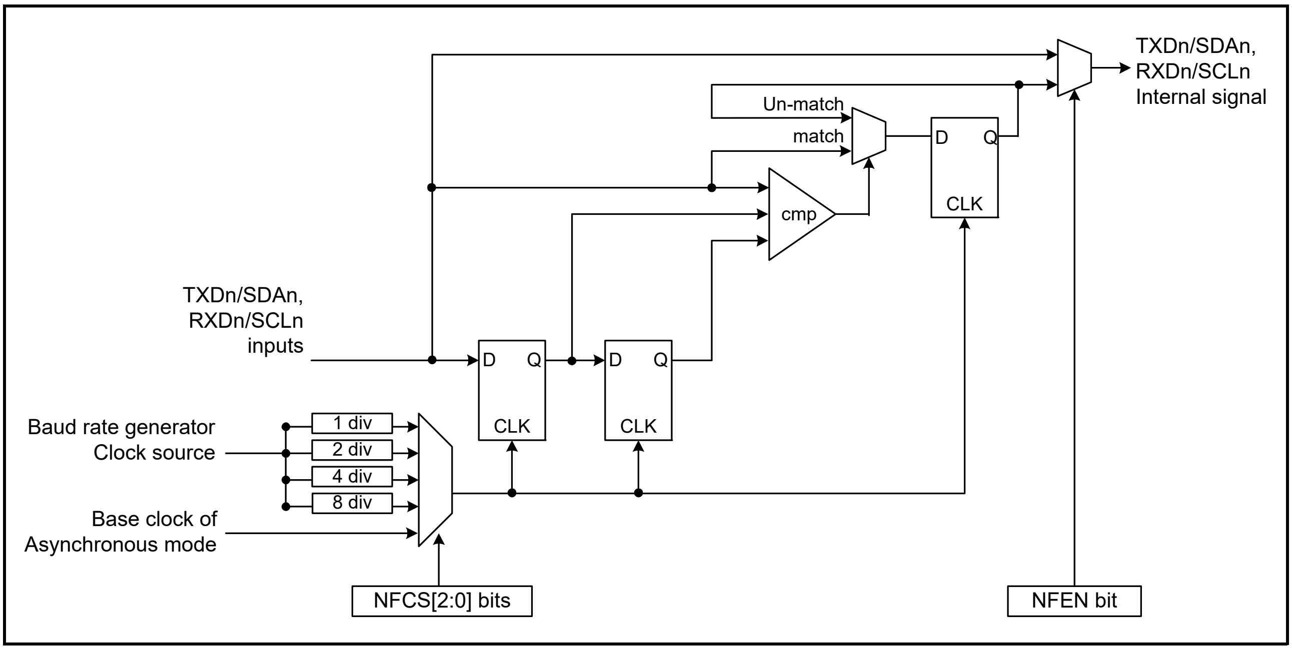

Figure 34.72 Digital noise filter circuit block diagram

34.14 Usage Notes

34.14.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

34.14.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected. The value is saved with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low power state is made after release from the module-stop state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 34.73 shows an example flow of transition to Software Standby mode during transmission. Figure 34.74 and Figure 34.75 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or making a transition to Software Standby mode from the transmission mode using DTC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC.

(2) Reception

(a) When address match function is not used as wakeup condition

Before specifying the module-stop state or making a transition to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 34.76 shows an example flow of transition to Software Standby mode during reception.

(b) When address match function is used as wakeup condition

Before specifying the module-stop state or making a transition to Software Standby mode:

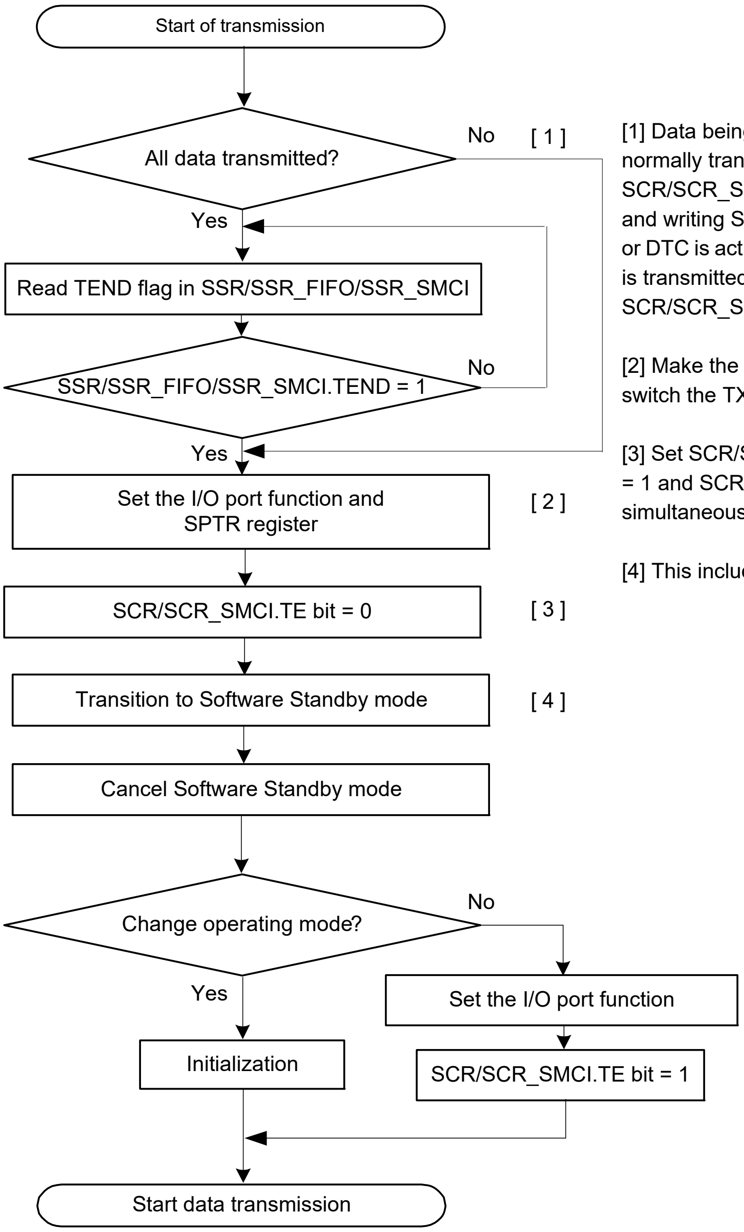
1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0. When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXDn pin) cannot be detected on release of the low power mode.

Figure 34.77 shows an example flow of transition to Software Standby mode during reception with address match.

(c) When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 11, Low Power Modes.



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the TE bit in SCR/SCR_SMCI to 1, reading SSR/SSR_FIFO/SSR_SMCI, and writing Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is transmitted when both the TE and TIE bits in SCR/SCR_SMCI are set to 1.

[2] Make the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[3] Set SCR/SCR_SMCI.TE bit to 0. If SCR/SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

[4] This includes the setting for the module-stop state.

Figure 34.73 Example flow of transition to Software Standby mode during transmission

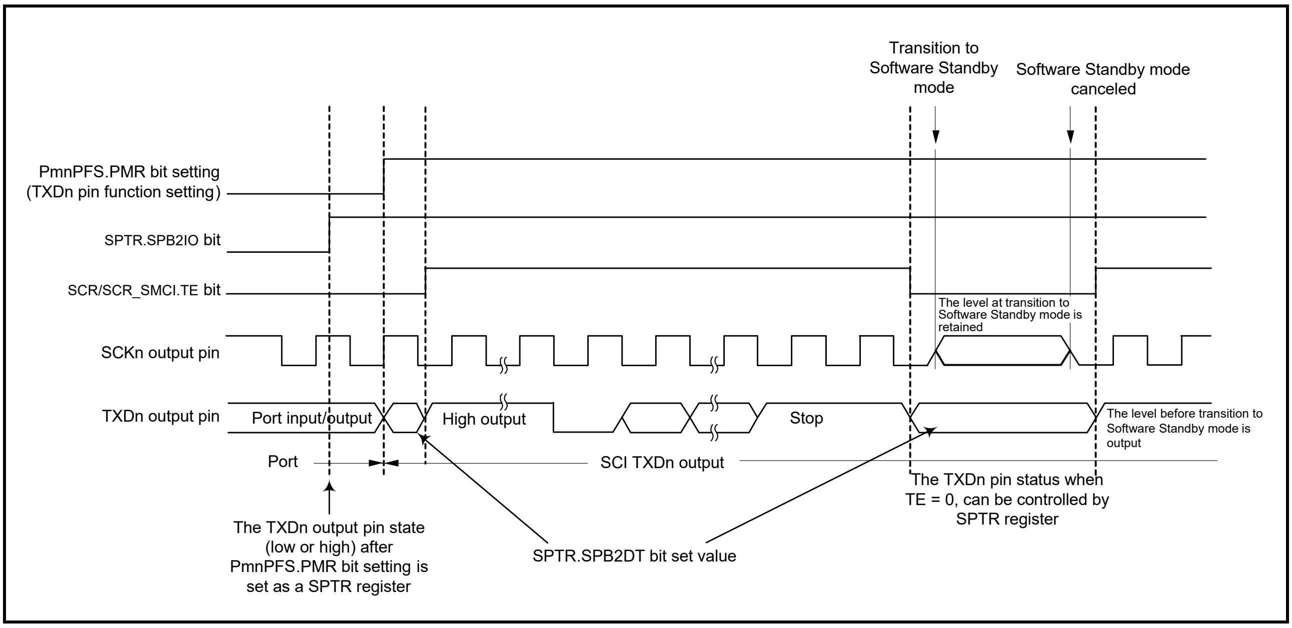


Figure 34.74 Port pin states during transition to Software Standby mode with internal clock and asynchronous transmission

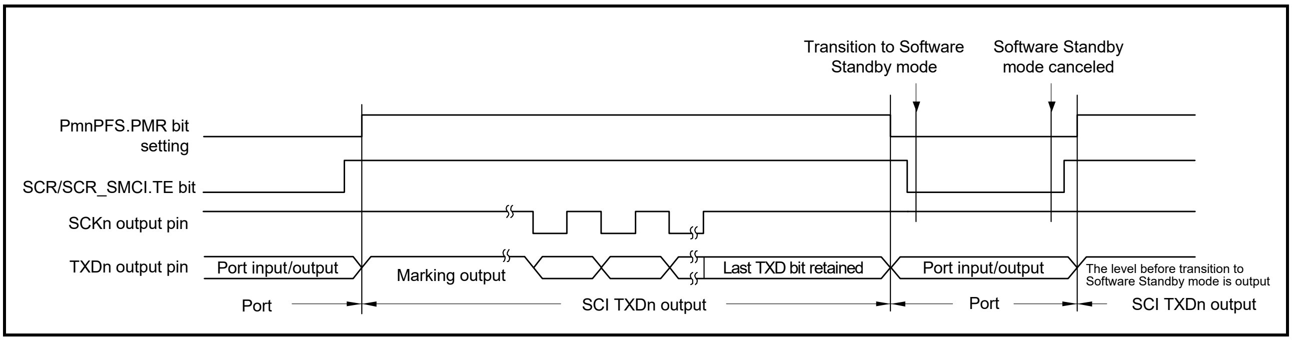

Figure 34.75 Port pin states during transition to Software Standby mode with internal clock and clock synchronous transmission

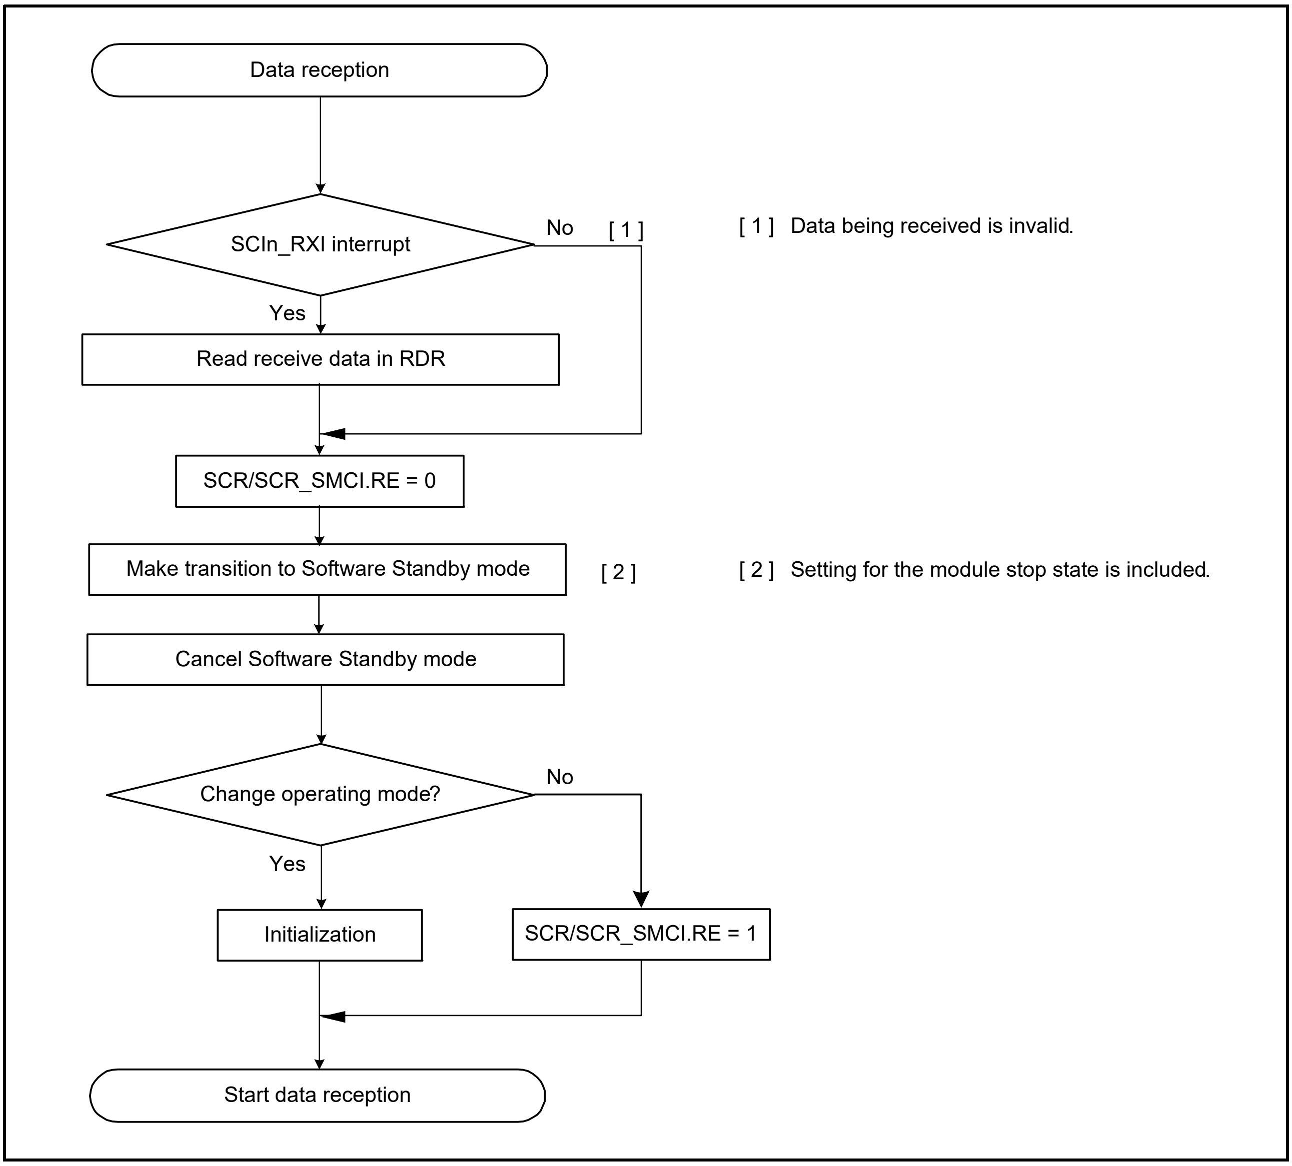

[1] Data being received is invalid.

[2] Setting for the module stop state is included.

Figure 34.76 Example flow of transition to Software Standby mode during reception

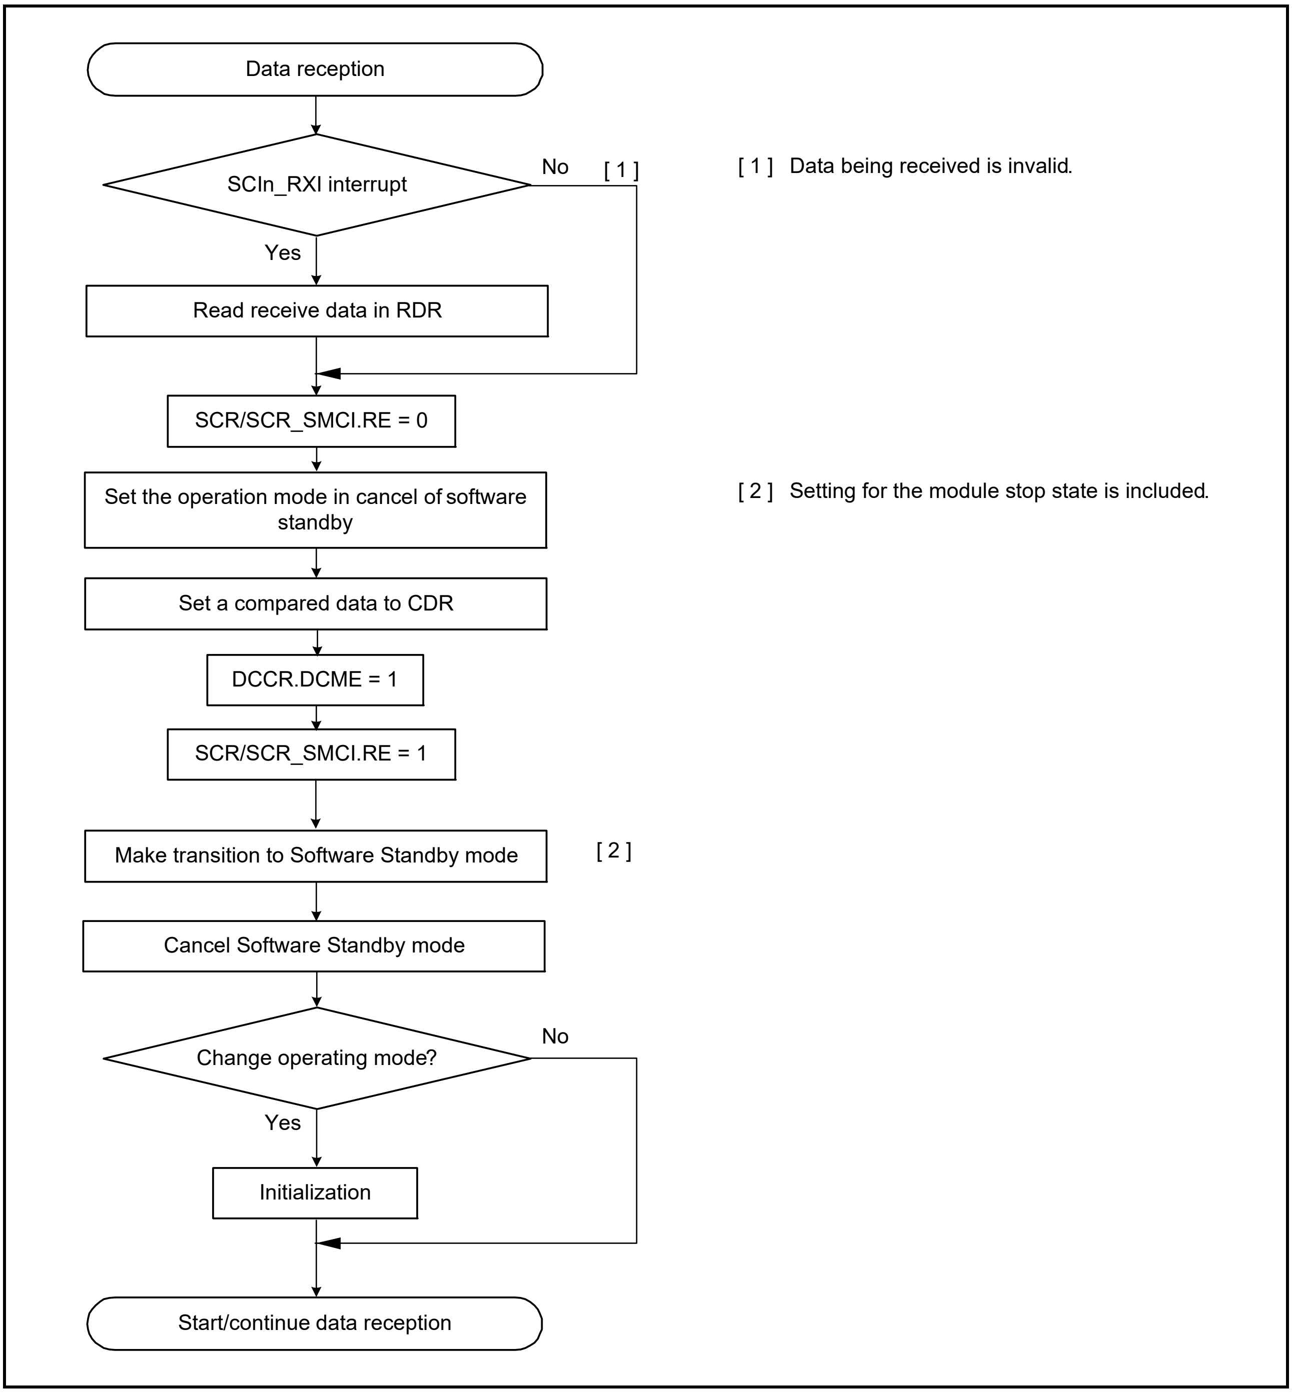

Figure 34.77 Example flow of transition to Software Standby mode during reception with address match

34.14.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the

RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON bit value. After the RXD signal is in the mark state and the break is finished, data reception to the FRDRHL register resumes.

34.14.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TxDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

34.14.5 Receive Error Flags and Transmit Operation in Clock Synchronous and Simple SPI Modes

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL*2. Always set the receive error flags to 0 before starting transmission.

Note 1. The receive error flags cannot be set to 0 when serial reception is disabled by setting the RE bit in SCR/SCR_SMCI to 0.

Note 2. Do not use the FTDRH register in simple SPI mode.

34.14.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous and Simple SPI Modes

When the external clock source is used as a synchronization clock, the following restrictions apply.

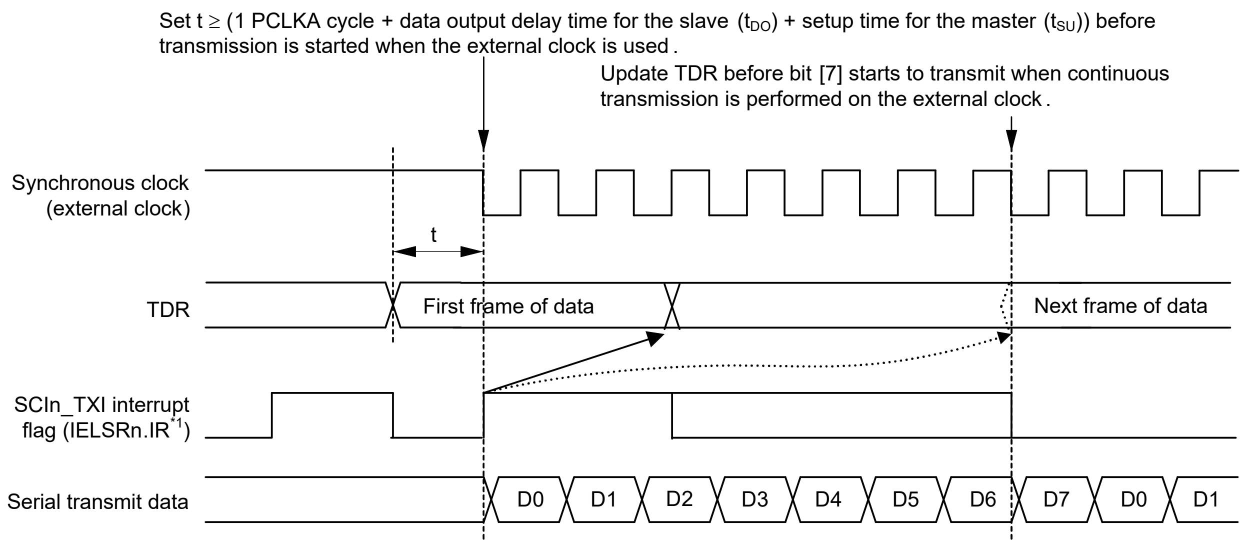
(1) Start of transmission

Wait at least the following time from writing transmit data to TDR to the start of the external clock input:
1 PCLKA cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 34.78.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] (see Figure 34.78).

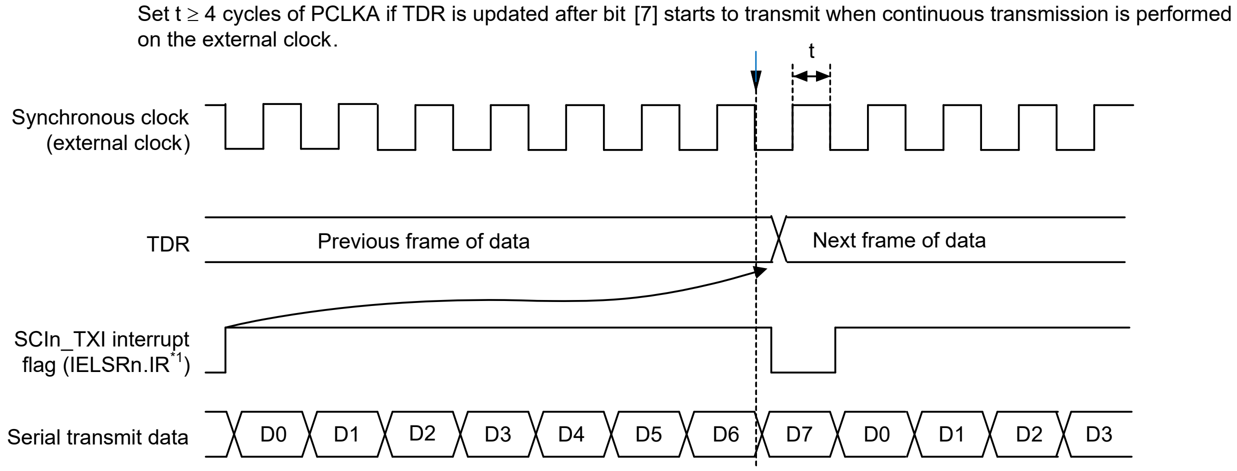
When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLKA cycles or longer (see Figure 34.78).



Set t ≥ (1 PCLKA cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU})) before transmission is started when the external clock is used.

Update TDR before bit [7] starts to transmit when continuous transmission is performed on the external clock.

(1) Start of transmission and (2) Continuous transmission (a)



Set t ≥ 4 cycles of PCLKA if TDR is updated after bit [7] starts to transmit when continuous transmission is performed on the external clock.

(2) Continuous transmission (b)

Note 1. See section 14, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 34.78 Restrictions on use of external clock in clock synchronous transmission

34.14.7 Restrictions on Using DMAC or DTC

During transmission or reception operations using the DMAC or DTC, do not set transfer data for the DMAC/DTC.

(1) Writing data to TDR (FTDRHL)

(a) Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

(b) FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.

(2) Reading data from RDR (FRDRHL)

When using the DMAC or DTC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

34.14.8 Notes on Starting Transfer

When transfer starts while the Interrupt Status flag (IELSRn.IR) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the Interrupt Status flag, see section 14, Interrupt Controller Unit (ICU).

- Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
- Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE) to 0
- Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
- Set the Interrupt Status flag, IELSRn.IR, in the ICU to 0.

34.14.9 External Clock Input in Clock Synchronous and Simple SPI Modes

In clock synchronous mode and simple SPI mode, the external clock (SCKn) must be input as follows:

High-pulse period, low-pulse period = 2 PCLKA cycles or more, period = 6 PCLKA cycles or more.

34.14.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 34.79. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

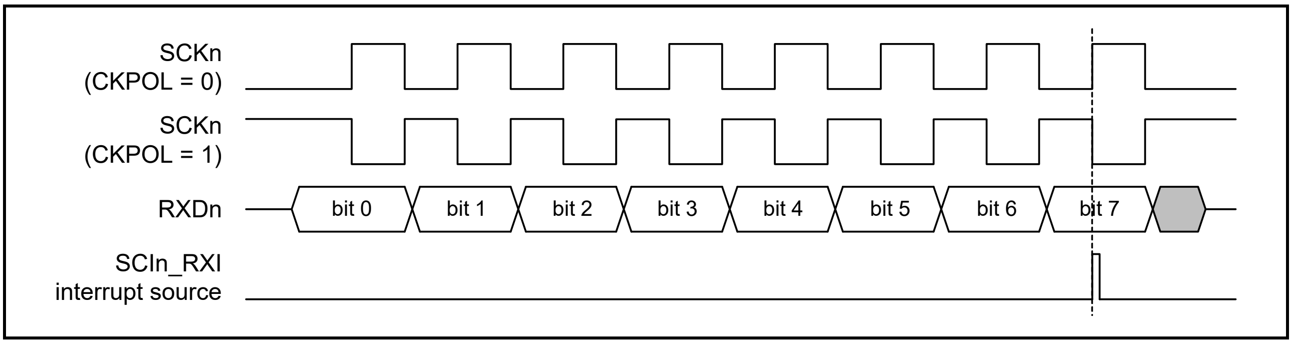


Figure 34.79 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.
  1 PCLKA cycle + data output delay for the slave (tDO) + setup time for the master (tSU)

  Also wait at least 5 PCLKA cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte.

35. IrDA Interface

35.1 Overview

The IrDA interface sends and receives IrDA data communication waveforms in cooperation with the SCI1 based on the IrDA (Infrared Data Association) standard 1.0.

Enabling the IrDA function in the IRE bit in the IRCR register allows encoding and decoding of the TXD1 and RXD1 signals of the SCI1 to the waveforms conforming to the IrDA standard 1.0 (IRTXD1 and IRRXD1 pins). Connecting the waveforms to an infrared transmitter/receiver implements infrared data communication conforming to the IrDA standard 1.0 system.

With the IrDA standard 1.0 system, data transfer can be started at 9,600 bps and the transfer rate can be changed whenever necessary. Because the IrDA interface cannot change the transfer rate automatically, the transfer rate must be changed through the software.

Figure 35.1 shows the cooperation between the IrDA interface and SCI1.

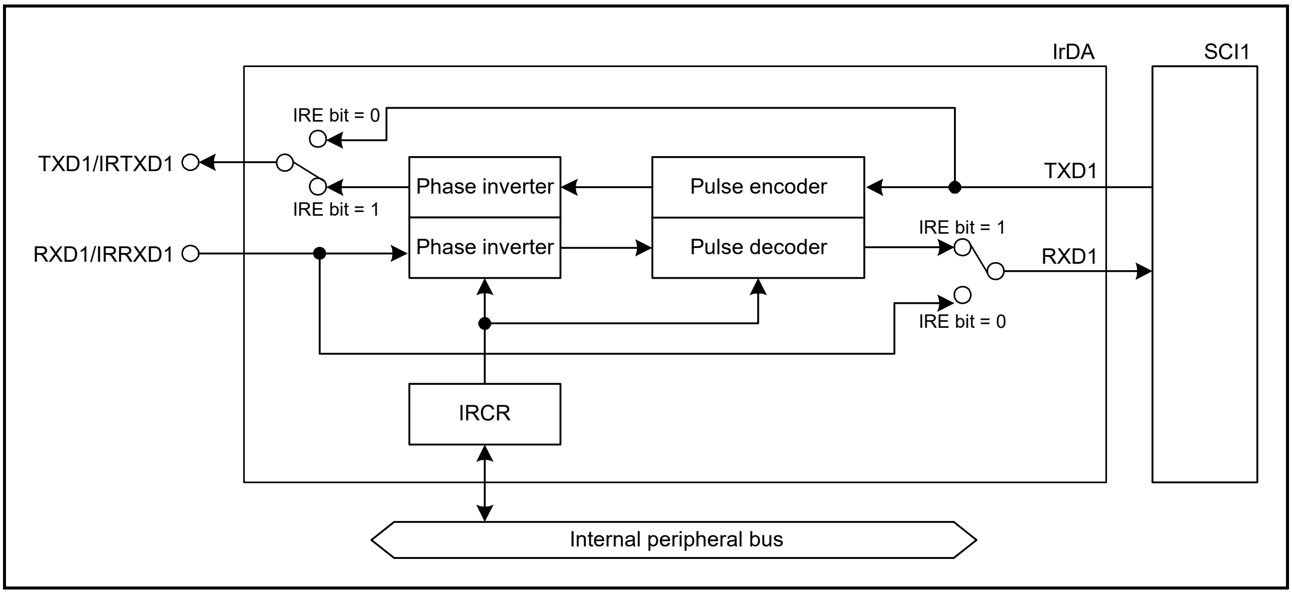

Figure 35.1 Cooperation between the IrDA interface and SCI1

Table 35.1 IrDA interface I/O pins

Pin name	I/O	Function
IRTXD1	Output	Data to be transmitted
IRRXD1	Input	Received data

35.2 Register Descriptions

35.2.1 IrDA Control Register (IRCR)

Address(es): IRDA.IRCR 4007 0F00h

	b7	b6	b5	b4	b3	b2	b1	b0
	IRE	—	—	—	IRTXINV	IRRXINV	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	IRRXINV	IRRXD Polarity Switching	0: Use IRRXD input as received data as-is 1: Use IRRXD input as received data after the polarity is inverted.	R/W
b3	IRTXINV	IRTXD Polarity Switching	0: Output data to be transmitted to IRTXD as-is 1: Output data to be transmitted IRTXD after the polarity is inverted.	R/W
b6 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	IRE	IrDA Enable	0: Use serial input/output pins for normal serial communication 1: Use serial input/output pins for IrDA data communication.	R/W

Note: The IRCR register values are retained in Sleep, Software Standby, and Deep Software Standby modes.

IRRXINV bit (IRRXD Polarity Switching)

The IRRXINV bit inverts the logic level of the IRRXD input. When inverted, the high-level pulse width is applied to the low-level pulse width.

IRTXINV bit (IRTXD Polarity Switching)

The IRTXINV bit inverts the logic level of the IRTXD output. When inverted, the high-level pulse width is applied to the low-level pulse width.

IRE bit (IrDA Enable)

The IRE bit configures the I/O pins for normal communication mode or IrDA data communication mode.

35.3 Operation

35.3.1 IrDA Interface Setup Procedure

To set up IrDA interface operation:

1. Set the associated pins to IRTXD1 and IRRXD1 in the Pin Function Control Register (PmnPFS.PSEL = 00101b) of the I/O ports function.
2. Specify the peripheral function in the Pin Function Control Register (PmnPFS.PMR = 1) of the I/O ports function.
3. Specify the IrDA function in the IRCR register.
4. Set the SCI1-related registers of the Serial Communications Interface (SCI).

35.3.2 Transmission

During transmission, the signals output from the SCI1 (UART frames) are converted to the IR frame data through the IrDA interface (see Figure 35.2). When the IRCR.IRTXINV bit is 0 and serial data is 0, high-level pulses with 3/16 the width of the bit rate (1-bit width period) are output (initial setting). The standard prescribes that the minimum high-level pulse width must be 1.41 µs and the maximum high-level pulse width must be (3/16 + 2.5%) × bit rate or (3/16 × bit rate) + 1.08 µs. When the serial data is 1, no pulses are output.

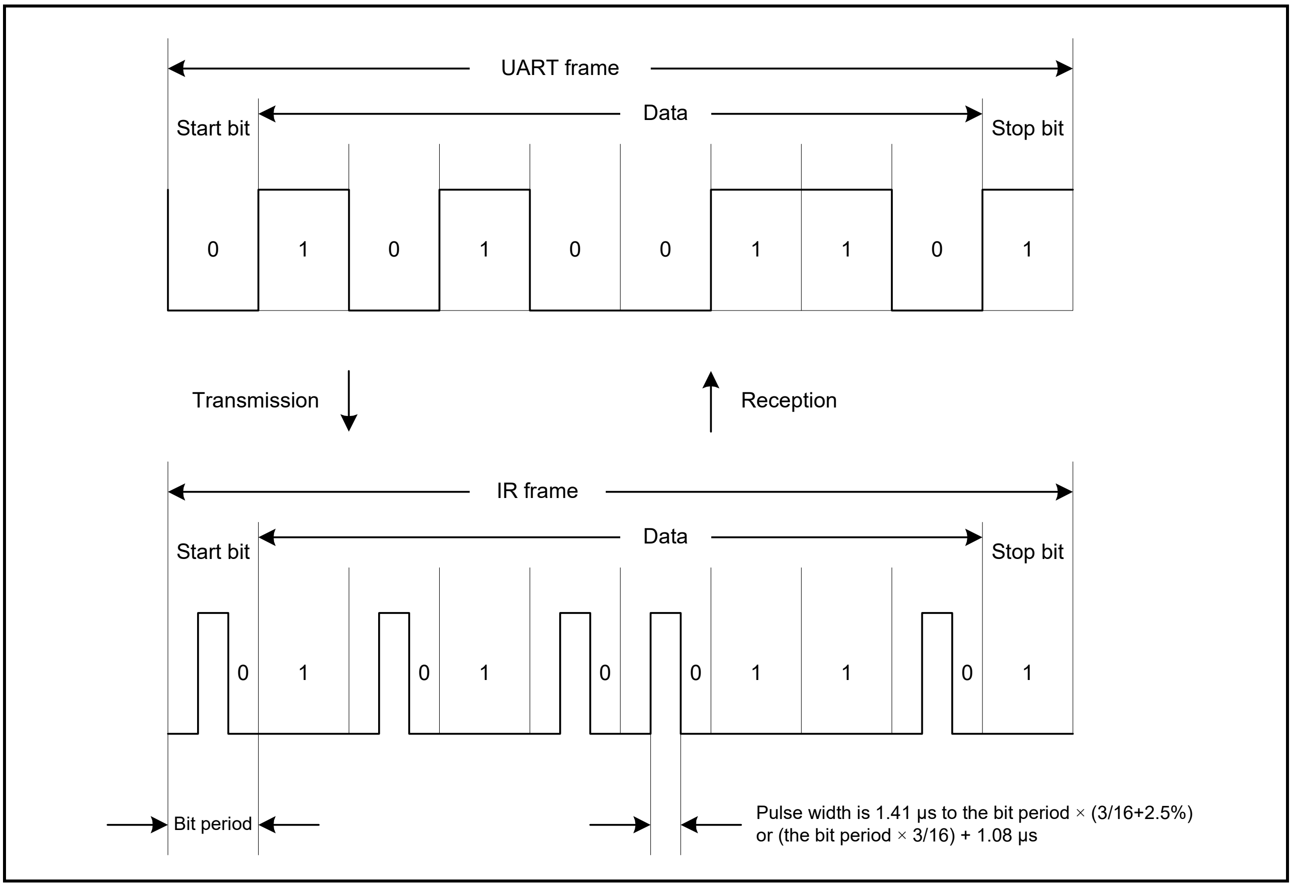

Figure 35.2 IrDA transmission and reception

35.3.3 Reception

During reception, the IR frame data is converted to the UART frame data through the IrDA interface and is input to the SCI1. Low-level data is input to SCI1 when the IRCR.IRRXINV bit is 0 and a high-level pulse is detected. High-level data is input to SCI1 when no pulse is detected for a 1-bit period.

35.4 Usage Notes

35.4.1 Settings for the Module-Stop Function

IrDA operation can be disabled or enabled using the Module Stop Control Register. The IrDA is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

35.4.2 Asynchronous Reference Clock for SCI1

The IrDA receives a clock with a frequency 16 times the bit rate from SCI1 and operates in conjunction with SCI1. When using the IrDA, set the SCI1.SEMR.ABCS bit to 0.

36. I^{2}C Bus Interface (IIC)

36.1 Overview

The 3-channel I^{2}C Bus Interface (IIC) module conforms with and provides a subset of the NXP I^{2}C bus (inter-integrated circuit bus) interface functions. Table 36.1 lists the IIC specifications, Figure 36.1 shows a block diagram, and Figure 36.2 shows an example of I/O pin connections to external circuits, with an I^{2}C bus configuration. Table 36.2 lists the I/O pins.

Table 36.1 IIC specifications (1 of 2)

Parameter	Specifications
Communications format	• I^{2}C-bus format or SMBus format • Master or slave mode selectable • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate
Transfer rate	Fast-mode Plus supported, up to 1 Mbps
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated • Start conditions (including restart conditions) and stop conditions are detectable
Slave address	• Configurable for up to three different slave addresses • 7- and 10-bit address formats supported, including simultaneous use • General call addresses, device ID addresses, and SMBus host addresses detectable
Acknowledgment	• For transmission, automatic loading of the acknowledge bit Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatical transmission of the acknowledge bit If a wait between the eighth and ninth clock cycles is selected, the software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the eighth and ninth clock cycles • Waiting between the ninth clock cycle and the first clock cycle of the next transfer
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed
Arbitration	• For multi-master operation: - SCL clock synchronization is possible when conflict occurs with the SCL signal from another master - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line - In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match • Loss of arbitration because non-matching of internal and line levels for data is detectable in slave transmission
Timeout function	Internal detection of long-interval stops of the SCL clock
Noise cancellation	• Digital noise filters for both the SCL and SDA signals • Programmable window for noise cancellation by the filters
Interrupt sources	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Module-stop function	Module-stop state can be set to reduce power consumption
IIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive

Table 36.1 IIC specifications (2 of 2)

Parameter	Specifications
Event link function (output)	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Wakeup function*1	CPU can return from Software Standby mode using a wakeup event

Note 1. Only supported for IIC0. IIC1 and IIC2 are not supported.

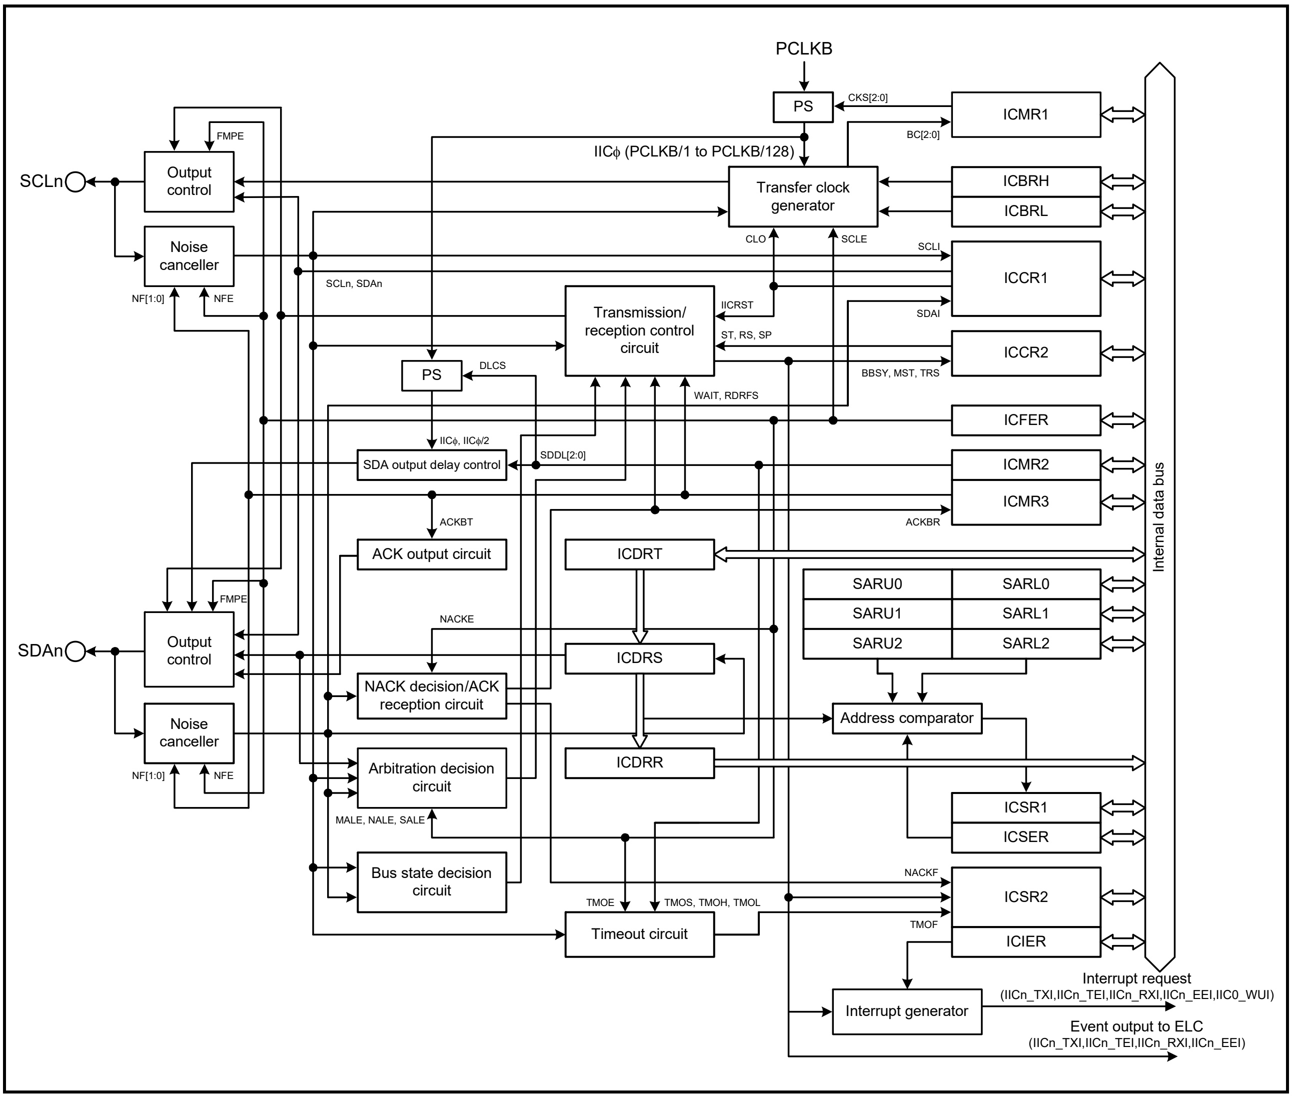

Figure 36.1 IIC block diagram

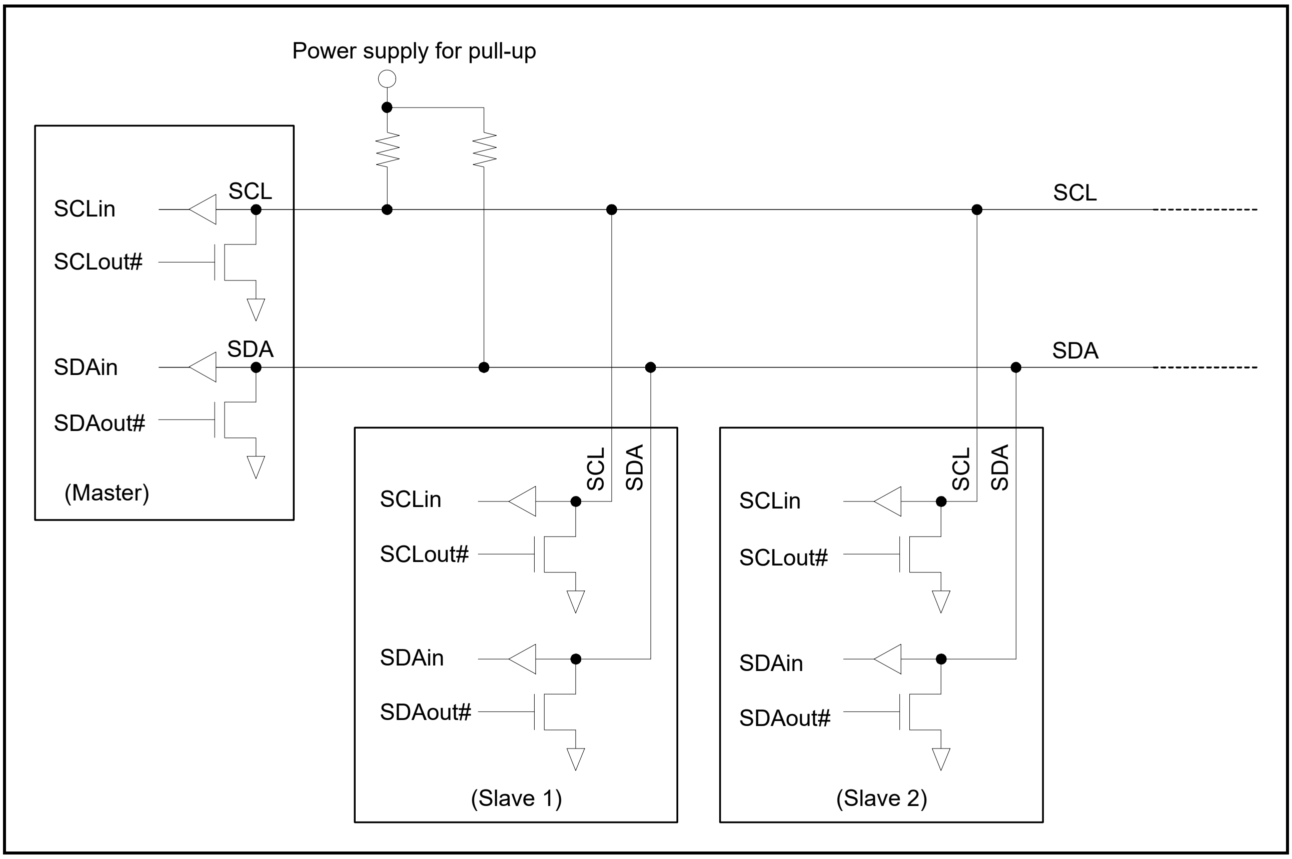

Figure 36.2 I/O pin connection to an external circuit (I^{2}C bus configuration example)

The input level of the signals for IIC is CMOS when I^{2}C bus is selected (ICMR3.SMBS = 0), or TTL when SMBus is selected (ICMR3.SMBS = 1).

Table 36.2 IIC I/O pins

Channel	Pin name	I/O	Function
IIC0	SCL0	I/O	IIC0 serial clock input/output pin
	SDA0	I/O	IIC0 serial data input/output pin
IIC1	SCL1	I/O	IIC1 serial clock input/output pin
	SDA1	I/O	IIC1 serial data input/output pin
IIC2	SCL2	I/O	IIC2 serial clock input/output pin
	SDA2	I/O	IIC2 serial data input/output pin

36.2 Register Descriptions

36.2.1 I^{2}C Bus Control Register 1 (ICCR1)

Address(es): IIC0.ICCR1 4005 3000h, IIC1.ICCR1 4005 3100h, IIC2.ICCR1 4005 3200h

	b7	b6	b5	b4	b3	b2	b1	b0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b0	SDAI	SDA Line Monitor	0: SDAn line is low 1: SDAn line is high.	R
b1	SCLI	SCL Line Monitor	0: SCLn line is low 1: SCLn line is high.	R
b2	SDAO	SDA Output Control/Monitor	• Read: 0: IIC drove SDAn pin low 1: IIC released SDAn pin. • Write: 0: Drive SDAn pin low through IIC 1: Release SDAn pin through IIC.	R/W
b3	SCLO	SCL Output Control/Monitor	• Read: 0: IIC drove SCLn pin low 1: IIC released SCLn pin. • Write: 0: Drive SCLn pin low through IIC 1: Release SCLn pin through IIC. Use an external pull-up resistor to drive the signal high.	R/W
b4	SOWP	SCLO/SDAO Write Protect	0: Write enable SCLO and SDAO bits 1: Write protect SCLO and SDAO bits. This bit is read as 1.	R/W
b5	CLO	Extra SCL Clock Cycle Output	0: Do not output extra SCL clock cycle (default) 1: Output extra SCL clock cycle. This bit clears automatically after one clock cycle is output.	R/W
b6	IICRST	IIC-Bus Interface Internal Reset	0: Release IIC reset or internal reset 1: Initiate IIC reset or internal reset. This setting clears the bit counter and the SCLn/SDAn output latch.	R/W
b7	ICE	IIC-Bus Interface Enable	0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state). Combined with the IICRST bit to select either IIC or internal reset.	R/W

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO bit directly controls the SDAn and SCLn signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 36.12.2, Extra SCL Clock Cycle Output Function.

IICRST bit (IIC-Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset.

Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 36.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the IIC.

The internal reset initializes the following in addition to the internal states of the IIC:

- Bit counter (ICMR1.BC[2:0] bits)
- I^{2}C Bus Shift Register (ICDRS)
- I^{2}C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits)
- I^{2}C Bus Control Register 2 (except ICCR2.BBSY bit).

For the reset conditions for each register, see section 36.15, State of Registers when Issuing each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC when the bus or IIC hangs up because of a communication error. If the IIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is necessary because the IIC hangs up with the SCLn line in a low level output state in slave mode, initiate an internal reset, and then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 36.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the IIC
	1	Internal reset	Resets the ICMR1.BC[2:0] bits, the ICSR1, ICSR2, ICDRS registers, and SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits), I2C Bus Control Register 2 (except ICCR2.BBSY bit) and the internal states of the IIC

ICE bit (IIC-Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 36.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

36.2.2 I^{2}C Bus Control Register 2 (ICCR2)

Address(es): IIC0.ICCR2 4005 3001h, IIC1.ICCR2 4005 3101h, IIC2.ICCR2 4005 3201h

	b7	b6	b5	b4	b3	b2	b1	b0
	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ST	Start Condition Issuance Request	0: Do not issue a start condition request 1: Issue a start condition request.	R/W
b2	RS	Restart Condition Issuance Request	0: Do not issue a restart condition request 1: Issue a restart condition request.	R/W
b3	SP	Stop Condition Issuance Request	0: Do not issue a stop condition request 1: Issue a stop condition request.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	TRS	Transmit/Receive Mode	0: Receive mode 1: Transmit mode.	R/W*1
b6	MST	Master/Slave Mode	0: Slave mode 1: Master mode.	R/W*1
b7	BBSY	Bus Busy Detection Flag	0: I^{2}C bus released (bus free state) 1: I^{2}C bus occupied (bus busy state).	R

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.

Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 36.11, Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).

Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the operating mode of the IIC.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the

received R/W# bit is 0, including when the received address is the general call address

- In slave mode, when a restart condition is detected (a start condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the operating mode of the IIC.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^{2}C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag then is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

36.2.3 I^{2}C Bus Mode Register 1 (ICMR1)

Address(es): IIC0.ICMR1 4005 3002h, IIC1.ICMR1 4005 3102h, IIC2.ICMR1 4005 3202h

	b7	b6	b5	b4	b3	b2	b1	b0
	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	BC[2:0]	Bit Counter	b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits.	R/W*1
b3	BCWP	BC Write Protect	0: Write enable BC[2:0] bits 1: Write protect BC[2:0] bits. This bit is read as 1.	R/W*1
b6 to b4	CKS[2:0]	Internal Reference Clock Select	Select the internal reference clock source (IICϕ) for the IIC. b6 b4 0 0 0: PCLKB clock 0 0 1: PCLKB/2 clock 0 1 0: PCLKB/4 clock 0 1 1: PCLKB/8 clock 1 0 0: PCLKB/16 clock 1 0 1: PCLKB/32 clock 1 1 0: PCLKB/64 clock 1 1 1: PCLKB/128 clock.	R/W
b7	MTWP	MST/TRS Write Protect	0: Write protect MST and TRS bits in ICCR2 1: Write enable MST and TRS bits in ICCR2.	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not normally necessary to access these bits.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

36.2.4 I^{2}C Bus Mode Register 2 (ICMR2)

Address(es): IIC0.ICMR2 4005 3003h, IIC1.ICMR2 4005 3103h, IIC2.ICMR2 4005 3203h

	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit name	Description	R/W

Bit	Symbol	Bit name	Description	R/W
b1	TMOL	Timeout L Count Control	0: Disable count while SCLn line is low 1: Enable count while SCLn line is low.	R/W
b2	TMOH	Timeout H Count Control	0: Disable count while SCLn line is high 1: Enable count while SCLn line is high.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6 to b4	SDDL[2:0]	SDA Output Delay Counter	• When ICMR2.DLCS = 0 (IICϕ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICϕ cycle 0 1 0: 2 IICϕ cycles 0 1 1: 3 IICϕ cycles 1 0 0: 4 IICϕ cycles 1 0 1: 5 IICϕ cycles 1 1 0: 6 IICϕ cycles 1 1 1: 7 IICϕ cycles. • When ICMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICϕ cycles 0 1 0: 3 or 4 IICϕ cycles 0 1 1: 5 or 6 IICϕ cycles 1 0 0: 7 or 8 IICϕ cycles 1 0 1: 9 or 10 IICϕ cycles 1 1 0: 11 or 12 IICϕ cycles 1 1 1: 13 or 14 IICϕ cycles.	R/W
b7	DLCS	SDA Output Delay Clock Source Select	0: Select internal reference clock (IICϕ) as clock source for SDA output delay counter 1: Select internal reference clock divided by 2 (IICϕ/2) as clock source for SDA output delay counter.[*1]	R/W

Note 1. The setting DLCS = 1 (IICϕ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14-bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source. For details on this function, see section 36.12.1, Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I^{2}C bus standard for the data enable time/acknowledge enable time,[*1] or the SMBus standard, within [data hold time (300 ns or more + the SCL-clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 36.5, SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time

3,450 ns for up to 100 kbps: Standard-mode (Sm)
900 ns for up to 400 kbps: Fast-mode (Fm)
450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

36.2.5 I^{2}C Bus Mode Register 3 (ICMR3)

Address(es): IIC0.ICMR3 4005 3004h, IIC1.ICMR3 4005 3104h, IIC2.ICMR3 4005 3204h

	b7	b6	b5	b4	b3	b2	b1	b0
	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	NF[1:0]	Noise Filter Stage Select	b1 b0 0 0: Filter out noise of up to 1 IICϕ cycle (single-stage filter) 0 1: Filter out noise of up to 2 IICϕ cycles (2-stage filter) 1 0: Filter out noise of up to 3 IICϕ cycles (3-stage filter) 1 1: Filter out noise of up to 4 IICϕ cycles (4-stage filter).	R/W
b2	ACKBR	Receive Acknowledge	0: 0 received as the acknowledge bit (ACK reception) 1: 1 received as the acknowledge bit (NACK reception).	R
b3	ACKBT	Transmit Acknowledge	0: Send 0 as the acknowledge bit (ACK transmission) 1: Send 1 as the acknowledge bit (NACK transmission).	R/W*1
b4	ACKWP	ACKBT Write Protect	0: Write protect ACKBT bit 1: Write enable ACKBT bit.	R/W*1
b5	RDRFS	RDRF Flag Set Timing Select	0: Set the RDRF flag on the rising edge of the ninth SCL clock cycle (no low-hold on the SCLn line on the falling edge of the eighth clock cycle) 1: Set the RDRF flag on the rising edge of the eighth SCL clock cycle (low-hold on the SCLn line low on the falling edge of the eighth clock cycle). Low-hold is released by writing to ACKBT.	R/W*2
b6	WAIT	WAIT	0: No wait (no low-hold between ninth clock cycle and first clock cycle) 1: Wait (low-hold between ninth clock cycle and first clock cycle). Low-hold is released by reading ICDRR.	R/W*2
b7	SMBS	SMBus/IIC-Bus Select	0: Select I^{2}C bus 1: Select SMBus.	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit does not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 36.6, Digital Noise Filter Circuits.

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICϕ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1

- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode.

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected (when a stop condition is detected with the SP bit in ICCR2 set to 1)
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the eighth SCL clock cycle, and the SCLn line is held low on the falling edge of the eighth SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation is continued without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/IIC-Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

36.2.6 I^{2}C Bus Function Enable Register (ICFER)

Address(es): IIC0.ICFER 4005 3005h, IIC1.ICFER 4005 3105h, IIC2.ICFER 4005 3205h

	b7	b6	b5	b4	b3	b2	b1	b0
	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Bit name	Description	R/W
b0	TMOE	Timeout Function Enable	0: Disable 1: Enable.	R/W
b1	MALE	Master Arbitration-Lost Detection Enable	0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost.	R/W
b2	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: Disable 1: Enable.	R/W
b3	SALE	Slave Arbitration-Lost Detection Enable	0: Disable 1: Enable.	R/W
b4	NACKE	NACK Reception Transfer Suspension Enable	0: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1: Suspend transfer operation during NACK reception (enable transfer suspension).	R/W
b5	NFE	Digital Noise Filter Circuit Enable	0: Do not use the digital noise filter circuit 1: Use the digital noise filter circuit.	R/W
b6	SCLE	SCL Synchronous Circuit Enable	0: Do not use the SCL synchronous circuit 1: Use the SCL synchronous circuit.	R/W
b7	FMPE*1	Fast-Mode Plus Enable	0: Do not use the Fm+ slope control circuit for the SCLn and SDAn pins 1: Use the Fm+ slope control circuit for the SCLn and SDAn pins.	R/W

Note 1. The Fast-mode Plus enable bit (FMPE) is supported only by IIC0 (SCL0-A, SDA0-A). Bit [7] is reserved in IIC1 and IIC2.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 36.12.1, Timeout Function.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is

0, the next transfer operation is continued regardless of the received acknowledge content.

For details, see section 36.9.2, NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^{2}C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuance of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I^{2}C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I^{2}C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

36.2.7 I^{2}C Bus Status Enable Register (ICSER)

Address(es): IIC0.ICSER 4005 3006h, IIC1.ICSER 4005 3106h, IIC2.ICSER 4005 3206h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Bit name	Description	R/W
b0	SAR0E	Slave Address Register 0 Enable	0: Disable slave address in SARL0 and SARU0 1: Enable slave address in SARL0 and SARU0.	R/W
b1	SAR1E	Slave Address Register 1 Enable	0: Disable slave address in SARL1 and SARU1 1: Enable slave address in SARL1 and SARU1.	R/W
b2	SAR2E	Slave Address Register 2 Enable	0: Disable slave address in SARL2 and SARU2 1: Enable slave address in SARL2 and SARU2.	R/W
b3	GCAE	General Call Address Enable	0: Disable general call address detection 1: Enable general call address detection.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DIDE	Device-ID Address Detection Enable	0: Disable device-ID address detection 1: Enable device-ID address detection.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOAE	Host Address Enable	0: Disable host address detection 1: Enable host address detection.	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 36.7.3, Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

36.2.8 I^{2}C Bus Interface Enable Register (ICIER)

Address(es): IIC0.ICIER 4005 3007h, IIC1.ICIER 4005 3107h, IIC2.ICIER 4005 3207h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	TMOIE	Timeout Interrupt Request Enable	0: Disable timeout interrupt (TMOI) request 1: Enable timeout interrupt (TMOI) request.	R/W
b1	ALIE	Arbitration-Lost Interrupt Request Enable	0: Disable arbitration-lost interrupt (ALI) request 1: Enable arbitration-lost interrupt (ALI) request.	R/W
b2	STIE	Start Condition Detection Interrupt Request Enable	0: Disable start condition detection interrupt (STI) request 1: Enable start condition detection interrupt (STI) request.	R/W
b3	SPIE	Stop Condition Detection Interrupt Request Enable	0: Disable stop condition detection interrupt (SPI) request 1: Enable stop condition detection interrupt (SPI) request.	R/W
b4	NAKIE	NACK Reception Interrupt Request Enable	0: Disable NACK reception interrupt (NAKI) request 1: Enable NACK reception interrupt (NAKI) request.	R/W
b5	RIE	Receive Data Full Interrupt Request Enable	0: Disable receive data full interrupt (IICn_RXI) request 1: Enable receive data full interrupt (IICn_RXI) request.	R/W
b6	TEIE	Transmit End Interrupt Request Enable	0: Disable transmit end interrupt (IICn_TEI) request 1: Enable transmit end interrupt (IICn_TEI) request.	R/W
b7	TIE	Transmit Data Empty Interrupt Request Enable	0: Disable transmit data empty interrupt (IICn_TXI) request 1: Enable transmit data empty interrupt (IICn_TXI) request.	R/W

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

36.2.9 I^{2}C Bus Status Register 1 (ICSR1)

Address(es): IIC0.ICSR1 4005 3008h, IIC1.ICSR1 4005 3108h, IIC2.ICSR1 4005 3208h

	b7	b6	b5	b4	b3	b2	b1	b0
	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 not detected 1: Slave address 0 detected.	R/(W) *1
b1	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 not detected 1: Slave address 1 detected.	R/(W) *1
b2	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 not detected 1: Slave address 2 detected.	R/(W) *1
b3	GCA	General Call Address Detection Flag	0: General call address not detected 1: General call address detected.	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DID	Device-ID Address Detection Flag	0: Device-ID command not detected 1: Device-ID command detected. This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]).	R/(W) *1

Bit	Symbol	Bit name	Description	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	HOA	Host Address Detection Flag	0: Host address not detected 1: Host address detected. This bit is set to 1 when the received slave address matches the host address (0001 000b).	R/(W) *1

Note 1. Only 0 can be written, to clear the flag.

AASy flag (Slave Address y Detection Flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled)

The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)
  The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

36.2.10 I^{2}C Bus Status Register 2 (ICSR2)

Address(es): IIC0.ICSR2 4005 3009h, IIC1.ICSR2 4005 3109h, IIC2.ICSR2 4005 3209h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	TMOF	Timeout Detection Flag	0: Timeout not detected 1: Timeout detected.	R/(W) *1

Bit	Symbol	Bit name	Description	R/W
b1	AL	Arbitration-Lost Flag	0: Arbitration not lost 1: Arbitration lost.	R/(W) *1
b2	START	Start Condition Detection Flag	0: Start condition not detected 1: Start condition detected.	R/(W) *1
b3	STOP	Stop Condition Detection Flag	0: Stop condition not detected 1: Stop condition detected.	R/(W) *1
b4	NACKF	NACK Detection Flag	0: NACK not detected 1: NACK detected.	R/(W) *1
b5	RDRF	Receive Data Full Flag	0: ICDRR contains no receive data 1: ICDRR contains receive data.	R/(W) *1
b6	TEND	Transmit End Flag	0: Data being transmitted 1: Data transmit complete.	R/(W) *1
b7	TDRE	Transmit Data Empty Flag	0: ICDRT contains transmit data 1: ICDRT contains no transmit data.	R

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the flag to indicate the detection of arbitration loss during NACK transmission in master mode or during data transmission in slave mode.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Table 36.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions

ICFER			ICSR2		
MALE	**NALE**	**SALE**	**AL**	**Error**	**Arbitration-lost generation source**
1	×	×	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

×: Don't care

START flag (Start Condition Detection Flag)

The START flag indicates whether a start condition was detected.

[Setting condition]

- When a start (or restart) condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the IDCRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
  The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start (or restart) condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TEND flag (Transmit End Flag)

The TEND flag indicates whether data transmission is still being transmitted or is complete.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. Here, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the ninth clock cycle, but the TDRE flag does not set to 1.

36.2.11 I^{2}C Bus Wakeup Unit Register (ICWUR)

Address(es): IIC0.ICWUR 4005 3016h

	b7	b6	b5	b4	b3	b2	b1	b0
	WUE	WUIE	WUF	WUACK	—	—	—	WUAFA
Value after reset:	0	0	0	1	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	WUAFA	Wakeup Analog Filter Additional Selection	0: Do not add the wakeup analog filter 1: Add the wakeup analog filter.	R/W
b3 to b1	—	Reserved	These bit are read as 0. The write value should be 0.	R/W
b4	WUACK	ACK Bit for Wakeup Mode	Choice of four response modes in combination with ICCR1.IICRST and WUACK. See Table 36.5.	R/W
b5	WUF	Wakeup Event Occurrence Flag	0: Slave address not matching during wakeup 1: Slave address matching during wakeup.	R/W
b6	WUIE	Wakeup Interrupt Request Enable	0: Disable wakeup interrupt request (IIC0_WUI) 1: Enable wakeup interrupt request (IIC0_WUI).	R/W
b7	WUE	Wakeup Function Enable	0: Disable wakeup function 1: Enable wakeup function.	R/W

Table 36.5 Wakeup mode

IICRST	WUACK	Operation mode	Description
0	0	Normal wakeup mode 1	ACK response on ninth SCL, and SCL low-hold after ninth SCL.
0	1	Normal wakeup mode 2	No ACK response immediately and SCL low-hold between eight and ninth SCL. SCL low-hold release and ACK response on ninth SCL.
1	0	Command recovery mode	ACK response on ninth SCL and no SCL low-hold.
1	1	EEP response mode	NACK response on ninth SCL and no SCL low-hold.

WUF flag (Wakeup Event Occurrence Flag)

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after a slave-address match in the first eighth SCL low during wakeup mode.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1
- When ICE = 0 and IICRST = 1.

36.2.12 I2C Bus Wakeup Unit Register 2 (ICWUR2)

Address(es): IIC0.ICWUR2 4005 3017h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	WUSYF	WUASYF	WUSEN
Value after reset:	1	1	1	1	1	1	0	1

Bit	Symbol	Bit name	Description	R/W
b0	WUSEN	Wakeup Function Synchronous Enable	0: IIC asynchronous circuit enable 1: IIC synchronous circuit enable.	R/W
b1	WUASYF	Wakeup Function Asynchronous Operation Status Flag	0: IIC synchronous circuit enable condition 1: IIC asynchronous circuit enable condition.	R
b2	WUSYF	Wakeup Function Synchronous Operation Status Flag	0: IIC asynchronous circuit enable condition 1: IIC synchronous circuit enable condition.	R
b7 to b3	—	Reserved	These bits are read as1. The write value should be 1.	R/W

WUSEN bit (Wakeup Function Synchronous Enable)

It combines with the WUASYF flag (or WUSYF flag) at wakeup effective function (ICWUR.WUE = 1), and the PCLKB synchronous operation and the PCLKB asynchronous operation are switched.

[When switching from the PCLKB synchronous operation to the PCLKB asynchronous operation]

It changes into the PCLKB asynchronous operation when the ICCR2.BBSY flag is 0 if the WUASYF flag writes 0 in the WUSEN bit in the state of 0. The reception can operate without depending on the state of operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation (wakeup event detection operation).

[When switching from the PCLKB asynchronous operation to the PCLKB synchronous operation]

It changes into the PCLKB synchronization and the WUASYF flag becomes 0 at once after writing of 1 when the wakeup event is detected if 1 is written in the WUSEN bit when the WUASYF flag is 1. At the same time, WUASYF flag becomes 0. In other case, it changes into the PCLKB synchronous operation when the stop condition is detected at the wakeup event undetected.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

It is shown that IIC is in the PCLKB asynchronous operation at wakeup effective function (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wakeup event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wakeup event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wakeup event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wakeup effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wakeup event with ICWUR.WUE bit set to 1 with WUSYF flag cleared to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wakeup event with WUSYF flag cleared to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

36.2.13 Slave Address Register L y (SARLy) (y = 0 to 2)

Address(es): IIC0.SARL0 4005 300Ah, IIC1.SARL0 4005 310Ah, IIC2.SARL0 4005 320Ah,
IIC0.SARL1 4005 300Ch, IIC1.SARL1 4005 310Ch, IIC2.SARL1 4005 320Ch,
IIC0.SARL2 4005 300Eh, IIC1.SARL2 4005 310Eh, IIC2.SARL2 4005 320Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	SVA[6:0]							SVA0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SVA0	10-Bit Address LSB	Slave address setting.	R/W
b7 to b1	SVA[6:0]	7-Bit Address/10-Bit Address Lower Bits	Slave address setting.	R/W

SVA0 bit (10-Bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

36.2.14 Slave Address Register U y (SARUy) (y = 0 to 2)

Address(es): IIC0.SARU0 4005 300Bh, IIC1.SARU0 4005 310Bh, IIC2.SARU0 4005 320Bh,
IIC0.SARU1 4005 300Dh, IIC1.SARU1 4005 310Dh, IIC2.SARU1 4005 320Dh,
IIC0.SARU2 4005 300Fh, IIC1.SARU2 4005 310Fh, IIC2.SARU2 4005 320Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	FS	7-Bit/10-Bit Address Format Select	0: Select 7-bit address format 1: Select 10-bit address format.	R/W

Bit	Symbol	Bit name	Description	R/W
b2, b1	SVA[1:0]	10-Bit Address Upper Bits	Slave address setting.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FS bit (7-Bit/10-Bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-Bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

36.2.15 I^{2}C Bus Bit Rate Low-Level Register (ICBRL)

Address(es): IIC0.ICBRL 4005 3010h, IIC1.ICBRL 4005 3110h, IIC2.ICBRL 4005 3210h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b4 to b0	BRL[4:0]	Bit Rate Low-Level Period	Low-level period of SCL clock.	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRL is a 5-bit register that sets the low-level period of the SCL clock. ICBRL also works to generate the data setup time for the automatic SCL low-hold operation (see section 36.9, Automatic Low-Hold Function for SCL). When the IIC is used only in slave mode, this register must be set to a value longer than the data setup time.*1 ICBRL counts the low-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1. If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns for up to 100 kbps: Standard-mode (Sm)
100 ns for up to 400 kbps: Fast-mode (Fm)
50 ns for up to 1 Mbps: Fast-mode plus (Fm+)

36.2.16 I^{2}C Bus Bit Rate High-Level Register (ICBRH)

Address(es): IIC0.ICBRH 4005 3011h, IIC1.ICBRH 4005 3111h, IIC2.ICBRH 4005 3211h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b4 to b0	BRH[4:0]	Bit Rate High-Level Period	High-level period of SCL clock.	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRH is a 5-bit register that sets the high-level period of the SCL clock. ICBRH is valid in master mode. If the IIC is used only in slave mode, no setting is required in this register. ICBRH counts the high-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1. If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = $1/\{[(BRH + 1) + (BRL + 1)]/IIC\varphi^{*1} + tr^{*2} + tf^{*2}\}$
   Duty cycle = $\{tr + [(BRH + 1)/IIC\varphi]\}/\{tr + tf + [(BRH + 1) + (BRL + 1)]/IIC\varphi\}$
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = $1/\{[(BRH + 3) + (BRL+ 3)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 3)/IIC\varphi]\}/\{tr + tf + [(BRH + 3) + (BRL + 3)]/IIC\varphi\}$
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = $1/\{[(BRH + 3 + nf^{*3}) + (BRL + 3 + nf)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 3 + nf)/IIC\varphi]\}/\{tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)]/IIC\varphi\}$
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = $1/\{[(BRH + 2) + (BRL + 2)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 2)/IIC\varphi]\}/\{tr + tf + [(BRH + 2) + (BRL + 2)]/IIC\varphi\}$
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = $1/\{[(BRH + 2 + nf) + (BRL + 2 + nf)]/IIC\varphi + tr + tf\}$
   Duty cycle = $\{tr + [(BRH + 2 + nf)/IIC\varphi]\}/\{tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)]/IIC\varphi\}$

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I^{2}C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

Table 36.6 Example of ICBRH/ICBRL settings for transfer rate when SCLE = 0

Transfer rate (kbps)	CKS[2:0]	BRH[4:0](ICBRH)	BRL[4:0](ICBRL)	PCLKB (MHz)	NF[1:0]	Computation expression
100	100b	14 (EEh)	17 (F1h)	60	—	(1)
400	010b	8 (E8h)	19 (F3h)	60	—	(1)
1000	000b	15 (EFh)	29 (FDh)	60	—	(1)

100	100b	11 (EBh)	14 (EEh)	60	01b	(5)
400	010b	5 (E5h)	16 (F0h)	60	01b	(5)
1000	000b	11 (EBh)	25 (F9h)	60	01b	(3)

36.2.17 I^{2}C Bus Transmit Data Register (ICDRT)

Address(es): IIC0.ICDRT 4005 3012h, IIC1.ICDRT 4005 3112h, IIC2.ICDRT 4005 3212h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the IIC-Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

36.2.18 I^{2}C Bus Receive Data Register (ICDRR)

Address(es): IIC0.ICDRR 4005 3013h, IIC1.ICDRR 4005 3113h, IIC2.ICDRR 4005 3213h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the IIC-Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

36.2.19 I²C Bus Shift Register (ICDRS)

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

36.3 Operation

36.3.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 36.3 shows the I²C bus format, and Figure 36.4 shows the I²C bus timing.

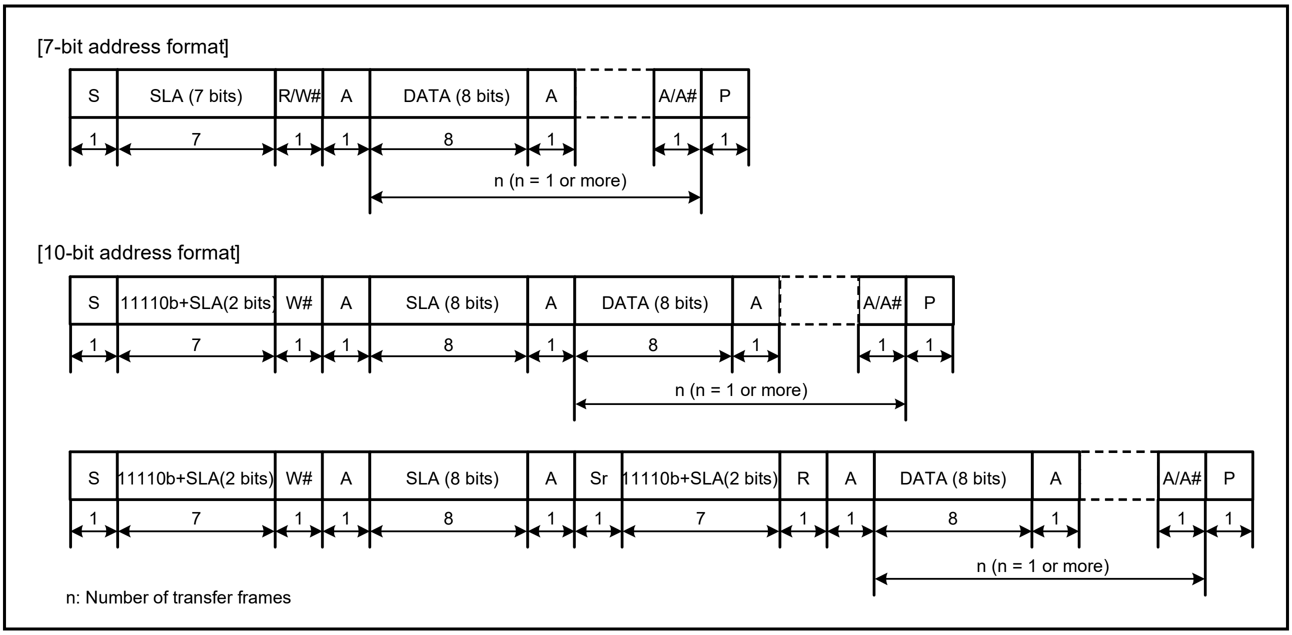

Figure 36.3 I²C bus format

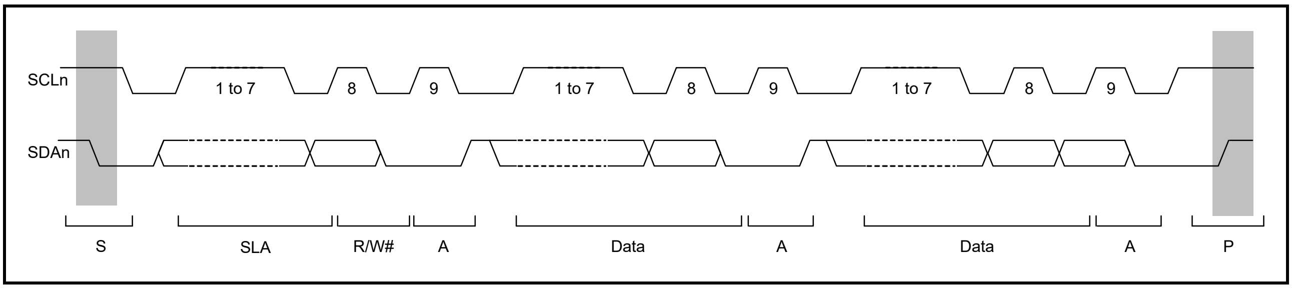

Figure 36.4 I²C bus timing when the SLA setting = 7 bits

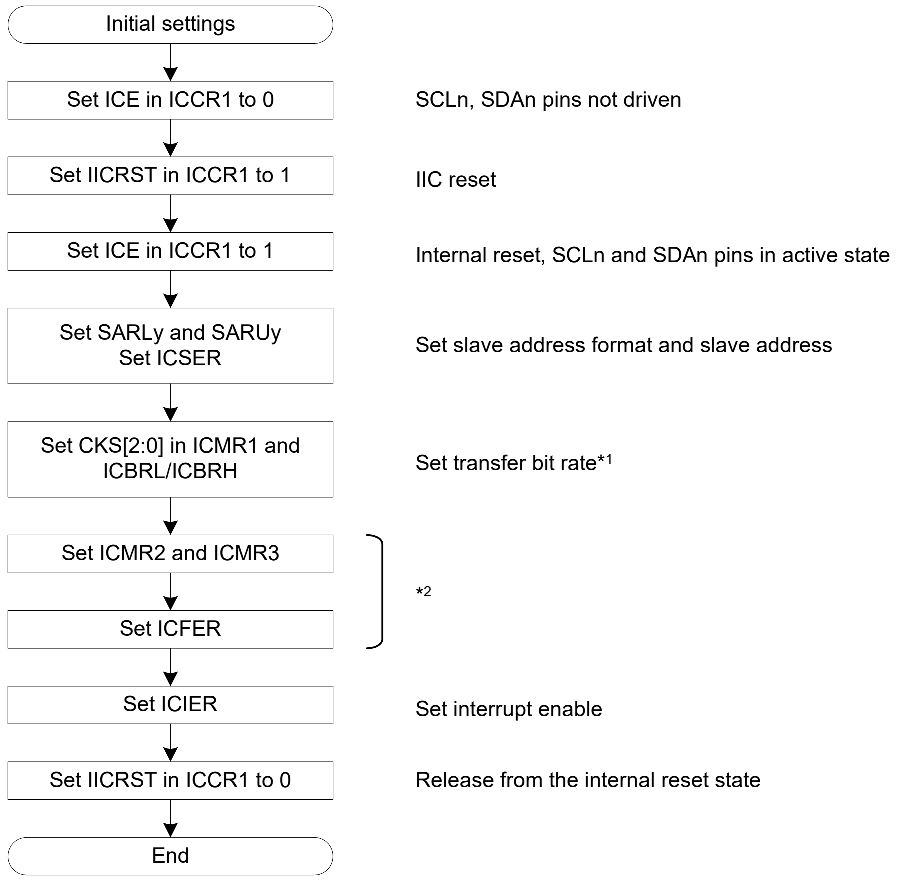
S: Start condition. The master device drives the SDAn line low from high while the SCLn line is high.

SLA: Slave address, by which the master device selects a slave device.

R/W#:	Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.
A:	Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
A#:	Not Acknowledge. The receive device drives the SDAn line high.
Sr:	Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
DATA:	Transmitted or received data.
P:	Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

36.3.2 Initial Settings

Before starting data transmission and reception, initialize the IIC using the procedure shown in Figure 36.5. Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (IIC reset) with the ICCR1.ICE bit set to 0 (SCLn and SDAn pins in inactive state). This internal reset procedure initializes the flags and the internal state of the ICSR1 register. Next, set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required (for the initial IIC settings, see Figure 36.5). When the required register settings are complete, set the ICCR1.IICRST bit to 0, releasing the IIC reset. This step is not necessary if initialization of the IIC is already complete.



y = 0 to 2

Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.

Note 2. Set these registers as required.

Figure 36.5 Example IIC initialization flow

36.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 36.6 shows an example of master transmission, and Figure 36.7 to Figure 36.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. For details on issuing a stop condition, see section 36.11.3, Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

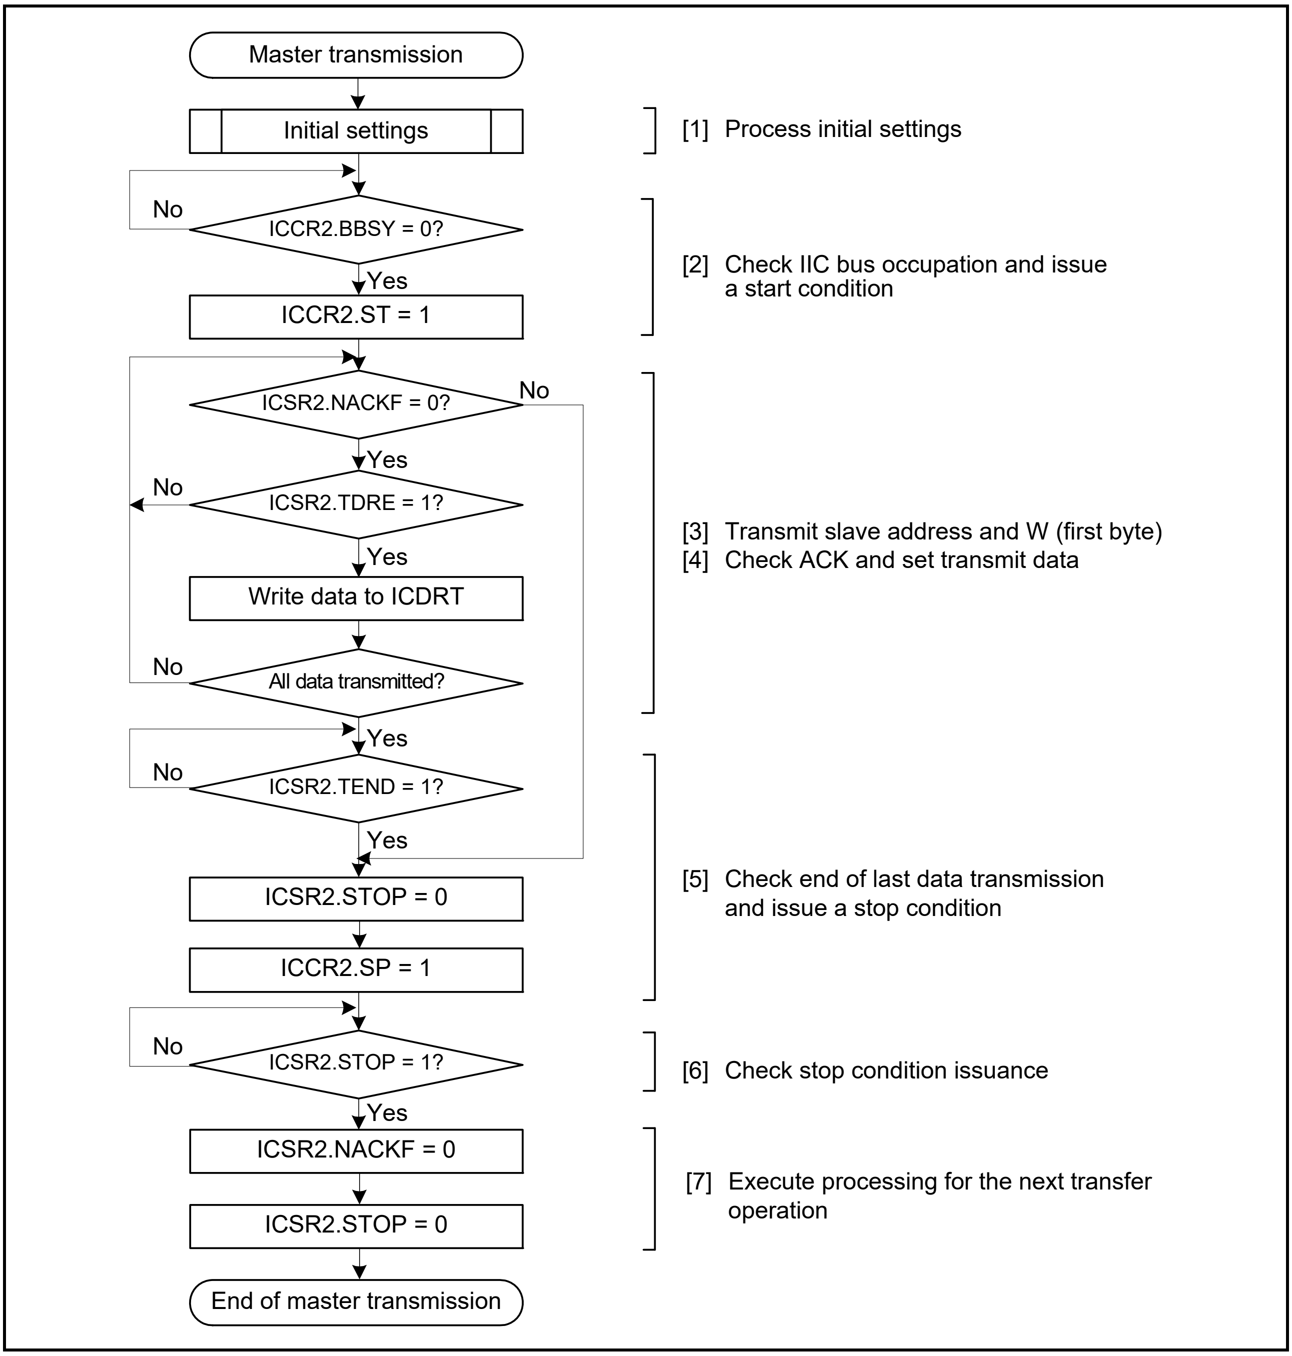


Figure 36.6 Example master transmission flow

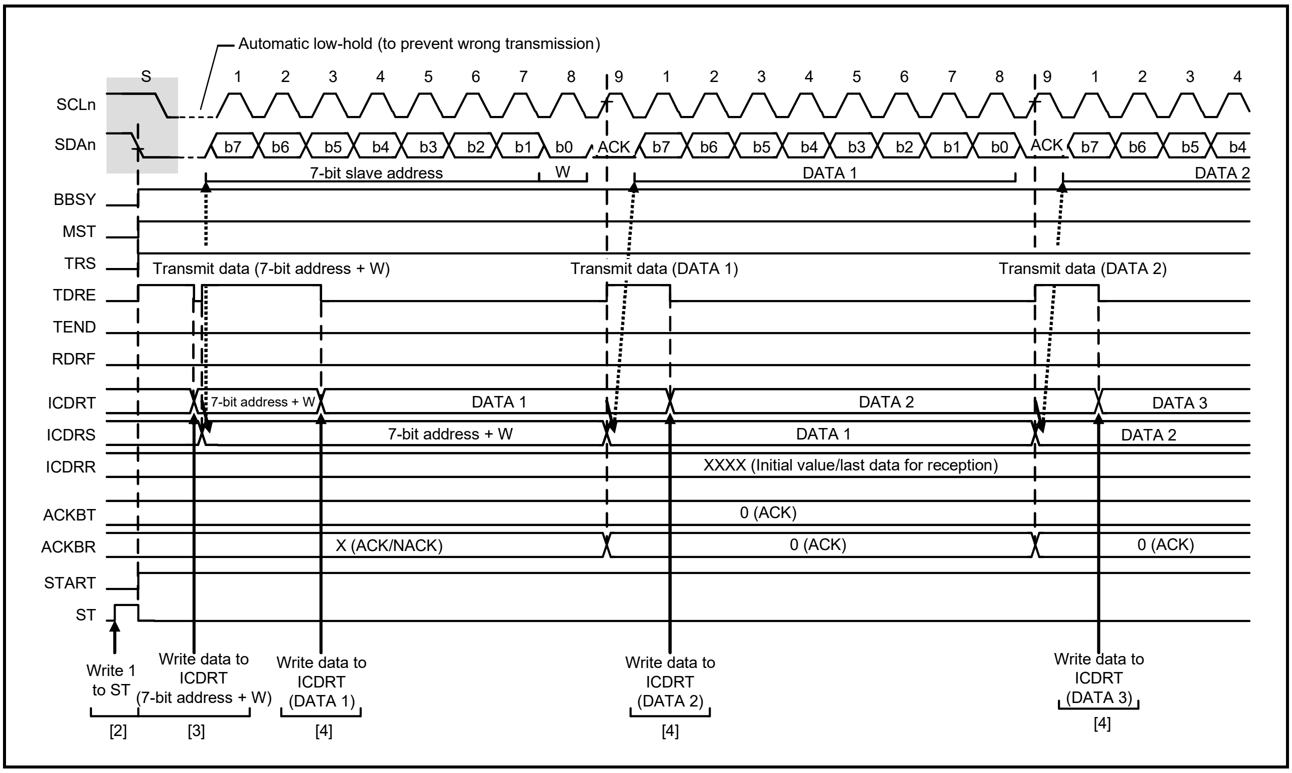

Figure 36.7 Master transmit operation timing (1) with 7-bit address format

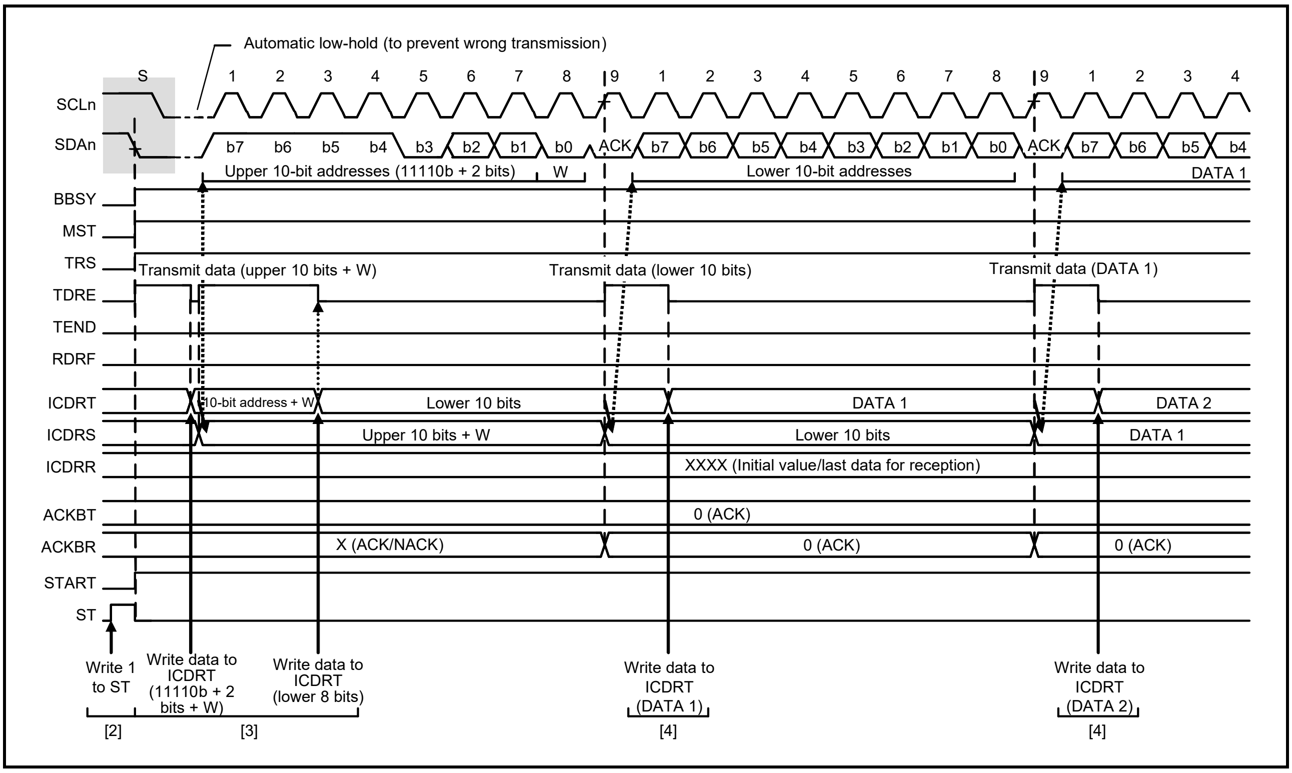

Figure 36.8 Master transmit operation timing (2) with 10-bit address format

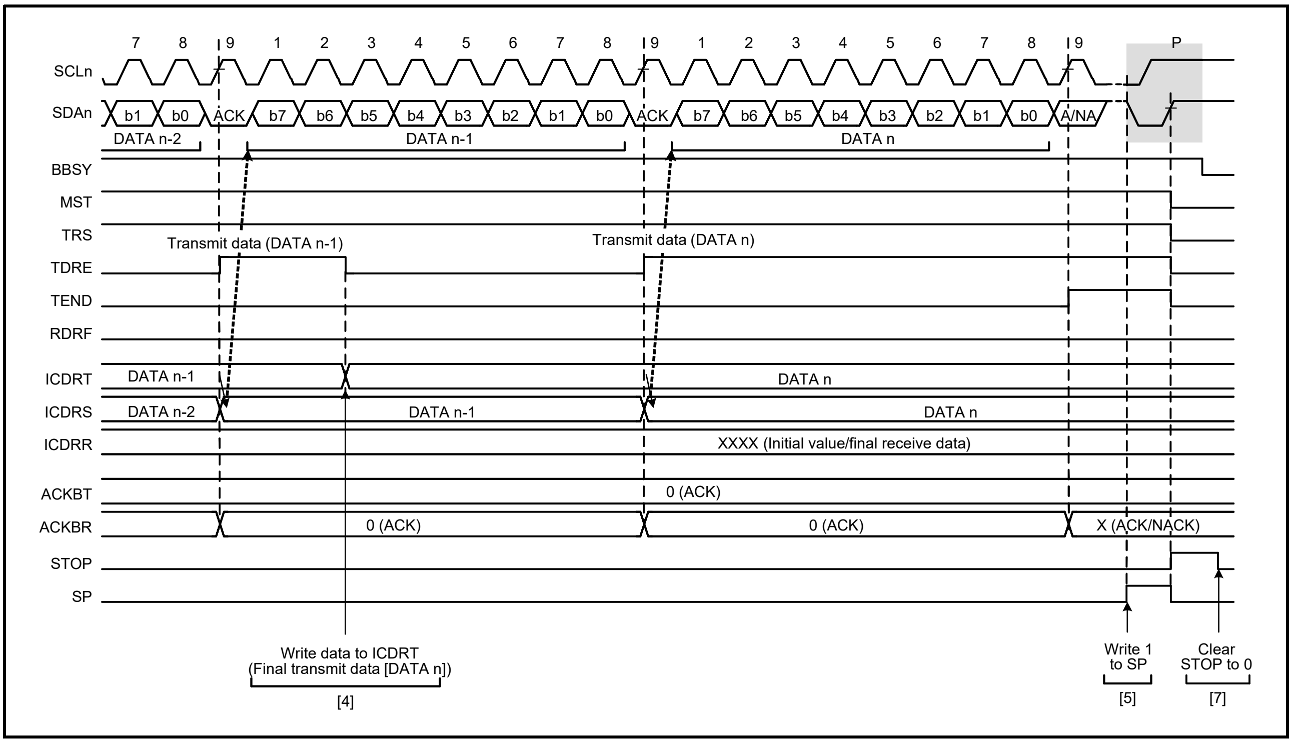

Figure 36.9 Master transmit operation timing (3)

36.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 36.10 and Figure 36.11 show examples of master reception (7-bit address format), and Figure 36.12 to Figure 36.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL

clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the eighth or ninth cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag automatically is set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1, for wait insertion, before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

36.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 36.15 shows an example of slave transmission, and Figure 36.16 and Figure 36.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
   After the initial settings, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit that was also received at this time is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TEND flag is 1, and then write the transmit data to the ICDRT register. At this time, if the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

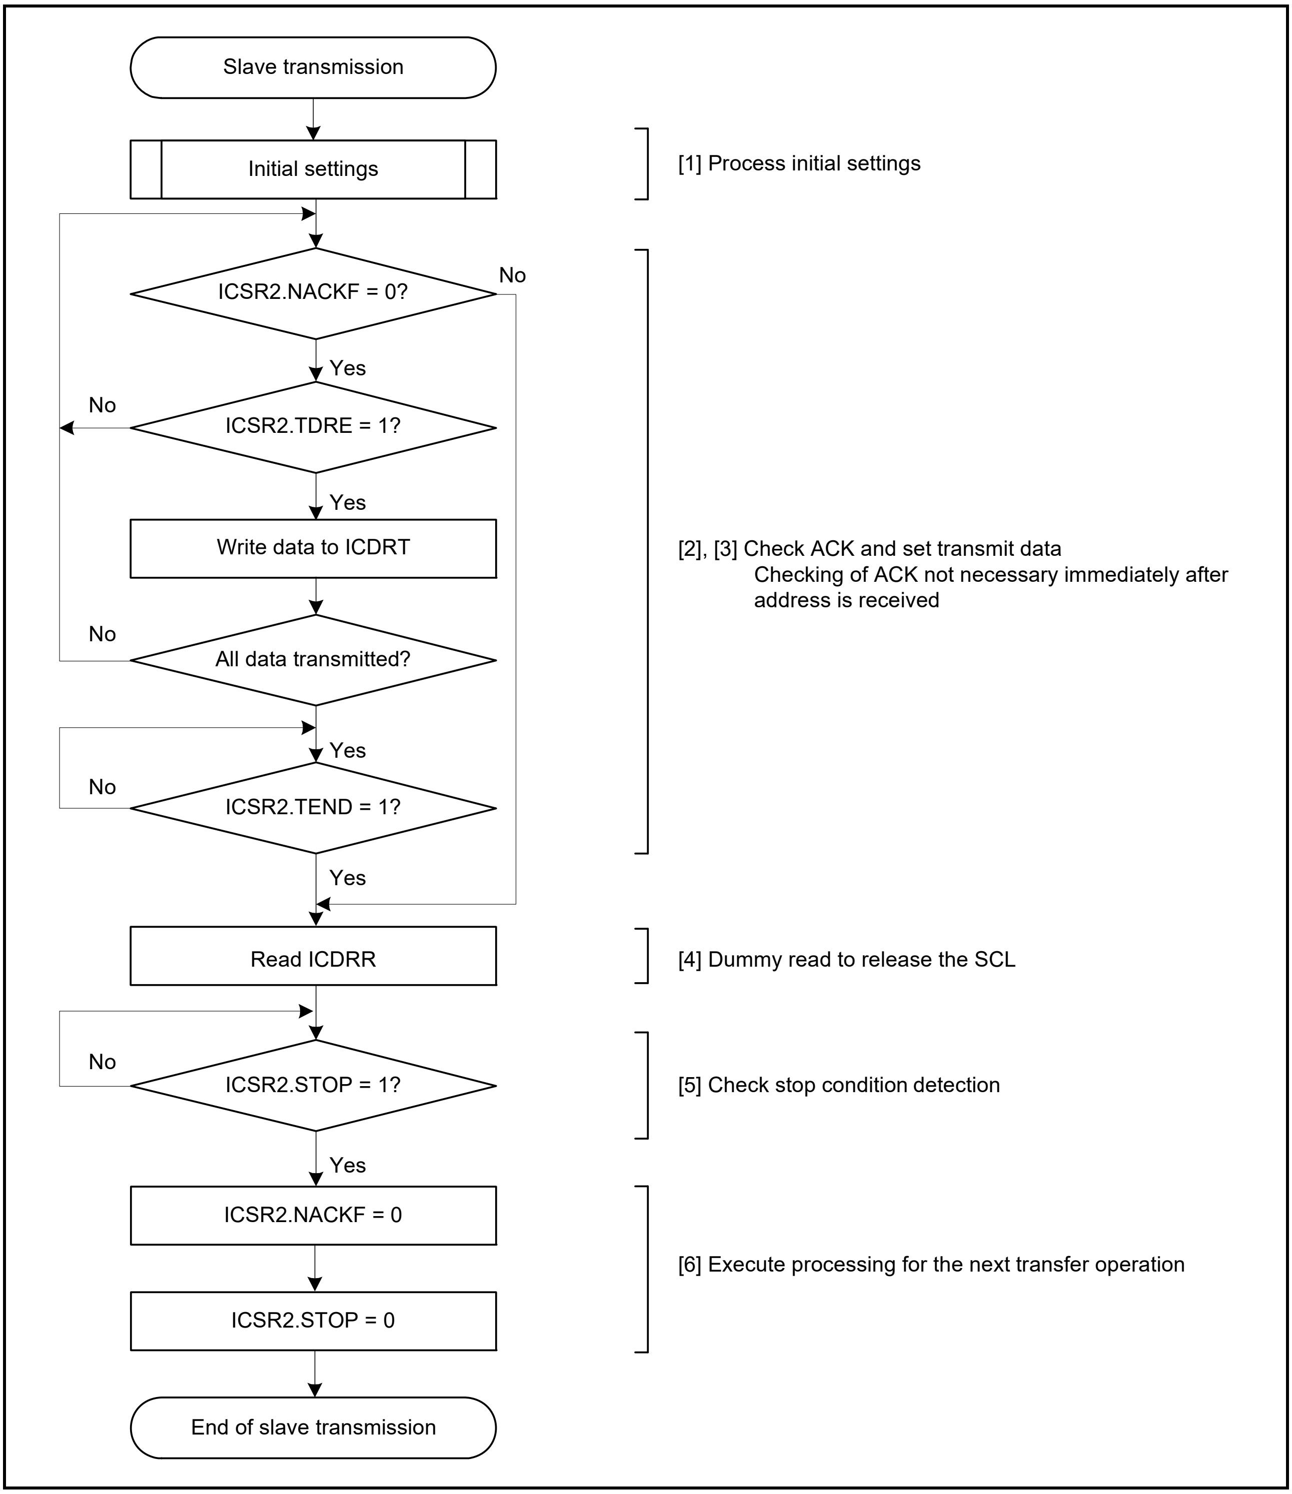

Figure 36.15 Example slave transmission flow

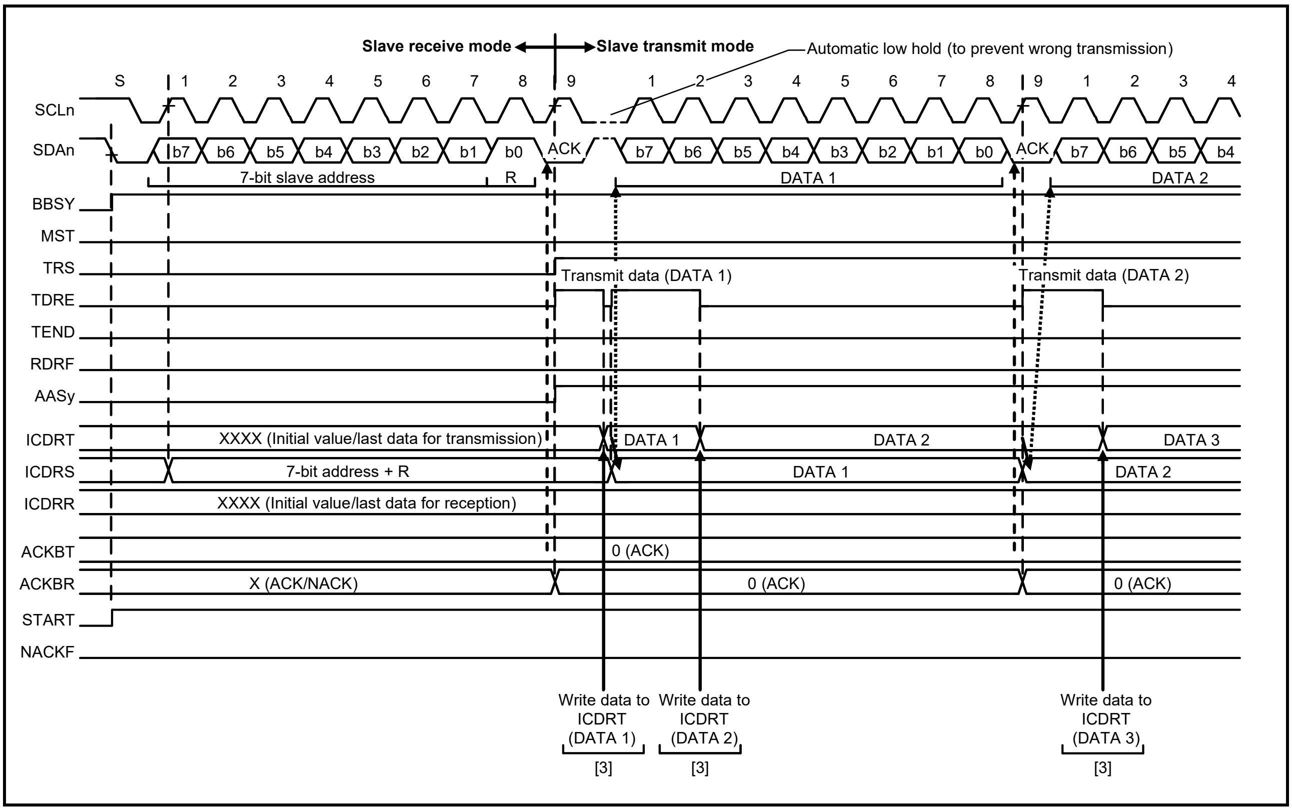

Figure 36.16 Slave transmit operation timing (1) with 7-bit address format

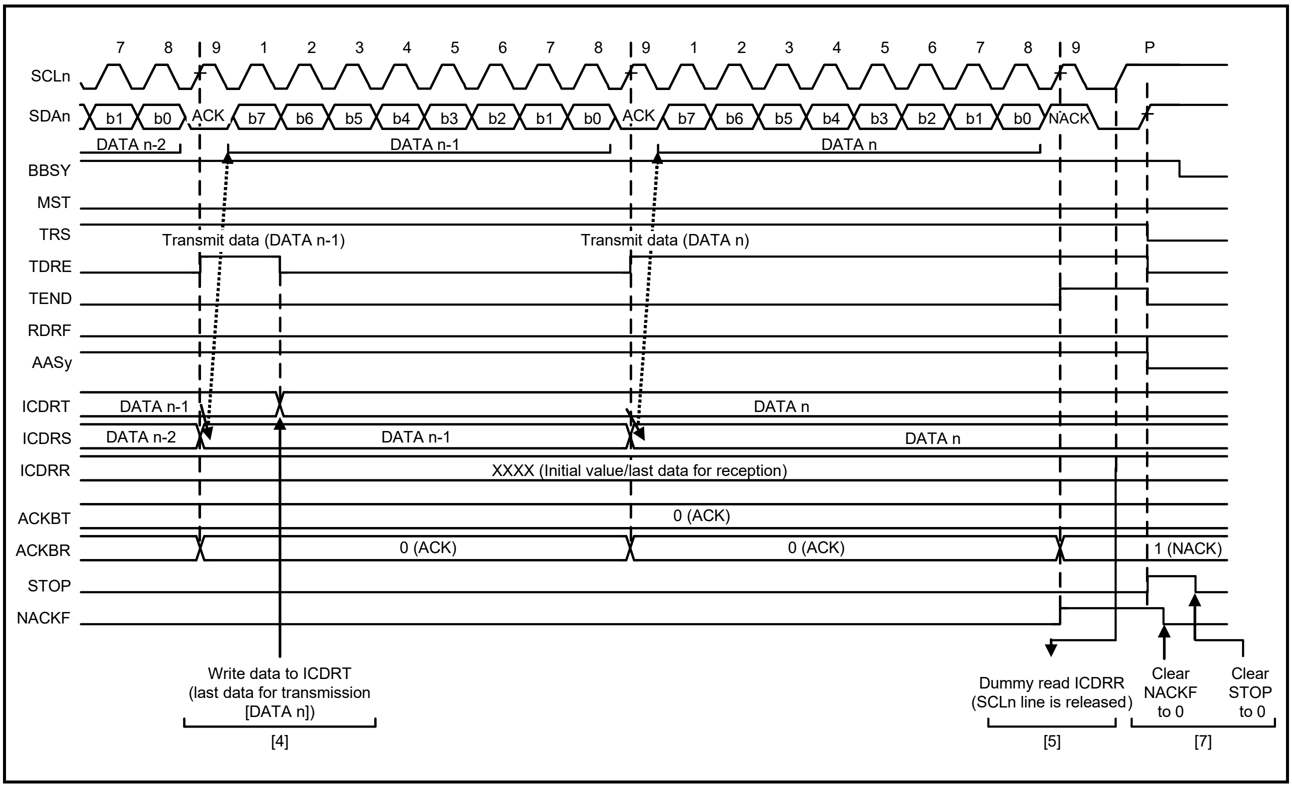

Figure 36.17 Slave transmit operation timing (2)

36.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 36.18 shows an example of slave reception, and Figure 36.19 and Figure 36.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Process initial settings. For details, see section 36.3.2, Initial Settings.
   After the initial settings, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit that was also received at this time is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, and then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until one SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held at the low level.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.STOP flag to 0 for the next transfer operation.

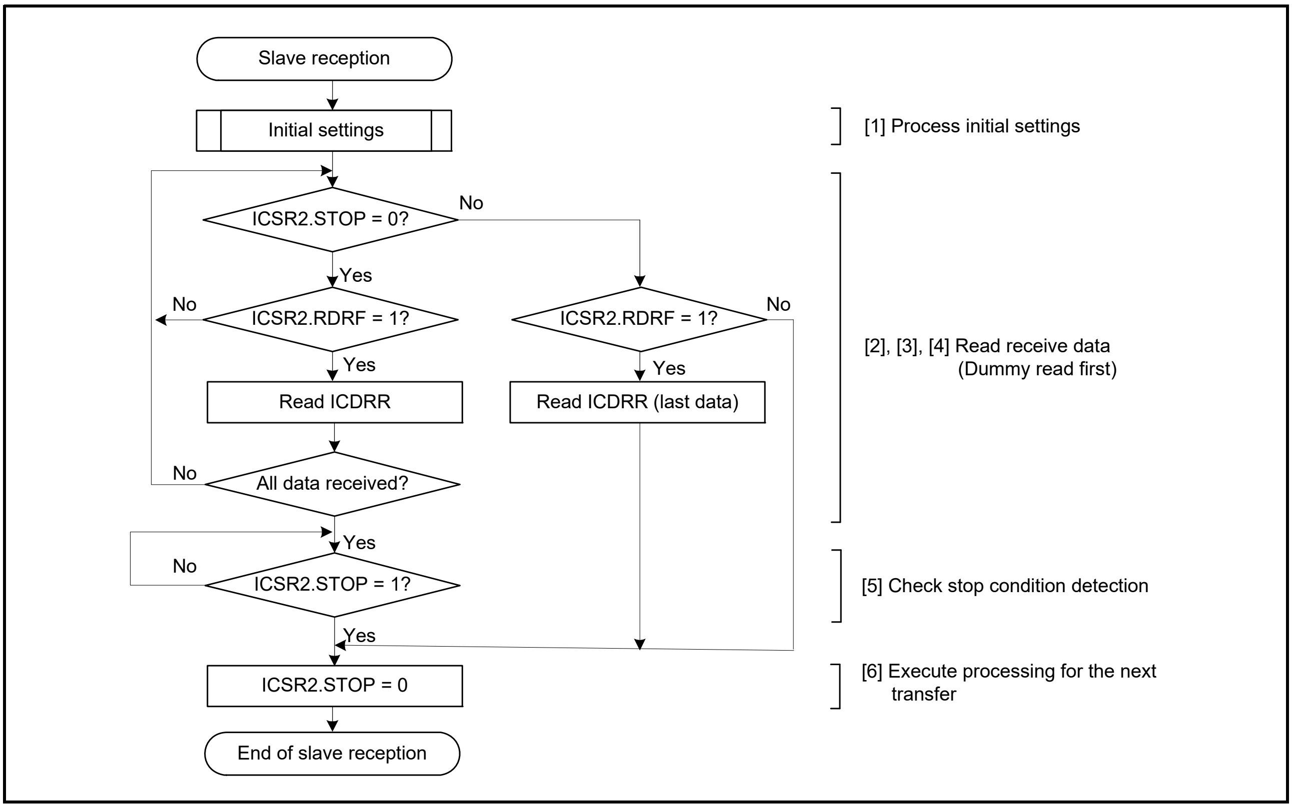

Figure 36.18 Example slave reception flow

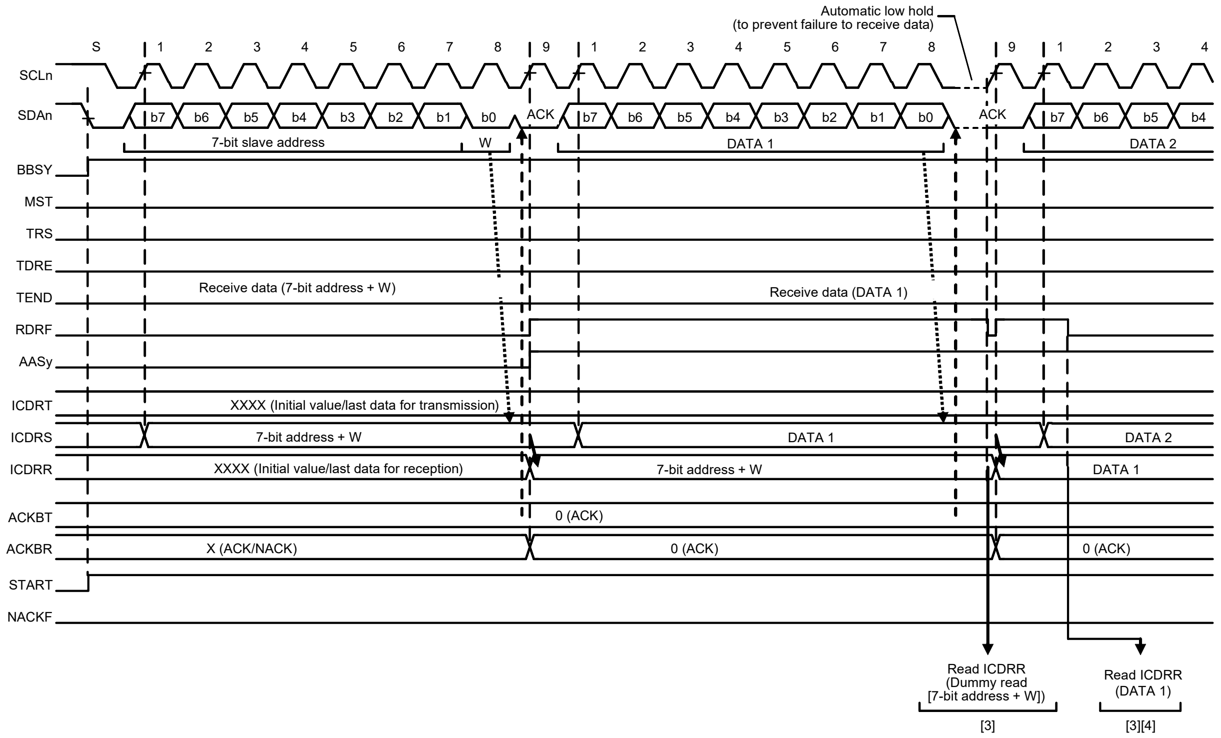

Figure 36.19 Slave receive operation timing (1) with 7-bit address format, when RDRFS = 0

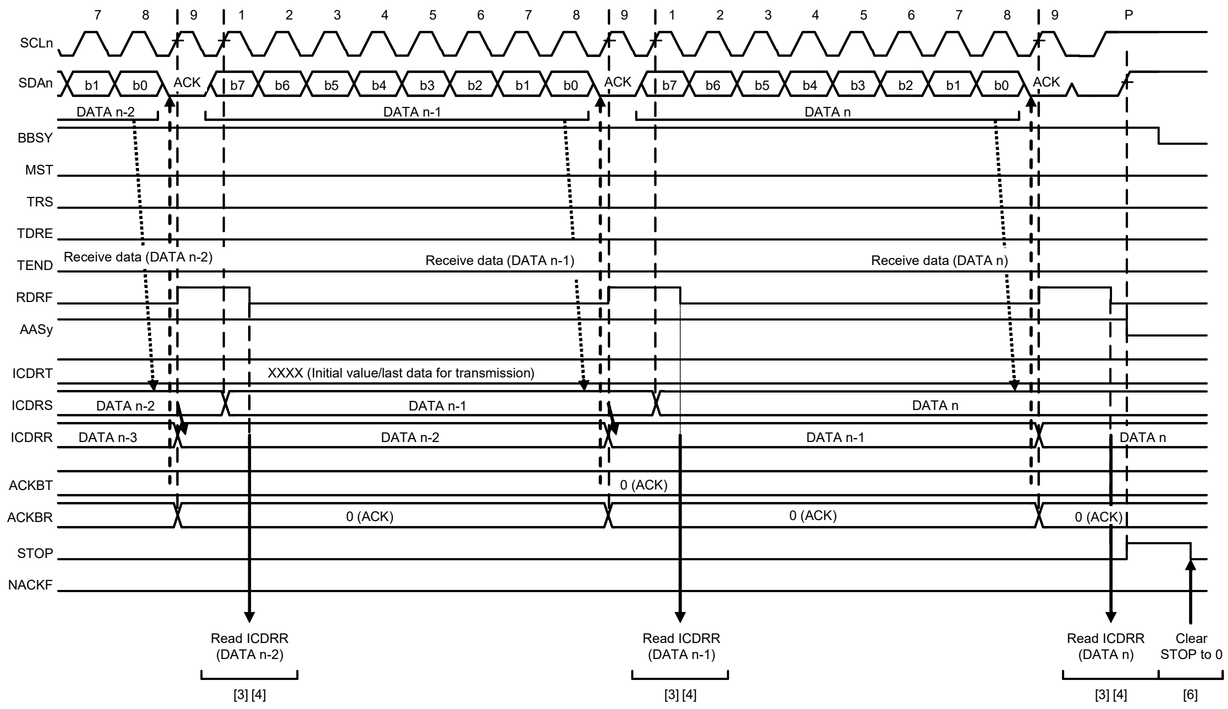

Figure 36.20 Slave receive operation timing (2) when RDRFS = 0

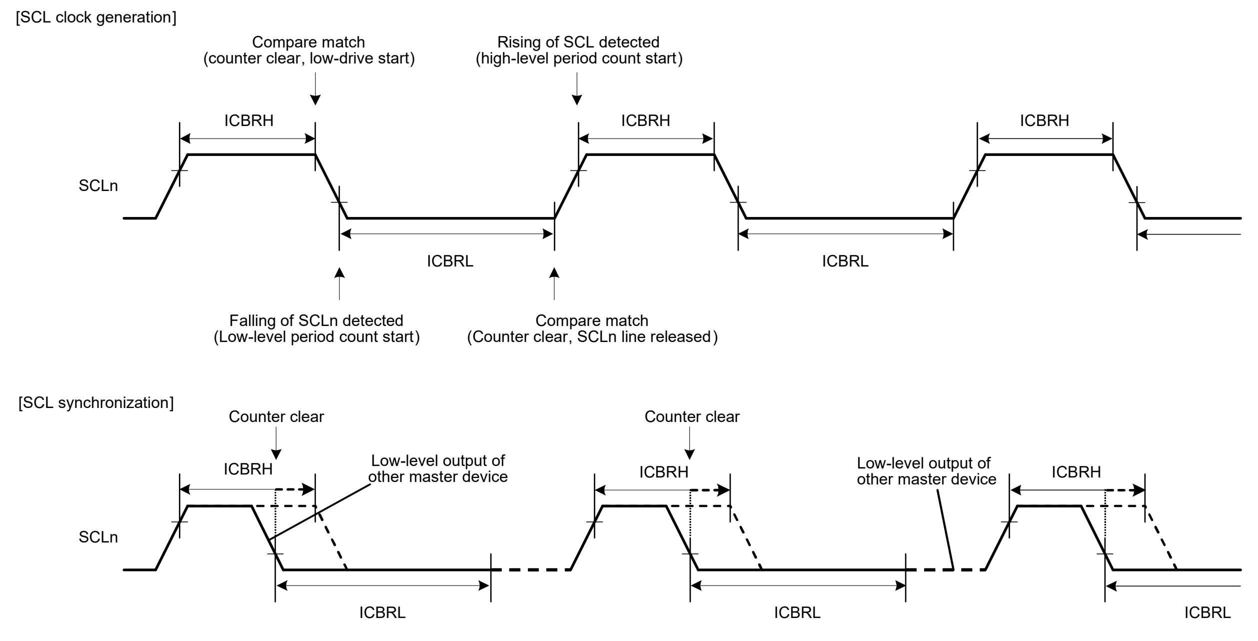
36.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit by bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and so starts counting out the high-level period specified in ICBRH, and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting the low-level period specified in ICBRL. When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. At this time, if the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device has ended, the SCL signal rises because the SCLn line was released. When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. This synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.



ICBRH: IIC-Bus Bit Rate High-Level Register (SCL clock high-level period counter)
ICBRL: IIC-Bus Bit Rate Low-Level Register (SCL clock low-level period counter)

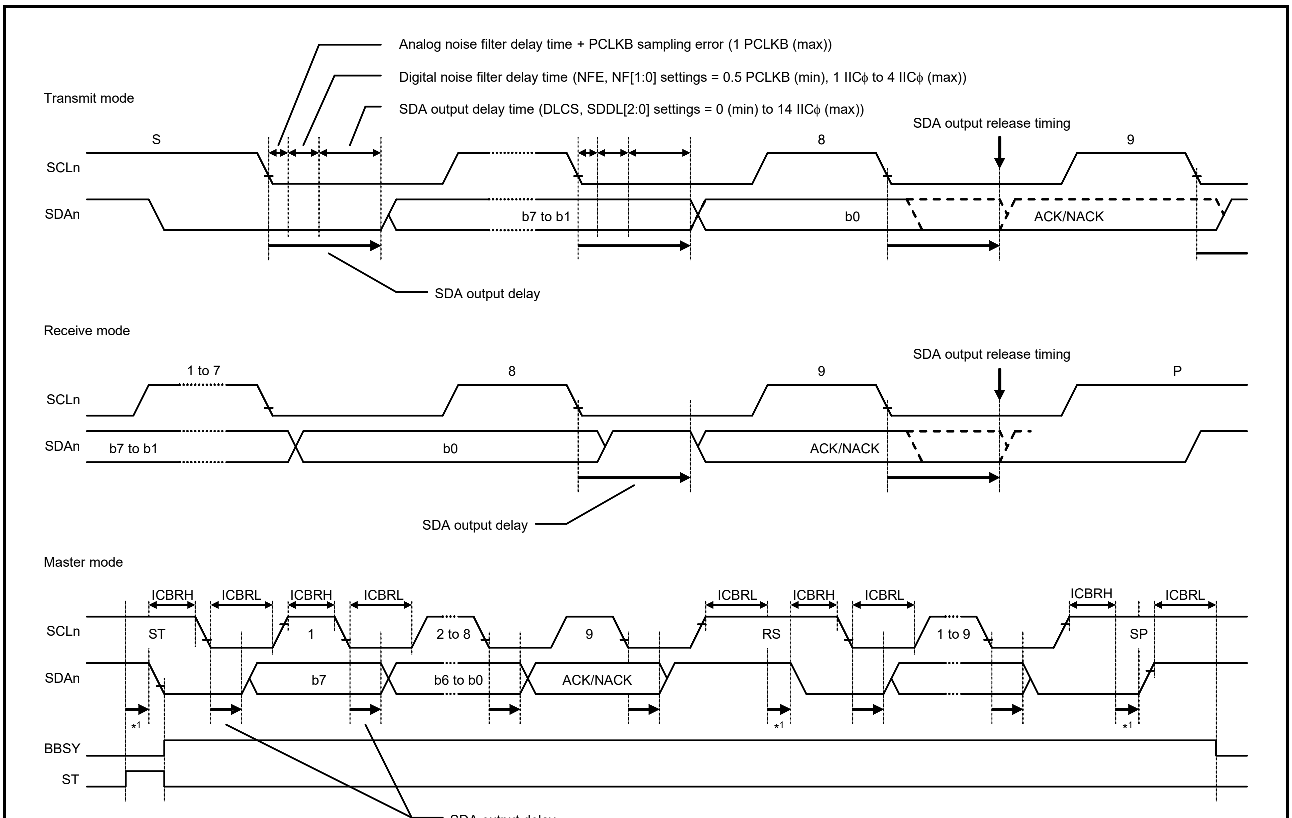
Figure 36.21 Generation and synchronization of SCL signal from IIC

36.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay function is enabled, for example, while the SDDL[2:0] bits in ICMR2 are set to any value other than 000b, the DLCS bit in ICMR2 selects the clock source for counting by the SDA output delay counter either as the internal base clock (IICϕ) for the IIC module or as the internal base clock divided by 2 (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. After the delay cycles count is complete, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 36.22 SDA output delay function

36.6 Digital Noise Filter Circuits

The states of the SCLn and SDAn pins are conveyed to the internal circuitry through analog and digital noise-filter circuits. Figure 36.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit, by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

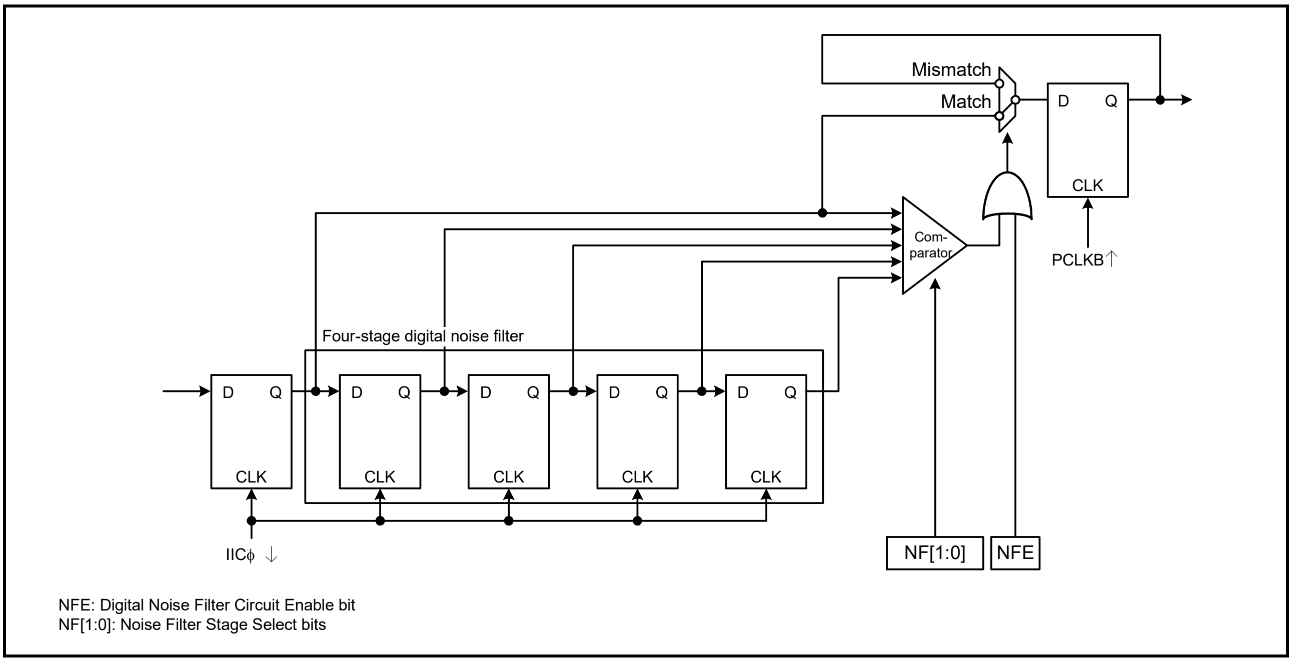


Figure 36.23 Digital noise filter circuit block diagram

36.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7- or 10-bit slave addresses.

36.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 36.24 to Figure 36.26 show the AASy flag set timing in three cases.

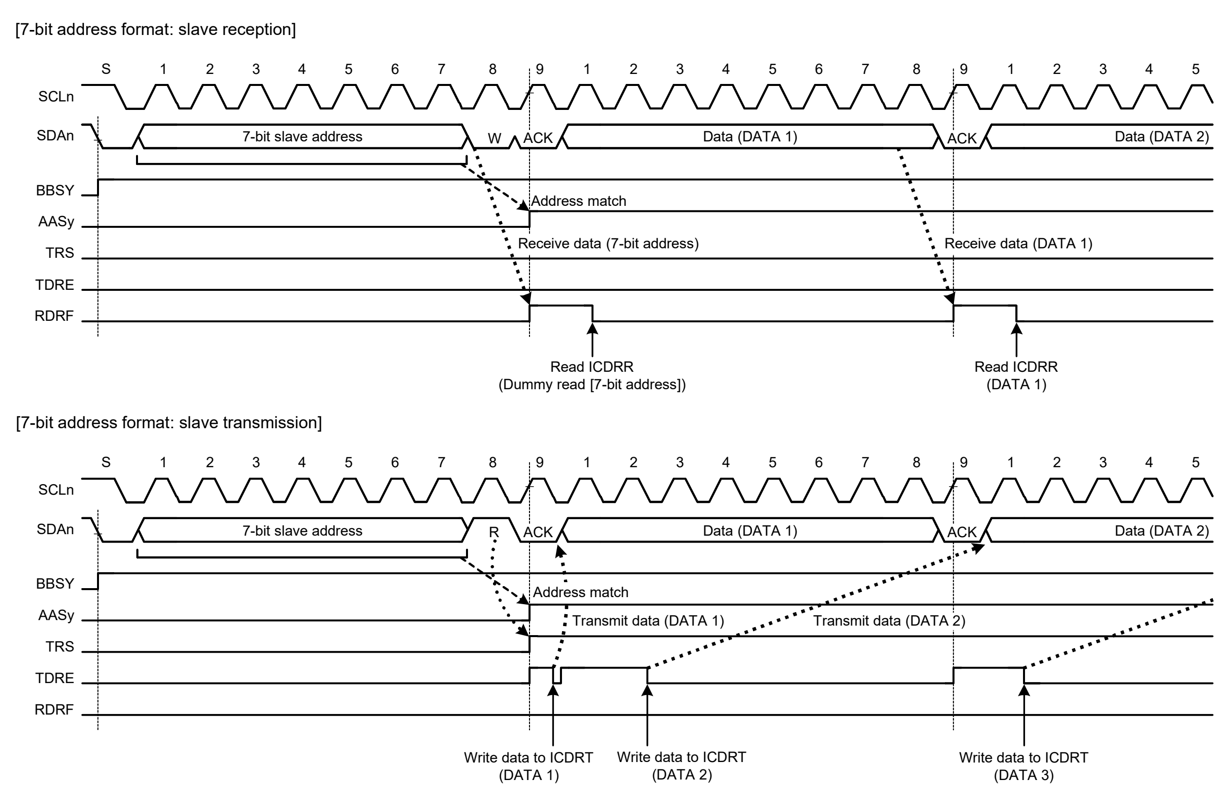

Figure 36.24 AASy flag set timing with 7-bit address format

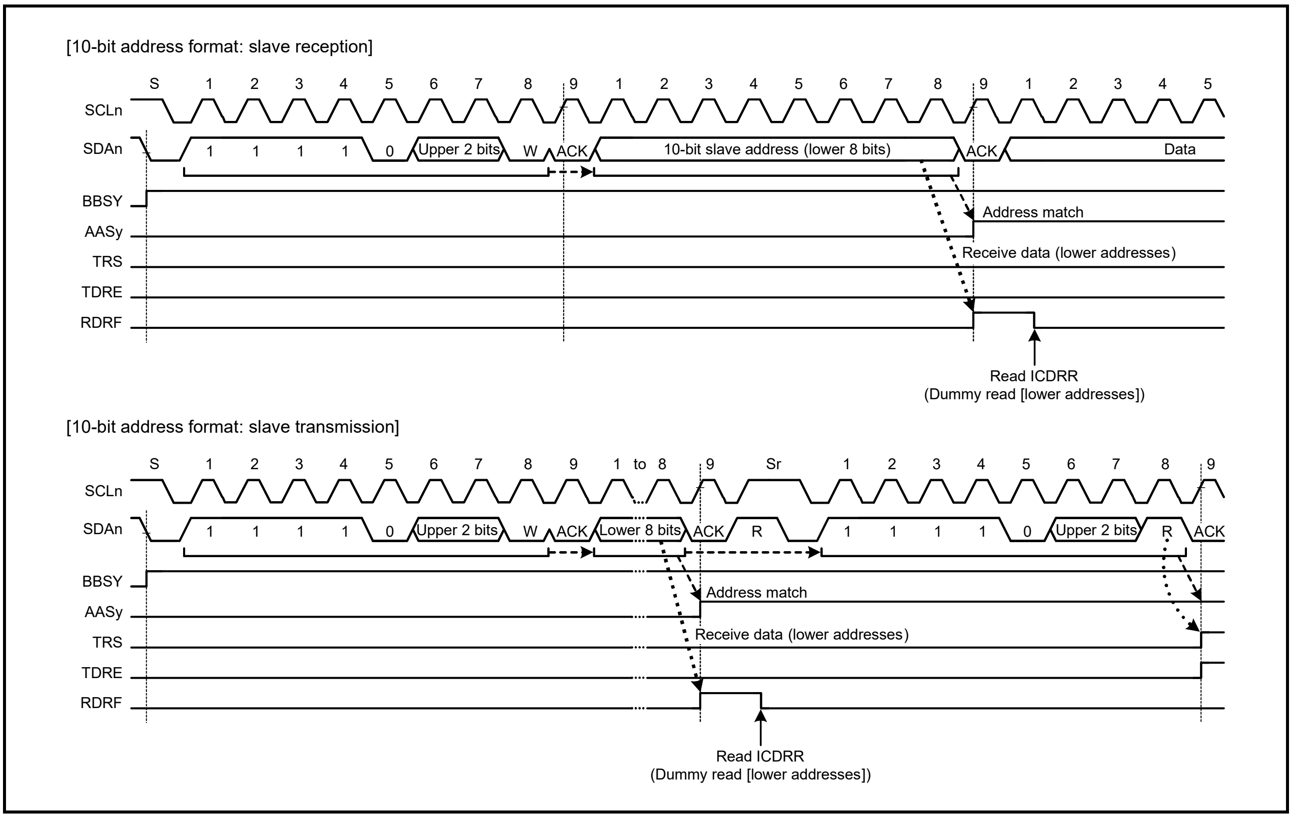

Figure 36.25 AASy flag set timing with 10-bit address format

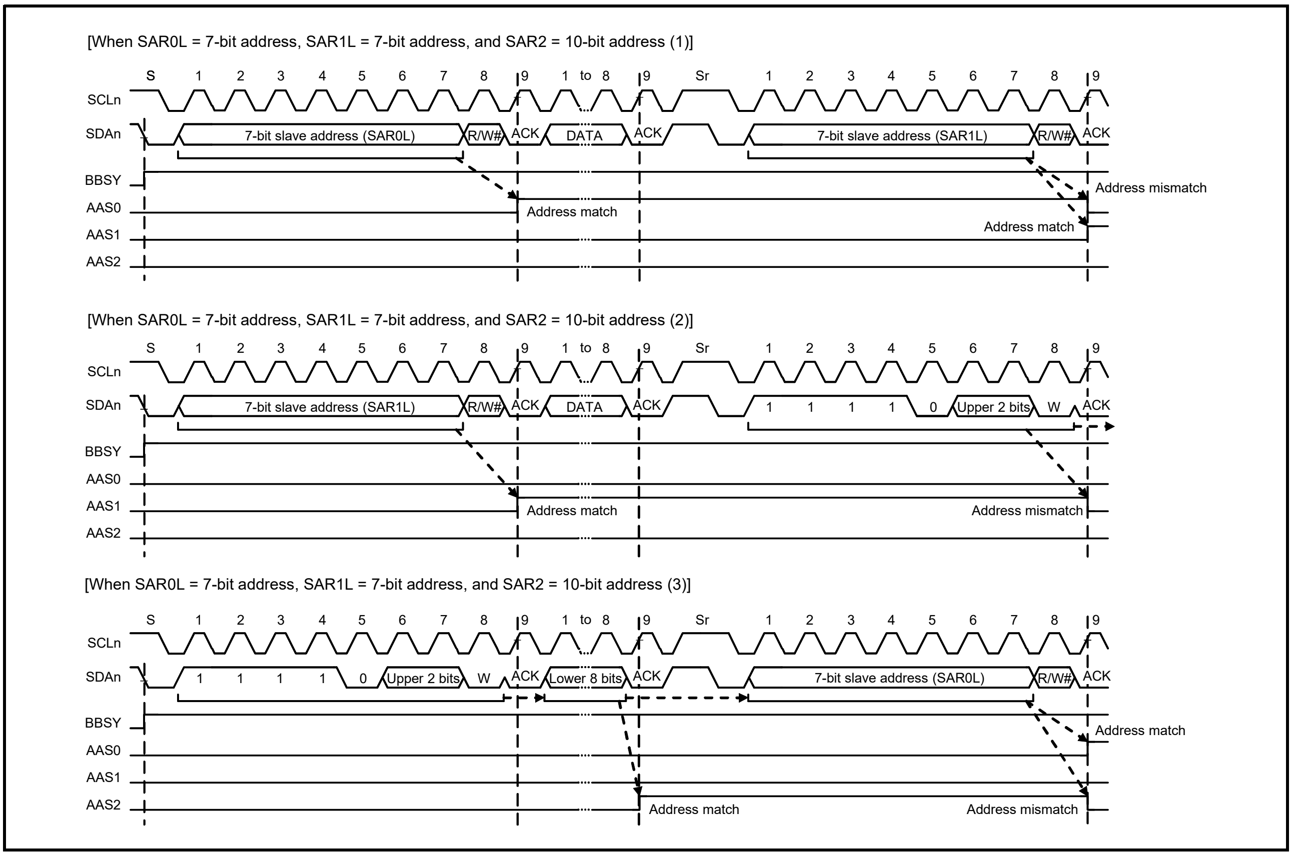

Figure 36.26 AASy flag set and clear timing with 7-bit and 10-bit address formats mixed

36.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

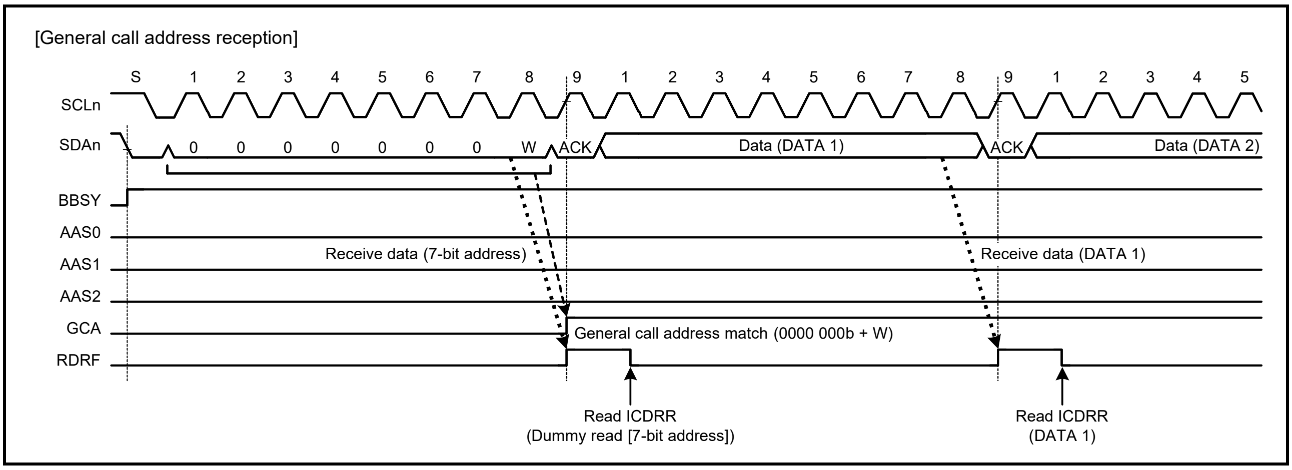

Figure 36.27 Timing of GCA flag setting during reception of general call address

36.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I2C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition was issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the eighth SCL clock cycle when the subsequent R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

After that, when the first byte received after issuance of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device-ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. In this way, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device-ID fields, contact NXP Semiconductors.

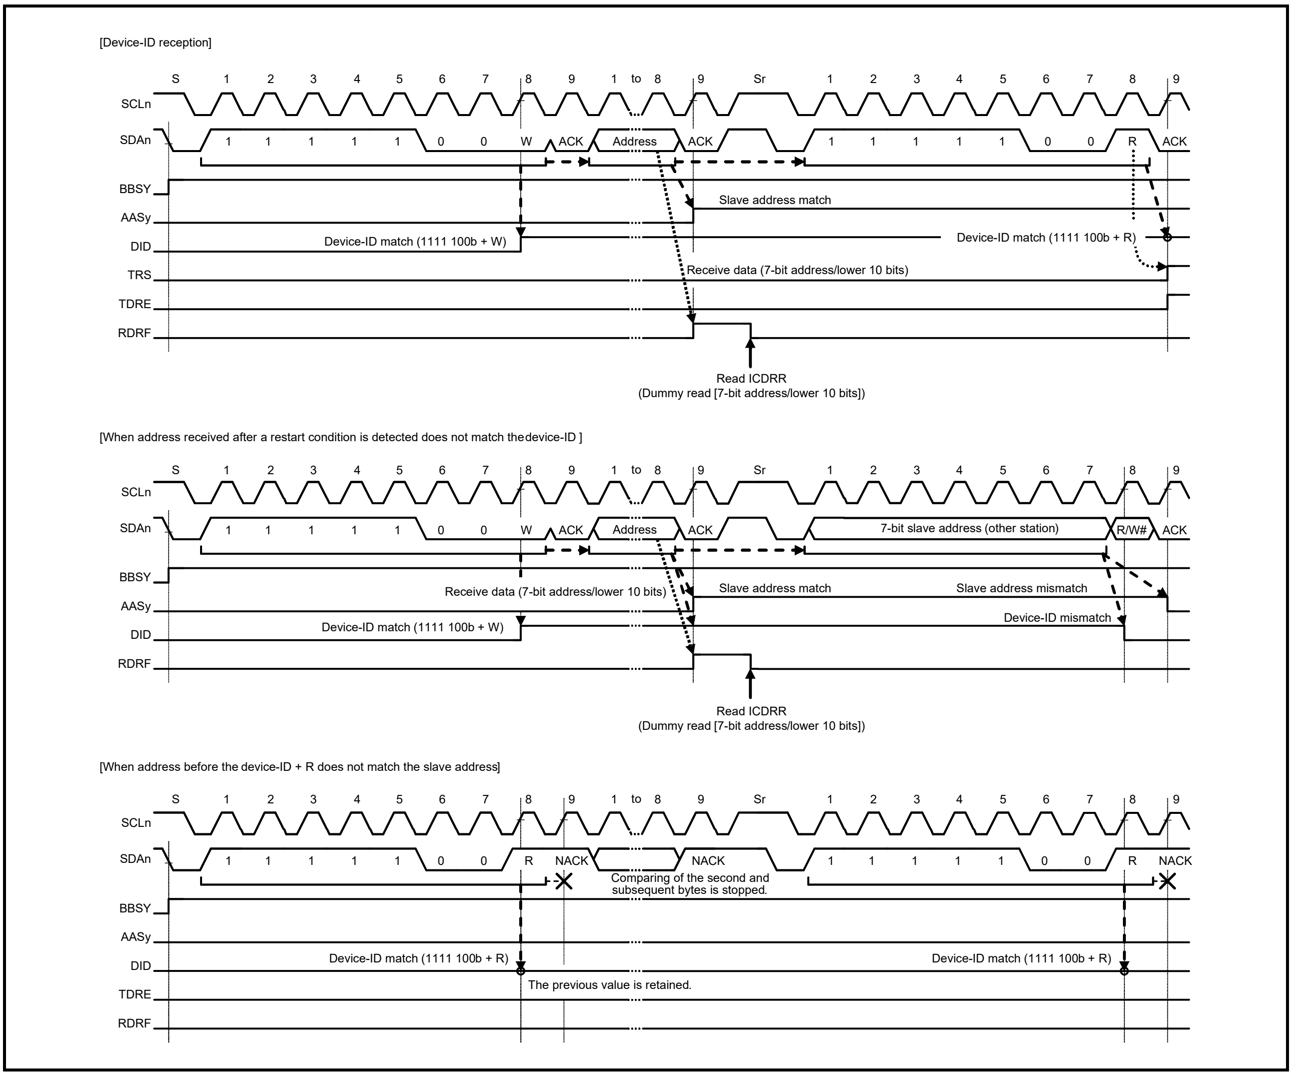

Figure 36.28 AASy and DID flag set and clear timing during reception of device-ID

36.7.4 Host Address Detection

The IIC provides host address detection while the SMBus is operating. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

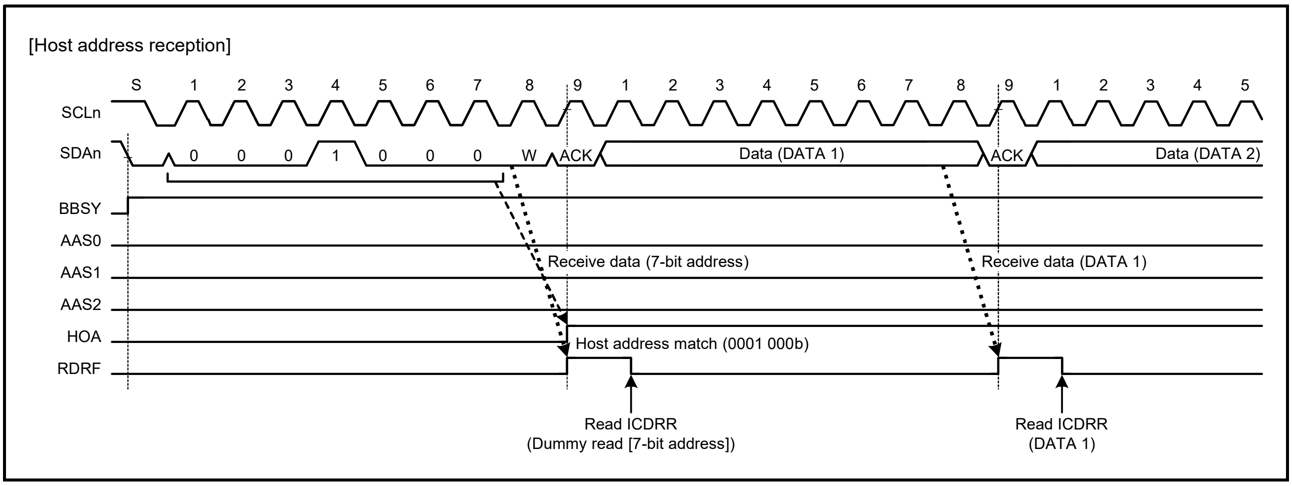

Figure 36.29 HOA flag set timing during reception of host address

36.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode to normal operation. The wakeup function enables the reception of data when the system clock is stopped, and it generates a wakeup interrupt signal on the match of the slave address of the received data. This interrupt signal triggers the return to normal operation.

The wakeup function has four operation modes: normal wakeup mode 1, normal wakeup mode 2, command recovery mode, and EEP response mode. Table 36.9 describes the behavior in these modes.

Table 36.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup	SCL state during wakeup
Normal wakeup mode 1	Before wakeup	ACK	Fixed low
Normal wakeup mode 2	After wakeup	Before wakeup: no response After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup	ACK	Open
EEP response mode	Before wakeup	NACK	Open

Precautions on the use of the wakeup function

1. Disable the wakeup function (WUE = 0) after a wakeup interrupt triggers the transition from Software Standby mode to normal operation.
2. Do not change the content of the IIC registers while WUF = 0, even if the wakeup interrupt recovers the system clock. Make register settings after confirming that WUF = 1.
3. Set WUE = WUIE = 1 and MST = TRS = 0 (slave reception mode) before entering Software Standby mode.
4. Do not invoke Software Standby mode while BBSY = 1.
5. The wakeup function supports the 7-bit slave address of slave address register SARL0, the general call address, and the host address. 10-bit slave addresses, SARL1 and SARL2, are not supported. Do not use them.
6. When the wakeup function is enabled, disable the interrupt selectable in the ICIER bits (TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE).
7. When the wakeup function is enabled, do not use the timeout function.
8. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31 and Figure 36.36.

36.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.32 provides detailed timing and Figure 36.30 shows an example operation.

   Before wakeup:ACK is sent in response to the data received with the own slave address of the IIC.

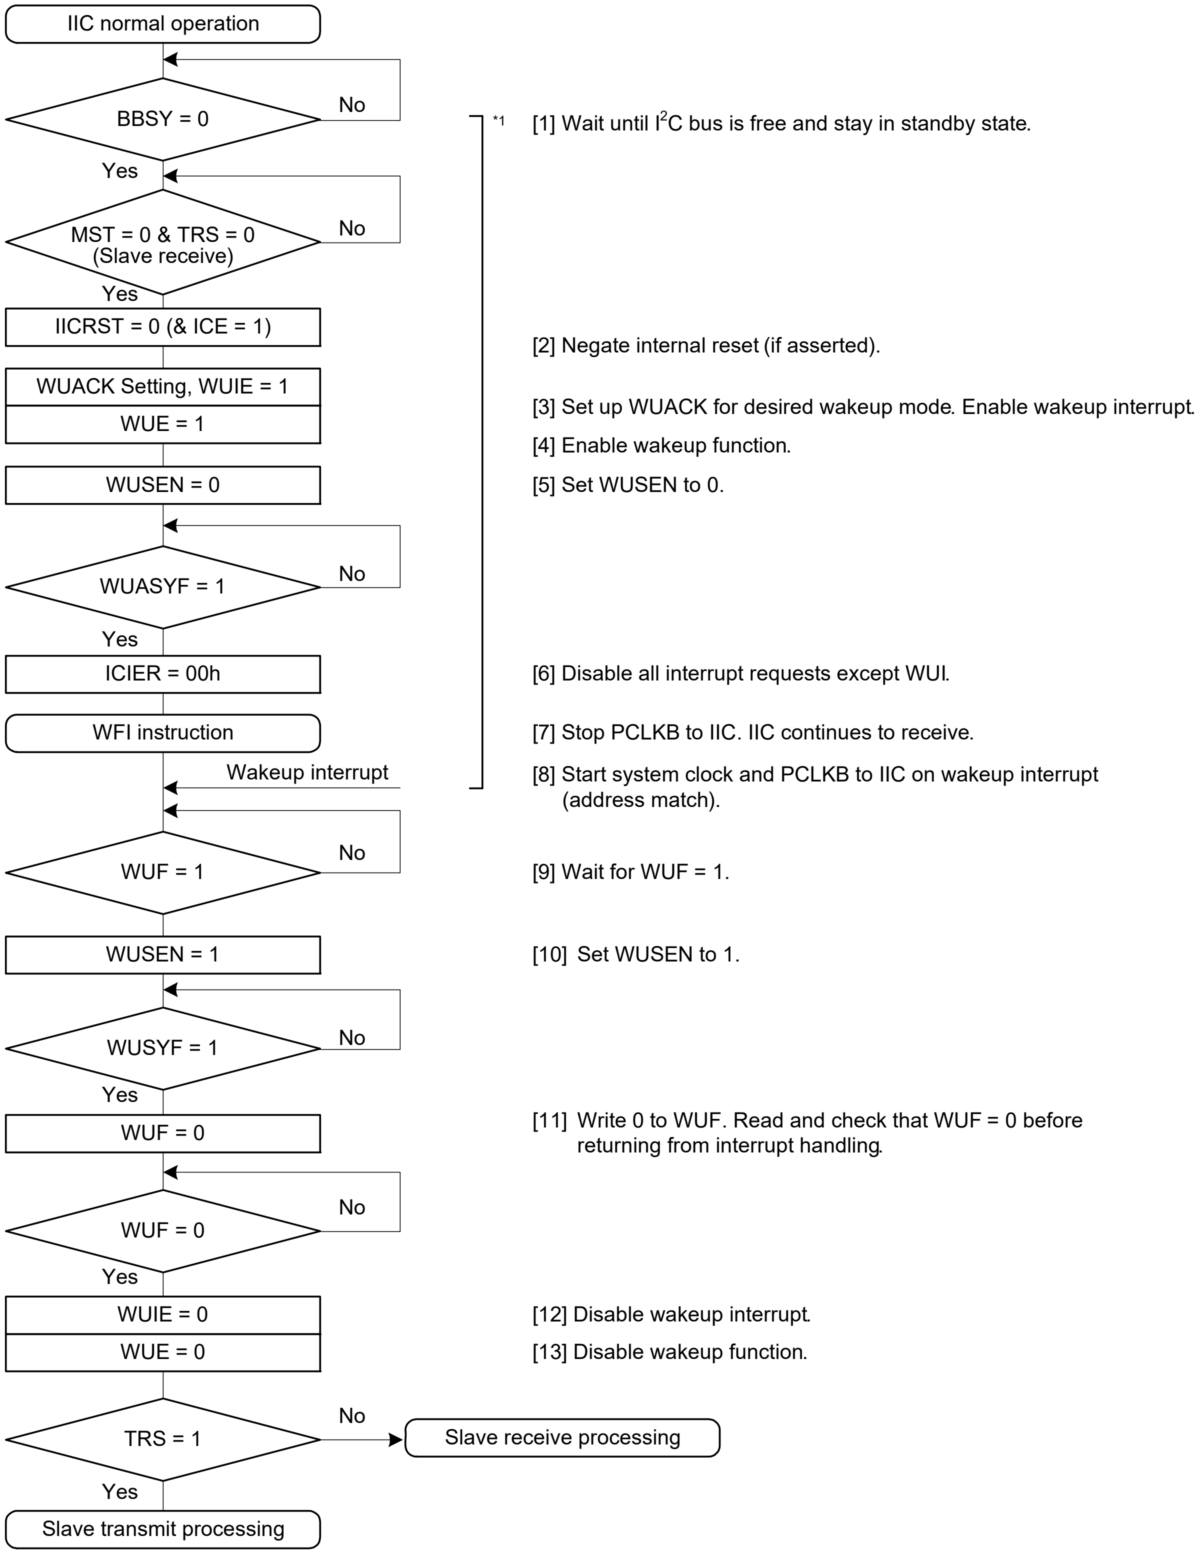
   During wakeup:ACK response is made on the ninth clock cycle of SCL, and SCL is held low afterwards.*1

   After wakeup:Normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the ninth clock cycle of SCL, and the slave operation continues.

Note 1. Between the ninth clock cycle and the first clock cycle during wakeup, WAIT = 1 is invalid.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31.



[1] Wait until I^2C bus is free and stay in standby state.

[2] Negate internal reset (if asserted).

[3] Set up WUACK for desired wakeup mode. Enable wakeup interrupt.

[4] Enable wakeup function.

[5] Set WUSEN to 0.

[6] Disable all interrupt requests except WUI.

[7] Stop PCLKB to IIC. IIC continues to receive.

[8] Start system clock and PCLKB to IIC on wakeup interrupt (address match).

[9] Wait for WUF = 1.

[10] Set WUSEN to 1.

[11] Write 0 to WUF. Read and check that WUF = 0 before returning from interrupt handling.

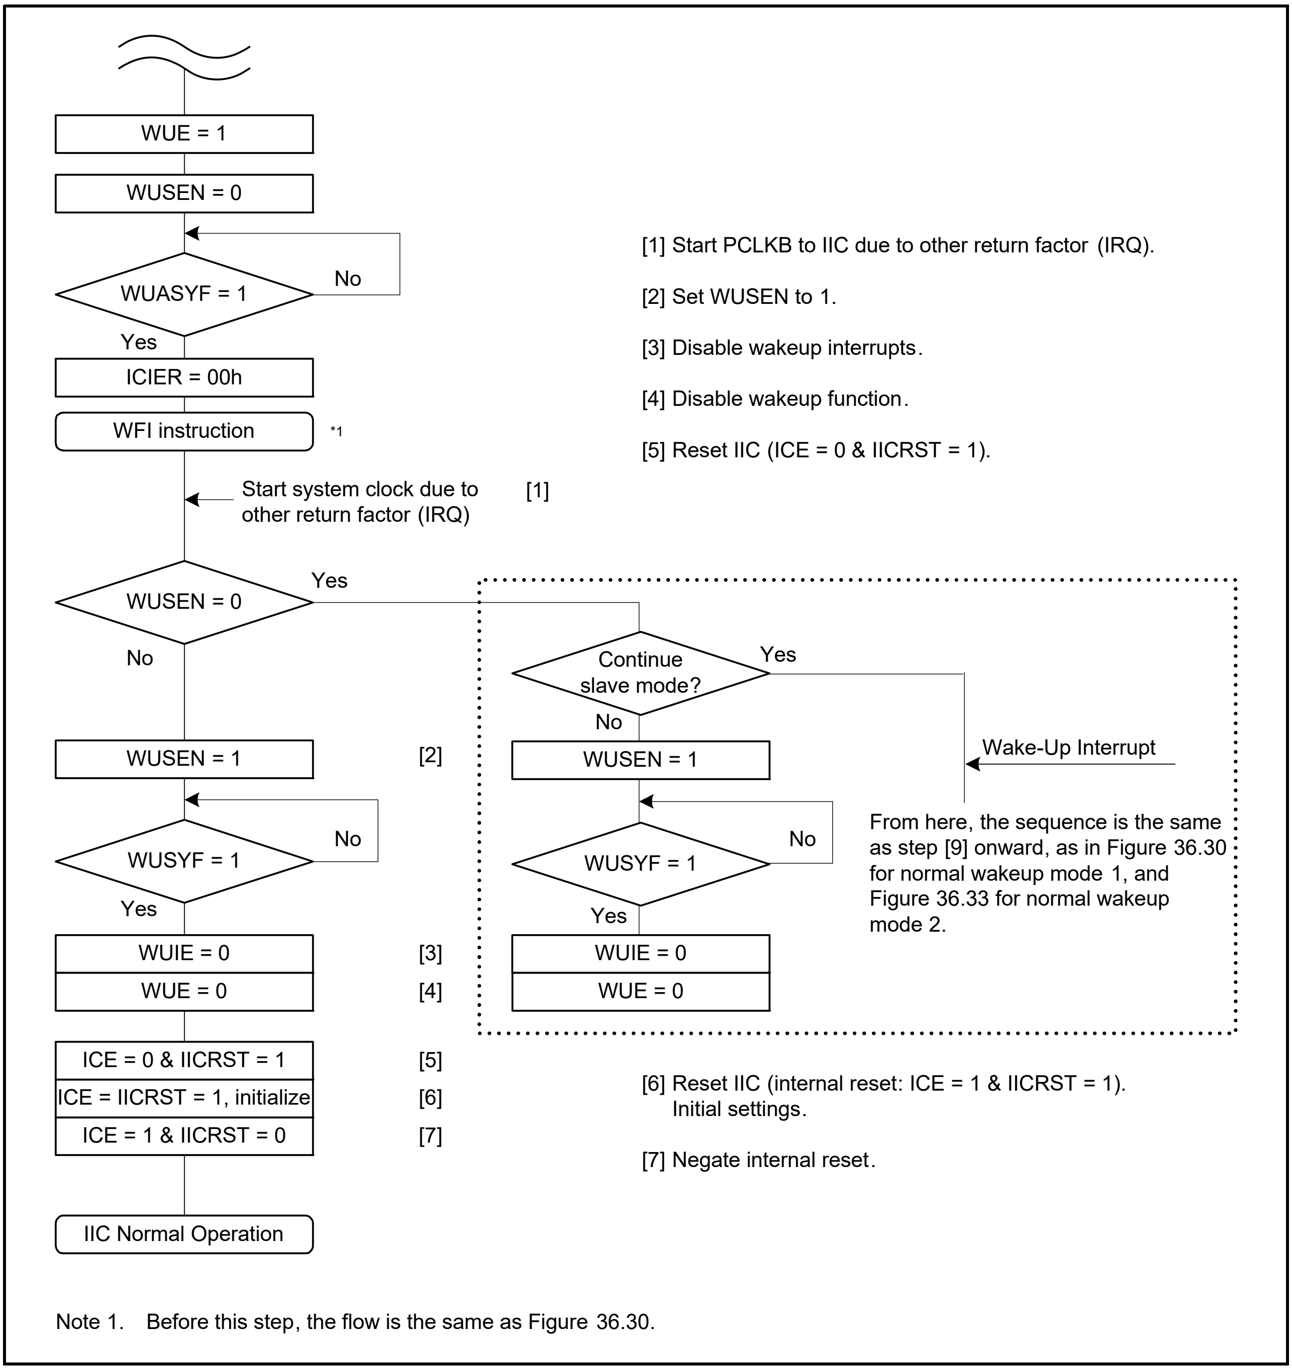
[12] Disable wakeup interrupt.

[13] Disable wakeup function.

Note 1. Do not issue start condition between BBSY = 0 and executing WFI instruction.

Figure 36.30 Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See Precautions on the use of the wakeup function.



[1] Start PCLKB to IIC due to other return factor (IRQ).

[2] Set WUSEN to 1.

[3] Disable wakeup interrupts.

[4] Disable wakeup function.

[5] Reset IIC (ICE = 0 & IICRST = 1).

From here, the sequence is the same as step [9] onward, as in Figure 36.30 for normal wakeup mode 1, and Figure 36.33 for normal wakeup mode 2.

[6] Reset IIC (internal reset: ICE = 1 & IICRST = 1).
Initial settings.

[7] Negate internal reset.

Note 1. Before this step, the flow is the same as Figure 36.30.

Figure 36.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example IRQn

Note: For details on the IIC initial settings, see section 36.3.2, Initial Settings.

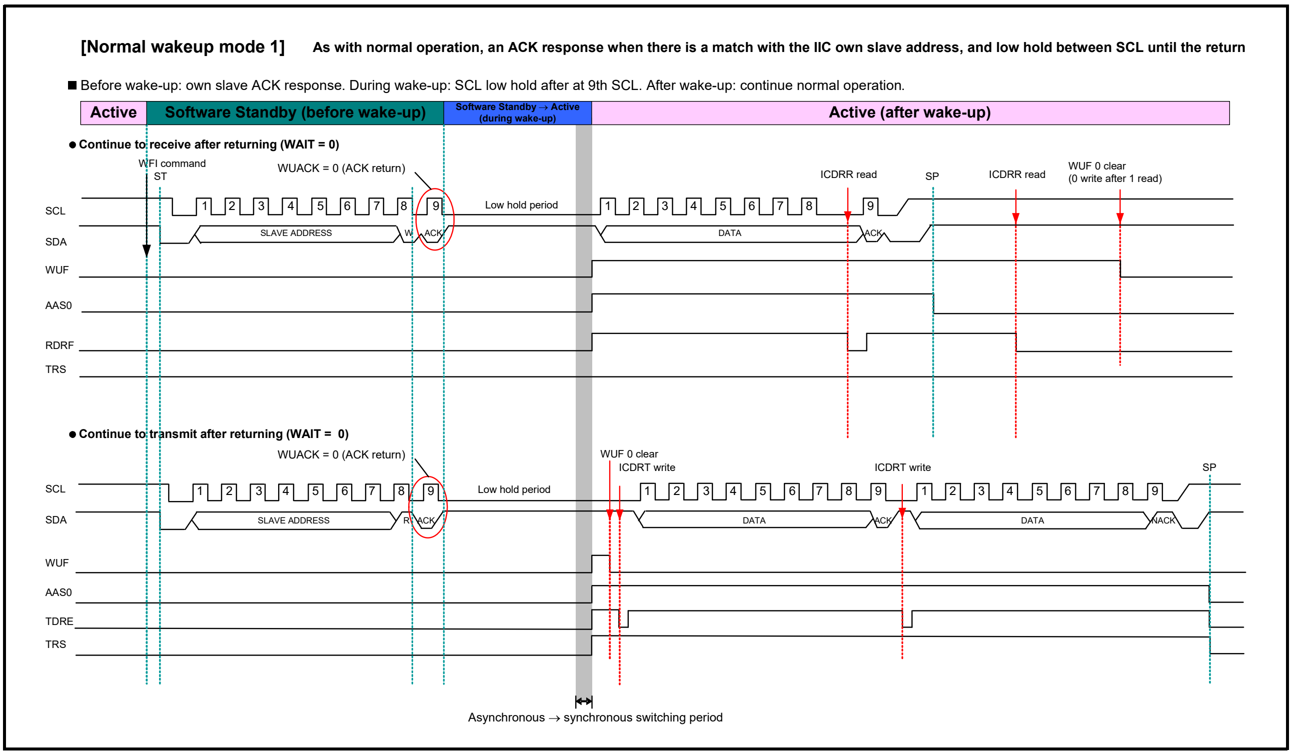


Figure 36.32 Timing of normal wakeup mode 1

36.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.34 provides detailed timing and Figure 36.33 shows an example operation.

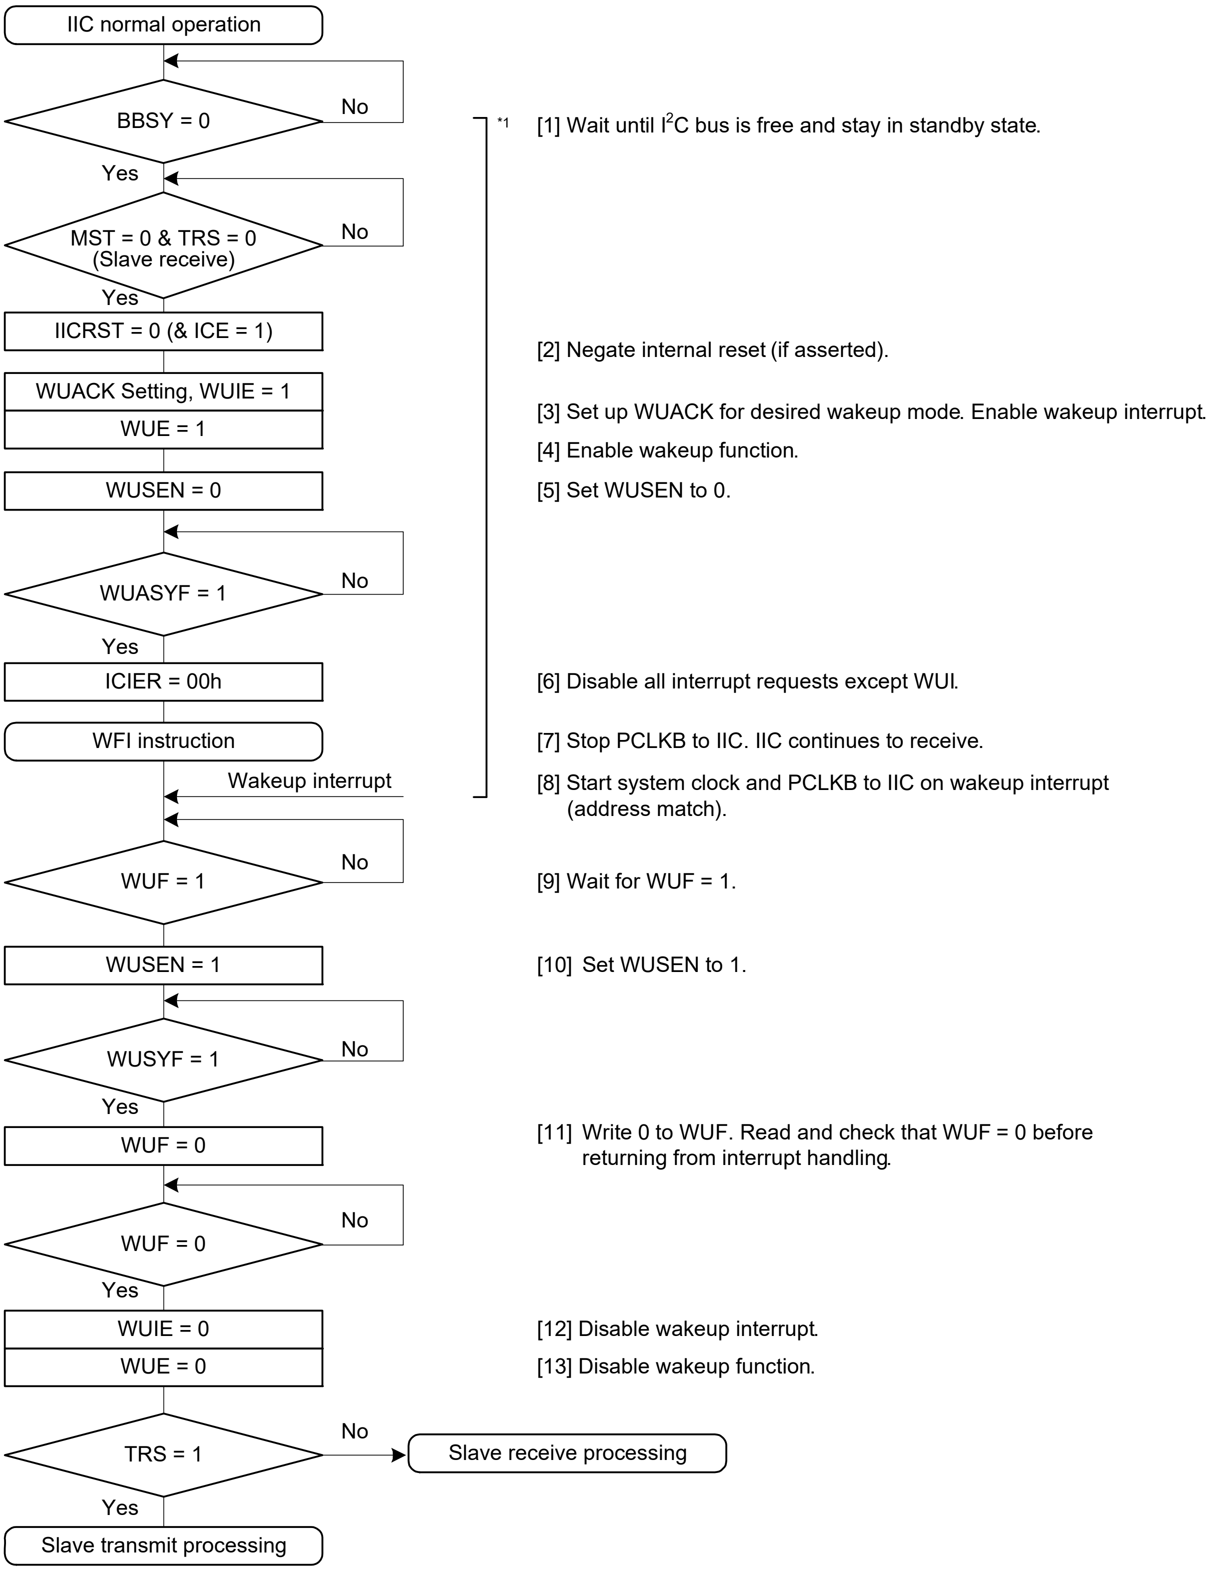
   Before wakeup:No response to the data received with the own slave address of the IIC until the end of the eighth SCL cycle.

   During wakeup:SCL line held low during the eighth and ninth clock cycles.

   After wakeup:ACK returns on the ninth clock cycle of SCL, and normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the eighth SCL clock cycle. The slave operation continues.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.31.



Note 1. Do not issue start condition between BBSY = 0 and executing WFI instruction.

Figure 36.33 Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See Precautions on the use of the wakeup function.

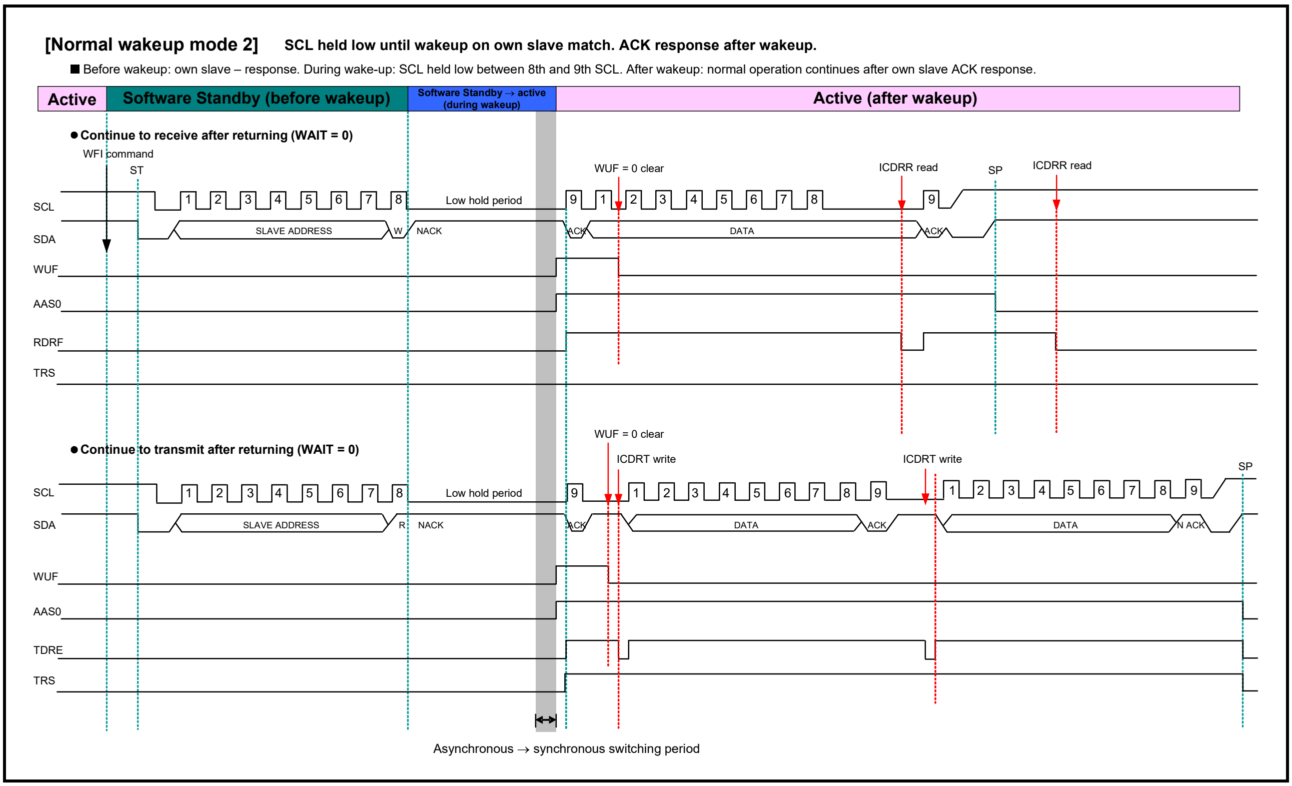


Figure 36.34 Timing of normal wakeup mode 2

36.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the ninth clock cycle of SCL), so other IIC devices can use the I2C bus during this period.

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

1. A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows. Figure 36.37 provides detailed timing and Figure 36.35 shows an example operation.

   Before wakeup:In response to the data received with the own slave address of the IIC, ACK (command recovery mode) or NACK (EEP response mode) is returned.

   During wakeup:The SCL line is not held low.

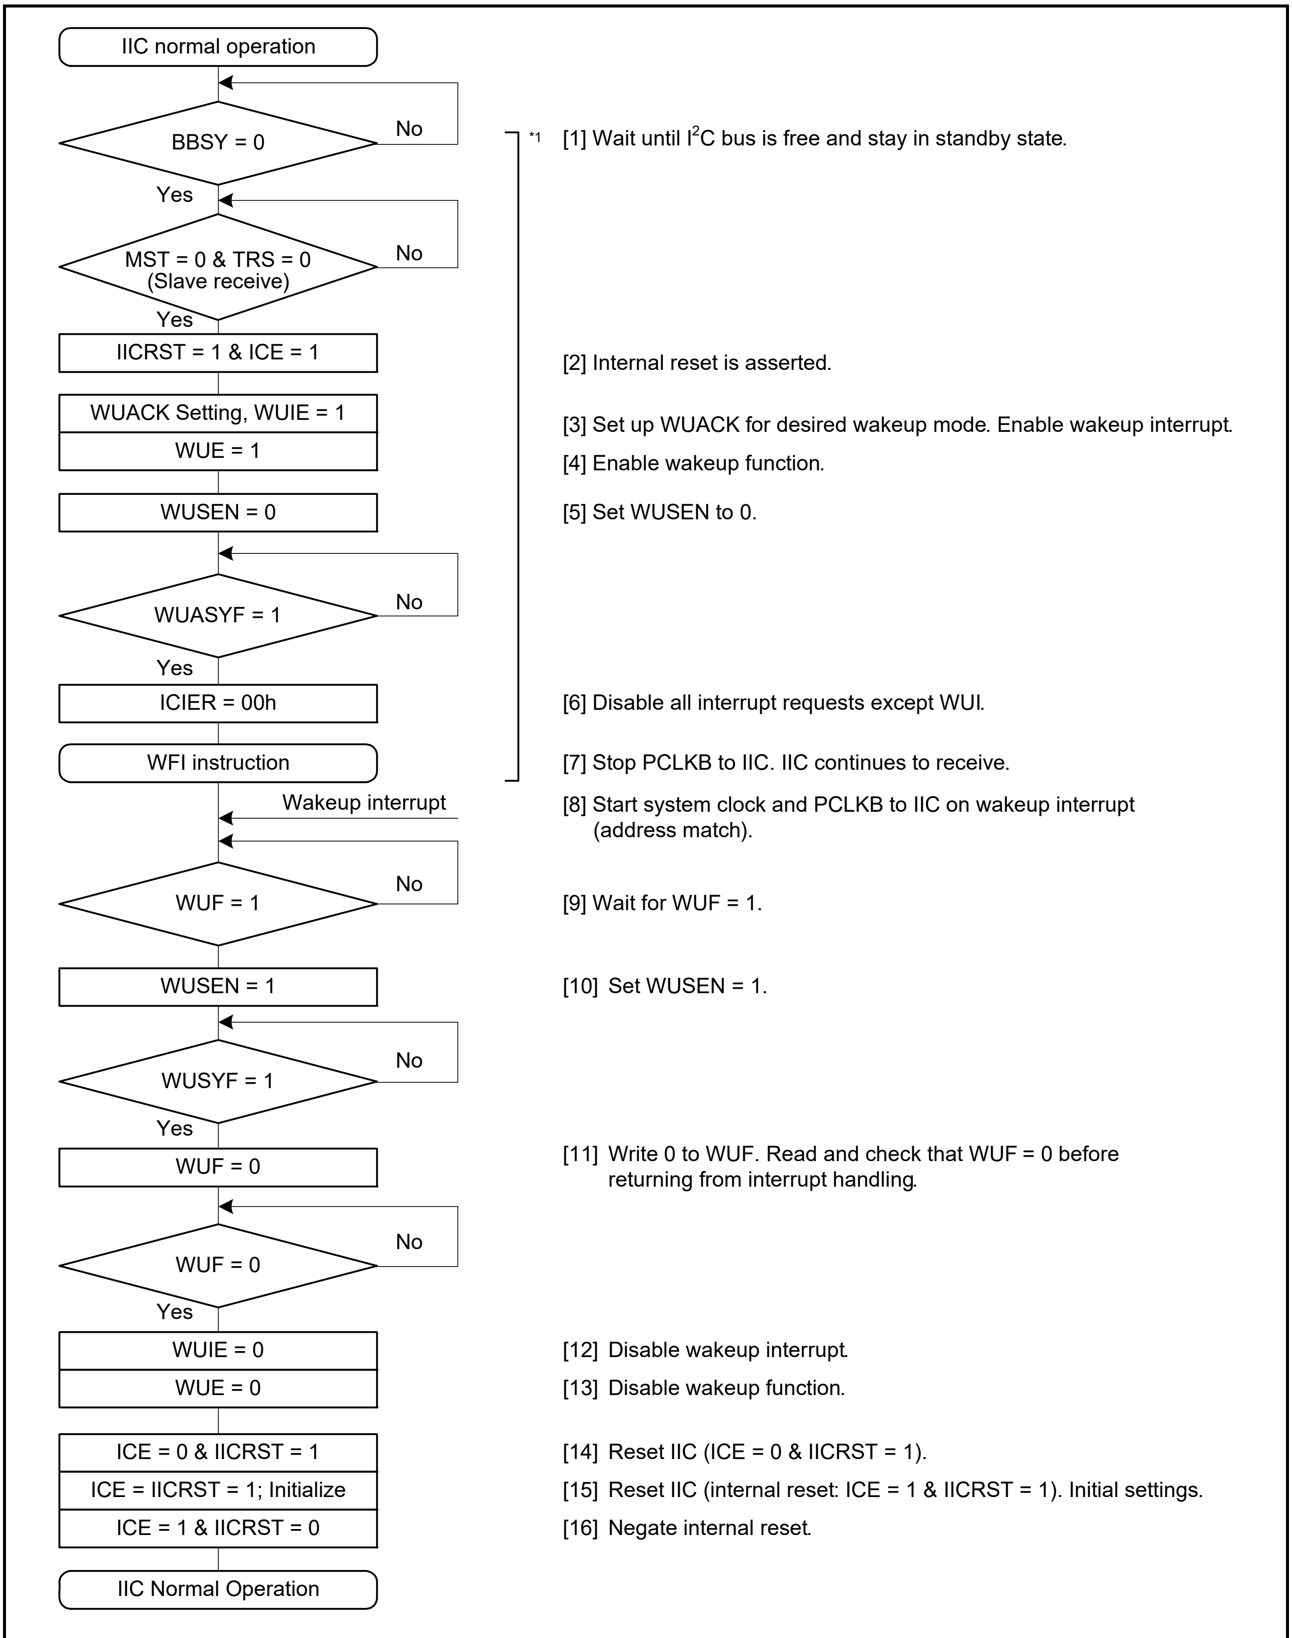
   After wakeup:Normal operation continues after the IIC initial settings.

   If the slave address does not match, the slave operation continues.

Note 1. Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note 2. The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the ICSR1 flags, HOA, GCA, and ASS0,ASS1,ASS2.

2. If the transition from Software Standby mode is triggered by the interrupt (such as IRQn) other than a wakeup interrupt. WUF is not set in this case. Follow the processing shown in Figure 36.36.



Note 1. Do not issue start condition between BBSY = 0 and executing WFI instruction.

Figure 36.35 Example operation of command recovery mode and EEP response mode when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See Precautions on the use of the wakeup function.

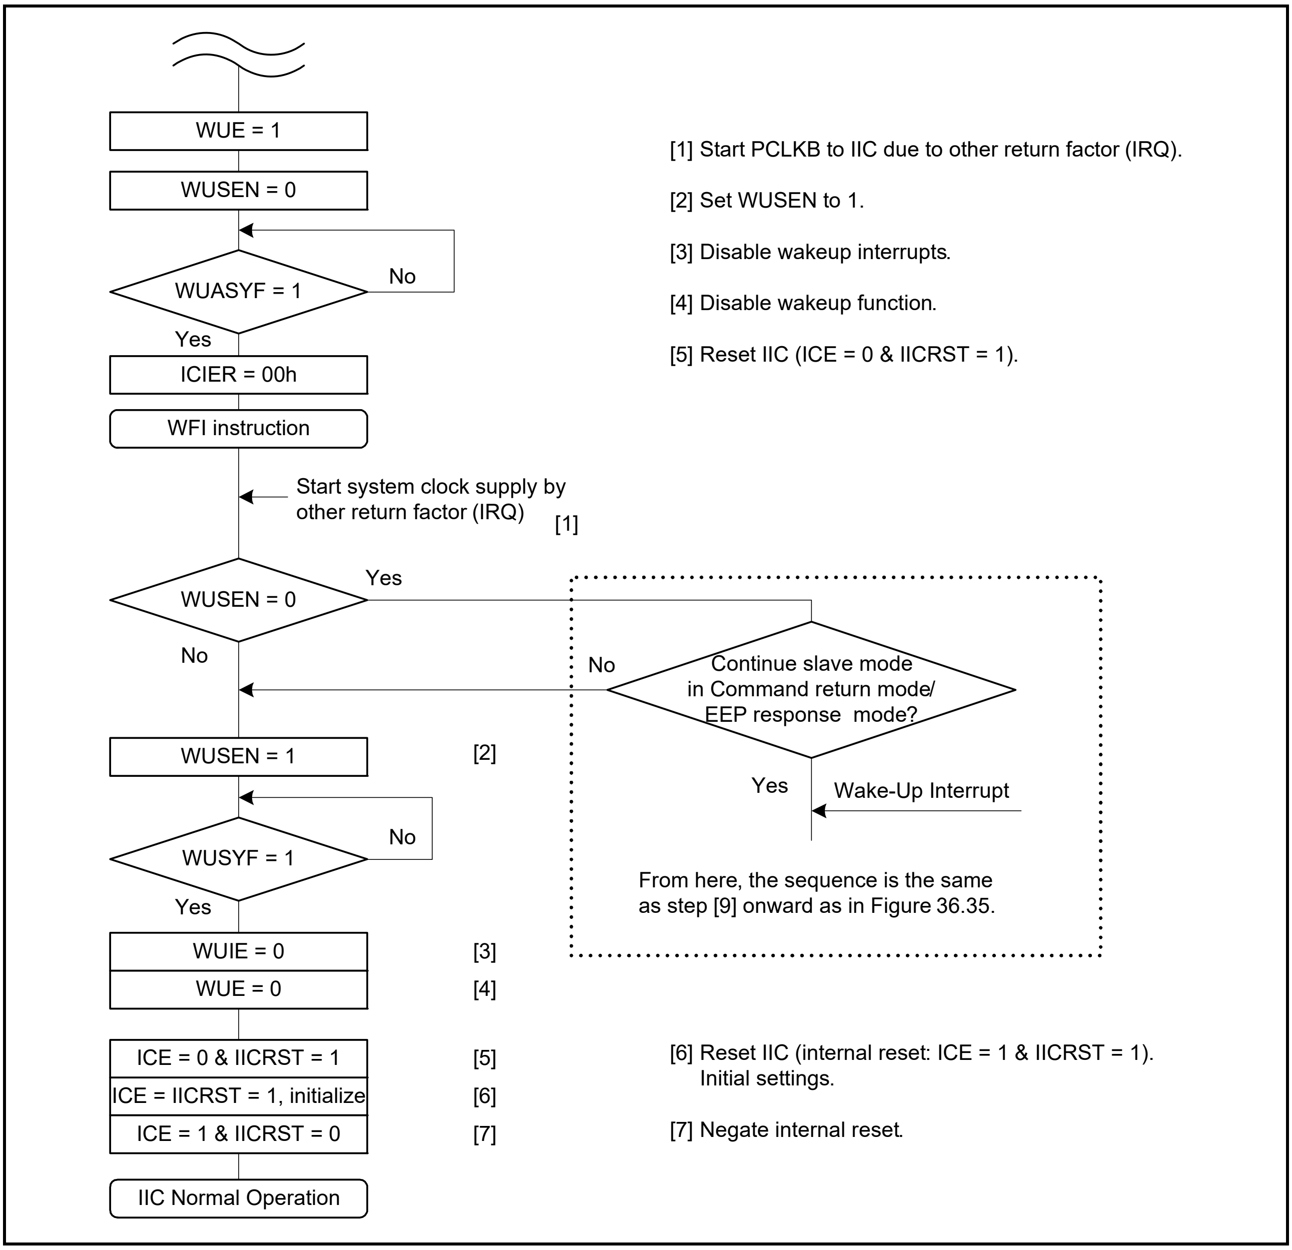


Figure 36.36 **Example operation of command recovery mode and EEP response mode when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example IRQn**

Note: For details on the IIC initial settings, see section 36.3.2, Initial Settings.

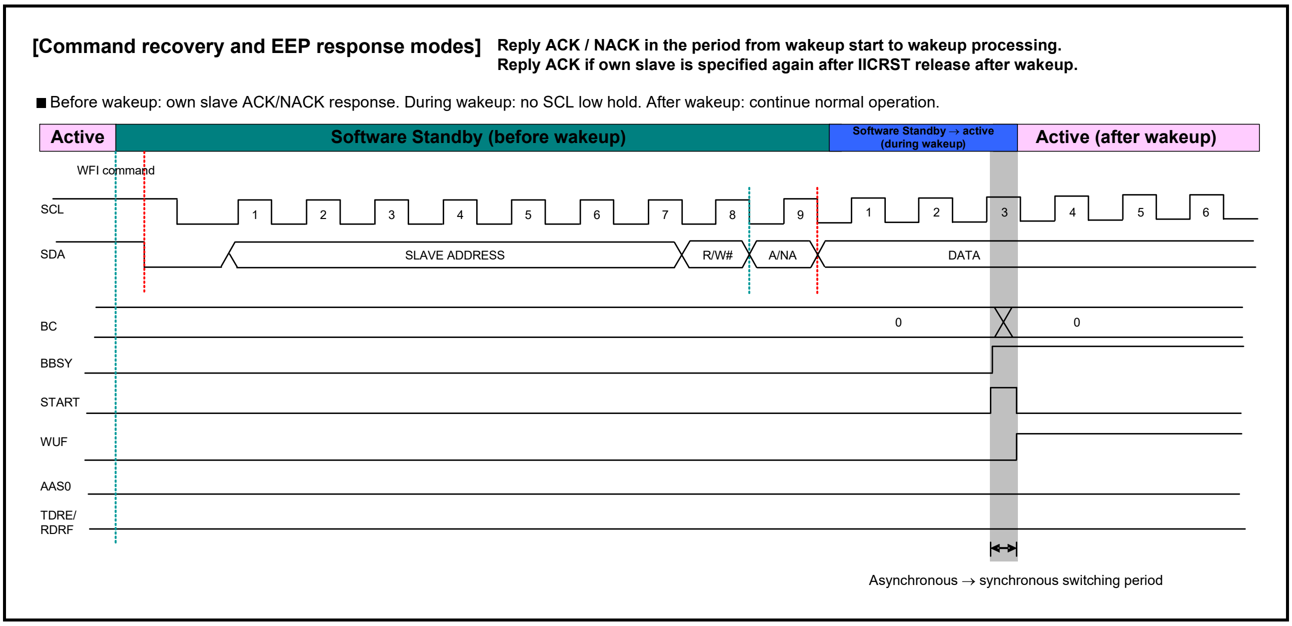

Figure 36.37 Timing of command recovery and EEP response modes

36.8.4 Precautions for WFI instruction Execution

In the example operations for the wakeup mode shown in Figure 36.30, Figure 36.33, and Figure 36.35, make sure that the start condition is not issued during the period from the setting of BBSY = 0 to the execution of the WFI instruction. When a start condition is issued during this period, NACK is returned after the reception of the first byte of the first data block. Then the detection of the start or restart condition enables the wakeup function.

36.9 Automatic Low-Hold Function for SCL

36.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I²C Bus Shift Register (ICDRS) is empty and data has not been written to the IIC-Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a start or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next.

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next.

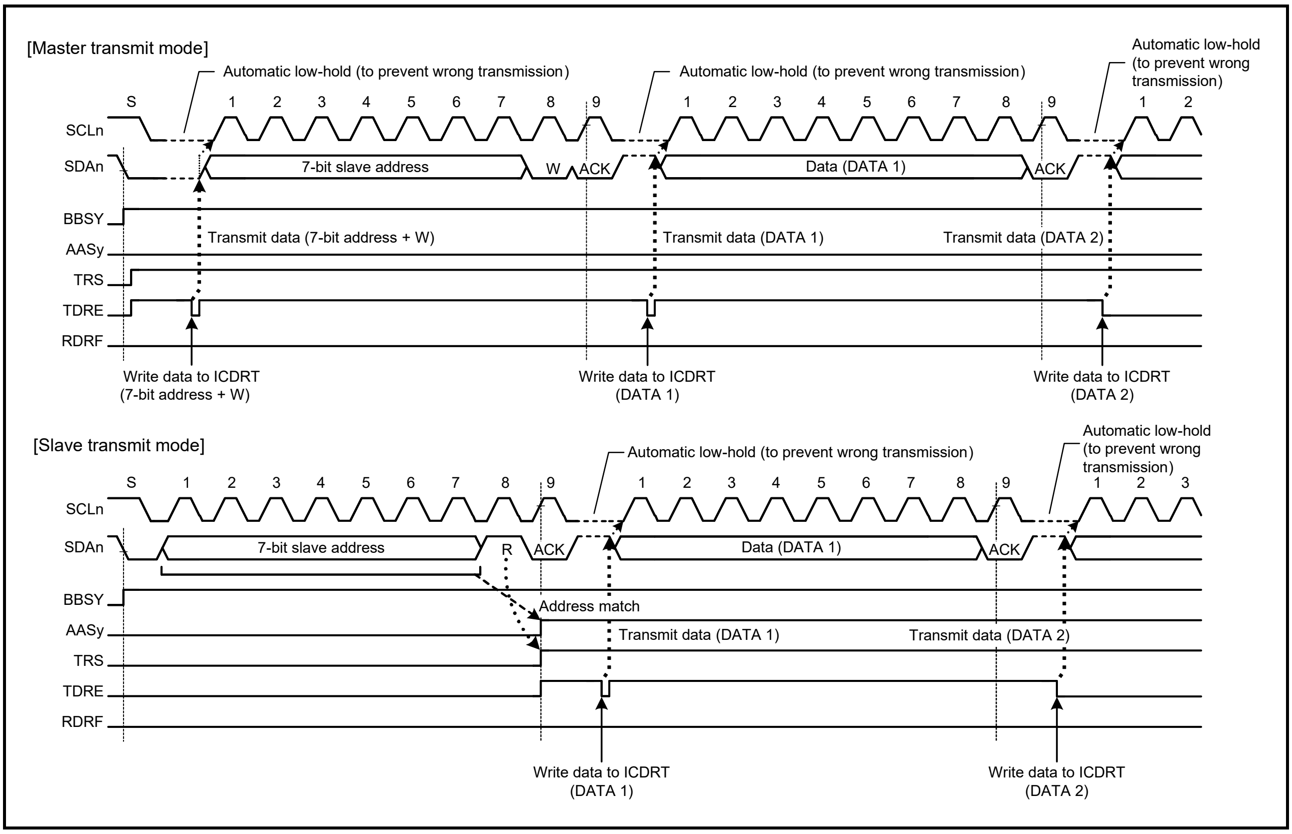

Figure 36.38 Automatic low-hold operation in transmit mode

36.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). It is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, you must set the NACKF flag to 0. In master transmit mode, after issue a restart or stop condition, set the NACKF flag to 0, and then issue a start condition again.

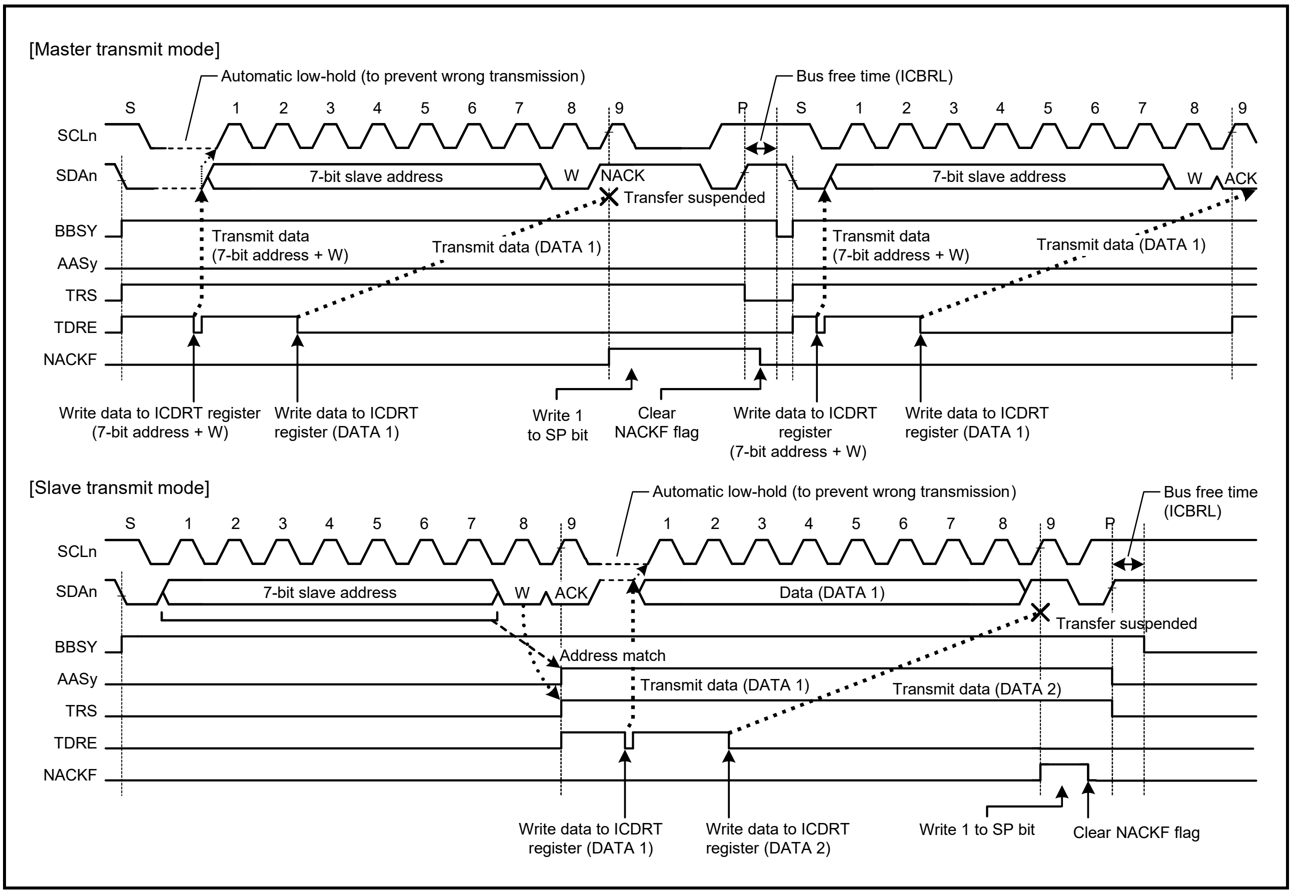

Figure 36.39 Suspension of data transfer when NACK is received, when NACKE = 1

36.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

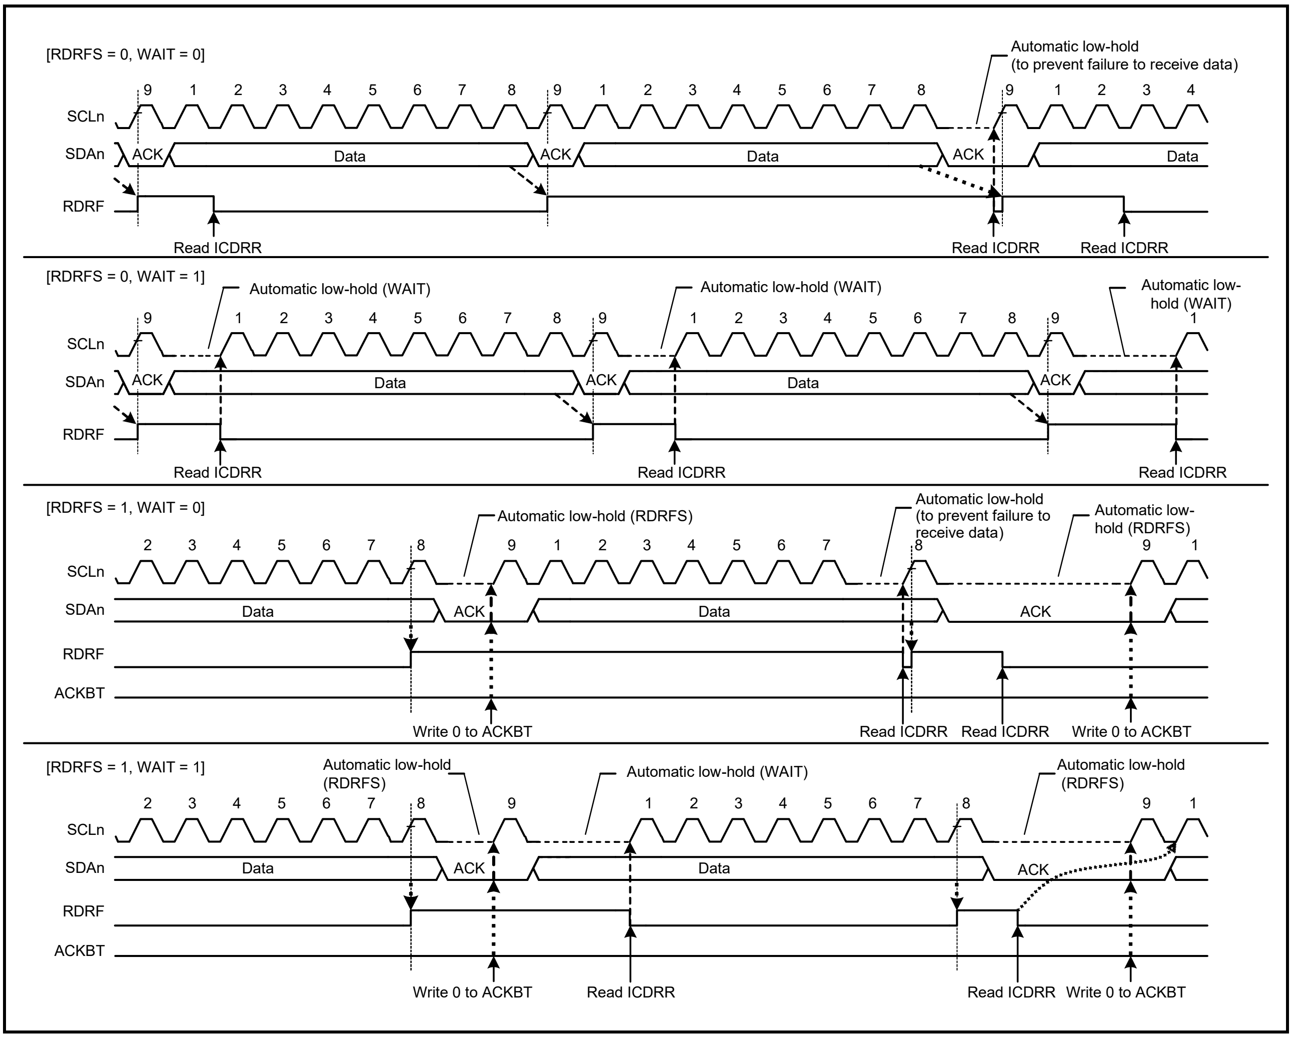

Figure 36.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

36.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^{2}C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

36.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and a low level is detected on the SDAn line, the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 was set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

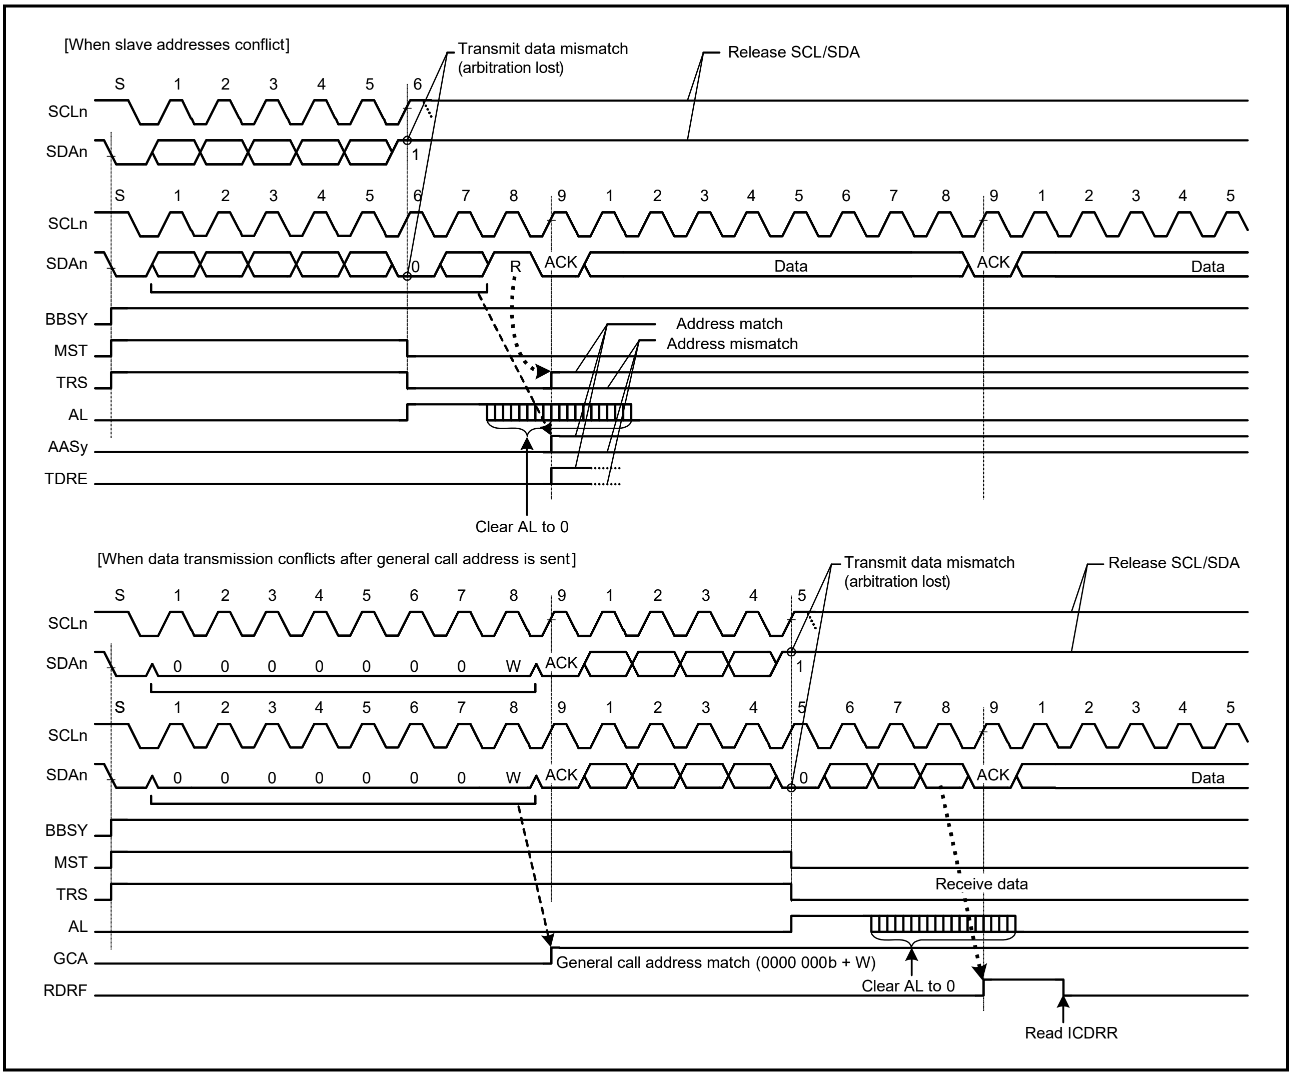

Figure 36.41 Examples of master arbitration-lost detection when MALE = 1

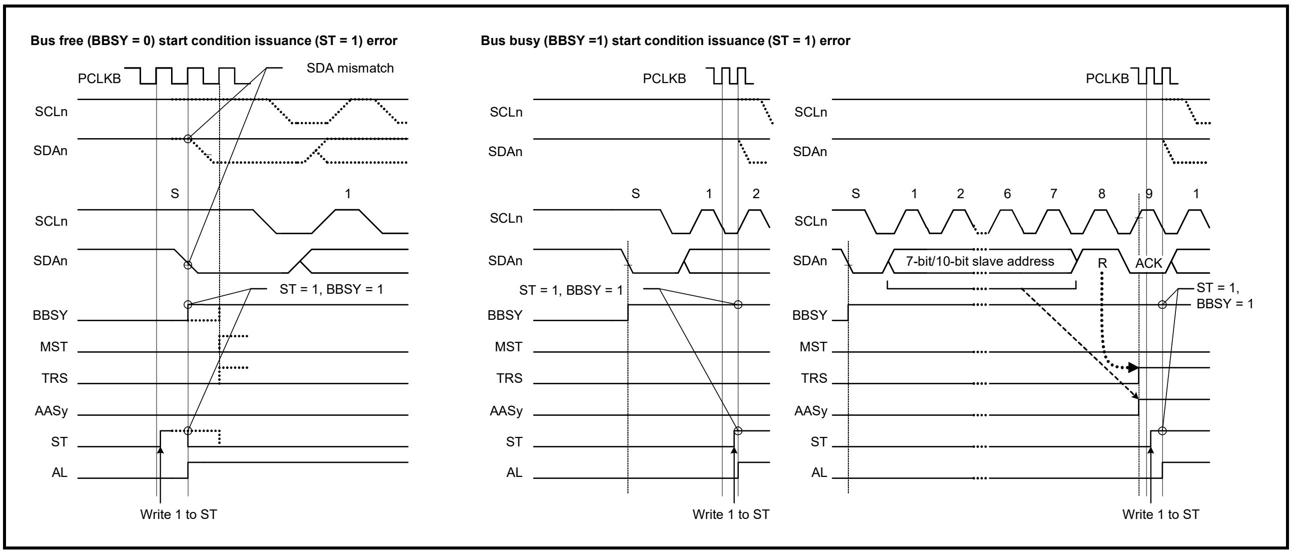

Figure 36.42 Arbitration-lost when start condition is issued when MALE = 1

36.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict of NACK and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 36.43 shows an example of arbitration-lost detection during transmission of NACK.

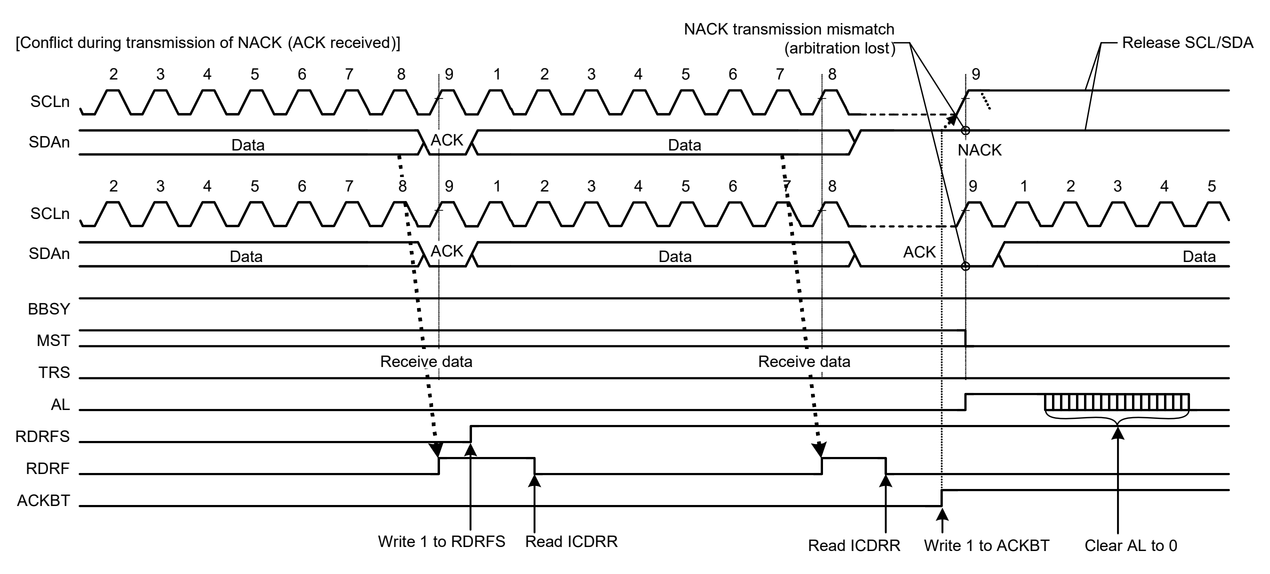

Figure 36.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example where two master devices (masters A and B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If masters A and B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or B during access to the slave device. Both masters A and B recognize that they obtained the bus mastership and operate as such. Here, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The issuance of the stop condition conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as FFh transmission processing, necessary if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3)

36.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When it loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of FFh.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

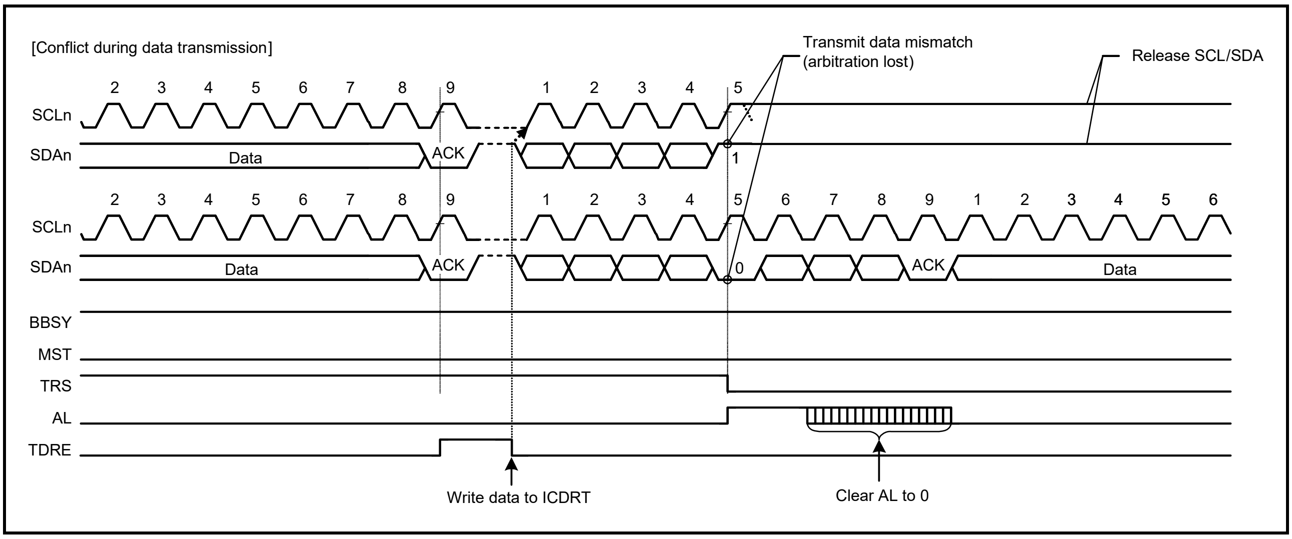

Figure 36.44 Example of slave arbitration-lost detection when SALE = 1

36.11 Start, Restart, and Stop Condition Issuing Function

36.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

36.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

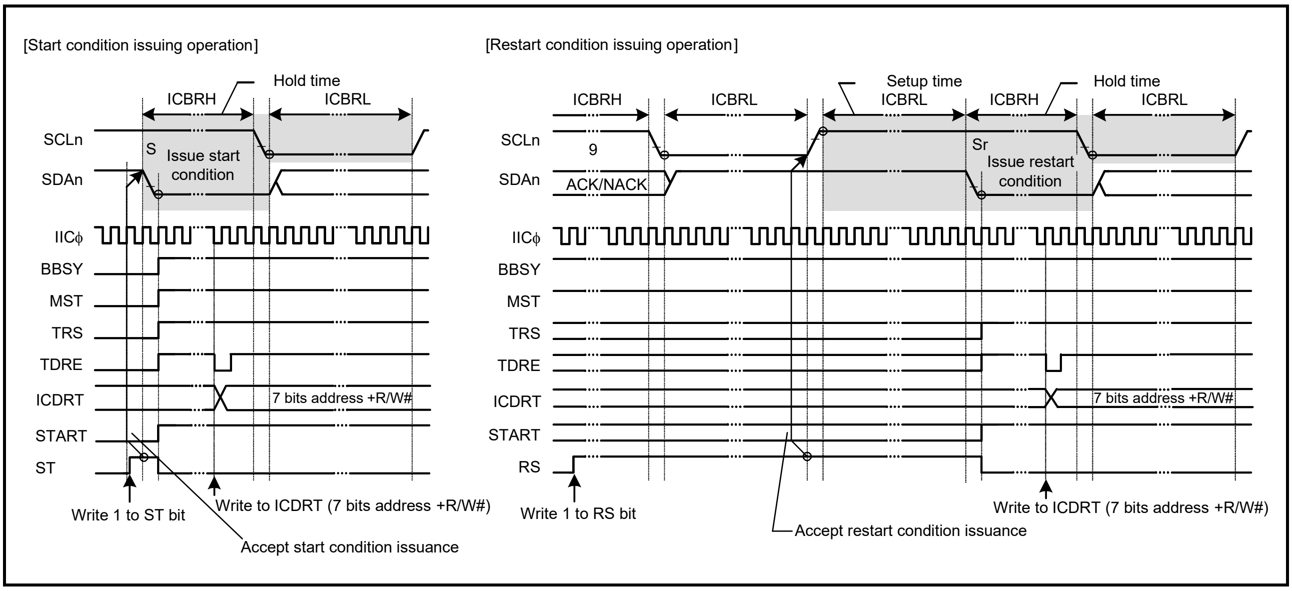

Figure 36.45 Start and restart condition issue timing using the ST and RS bits

Figure 36.46 shows the operation timing when a restart condition is issued after the master transmission.

[Restart condition issuance after the master transmission]

1. Initial setting. For details, refer to section 36.3.2, Initial Settings.
2. Read the BBSY flag in IICR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition issuance request). Upon receiving the request, the IIC issues a start condition. At the same time, the BBSY flag and the START flag in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the ST bit is 1, the IIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 in response to setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. Once the data for transmission are written to ICDRT, the TDRE flag is automatically set to 0, the data are transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave

address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.

4. After confirming that the TDRE flag in ICSR2 is 1, write the data for transmission to the ICDRT register. The IIC automatically holds the SCLn line low until the data for transmission are ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission have been written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1, and then, after check that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issuance request). Upon receiving the request, the IIC issues a restart condition.
7. After check that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

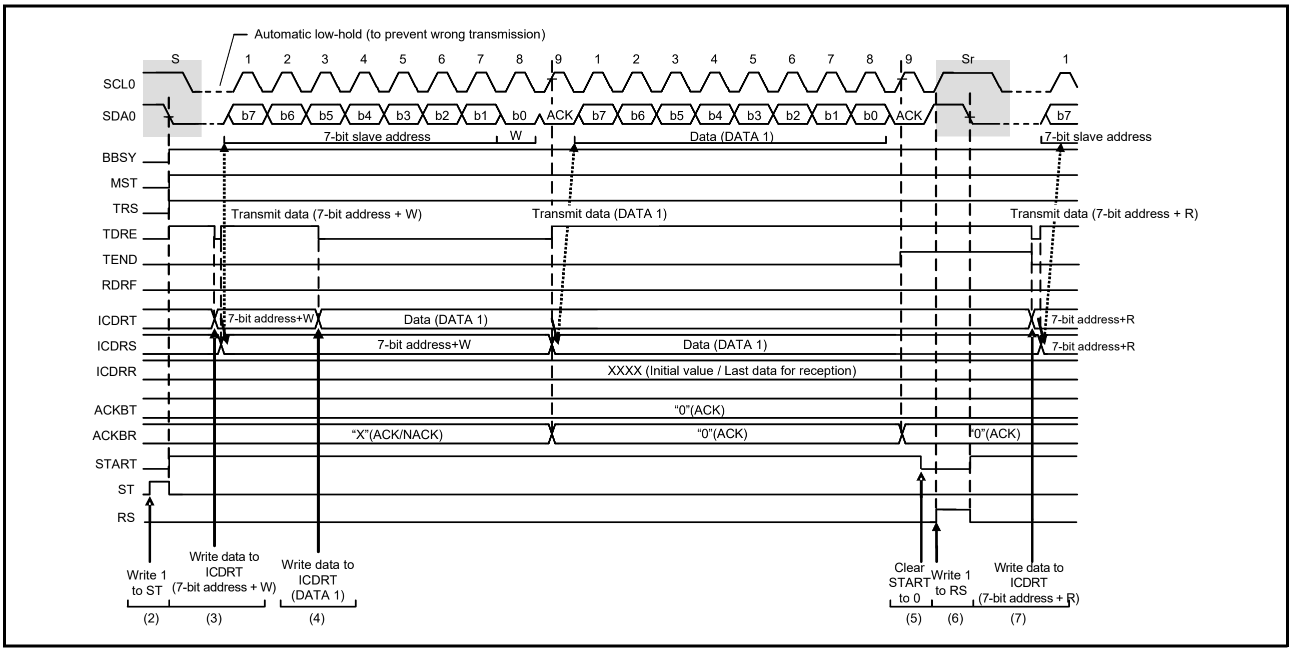

Figure 36.46 Restart condition issue timing after master transmission.

36.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.

7. Clear the BBSY flag to 0 to release the bus mastership.

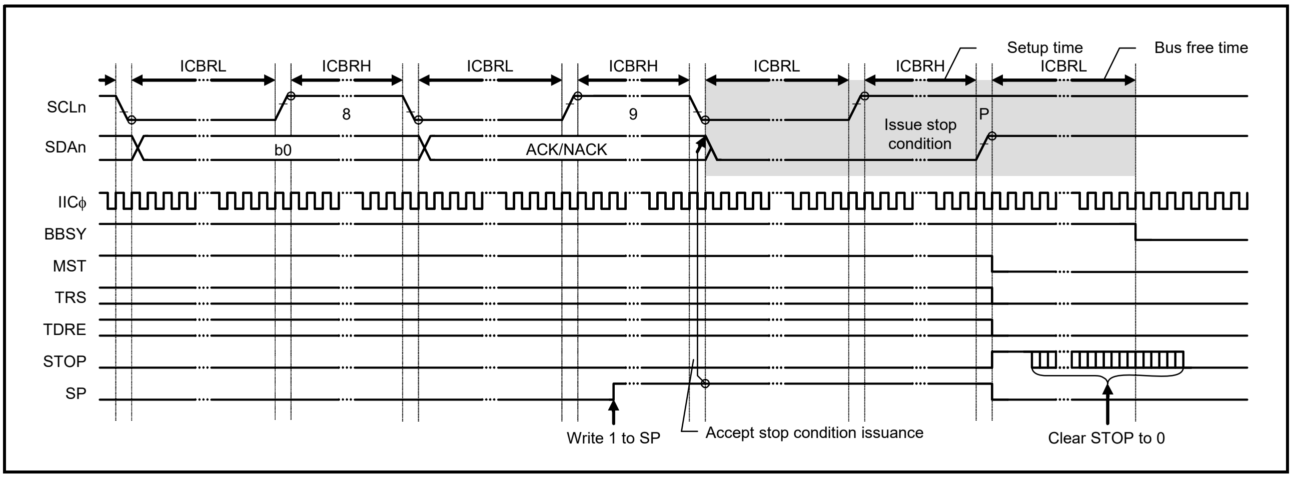

Figure 36.47 Stop condition issue timing using the SP bit

36.12 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization because of noise or other factors, the I^{2}C bus might hang with a fixed level on the SCLn or SDAn line.

To manage bus hanging, the IIC has:

- A timeout function to detect hanging by monitoring the SCLn line
- A function for the output of an extra SCL clock cycle to release the bus from a hung state because of clock signals being out of synchronization
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

36.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is free (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICϕ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter does not work.

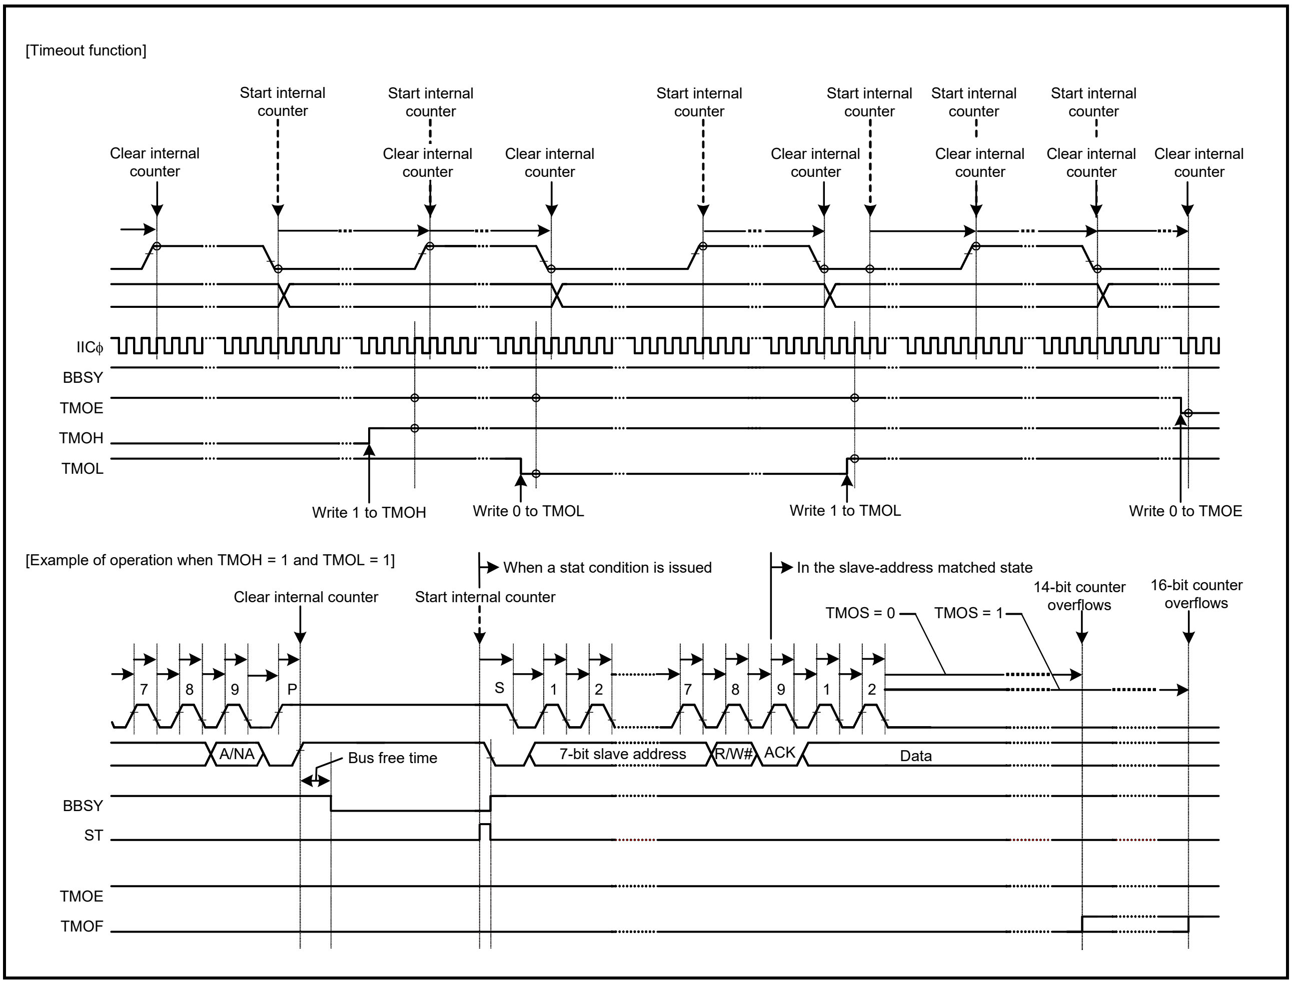

Figure 36.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

36.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the transfer rate specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit automatically is set to 0. More extra clock cycles can be output consecutively by software writing 1 to the CLO bit after having read CLO = 0.

When the IIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device was lost because of noise or other effects, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, and so recovering the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

Use this function with the MALE bit in ICFER set to 0 (master arbitration-lost detection disabled). If the MALE bit is set to 1 (enabled), arbitration is lost when the value of the SDAO bit in ICCR1 does not match the state of the SDAn line.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is free (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)

- When the communication device does not hold the SCLn line low.

Figure 36.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

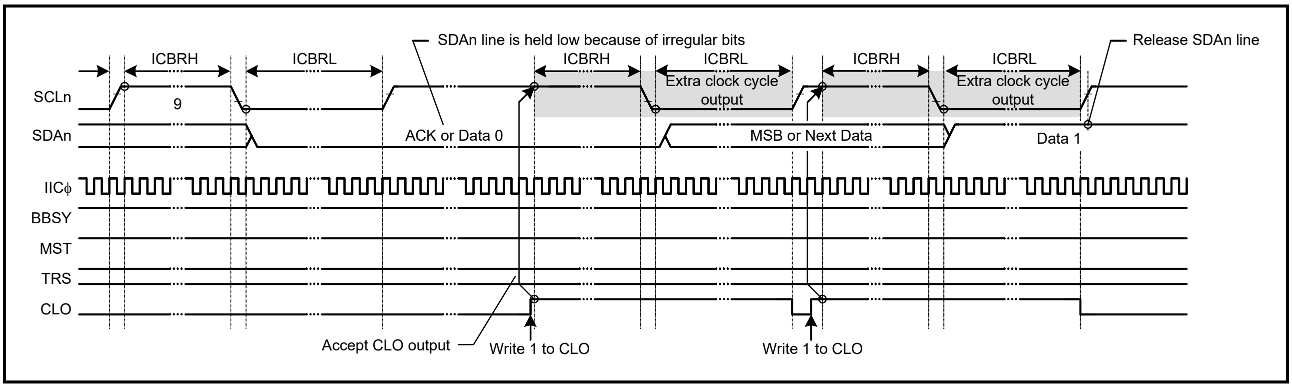

Figure 36.49 Extra SCL clock cycle output function using the CLO bit

36.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets: an IIC reset, which initializes all registers, including the BBSY flag in ICCR2, and an internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings. After issuing a reset, always set the IICRST bit in ICCR1 to 0.

Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 36.15, State of Registers when Issuing each Condition.

36.13 SMBus Operation

The IIC is available for data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, ICBRH, and ICBRL. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

36.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW: SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW: SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW: MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW: MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW: MEXT}$ values from start condition to stop condition must be within $T_{LOW: SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW: MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to ICDRT).

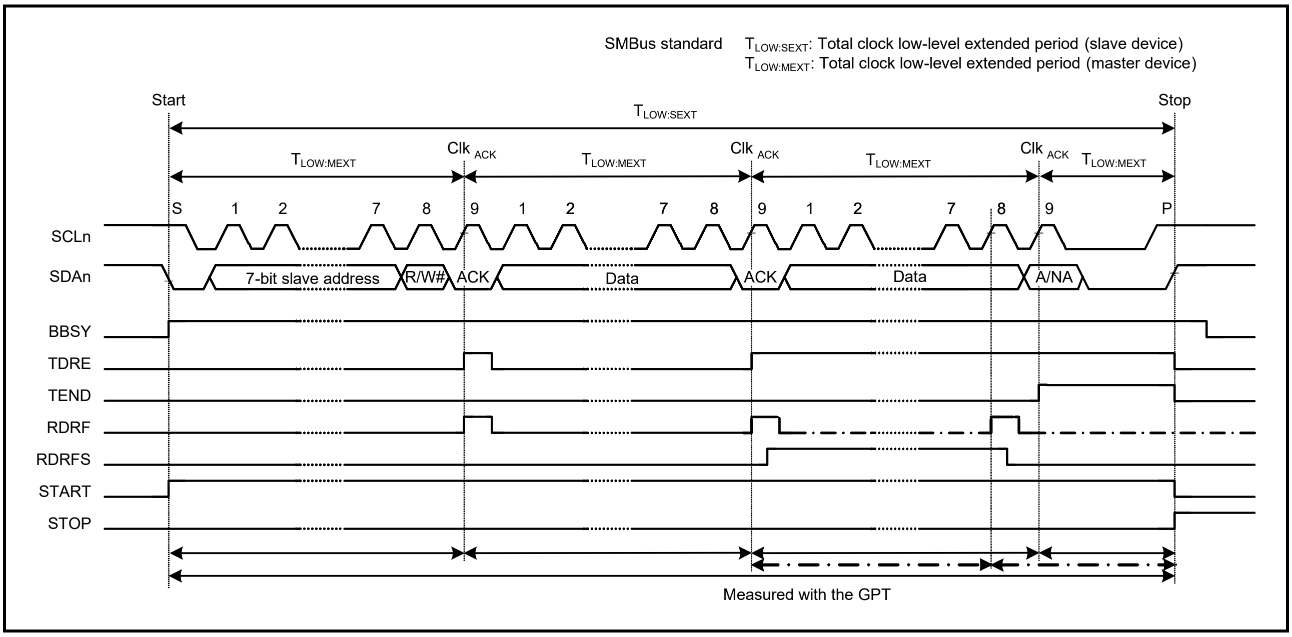

Figure 36.50 SMBus timeout measurement

36.13.2 Packet Error Code (PEC)

The MCU incorporates a CRC calculator, which enables transmission of a packet error code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 40, Cyclic Redundancy Check (CRC) Calculator.

In master transmit mode, the PEC data can be invoked by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the eighth clock cycle.

36.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating on an SMBus, a slave device can temporarily act as a master device to notify the SMBus host or ARP master of, or request the SMBus host for, its own slave address or request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

36.14 Interrupt Sources

The IIC issues four types of interrupt requests: transfer error or event occurrence (detection of arbitration-lost, NACK, timeout, start or restart condition, or stop condition), receive data full, transmit data empty, and transmit end. Table 36.10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts are both capable of activating data transfer by the DTC or DMAC.

Table 36.10 Interrupt sources

Symbol	Interrupt source	Interrupt flag	DMAC/DTC activation	Interrupt condition
IICn_EEI*5	Transfer error or event occurrence	AL	Not possible	AL = 1, ALIE = 1
		NACKF		NACKF = 1, NAKIE = 1
		TMOF		TMOF = 1, TMOIE = 1
		START		START = 1, STIE = 1
		STOP		STOP = 1, SPIE = 1
IICn_RXI*2, *5	Receive data full	RDRF	Possible	RDRF = 1, RIE = 1
IICn_TXI*1, *5	Transmit data empty	TDRE	Possible	TDRE = 1, TIE = 1
IICn_TEI*3, *5	Transmit end	TEND	Not possible	TEND = 1, TEIE = 1
IIC0_WUI*4	Slave address match during wakeup function	WUF	Not possible	Slave address match Slave receive complete RWAK operation ASY0 = 1 WUIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, and then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

Note 1. Because IICn_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) automatically is set to 0 when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 2. Because IICn_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) automatically is set to 0 when data is read from ICDRR.

Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 4. Only channel 0 has a wakeup function, so IIC0_WUI is for channel 0 only.

Note 5. Channel number (n = 0 to 2).

Clear or mask each flag during interrupt handling.

36.14.1 Buffer Operation for IICn_TXI and IICn_RXI Interrupts

If the conditions for generating an IICn_TXI or IICn_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but saved internally. One request per source can be saved internally.

An interrupt request that was being saved in the ICU is output when the ICU.IELSRn.IR flag is set to 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the given peripheral module.

36.15 State of Registers when Issuing each Condition

The IIC has two dedicated resets, IIC reset and internal reset. Table 36.11 shows the register states when issuing each condition.

Table 36.11 Register states when issuing each condition (1 of 2)

Registers		Reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection

36.16 Output to the Event Link Controller (ELC)

The IIC0 to IIC2 modules handle event output for the ELC for the following sources:

(1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

(2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

(4) Transmit end

On completion of transfer, the associated event signal can be output to another module by the ELC.

36.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see Table 36.10) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see Table 36.10.

36.17 Usage Notes

36.17.1 Settings for the Module-Stop Function

IIC operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

36.17.2 Starting Transfer after an Interrupt Occurrence

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure shown here to clear interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unanticipated behavior of the IR flag.

To clear interrupts before starting transfer:

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits, such as ICIER.TIE, in the peripheral function to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, in the peripheral function and confirm that their value is 0.
4. Set the IR flag to 0.

37. Controller Area Network (CAN) Module

37.1 Overview

The Controller Area Network (CAN) module uses a message-based protocol to receive and transmit data between multiple slaves and masters in electromagnetically noisy applications. The module complies with the ISO 11898-1 (CAN 2.0A/CAN 2.0B) standard and supports up to 32 mailboxes, which can be configured for transmission or reception in normal mailbox and FIFO modes. Both standard (11-bit) and extended (29-bit) messaging formats are supported.

Table 37.1 lists the CAN module specifications and Figure 37.1 shows a block diagram. The CAN module requires an additional external CAN transceiver.

Table 37.1 CAN module specifications (1 of 2)

Parameter	Specifications
Data transfer rate	ISO11898-1-compliant for standard and extended frames
Bit rate	Data transfer rate programmable up to 1 Mbps (fCAN ≥ 8 MHz) fCAN: CAN clock source
Message box	32 mailboxes, with two selectable mailbox modes • Normal mode: 32 mailboxes independently configurable for either transmission or reception • FIFO mode: 24 mailboxes independently configurable for either transmission or reception, with remaining mailboxes used for receive and transmit 4-stage FIFOs.
Reception	• Support for data frame and remote frame reception • Reception ID format selectable to only standard ID, only extended ID, or mixed IDs • Programmable one-shot reception function • Selectable between overwrite mode (unread message overwritten) and overrun mode (unread message saved) • Reception complete interrupt independently enabled or disabled for each mailbox.
Acceptance filter	• Eight acceptance masks (one for every four mailboxes) • Masks independently enabled or disabled for each mailbox.
Transmission	• Support for data frame and remote frame transmission • Transmission ID format selectable to only standard ID, only extended ID, or mixed IDs) • Programmable one-shot transmission function • Broadcast messaging function • Priority mode selectable based on message ID or mailbox number • Support for transmission request abort, with abort completion comfirmable in status flag • Transmission complete interrupt independently enabled or disabled for each mailbox.
Mode transition for bus-off recovery	Mode transition for the recovery from the bus-off state selectable to: • ISO11898-1 specification-compliant • Automatic invoking of CAN halt mode on bus-off entry • Automatic invoking of CAN halt mode on bus-off end • Invoking of CAN halt mode through the software • Transition to error-active state through the software.
Error status monitoring	• Monitoring of CAN bus errors, including stuff error, form error, ACK error, 15-bit CRC error, bit error, and ACK delimiter error • Detection of transition to error states, including error-warning, error-passive, bus-off entry, and bus-off recovery • Supports reading of error counters.
Time stamping	• Time stamp function using a 16-bit counter • Reference clock selectable to 1-bit, 2-bit, 4-bit, and 8-bit time periods.
Interrupt function	Supports five interrupt sources: reception complete, transmission complete, receive FIFO, transmit FIFO, and error interrupts
CAN sleep mode	CAN clock stopped to reduce power consumption
Software support unit	Three software support units: • Acceptance filter support • Mailbox search support, including receive mailbox search, transmit mailbox search, and message lost search • Channel search support.
CAN clock source	PCLKB or CANMCLK

Table 37.1 CAN module specifications (2 of 2)

Parameter	Specifications
Test mode	Three test modes available for evaluation purposes: • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback).
Module-stop function	Module-stop state can be set to reduce power consumption

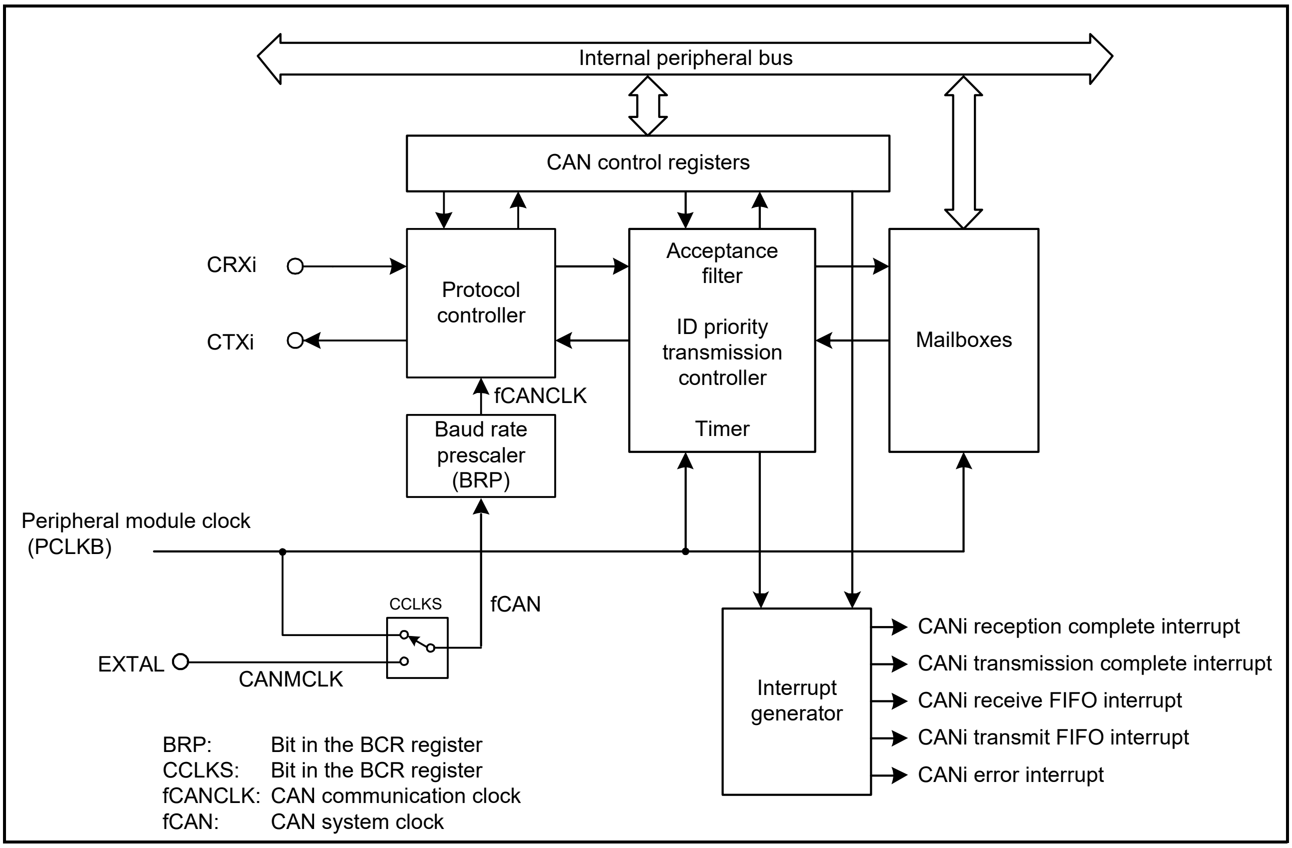

Figure 37.1 CAN module block diagram (i = 0, 1)

The CAN module includes the following blocks:

- CAN input and output pins
  CRXi and CTXi, where i = 0, 1
- Protocol controller
  Handles CAN protocol processing such as bus arbitration, bit timing during transmission and reception, stuffing, and error handling.
- Mailboxes
  Consists of 32 mailboxes, which can be configured as either transmit or receive. Each mailbox has an individual ID, data length code (DLC), data field (8 bytes), and time stamp.
- Acceptance filter
  Performs filtering of received messages. MKR0 to MKR7 are used for the filtering process.
- Timer
  Used for the time stamp function. The timer value when a message is stored in the mailbox is written as the time stamp value.
- Interrupt generator
  Generates five types of interrupts:
  - CANi reception complete interrupt

- CANi transmission complete interrupt
- CANi receive FIFO interrupt
- CANi transmit FIFO interrupt
- CANi error interrupt.

The CAN module communicates on the pins listed in Table 37.2. These pins are multiplexed with other signals on the MCU. For details, see section 20, I/O Ports.

Table 37.2 CAN module I/O pins

Pin name	I/O	Function
CRX0	Input	Data receive pin
CTX0	Output	Data transmit pin
CRX1	Input	Data receive pin
CTX1	Output	Data transmit pin

37.2 Register Descriptions

37.2.1 Control Register (CTLR)

Address(es): CAN0.CTLR 4005 0840h, CAN1.CTLR 4005 1840h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RBOC	BOM[1:0]		SLPM	CANM[1:0]		TSPS[1:0]		TSRC	TPM	MLM	IDFM[1:0]		MBM
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	MBM	CAN Mailbox Mode Select*1	0: Normal mailbox mode 1: FIFO mailbox mode.	R/W
b2, b1	IDFM[1:0]	ID Format Mode Select *1	b2 b1 0 0: Standard ID mode All mailboxes, including FIFO mailboxes, handle only standard IDs 0 1: Extended ID mode All mailboxes, including FIFO mailboxes, handle only extended IDs 1 0: Mixed ID mode All mailboxes, including FIFO mailboxes, handle both standard and extended IDs. In normal mailbox mode, use the associated IDE bit to differentiate standard and extended IDs. In FIFO mailbox mode, the associated IDE bits are used for mailboxes 0 to 23, the IDE bits in FIDCR0 and FIDCR1 are used for the receive FIFO, and the IDE bit associated with mailbox 24 is used for the transmit FIFO. 1 1: Setting prohibited.	R/W
b3	MLM	Message Lost Mode Select*1	0: Overwrite mode 1: Overrun mode.	R/W
b4	TPM	Transmission Priority Mode Select*1	0: ID priority transmit mode 1: Mailbox number priority transmit mode.	R/W
b5	TSRC	Time Stamp Counter Reset Command*4	0: Nothing occurred 1: Reset.*3	R/W

Bit	Symbol	Bit name	Description	R/W
b9, b8	CANM[1:0]	CAN Operating Mode Select*5	b9 b8 0 0: CAN operation mode 0 1: CAN reset mode 1 0: CAN halt mode 1 1: CAN reset mode (forced transition).	R/W
b10	SLPM	CAN Sleep Mode*5,*6	0: All other modes 1: CAN sleep mode.	R/W
b12, b11	BOM[1:0]	Bus-Off Recovery Mode*1	b12 b11 0 0: Normal mode (ISO11898-1-compliant) 0 1: Enter CAN halt mode automatically on entering bus-off state 1 0: Enter CAN halt mode automatically on end of bus-off state 1 1: Enter CAN halt mode during bus-off recovery period through a software request.	R/W
b13	RBOC	Forcible Return from Bus-Off*2	0: Nothing occurred 1: Forced return from bus-off state.*3	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Write to the BOM[1:0], TSPS[1:0], TPM, MLM, IDFM[1:0], and MBM bits in CAN reset mode.
Note 2. Set the RBOC bit to 1 in the bus-off state.
Note 3. This bit automatically is set to 0 after being set to 1. It should read as 0.
Note 4. Set the TSRC bit to 1 in CAN operation mode.
Note 5. When the CANM[1:0] and SLPM bits are changed, check STR to ensure that the mode is switched. Do not change the CANM[1:0] bits or SLPM bit until the mode is switched.
Note 6. Write to the SLPM bit in CAN reset mode or CAN halt mode. When changing the SLPM bit, write 0 or 1 to only the SLPM bit.

MBM bit (CAN Mailbox Mode Select)

When the MBM bit is 0 (normal mailbox mode), mailboxes 0 to 31 are configured as transmit or receive mailboxes. When the MBM bit is 1 (FIFO mailbox mode), mailboxes 0 to 23 are configured as transmit or receive mailboxes. Mailboxes 24 to 27 are configured as a transmit FIFO, and mailboxes 28 to 31 are configured as a receive FIFO. Transmit data is written into mailbox 24, the window mailbox for the transmit FIFO. Receive data is read from mailbox 28, the window mailbox for the receive FIFO.

Table 37.3 lists the mailbox configuration.

IDFM[1:0] bits (ID Format Mode Select)

The IDFM[1:0] bits specify the ID format.

MLM bit (Message Lost Mode Select)

The MLM bit specifies the operation when a new message is captured in the unread mailbox. Overwrite mode or overrun mode can be selected. In both cases, the mode applies to all mailboxes, including the receive FIFO.

When the MLM bit is 0, all mailboxes are set to overwrite mode. Any new message received overwrites the pre-existing message.

When the MLM bit is 1, all mailboxes are set to overrun mode. Any new message received does not overwrite the pre-existing message, and it is discarded.

TPM bit (Transmission Priority Mode Select)

The TPM bit specifies the priority when transmitting messages. ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission.

When TPM is 0, ID priority transmit mode is selected and transmission priority is arbitrated as defined in the ISO11898-1 CAN specification. In ID priority transmit mode, mailboxes 0 to 31 (in normal mailbox mode), and mailboxes 0 to 23 (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority.

Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration.

When TPM is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (0 to 23).

TSRC bit (Time Stamp Counter Reset Command)

The TSRC bit resets the time stamp counter. When it is set to 1, TSR is set to 0000h. TSRC is set to 0 automatically.

TSPS[1:0] bits (Time Stamp Prescaler Select)

The TSPS[1:0] bits select the prescaler for the time stamp. The reference clock for the time stamp can be selected to 1-bit, 2-bit, 4-bit, or 8-bit time periods.

CANM[1:0] bits (CAN Operating Mode Select)

The CANM[1:0] bits select one of the following modes for the CAN module: CAN operation mode, CAN reset mode, or CAN halt mode. CAN sleep mode is set in the SLPM bit. For details, see section 37.3, Operation Modes.

When the CAN module enters CAN halt mode based on the BOM[1:0] setting, the CANM[1:0] bits are automatically set to 10b.

SLPM bit (CAN Sleep Mode)

When the SLPM bit is set to 1, the CAN module enters CAN sleep mode. When the SLPM bit is set to 0, the CAN module exits CAN sleep mode. For details, see section 37.3, Operation Modes.

BOM[1:0] bits (Bus-Off Recovery Mode)

The BOM[1:0] bits select bus-off recovery mode for the CAN module.

When the BOM[1:0] bits are 00b, the recovery from bus-off is compliant with the ISO11898-1 specification. The CAN module recovers CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off.

When the BOM[1:0] bits are 01b and the CAN module reaches the bus-off state, the CANM[1:0] bits in CTLR set 10b to enter CAN halt mode. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 00h.

When the BOM[1:0] bits are 10b, the CANM[1:0] bits are set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, and after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 00h.

When the BOM[1:0] bits are 11b, the CAN module enters CAN halt mode by setting the CANM[1:0] bits to 10b while the CAN module is still in the bus-off state. No bus-off recovery interrupt request occurs when recovering from bus-off, and TECR and RECR are set to 00h. However, the interrupt does occur if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM[1:0] bits are set to 10b.

If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM[1:0] bits are 01b, or at bus-off end when the BOM[1:0] bits are 10b), then the CPU request has higher priority.

RBOC bit (Forcible Return from Bus-Off)

When the RBOC bit is set to 1 in the bus-off state, the CAN module forcibly exits bus-off. It is set to 0 automatically, and the error state changes from bus-off to error-active. When the RBOC bit is set to 1, RECR and TECR clear to 00h and the BOST bit in STR is set to 0, indicating no bus-off state. The other registers remain unchanged when RBOC is set to 1. No bus-off recovery interrupt request occurs. Use the RBOC bit only when the BOM[1:0] bits are 00b (normal mode).

Table 37.3 Mailbox configuration

Mailbox	MBM bit = 0 (normal mailbox mode)	MBM bit = 1 (FIFO mailbox mode)*1 to *5
Mailboxes 0 to 23	Normal mailbox	Normal mailbox
Mailboxes 24 to 27		Transmit FIFO
Mailboxes 28 to 31		Receive FIFO

Note 1. The transmit FIFO is controlled by TFCR. The MCTL_TXj registers associated with mailboxes 24 to 27 are disabled. MCTL_TX24 to MCTL_TX27 cannot be used by the transmit FIFO.

Note 2. The receive FIFO is controlled by RFCR. The MCTL_RXj registers associated with mailboxes 28 to 31 are disabled. MCTL_RX28 to MCTL_RX31 cannot be used by the receive FIFO.
Note 3. See the MIER_FIFO description for information on the FIFO interrupts.
Note 4. The bits in MKIVLR associated with mailboxes 24 to 31 are disabled. Set 0 to these bits.
Note 5. The transmit and receive FIFOs can be used for both data frames and remote frames.

37.2.2 Bit Configuration Register (BCR)

Address(es): CAN0.BCR 4005 0844h, CAN1.BCR 4005 1844h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	BRP[9:0]	Baud Rate Prescaler Select *1	These bits set the frequency of the CAN communication clock (fCANCLK).	R/W
b27, b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	TSEG1[3:0]	Time Segment 1 Control	b31 b28 0 0 0 0: Setting prohibited 0 0 0 1: Setting prohibited 0 0 1 0: Setting prohibited 0 0 1 1: 4 Tq 0 1 0 0: 5 Tq 0 1 0 1: 6 Tq 0 1 1 0: 7 Tq 0 1 1 1: 8 Tq 1 0 0 0: 9 Tq 1 0 0 1: 10 Tq 1 0 1 0: 11 Tq 1 0 1 1: 12 Tq 1 1 0 0: 13 Tq 1 1 0 1: 14 Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq.	R/W

Tq: Time Quantum

Note 1. Do not select a value less than or equal to 1 while the SCKSCR.CKSEL[2:0] bits are 011b (selecting the main clock oscillator).

For setting the bit timing, see section 37.4, Data Transfer Rate Configuration. Set BCR before entering CAN halt or operation mode from reset mode. After the setting is made once, this register can be written to in CAN reset or CAN halt mode. 32-bit read/write accesses must be performed carefully so as not to change bits [7:0].

CCLKS bit (CAN Clock Source Selection)

When the CCLKS bit is 0, the peripheral module clock (PCLKB) produced by the PLL frequency synthesizer is used as the CAN clock source (fCAN). When the CCLKS bit is 1, CANMCLK produced externally by the EXTAL pins is used as the CAN clock source (fCAN).

TSEG2[2:0] bits (Time Segment 2 Control)

The TSEG2[2:0] bits specify the length of phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 8 Tq can be set. Set a value smaller than that of the TSEG1[3:0] bits.

SJW[1:0] bits (Synchronization Jump Width Control)

The SJW[1:0] bits specify the synchronization jump width with a Tq value. A value from 1 to 4 Tq can be set. Set a value smaller than or equal to that of the TSEG2[2:0] bits.

BRP[9:0] bits (Baud Rate Prescaler Select)

The BRP[9:0] bits set the frequency of the CAN communication clock (fCANCLK). The fCANCLK cycle is 1 Tq. If the setting is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

TSEG1[3:0] bits (Time Segment 1 Control)

The TSEG1[3:0] bits specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a time quantum (Tq) value. A value from 4 to 16 Tq can be set.

37.2.3 Mask Register k (MKRk) (k = 0 to 7)

Address(es): CAN0.MKR[0] 4005 0400h to CAN0.MKR[7] 4005 041Ch, CAN1.MKR[0] 4005 1400h to CAN1.MKR[7] 4005 141Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	SID[10:0]											EID[17:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EID[17:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b17 to b0	EID[17:0]	Extended ID	0: Do not compare associated EID[17:0] bits 1: Compare associated EID[17:0] bits.	R/W
b28 to b18	SID[10:0]	Standard ID	0: Do not compare associated SID[10:0] bits 1: Compare associated SID[10:0] bits.	R/W
b31 to b29	—	Reserved	The read value is undefined. The write value should be 0.	R/W

For the mask function in FIFO mailbox mode, see section 37.6, Acceptance Filtering and Masking Functions.

Write to MKR0 to MKR7 in CAN reset mode or CAN halt mode.

EID[17:0] bits (Extended ID)

The EID[17:0] bits are the filter mask bits associated with the CAN extended ID bits. They are used to receive extended ID messages. When an EID[17:0] bit is set to 0, the received ID is not compared with the associated mailbox ID. When the EID[17:0] bits are set to 1, the received ID is compared with the associated mailbox ID.

SID[10:0] bits (Standard ID)

The SID[10:0] bits are the filter mask bits associated with the CAN standard ID bits. They are used to receive both standard ID and extended ID messages. When the SID[10:0] bits are set to 0, the received ID is not compared with the associated mailbox ID. When the SID[10:0] bits are set to 1, the received ID is compared with the associated mailbox ID.

37.2.4 FIFO Received ID Compare Registers 0 and 1 (FIDCR0 and FIDCR1)

Address(es): CAN0.FIDCR0 4005 0420h, CAN0.FIDCR1 4005 0424h, CAN1.FIDCR0 4005 1420h, CAN1.FIDCR1 4005 1424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	—	SID[10:0]											EID[17:0]	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EID[17:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b17 to b0	EID[17:0]	Extended ID	Extended ID of the data and remote frames	R/W
b28 to b18	SID[10:0]	Standard ID	Standard ID of the data and remote frames	R/W
b29	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame.	R/W
b31	IDE	ID Extension*1	0: Standard ID 1: Extended ID.	R/W

Note 1. The IDE bit is enabled when the CTLR.IDFM[1:0] bits are 10b (mixed ID mode). When the IDFM[1:0] bits are not 10b, only write 0 to IDE. It reads as 0.

FIDCR0 and FIDCR1 are enabled when the MBM bit in CTLR is set to 1 (FIFO mailbox mode). In this mode, the EID[17:0], SID[10:0], RTR, and IDE bits in mailbox 28 to mailbox 31 are disabled. Write to FIDCR0 and FIDCR1 in CAN reset mode or CAN halt mode. For information on using FIDCR0 and FIDCR1, see section 37.6, Acceptance Filtering and Masking Functions.

EID[17:0] bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames. They are used to receive extended ID messages.

SID[10:0] bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames. They are used to receive both standard ID and extended ID messages.

RTR bit (Remote Transmission Request)

The RTR bit sets the frame format to data frames or remote frames:

- When both RTR bits in FIDCR0 and FIDCR1 are set to 0, only data frames are received
- When both RTR bits in FIDCR0 and FIDCR1 are set to 1, only remote frames are received
- When the RTR bits in FIDCR0 and FIDCR1 are set to different values, both data frames and remote frames are received.

IDE bit (ID Extension)

The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode):

- When both IDE bits in FIDCR0 and FIDCR1 are set to 0, only standard ID frames are received
- When both IDE bits in FIDCR0 and FIDCR1 are set to 1, only extended ID frames are received
- When the IDE bits in FIDCR0 and FIDCR1 are set to different values, both standard ID and extended ID frames are received.

37.2.5 Mask Invalid Register (MKIVLR)

Address(es): CAN0.MKIVLR 4005 0428h, CAN1.MKIVLR 4005 1428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MB31	MB30	MB29	MB28	MB27	MB26	MB25	MB24	MB23	MB22	MB21	MB20	MB19	MB18	MB17	MB16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b31 to b0	MB31 to MB0	Mask Invalid	0: Mask valid 1: Mask invalid.	R/W

Each bit in MKIVLR is associated with a mailbox of the same number. Bit [0] in MKIVLR corresponds to mailbox 0 (MB0), and bit [31] corresponds to mailbox 31 (MB31).*1

When a bit is set to 1, the associated acceptance mask register becomes invalid for the associated mailbox. When a mask invalid bit is set to 1, a message is received by the associated mailbox only if the receive message ID matches the mailbox ID exactly.

Write to MKIVLR in CAN reset or halt mode.

Note 1. Set bits [31:24] to 0 in FIFO mailbox mode.

37.2.6 Mailbox Register j (MBj_ID, MBj_DL, MBj_Dm, MBj_TS) (j = 0 to 31; m = 0 to 7)

Table 37.4 lists the CANi mailbox memory mapping, and Table 37.5 lists the CAN data frame configuration.

The value after reset of the CANi mailbox is undefined.

Write to MBj_ID, MBj_DL, MBj_Dm, and MBj_TS only when the related MCTL_TXj or MCTL_RXj register (j = 0 to 31) is 00h and the associated mailbox is not processing an abort request.

See Table 37.4 for detailed register addresses.

Table 37.4 CANi mailbox memory mapping (1 of 2)

Address		Message content
CAN0	**CAN1**	**Memory mapping**
4005 0200h + 16 × j + 0	4005 1200h + 16 × j + 0	IDE, RTR, SID10 to SID6
4005 0200h + 16 × j + 1	4005 1200h + 16 × j + 1	SID5 to SID0, EID17, EID16

	TSH[7:0]								TSL[7:0]							
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b7 to b0	TSL[7:0]	Time Stamp Lower Byte	The TSH[7:0] and TSL[7:0] bits store the counter value of the time stamp when received messages are stored in the mailbox.	R/W
b15 to b8	TSH[7:0]	Time Stamp Higher Byte		R/W

EID[17:0] bits (Extended ID)

The EID[17:0] bits set the extended ID of data frames and remote frames. They are used to transmit or receive extended ID messages.

SID[10:0] bits (Standard ID)

The SID[10:0] bits set the standard ID of data frames and remote frames. They are used to transmit or receive both standard ID and extended ID messages.

RTR bit (Remote Transmission Request)

The RTR bit sets the frame format to data frames or remote frames.

- The receive mailbox only receives frames with the format specified in the RTR bit
- The transmit mailbox transmits with the frame format specified in the RTR bit
- The receive FIFO mailbox receives the data frame, remote frame, or both frames specified in the RTR bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits the data frame or remote frame specified in the RTR bit in the transmit message.

IDE bit (ID Extension)

The IDE bit sets the ID format to standard IDs or extended IDs. The IDE bit is enabled when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

- The receive mailbox only receives the ID format specified in the IDE bit
- The transmit mailbox transmits with the ID format specified in the IDE bit
- The receive FIFO mailbox receives messages with the standard ID and extended ID settings specified in the IDE bit in FIDCR0 and FIDCR1
- The transmit FIFO mailbox transmits messages with the standard ID or extended ID settings specified in the IDE bit in the transmit message.

DLC[3:0] bits (Data Length Code)

The DLC[3:0] bits specify the data length to be transmitted in data frames. When a remote frame is used to request data, this field specifies the requested data length.

When a data frame is received, the received data length is stored in this field. When a remote frame is received, this field stores the requested data length.

37.2.7 Mailbox Interrupt Enable Register (MIER)

Address(es): CAN0.MIER 4005 042Ch, CAN1.MIER 4005 142Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MB31	MB30	MB29	MB28	MB27	MB26	MB25	MB24	MB23	MB22	MB21	MB20	MB19	MB18	MB17	MB16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MB15	MB14	MB13	MB12	MB11	MB10	MB9	MB8	MB7	MB6	MB5	MB4	MB3	MB2	MB1	MB0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b31 to b0	MB31 to MB0	Interrupt Enable	0: Disable interrupt 1: Enable interrupt. Bit [31] is associated with mailbox 31 (MB31), and bit [0] with mailbox 0 (MB0).	R/W

MIER can enable interrupts for each mailbox independently. This register is available in normal mailbox mode. Do not access this register in FIFO mailbox mode.

Each bit is associated with the mailbox having the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes:

- Bit [0] in MIER corresponds to mailbox 0 (MB0)
- Bit [31] in MIER corresponds to mailbox 31 (MB31).

Write to MIER only when the associated MCTL_TXj or MCTL_RXj register (j = 0 to 31) is 00h and the associated mailbox is not processing a transmission or reception abort request.

37.2.8 Mailbox Interrupt Enable Register for FIFO Mailbox Mode (MIER_FIFO)

Address(es): CAN0.MIER_FIFO 4005 042Ch, CAN1.MIER_FIFO 4005 142Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	MB29	MB28	—	—	MB25	MB24	MB23	MB22	MB21	MB20	MB19	MB18	MB17	MB16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MB15	MB14	MB13	MB12	MB11	MB10	MB9	MB8	MB7	MB6	MB5	MB4	MB3	MB2	MB1	MB0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b23 to b0	MB23 to MB0	Interrupt Enable	0: Disable interrupt 1: Enable interrupt. Bit [23] is associated with mailbox 23 (MB23), and bit [0] with mailbox 0 (MB0).	R/W
b24	MB24	Transmit FIFO Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b25	MB25	Transmit FIFO Interrupt Generation Timing Control	0: Generate every time transmission completes 1: Generate when the transmit FIFO empties on transmission completion.	R/W
b27, b26	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b28	MB28	Receive FIFO Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b29	MB29	Receive FIFO Interrupt Generation Timing Control*1	0: Generate every time reception completes 1: Generate when the receive FIFO becomes a buffer warning*2 on reception completion.	R/W
b31, b30	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note 1. No interrupt request occurs when the receive FIFO becomes buffer warning because it is full.
Note 2. "Buffer warning" indicates a state in which the third message is stored in the receive FIFO.

MIER_FIFO can individually enable interrupts for each mailbox and FIFO. This register is available in normal mailbox mode and FIFO mailbox mode. Do not access it in normal mailbox mode.

The MB0 to MB23 bits are associated with the mailbox having the same number. These bits enable or disable transmission and reception complete interrupts for the associated mailboxes:

- Bit [0] in MIER_FIFO is associated with mailbox 0 (MB0)
- Bit [23] in MIER_FIFO is associated with mailbox 23 (MB23).

MB24, MB25, MB28, and MB29 specify whether transmit and receive FIFO interrupts are enabled or disabled, and the timing of interrupt requests.

Write to MIER_FIFO only when the associated MCTL_TXj or MCTL_RXj register (j = 0 to 31) is 00h and the associated mailbox is not processing a transmission or reception abort request. In addition, change the bits in MIER_FIFO for the associated FIFO only when the TFE bit in TFCR is 0 and the TFEST bit is 1, and the RFE bit in RFCR is 0 and the RFEST bit in RFCR is 1.

37.2.9 Message Control Register for Transmit (MCTL_TXj) (j = 0 to 31)

- Transmit mode (when the TRMREQ bit is 1 and the RECREQ bit is 0)

Address(es): CAN0.MCTL_TX[0] 4005 0820h to CAN0.MCTL_TX[31] 4005 083Fh,
CAN1.MCTL_TX[0] 4005 1820h to CAN1.MCTL_TX[31] 4005 183Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	TRMREQ	RECREQ	—	ONESHOT	—	TRMABT	TRMACTIVE	SENTDATA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SENTDATA	Transmission Complete Flag *1,*2	0: Transmission not complete 1: Transmission complete.	R/W
b1	TRMACTIVE	Transmission-in-Progress Status Flag	0: Transmission pending or not requested 1: Transmission in progress.	R
b2	TRMABT	Transmission Abort Complete Flag *1,*2	0: Transmission started, transmission abort failed because transmission completed, or transmission abort not requested 1: Transmission abort complete.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ONESHOT	One-Shot Enable *2,*3	0: Disable one-shot transmission 1: Enable one-shot transmission.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	RECREQ	Receive Mailbox Request *2,*3,*4,*5	0: Do not configure for reception 1: Configure for reception.	R/W
b7	TRMREQ	Transmit Mailbox Request *2,*4	0: Do not configure for transmission 1: Configure for transmission.	R/W

Note 1. Write 0 only. Writing 1 has no effect.
Note 2. When writing to bits of this register, write 1 to SENTDATA and TRMABT if these bits are not the write target.
Note 3. To enter one-shot transmit mode, write 1 to the ONESHOT bit at the same time as setting the TRMREQ bit to 1. To exit one-shot transmit mode, write 0 to the ONESHOT bit after the message is transmitted or aborted.
Note 4. Do not set both the RECREQ and TRMREQ bits to 1.
Note 5. When setting the RECREQ bit to 0, set the SENTDATA, TRMACTIVE, and TRMABT flags to 0 simultaneously.

MCTL_TXj sets mailbox j to transmit mode or receive mode. In transmit mode, MCTL_TXj also controls and indicates the transmission status. Do not access MCTL_TXj if mailbox j is in receive mode. Only write to MCTL_TXj in CAN operation or halt mode. Do not use MCTL_TX24 to MCTL_TX31 in FIFO mailbox mode.

SENTDATA flag (Transmission Complete Flag)

The SENTDATA flag is set to 1 when data transmission from the associated mailbox is complete. The SENTDATA flag is set to 0 through a software write. To set it to 0, first set the TRMREQ bit to 0. The SENTDATA and TRMREQ flags cannot be set to 0 simultaneously. To transmit a new message from the associated mailbox, set the SENTDATA flag to 0.

TRMACTIVE flag (Transmission-in-Progress Status Flag)

The TRMACTIVE flag is set to 1 when the associated mailbox of the CAN module begins transmitting a message. It is set to 0 when the CAN module loses CAN bus arbitration, a CAN bus error occurs, or data transmission completes.

TRMABT flag (Transmission Abort Complete Flag)

The TRMABT flag is set to 1 in the following cases:

- Following a transmission abort request, when the transmission abort is complete before starting transmission
- Following a transmission abort request, when the CAN module detects CAN bus arbitration-lost or a CAN bus error
- In one-shot transmission mode (RECREQ = 0, TRMREQ = 1, and ONESHOT = 1), when the CAN module detects a CAN bus arbitration-lost or a CAN bus error.

The TRMABT flag does not set to 1 when data transmission is complete. The SENTDATA flag is set to 1. The TRMABT flag is set to 0 through a software write.

ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in transmit mode (RECREQ = 0 and TRMREQ = 1), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration-lost occurs. When transmission is complete, the SENTDATA flag is set to 1. If transmission does not complete because of a CAN bus error or CAN bus arbitration-lost error, the TRMABT flag is set to 1. Set the ONESHOT bit to 0 after the SENTDATA or TRMABT flag is set to 1.

RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects the receive modes listed in Table 37.10.

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL_TXj.RECREQ is the mirror bit of MCTL_RXj.RECREQ.

TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in Table 37.10.

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception, and then set the NEWDATA and MSGLOST bits to 0 before changing to transmission.

Note: MCTL_TXj.TRMREQ is the mirror bit of MCTL_RXj.TRMREQ.

37.2.10 Message Control Register for Receive (MCTL_RXj) (j = 0 to 31)

- Receive mode (when the TRMREQ bit is 0 and the RECREQ bit is 1)

Address(es): CAN0.MCTL_RX[0] 4005 0820h to CAN0.MCTL_RX[31] 4005 083Fh,
CAN1.MCTL_RX[0] 4005 1820h to CAN1.MCTL_RX[31] 4005 183Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	TRMREQ	RECREQ	—	ONESHOT	—	MSGLOST	INVALDATA	NEWDATA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	NEWDATA	Reception Complete Flag*1,*2	0: No data received, or 0 was written to the bit 1: New message being stored or was stored in the mailbox.	R/W
b1	INVALDATA	Reception-in-Progress Status Flag	0: Message valid 1: Message being updated.	R
b2	MSGLOST	Message Lost Flag*1,*2	0: Message not overwritten or overrun 1: Message overwritten or overrun.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ONESHOT	One-Shot Enable*2,*3	0: Disable one-shot reception 1: Enable one-shot reception.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	RECREQ	Receive Mailbox Request *2,*3,*4,*5	0: Do not configure for reception 1: Configure for reception.	R/W
b7	TRMREQ	Transmit Mailbox Request *2,*4	0: Do not configure for transmission 1: Configure for transmission.	R/W

Note 1. Write 0 only. Writing 1 has no effect.
Note 2. When writing to bits of this register, write 1 to the NEWDATA and MSGLOST bits if they are not the write target.
Note 3. To enter one-shot receive mode, write 1 to the ONESHOT bit at the same time as setting the RECREQ bit to 1. To exit one-shot receive mode, write 0 to the ONESHOT bit after writing 0 to the RECREQ bit and confirming that it is 0.
Note 4. Do not set both the RECREQ and TRMREQ bits to 1.
Note 5. When setting the RECREQ bit to 0, set the MSGLOST, NEWDATA, and RECREQ bits to 0 simultaneously.

MCTL_RXj sets mailbox j to transmit or receive mode. In receive mode, MCTL_RXj also controls and indicates the reception status. Do not access MCTL_RXj if mailbox j is in transmit mode. Only write to the MCTL_RXj in CAN operation or halt mode. Do not use MCTL_RX24 to MCTL_RX31 in FIFO mailbox mode.

NEWDATA flag (Reception Complete Flag)

The NEWDATA flag is set to 1 when a new message is being stored or was stored in the mailbox. Always set this bit to 1 simultaneously with the INVALDATA flag. The NEWDATA flag is cleared to 0 through a software write. The NEWDATA flag cannot be set to 0 through a software write while the associated INVALDATA flag is 1.

INVALDATA flag (Reception-in-Progress Status Flag)

After the completion of a message reception, the INVALDATA flag is set to 1 while the received message is being updated into the associated mailbox. The INVALDATA flag is set to 0 immediately after the message is stored. If the mailbox is read while the INVALDATA flag is 1, the data is undefined.

MSGLOST flag (Message Lost Flag)

The MSGLOST flag is set to 1 when the mailbox is overwritten or overrun by a new received message while the NEWDATA flag is 1. The MSGLOST flag is set to 1 at the end of the 6th bit of EOF. The MSGLOST flag is set to 0 through a software write.

In both overwrite and overrun modes, the MSGLOST flag cannot be set to 0 through a software write during the 5 PCLKB cycles following the 6th bit of EOF.

ONESHOT bit (One-Shot Enable)

When the ONESHOT bit is set to 1 in receive mode (RECREQ = 1 and TRMREQ = 0), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of the NEWDATA and INVALDATA flags is the same as in normal receive mode. In one-shot receive mode, the MSGLOST flag does not set to 1. To set the ONESHOT bit to 0, first write 0 to the RECREQ bit and ensure that it is 0.

RECREQ bit (Receive Mailbox Request)

The RECREQ bit selects receive modes listed in Table 37.10.

When the RECREQ bit is set to 1, the associated mailbox is configured for reception of a data or remote frame.

When the RECREQ bit is set to 0, the associated mailbox is not configured for reception of a data or remote frame.

Due to hardware protection, the RECREQ bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from the acceptance filter processing (the beginning of the CRC field)
- Hardware protection is released:
  - For the mailbox that is specified to receive the incoming message, after the received data is stored in the mailbox or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - For the other mailboxes, after acceptance filter processing
  - If no mailbox is specified to receive the message, after acceptance filter processing.

When setting the RECREQ bit to 1, do not set the TRMREQ bit to 1. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set the SENTDATA and TRMABT flags to 0 before changing to reception.

Note: MCTL_RXj.RECREQ is the mirror bit of MCTL_TXj.RECREQ.

TRMREQ bit (Transmit Mailbox Request)

The TRMREQ bit selects the transmit modes listed in Table 37.10.

When the TRMREQ bit is set to 1, the associated mailbox is configured for transmission of a data or remote frame.

When the TRMREQ bit is set to 0, the associated mailbox is not configured for transmission of a data or remote frame.

If the TRMREQ bit is changed from 1 to 0 to cancel the associated transmission request, either the TRMABT or SENTDATA flag is set to 1. When setting the TRMREQ bit to 1, do not set the RECREQ bit to 1. To change the configuration of a mailbox from reception to transmission, first abort the reception and then set the NEWDATA and MSGLOST bits to 0 before changing to transmission.

Note: MCTL_RXj.TRMREQ is the mirror bit of MCTL_TXj.TRMREQ.

37.2.11 Receive FIFO Control Register (RFCR)

Address(es): CAN0.RFCR 4005 0848h, CAN1.RFCR 4005 1848h

	b7	b6	b5	b4	b3	b2	b1	b0
	RFEST	RFWST	RFFST	RFMLF	RFUST[2:0]			RFE
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	RFE	Receive FIFO Enable	0: Disable receive FIFO 1: Enable receive FIFO.	R/W

Bit	Symbol	Bit name	Description	R/W
b3 to b1	RFUST[2:0]	Receive FIFO Unread Message Number Status	b3 b1 0 0 0: No unread message 0 0 1: 1 unread message 0 1 0: 2 unread messages 0 1 1: 3 unread messages 1 0 0: 4 unread messages 1 0 1: Reserved 1 1 0: Reserved 1 1 1: Reserved.	R
b4	RFMLF	Receive FIFO Message Lost Flag	0: Receive FIFO message not lost 1: Receive FIFO message lost.	R/W
b5	RFFST	Receive FIFO Full Status Flag	0: Receive FIFO not full 1: Receive FIFO full (4 unread messages).	R
b6	RFWST	Receive FIFO Buffer Warning Status Flag	0: Receive FIFO is not buffer warning 1: Receive FIFO is buffer warning (3 unread messages).	R
b7	RFEST	Receive FIFO Empty Status Flag	0: Unread message in receive FIFO 1: No unread message in receive FIFO.	R

Write to RFCR in CAN operation or halt mode.

RFE bit (Receive FIFO Enable)

When the RFE bit is set to 1, the receive FIFO is enabled.

When the RFE bit is set to 0, the receive FIFO is disabled for reception and becomes empty (RFEST bit = 1). Write 0 to the RFE bit simultaneously with setting the RFMLF flag.

Do not set this bit to 1 in normal mailbox mode (MBM bit in CTLR = 0). Due to hardware protection, the RFE bit cannot be set to 0 through a software write during the following period:

- Hardware protection is started from acceptance filter processing (the beginning of the CRC field)
- When hardware protection is released:
  - If the receive FIFO is specified to receive the incoming message, after the received data is stored in the receive FIFO or a CAN bus error occurs. This means that the maximum period of hardware protection is from the beginning of the CRC field to the end of the 7th bit of EOF.
  - If the receive FIFO is not specified to receive the message, after acceptance filter processing.

RFUST[2:0] bits (Receive FIFO Unread Message Number Status)

The RFUST[2:0] bits indicate the number of unread messages in the receive FIFO. The value of the RFUST[2:0] bits initializes to 000b when the RFE bit is set to 0.

RFMLF flag (Receive FIFO Message Lost Flag)

The RFMLF flag is set to 1 (receive FIFO message lost) when the receive FIFO receives a new message and is full. It is set to 1 at the end of the 6th bit of EOF.

The RFMLF flag is set to 0 through a software write. Writing 1 has no effect. In both overwrite and overrun modes, if the receive FIFO is full and determined to have received a message, the RFMLF flag cannot be set to 0 (receive FIFO message was not lost) through a software write because of hardware protection during the 5 PCLKB cycles following the 6th bit of EOF.

RFFST flag (Receive FIFO Full Status Flag)

The RFFST flag is set to 1 (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. It is 0 (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The flag is set to 0 when the RFE bit is 0.

RFWST flag (Receive FIFO Buffer Warning Status Flag)

The RFWST flag is set to 1 (receive FIFO is a buffer warning) when the number of unread messages in the receive FIFO is 3. It is 0 (receive FIFO is not a buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST flag is set to 0 when the RFE bit is 0.

RFEST flag (Receive FIFO Empty Status Flag)

The RFEST flag is set to 1 (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is 0. It is set to 1 when the RFE bit is set to 0. The flag is set to 0 (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more. Figure 37.2 shows the receive FIFO mailbox operation.

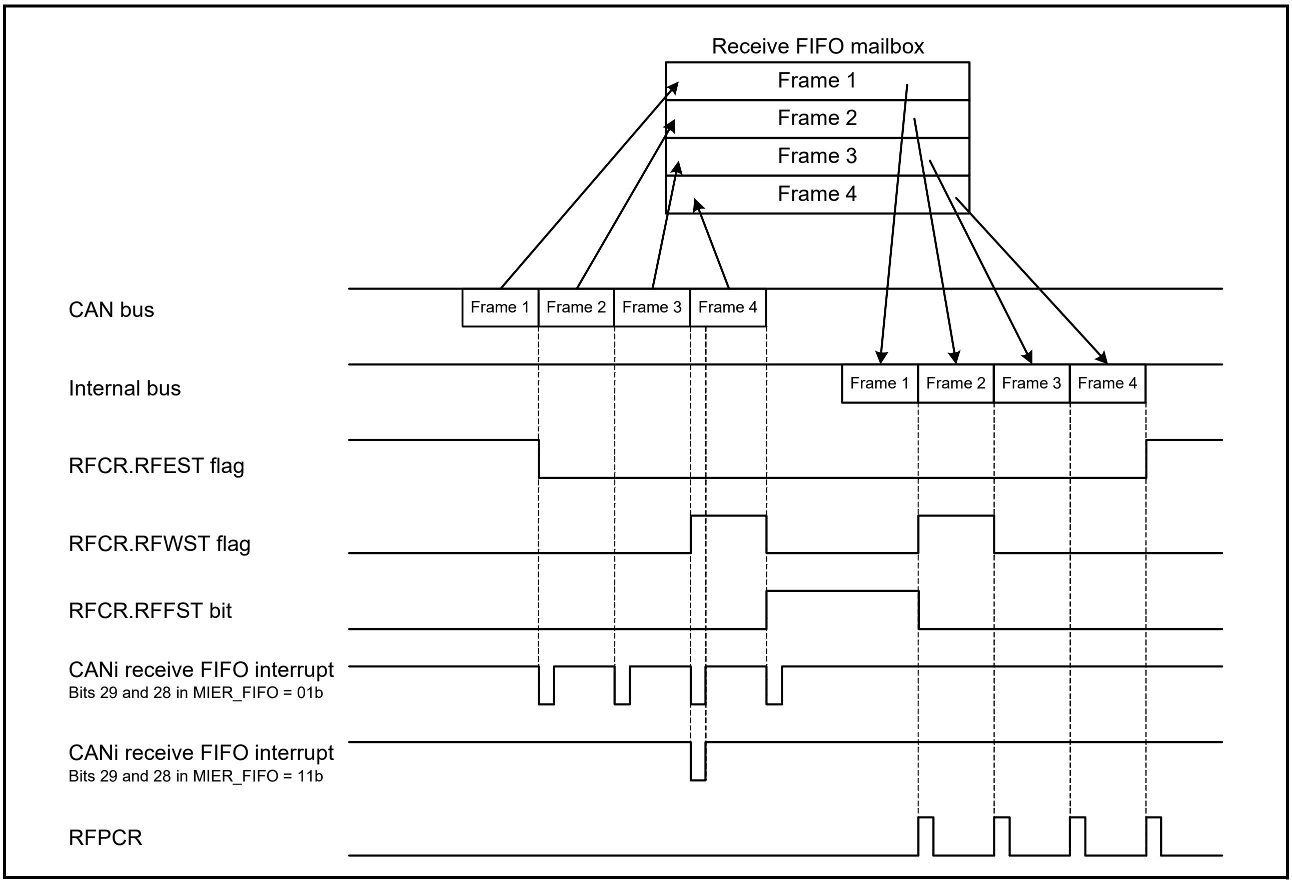

Figure 37.2 Receive FIFO mailbox operation when bits [29] and [28] in MIER_FIFO = 01b or 11b

37.2.12 Receive FIFO Pointer Control Register (RFPCR)

Address(es): CAN0.RFPCR 4005 0849h, CAN1.RFPCR 4005 1849h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	The CPU-side pointer for the receive FIFO is incremented by writing FFh to RFPCR.	W

When the receive FIFO is not empty, write FFh to RFPCR through the software to increment the CPU pointer to the next mailbox location. Do not write to RFPCR when the RFE bit in RFCR is 0 (receive FIFO disabled).

Both the CAN and CPU pointers increment when a new message is received and the RFFST flag is 1 (receive FIFO is full) in overwrite mode. When the RFMLF flag is 1 in this state, the CPU pointer does not increment on a software write to RFPCR.

37.2.13 Transmit FIFO Control Register (TFCR)

Address(es): CAN0.TFCR 4005 084Ah, CAN1.TFCR 4005 184Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	TFEST	TFFST	—	—	TFUST[2:0]			TFE
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	TFE	Transmit FIFO Enable	0: Disable transmit FIFO 1: Enable transmit FIFO.	R/W
b3 to b1	TFUST[2:0]	Transmit FIFO Unsent Message Number Status	b3 b1 0 0 0: 0 unsent messages 0 0 1: 1 unsent message 0 1 0: 2 unsent messages 0 1 1: 3 unsent messages 1 0 0: 4 unsent messages 1 0 1: Reserved 1 1 0: Reserved 1 1 1: Reserved.	R
b5, b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	TFFST	Transmit FIFO Full Status	0: Transmit FIFO not full 1: Transmit FIFO full (4 unsent messages).	R
b7	TFEST	Transmit FIFO Empty Status	0: Unsent message in transmit FIFO 1: No unsent message in transmit FIFO.	R

Write to TFCR in CAN operation or halt mode.

TFE bit (Transmit FIFO Enable)

Setting the TFE bit set to 1 enables the transmit FIFO. Setting the TFE bit to 0 empties the transmit FIFO (TFEST bit = 1), and unsent messages in the transmit FIFO are lost in the following ways:

- Immediately if a message from the transmit FIFO is not scheduled for the next transmission or is already in transmission
- On completion of transmission, on a CAN bus error, CAN bus arbitration-lost, or entry to CAN halt mode, if a message from the transmit FIFO is scheduled for the next transmission or is already in transmission.

Before setting the TFE bit to 1 again, ensure that the TFEST bit is set to 1. After setting the TFE bit to 1, write transmit data to mailbox 24.

Do not set the TFE bit to 1 in normal mailbox mode (MBM bit in CTLR = 0).

TFUST[2:0] bits (Transmit FIFO Unsent Message Number Status)

The TFUST[2:0] bits indicate the number of unsent messages in the transmit FIFO. They are set to 000b after TFE bit is set to 0 and transmission aborts or completes.

TFFST bit (Transmit FIFO Full Status)

The TFFST bit is set to 1 (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. The TFFST bit is set to 0 (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. The TFFST bit is set to 0 when transmission from the transmit FIFO is aborted.

TFEST bit (Transmit FIFO Empty Status)

The TFEST bit is set to 1 (no message in transmit FIFO) when the number of unsent messages in the transmit FIFO is 0. The TFEST bit is set to 1 when transmission from the transmit FIFO is aborted. The TFEST bit is set to 0 (message in transmit FIFO) when the number of unsent messages in the transmit FIFO is not 0.

Figure 37.3 shows the transmit FIFO mailbox operation.

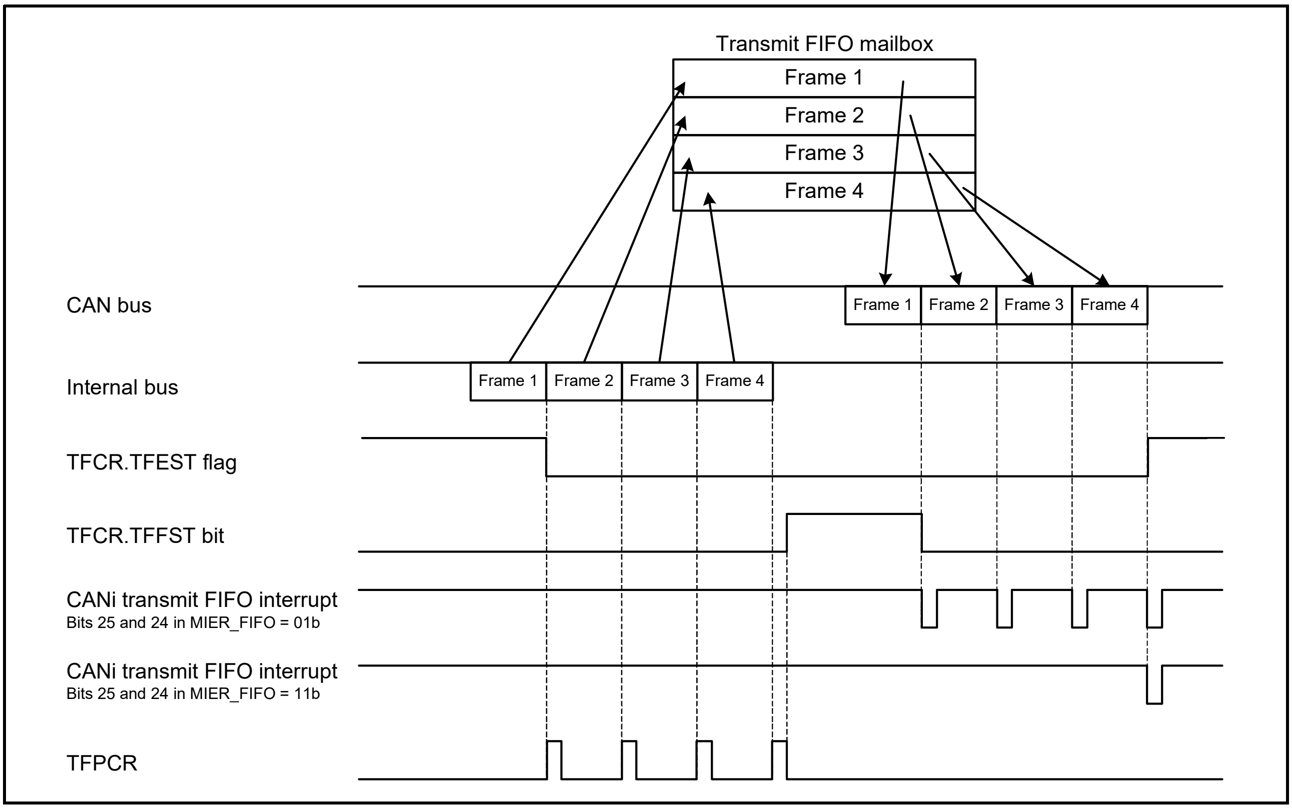

Figure 37.3 **Transmit FIFO mailbox operation when bits [25] and [24] in MIER_FIFO = 01b or 11b**

37.2.14 Transmit FIFO Pointer Control Register (TFPCR)

Address(es): CAN0.TFPCR 4005 084Bh, CAN1.TFPCR 4005 184Bh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	The CPU pointer for the transmit FIFO is incremented by writing FFh to TFPCR.	W

When the transmit FIFO is not full, write FFh to TFPCR through the software to increment the CPU pointer for the transmit FIFO to the next mailbox location.

Do not write to TFPCR when the TFE bit in TFCR is 0 (transmit FIFO disabled).

37.2.15 Status Register (STR)

Address(es): CAN0.STR 4005 0842h, CAN1.STR 4005 1842h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	RECST	TRMST	BOST	EPST	SLPST	HLTST	RSTST	EST	TABST	FMLST	NMLST	TFST	RFST	SDST	NDST
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	NDST	NEWDATA Status Flag	0: No mailbox with NEWDATA = 1 1: 1 or more mailboxes with NEWDATA = 1.	R
b1	SDST	SENTDATA Status Flag	0: No mailbox with SENTDATA = 1 1: 1 or more mailboxes with SENTDATA = 1.	R
b2	RFST	Receive FIFO Status Flag	0: Empty receive FIFO 1: Message in receive FIFO.	R
b3	TFST	Transmit FIFO Status Flag	0: Transmit FIFO is full 1: Transmit FIFO is not full.	R
b4	NMLST	Normal Mailbox Message Lost Status Flag	0: No mailbox with MSGLOST = 1 1: 1 or more mailboxes with MSGLOST = 1.	R
b5	FMLST	FIFO Mailbox Message Lost Status Flag	0: RFMLF = 0 1: RFMLF = 1.	R
b6	TABST	Transmission Abort Status Flag	0: No mailbox with TRMABT = 1 1: 1 or more mailboxes with TRMABT = 1.	R
b7	EST	Error Status Flag	0: No error occurred 1: Error occurred.	R
b8	RSTST	CAN Reset Status Flag	0: Not in CAN reset mode 1: In CAN reset mode.	R
b9	HLTST	CAN Halt Status Flag	0: Not in CAN halt mode 1: In CAN halt mode.	R
b10	SLPST	CAN Sleep Status Flag	0: Not in CAN sleep mode 1: In CAN sleep mode.	R
b11	EPST	Error-Passive Status Flag	0: Not in error-passive state 1: In error-passive state.	R
b12	BOST	Bus-Off Status Flag	0: Not in bus-off state 1: In bus-off state.	R
b13	TRMST	Transmit Status Flag	0: Bus idle or reception in progress 1: Transmission in progress or module in bus-off state.	R
b14	RECST	Receive Status Flag	0: Bus idle or transmission in progress 1: Reception in progress.	R
b15	—	Reserved	This bit is read as 0.	R

NDST flag (NEWDATA Status Flag)

The NDST flag is set to 1 when at least one NEWDATA flag in MCTL_RXj (j = 0 to 31) is 1, regardless of the value of MIER or MIER_FIFO. It is set to 0 when all NEWDATA flags are 0.

SDST flag (SENTDATA Status Flag)

The SDST flag is set to 1 when at least one SENTDATA flag in MCTL_TXj (j = 0 to 31) is 1, regardless of the value of MIER or MIER_FIFO. It is set to 0 when all SENTDATA flags are 0.

RFST flag (Receive FIFO Status Flag)

The RFST flag is set to 1 when the receive FIFO is not empty. It is set to 0 when the receive FIFO is empty or normal mailbox mode is selected.

TFST flag (Transmit FIFO Status Flag)

The TFST flag is set to 1 when the transmit FIFO is not full. It is set to 0 when the transmit FIFO is full or normal mailbox mode is selected.

NMLST flag (Normal Mailbox Message Lost Status Flag)

The NMLST flag is set to 1 when at least one MSGLOST flag in MCTL_RXj (j = 0 to 31) is 1, regardless of the value of MIER or MIER_FIFO. It is set to 0 when all MSGLOST flags are 0.

FMLST flag (FIFO Mailbox Message Lost Status Flag)

The FMLST flag is set to 1 when the RFMLF flag in RFCR is 1, regardless of the value of MIER_FIFO. It is set to 0 when the RFMLF flag is 0.

TABST flag (Transmission Abort Status Flag)

The TABST flag is set to 1 when at least one TRMABT flag in MCTL_TXj (j = 0 to 31) is 1, regardless of the value of MIER or MIER_FIFO. It is set to 0 when all TRMABT flags are 0.

EST flag (Error Status Flag)

The EST flag is set to 1 when at least one error is detected by EIFR, regardless of the value of EIER. It is set to 0 when no error is detected by EIFR.

RSTST flag (CAN Reset Status Flag)

The RSTST flag is set to 1 when the CAN module is in CAN reset mode. It is 0 when the CAN module is not in CAN reset mode. It remains 1, even when the state changes from CAN reset to sleep mode.

HLTST flag (CAN Halt Status Flag)

The HLTST flag is set to 1 when the CAN module is in CAN halt mode. It is set to 0 when the CAN module is not in CAN halt mode. It remains 1, even when the state changes from CAN halt to sleep mode.

SLPST flag (CAN Sleep Status Flag)

The SLPST flag is set to 1 when the CAN module is in CAN sleep mode. It is set to 0 when the CAN module is not in CAN sleep mode.

EPST flag (Error-Passive Status Flag)

The EPST flag is set to 1 when the value of TECR or RECR exceeds 127 and the CAN module is in an error-passive state ($128 \leq TEC < 256$ or $128 \leq REC < 256$). It is set to 0 when the CAN module is not in the error-passive state.

BOST flag (Bus-Off Status Flag)

The BOST flag is set to 1 when the value of TECR exceeds 255 and the CAN module is in the bus-off state ($TEC \geq 256$). It is set to 0 when the CAN module is not in the bus-off state.

TRMST flag (Transmit Status Flag)

The TRMST flag is set to 1 when the CAN module performs as a transmitter node or is in the bus-off state. It is set to 0 when the CAN module performs as a receiver node or is in the bus-idle state.

RECST flag (Receive Status Flag)

The RECST flag is set to 1 when the CAN module performs as a receiver node. It is set to 0 when the CAN module performs as a transmitter node or is in the bus-idle state.

37.2.16 Mailbox Search Mode Register (MSMR)

Address(es): CAN0.MSMR 4005 0853h, CAN1.MSMR 4005 1853h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MBSM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	MBSM[1:0]	Mailbox Search Mode Select	b1 b0 0 0: Receive mailbox search mode 0 1: Transmit mailbox search mode 1 0: Message lost search mode 1 1: Channel search mode.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Write to MSMR in CAN operation or halt mode.

MBSM[1:0] bits (Mailbox Search Mode Select)

The MBSM[1:0] bits select the search mode for the mailbox search function.

When the MBSM[1:0] bits are 00b, receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA flag in MCTL_RXj (j = 0 to 31) for the normal mailbox and the RFEST bit in RFCR.

When the MBSM[1:0] bits are 01b, transmit mailbox search mode is selected. In this mode, the search target is the SENTDATA flag in MCTL_TXj.

When the MBSM[1:0] bits are 10b, message lost search mode is selected. In this mode, the search targets are the MSGLOST flag in MCTL_RXj for the normal mailbox and the RFMLF flag in RFCR.

When the MBSM[1:0] bits are 11b, channel search mode is selected. In this mode, the search target is CSSR. See section 37.2.18, Channel Search Support Register (CSSR).

37.2.17 Mailbox Search Status Register (MSSR)

Address(es): CAN0.MSSR 4005 0852h, CAN1.MSSR 4005 1852h

	b7	b6	b5	b4	b3	b2	b1	b0
	SEST	—	—	MBNST[4:0]				
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	MBNST[4:0]	Search Result Mailbox Number Status	These bits output the smallest mailbox number that is found in each mode of MSMR.	R
b6, b5	—	Reserved	These bits are read as 0.	R
b7	SEST	Search Result Status	0: Search result found 1: No search result.	R

MBNST[4:0] bits (Search Result Mailbox Number Status)

In all MSMR modes, the MBNST[4:0] bits output the smallest found mailbox number. In receive mailbox search mode, transmit mailbox search mode, and message lost search mode, the value of the mailbox (the search result to be output) is updated under the following conditions:

- When the NEWDATA, SENTDATA, or MSGLOST flag for a mailbox output by MBNST is set to 0
- When the NEWDATA, SENTDATA, or MSGLOST flag for a mailbox with a smaller number than of MBNST is

set to 1.

If the MBSM[1:0] bits are set to 00b (receive mailbox search mode) or 10b (message lost search mode), the receive FIFO (mailbox 28) is output when it is not empty and there are no unread received messages and no lost messages in any of the normal mailboxes (0 to 23). If the MBSM[1:0] bits are set to 01b (transmit mailbox search mode), the transmit FIFO (mailbox 24) is not output. Table 37.6 lists the behavior of the MBNST[4:0] bits in FIFO mailbox mode.

In channel search mode, the MBNST[4:0] bits output the associated channel number. After MSSR is read by software, the next target channel number is output.

SEST bit (Search Result Status)

The SEST bit is set to 1 (no search result) when no associated mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST bit is set to 1 when no SENTDATA flag for the mailboxes is 1. The SEST bit is set to 0 when at least one SENTDATA flag is 1. When the SEST bit is 1, the value of the MBNST[4:0] bits is undefined.

Table 37.6 Behavior of MBNST[4:0] bits in FIFO mailbox mode

MBSM[1:0] bits	Mailbox 24 (transmit FIFO)	Mailbox 28 (receive FIFO)
00b	Mailbox 24 is not output.	Mailbox 28 is output when no MCTL_RXj.NEWDATA flag for the normal mailboxes is set to 1 (new message is being stored or was stored in the mailbox) and the receive FIFO is not empty.
01b		Mailbox 28 is not output.
10b		Mailbox 28 is output when no MCTL_RXj.MSGLOST flag for the normal mailboxes is set to 1 (message is overwritten or overrun) and the RFCR.RFMLF flag is set to 1 (receive FIFO message lost) in the receive FIFO.
11b		Mailbox 28 is not output.

37.2.18 Channel Search Support Register (CSSR)

Address(es): CAN0.CSSR 4005 0851h, CAN1.CSSR 4005 1851h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b7 to b0	When the value for the channel search is input, the channel number is output to MSSR.	R/W

The bits in CSSR, which are set to 1, are encoded by an 8/3 encoder (the LSB position has the higher priority) and output to the MBNST[4:0] bits in MSSR. MSSR outputs the updated value whenever MSSR is read by software.

Write to CSSR only when the MSMR.MBSM[1:0] bits are 11b (channel search mode). Write to CSSR in CAN operation mode or CAN halt mode.

Figure 37.4 shows writes to and reads from CSSR and MSSR.

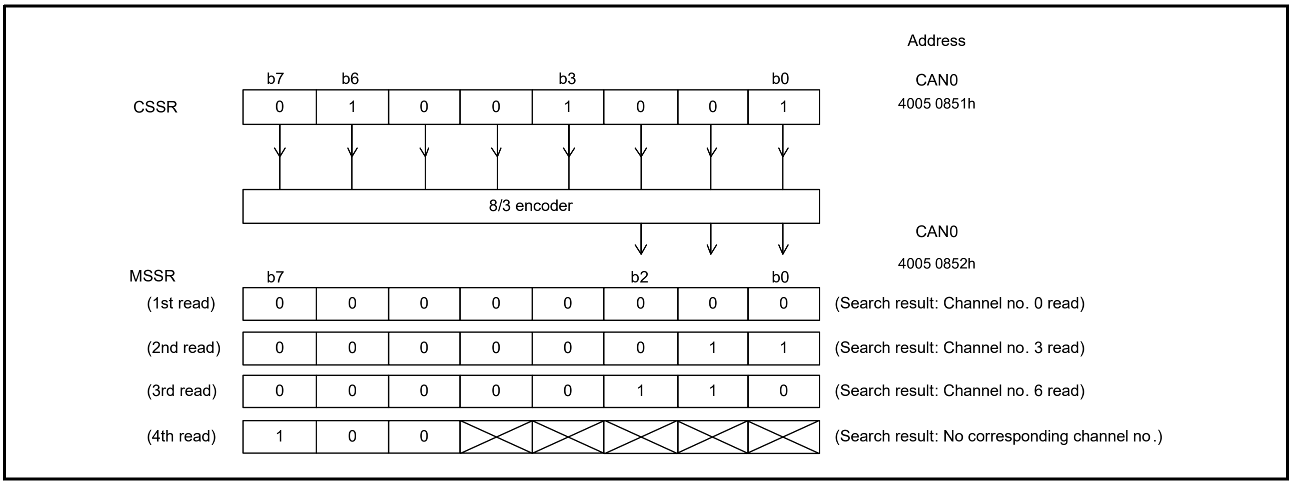

Figure 37.4 Writes to and reads from CSSR and MSSR

The value of CSSR is also updated whenever MSSR is read. On this read, the value prior to conversion by the 8/3 encoder can be read.

37.2.19 Acceptance Filter Support Register (AFSR)

Address(es): CAN0.AFSR 4005 0856h, CAN1.AFSR 4005 1856h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Description	R/W
b15 to b0	After the standard ID of a received message is written, the value converted for data table search can be read.	R/W

Note: Write to AFSR in CAN operation mode or CAN halt mode.

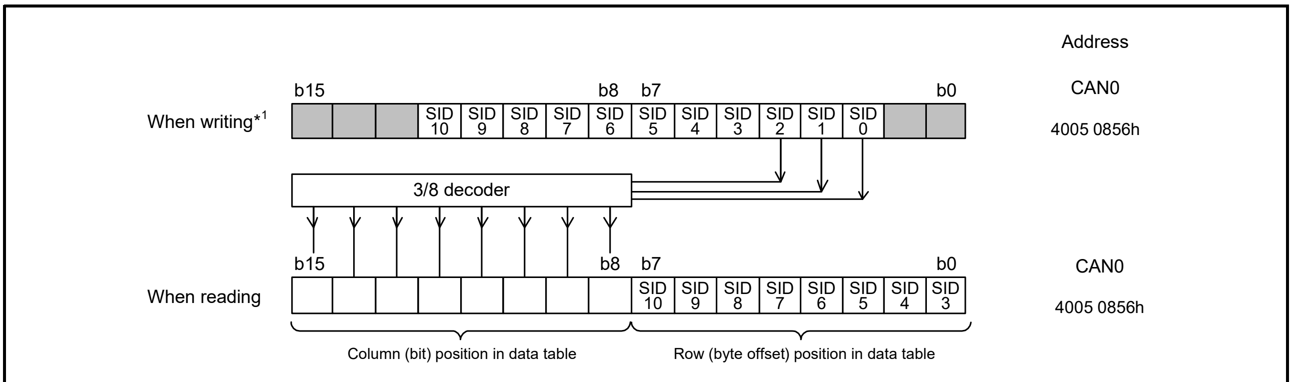
The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) searches. In the data table, all standard IDs that you create are set as valid or invalid in bit units. When AFSR is written with data in 16-bit units including the SID[10:0] bits in MBj_ID (j = 0 to 31), in which a received standard ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to be received cannot be masked by the acceptance filter. For example, if IDs to be received are 078h, 087h, and 111h
- When there are too many IDs to receive, and the software filtering time is expected to be shortened.

Note: AFSR cannot be set in CAN reset mode.

Figure 37.5 shows the writes to and reads from AFSR.



Note 1. Write the same value as the 16-bit unit data, including the SID[10:0] bits in MBj_ID (j = 0 to 31).

Figure 37.5 Writes to and reads from AFSR

37.2.20 Error Interrupt Enable Register (EIER)

Address(es): CAN0.EIER 4005 084Ch, CAN1.EIER 4005 184Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	BLIE	OLIE	ORIE	BORIE	BOEIE	EPIE	EWIE	BEIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	BEIE	Bus Error Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b1	EWIE	Error-Warning Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b2	EPIE	Error-Passive Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b3	BOEIE	Bus-Off Entry Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b4	BORIE	Bus-Off Recovery Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b5	ORIE	Overrun Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b6	OLIE	Overload Frame Transmit Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W
b7	BLIE	Bus Lock Interrupt Enable	0: Disable interrupt 1: Enable interrupt.	R/W

EIER enables or disables each error interrupt source independently in EIFR. Write to EIER in CAN reset mode.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE bit is 0, no error interrupt request occurs even if the BEIF bit in EIFR is 1. When the BEIE bit is 1, an error interrupt request occurs if the BEIF bit is set to 1.

EWIE bit (Error-Warning Interrupt Enable)

When the EWIE bit is 0, no error interrupt request occurs even if the EWIF bit in EIFR is 1. When the EWIE bit is 1, an error interrupt request is generated if the EWIF bit is set to 1.

EPIE bit (Error-Passive Interrupt Enable)

When the EPIE bit is 0, no error interrupt request occurs even if the EPIF bit in EIFR is 1. When the EPIE bit is 1, an error interrupt request occurs if the EPIF bit is set to 1.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE bit is 0, no error interrupt request occurs even if the BOEIF bit in EIFR is 1. When the BOEIE bit is 1, an error interrupt request occurs if the BOEIF bit is set to 1.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE bit is 0, no error interrupt request occurs even if the BORIF bit in EIFR is 1. When the BORIE bit is 1, an error interrupt request occurs if the BORIF bit is set to 1.

ORIE bit (Overrun Interrupt Enable)

When the ORIE bit is 0, no error interrupt request occurs even if the ORIF bit in EIFR is 1. When the ORIE bit is 1, an error interrupt request occurs if the ORIF bit is set to 1.

OLIE bit (Overload Frame Transmit Interrupt Enable)

When the OLIE bit is 0, no error interrupt request occurs even if the OLIF bit in EIFR is 1. When the OLIE bit is 1, an error interrupt request occurs if the OLIF bit is set to 1.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE bit is 0, no error interrupt request occurs even if the BLIF bit in EIFR is 1. When the BLIE bit is 1, an error interrupt request occurs if the BLIF bit is set to 1.

37.2.21 Error Interrupt Factor Judge Register (EIFR)

Address(es): CAN0.EIFR 4005 084Dh, CAN1.EIFR 4005 184Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	BLIF	OLIF	ORIF	BORIF	BOEIF	EPIF	EWIF	BEIF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	BEIF	Bus Error Detect Flag	0: No bus error detected 1: Bus error detected.	R/W
b1	EWIF	Error-Warning Detect Flag	0: No error-warning detected 1: Error-warning detected.	R/W
b2	EPIF	Error-Passive Detect Flag	0: No error-passive detected 1: Error-passive detected.	R/W
b3	BOEIF	Bus-Off Entry Detect Flag	0: No bus-off entry detected 1: Bus-off entry detected.	R/W
b4	BORIF	Bus-Off Recovery Detect Flag	0: No bus-off recovery detected 1: Bus-off recovery detected.	R/W
b5	ORIF	Receive Overrun Detect Flag	0: No receive overrun detected 1: Receive overrun detected.	R/W
b6	OLIF	Overload Frame Transmission Detect Flag	0: No overload frame transmission detected 1: Overload frame transmission detected.	R/W
b7	BLIF	Bus Lock Detect Flag	0: No bus lock detected 1: Bus lock detected.	R/W

If an event associated with one of these bits occurs, the associated bit in EIFR is set to 1, regardless of the setting of EIER.

Clear the bits to 0 through a software write. If a bit is set to 1 at the same time that the software clears it, it becomes 1. When setting a single bit to 0 in the software, use the transfer instruction (MOV) to ensure that only the specified bit is set to 0 and the other bits are set to 1. Writing 1 has no effect to these bit values.

BEIF flag (Bus Error Detect Flag)

The BEIF flag is set to 1 when a bus error is detected.

EWIF flag (Error-Warning Detect Flag)

The EWIF flag is set to 1 when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. It is set to 1 only when REC or TEC initially exceeds 95. If 0 is written to the EWIF flag by software while REC or TEC remains greater than 95, the EWIF flag does not set to 1 until REC or TEC goes below 95 and then exceeds 95 again.

EPIF flag (Error-Passive Detect Flag)

The EPIF flag is set to 1 when the CAN error state becomes error-passive, when the receive error counter (REC) or transmit error counter (TEC) value exceeds 127. It is set to 1 only when REC or TEC initially exceeds 127. If 0 is written to the EPIF flag by software while REC or TEC remains greater than 127, the flag does not set to 1 until REC or TEC goes below 127 and then exceeds 127 again.

BOEIF flag (Bus-Off Entry Detect Flag)

The BOEIF flag is set to 1 when the CAN error state becomes bus-off, when the transmit error counter (TEC) value exceeds 255. It also is set to 1 when the BOM[1:0] bits in CTLR are 01b (automatic entry to CAN halt mode on bus-off entry) and the CAN module becomes the bus-off state.

BORIF flag (Bus-Off Recovery Detect Flag)

The BORIF flag is set to 1 when the CAN module recovers from the bus-off state normally by detecting 11 consecutive recessive bits 128 times in the following conditions:

- When the BOM[1:0] bits in CTLR are 00b
- When the BOM[1:0] bits in CTLR are 10b
- When the BOM[1:0] bits in CTLR are 11b.

However, the BORIF flag does not set to 1 if the CAN module recovers from the bus-off state in the following conditions:

- When the CANM[1:0] bits in CTLR are set to 01b or 11b (CAN reset mode)
- When the RBOC bit in CTLR is set to 1 (forced return from bus-off)
- When the BOM[1:0] bits in CTLR are set to 01b
- When the BOM[1:0] bits in CTLR are set to 11b and the CANM[1:0] bits in CTLR are set to 10b (CAN halt mode) before normal recovery occurs.

Table 37.7 lists the behavior of the BOEIF and BORIF bits for each CTLR.BOM[1:0] bit setting.

Table 37.7 Behavior of BOEIF and BORIF flags for each CTLR.BOM[1:0] setting

BOM[1:0] bits	BOEIF bit	BORIF bit
00b	Set to 1 on entry to the bus-off state	Sets to 1 on exit from the bus-off state
01b		Does not set to 1
10b		Sets to 1 on exit from the bus-off state
11b		Sets to 1 if normal bus-off recovery occurs before the CANM[1:0] bits are set to 10b (CAN halt mode)

ORIF flag (Receive Overrun Detect Flag)

The ORIF flag is set to 1 when a receive overrun occurs. It does not set to 1 in overwrite mode.

In overwrite mode, a reception complete interrupt request occurs if an overwrite condition occurs and the ORIF bit is not set to 1.

In overrun mode with normal mailbox mode, if an overrun occurs in any of mailboxes 0 to 31, this flag is set to 1. In overrun mode with FIFO mailbox mode, if an overrun occurs in any of mailboxes 0 to 23 or the receive FIFO, this bit is set to 1.

OLIF flag (Overload Frame Transmission Detect Flag)

The OLIF flag is set to 1 if the transmitting condition of an overload frame is detected when the CAN module is transmitting or receiving.

BLIF flag (Bus Lock Detect Flag)

The BLIF flag is set to 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode. After the BLIF flag is set to 1, 32 consecutive dominant bits are detected again under either of the following conditions:

- Recessive bits are detected after this flag changes to 0 from 1
- The CAN module enters CAN reset or halt mode and then enters CAN operation mode again after this flag changes to 0 from 1.

37.2.22 Receive Error Count Register (RECR)

Address(es): CAN0.RECR 4005 084Eh, CAN1.RECR 4005 184Eh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Description	R/W
b7 to b0	Receive error count function RECR increments or decrements the counter value based on the error status of the CAN module during reception.	R

RECR indicates the value of the receive error counter. See the CAN specification (ISO11898-1) for the increment and decrement conditions of the receive error counter. The value of RECR in the bus-off state is undefined.

37.2.23 Transmit Error Count Register (TECR)

Address(es): CAN0.TECR 4005 084Fh, CAN1.TECR 4005 184Fh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Description	R/W
b7 to b0	Transmit error count function TECR increments or decrements the counter value based on the error status of the CAN module during transmission.	R

TECR indicates the value of the transmit error counter. See the CAN specification (ISO11898-1) for the increment and decrement conditions of the transmit error counter. The value of TECR in the bus-off state is undefined.

37.2.24 Error Code Store Register (ECSR)

Address(es): CAN0.ECSR 4005 0850h, CAN1.ECSR 4005 1850h

	b7	b6	b5	b4	b3	b2	b1	b0
	EDPM	ADEF	BE0F	BE1F	CEF	AEF	FEF	SEF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SEF	Stuff Error Flag*1,*2	0: No stuff error detected 1: Stuff error detected.	R/W
b1	FEF	Form Error Flag*1,*2	0: No form error detected 1: Form error detected.	R/W
b2	AEF	ACK Error Flag*1,*2	0: No ACK error detected 1: ACK error detected.	R/W
b3	CEF	CRC Error Flag*1,*2	0: No CRC error detected 1: CRC error detected.	R/W
b4	BE1F	Bit Error (recessive) Flag*1,*2	0: No bit error (recessive) detected 1: Bit error (recessive) detected.	R/W
b5	BE0F	Bit Error (dominant) Flag*1,*2	0: No bit error (dominant) detected 1: Bit error (dominant) detected.	R/W
b6	ADEF	ACK Delimiter Error Flag*1,*2	0: No ACK delimiter error detected 1: ACK delimiter error detected.	R/W
b7	EDPM	Error Display Mode Select*3,*4	0: Output first detected error code 1: Output accumulated error code.	R/W

Note 1. Writing 1 has no effect on these bit values.
Note 2. To write 0 to the SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF bits, use the transfer (MOV) instruction to ensure that only the specified bit is set to 0 and the other bits are set to 1.
Note 3. Write to the EDPM bit in CAN reset or halt mode.
Note 4. If more than one error condition is detected simultaneously, all related bits are set to 1.

ECSR indicates whether an error occurs on the CAN bus. See the CAN specification (ISO11898-1) for the conditions when each error occurs.

Clear all of the bits except for the EDPM bit to 0 through a software write. If a bit is set to 1 at the same time that the software clears it, it becomes 1.

SEF flag (Stuff Error Flag)

The SEF flag is set to 1 when a stuff error is detected.

FEF flag (Form Error Flag)

The FEF flag is set to 1 when a form error is detected.

AEF flag (ACK Error Flag)

The AEF flag is set to 1 when an ACK error is detected.

CEF flag (CRC Error Flag)

The CEF flag is set to 1 when a CRC error is detected.

BE1F flag (Bit Error (recessive) Flag)

The BE1F flag is set to 1 when a recessive bit error is detected.

BE0F flag (Bit Error (dominant) Flag)

The BE0F flag is set to 1 when a dominant bit error is detected.

ADEF flag (ACK Delimiter Error Flag)

The ADEF flag is set to 1 when a form error is detected with the ACK delimiter during transmission.

EDPM bit (Error Display Mode Select)

The EDPM bit selects the output mode of ECSR. When the EDPM bit is set to 0, ECSR outputs the first error code. When the EDPM bit is set to 1, ECSR outputs the accumulated error code.

37.2.25 Time Stamp Register (TSR)

Address(es): CAN0.TSR 4005 0854h, CAN1.TSR 4005 1854h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Description	R/W
b15 to b0	Free-running counter value for the time stamp function	R

Note: Read TSR in 16-bit units.

When TSR is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read. The time stamp counter reference clock is configured in the TSPS[1:0] bits in CTLR. The counter stops in CAN sleep and halt modes, and is initialized in CAN reset mode. Its value is stored in the TSL[7:0] and TSH[7:0] bits in MBj_TS when a received message is stored in a receive mailbox.

37.2.26 Test Control Register (TCR)

Address(es): CAN0.TCR 4005 0858h, CAN1.TCR 4005 1858h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TSTM[1:0]		TSTE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	TSTE	CAN Test Mode Enable	0: Disable CAN test mode 1: Enable CAN test mode.	R/W
b2, b1	TSTM[1:0]	CAN Test Mode Select	b2 b1 0 0: Not CAN test mode 0 1: Listen-only mode 1 0: Self-test mode 0 (external loopback) 1 1: Self-test mode 1 (internal loopback).	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TCR controls the CAN test mode. Write to TCR in CAN halt mode only.

(1) Listen-only mode

The CAN specification (ISO11898-1) recommends an optional bus monitoring mode. In listen-only mode, valid data frames and valid remote frames can be received. However, only recessive bits can be sent on the CAN bus. The ACK bit, overload flag, and active error flag cannot be sent.

Listen-only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in listen-only mode.

Figure 37.6 shows the connection when listen-only mode is selected.

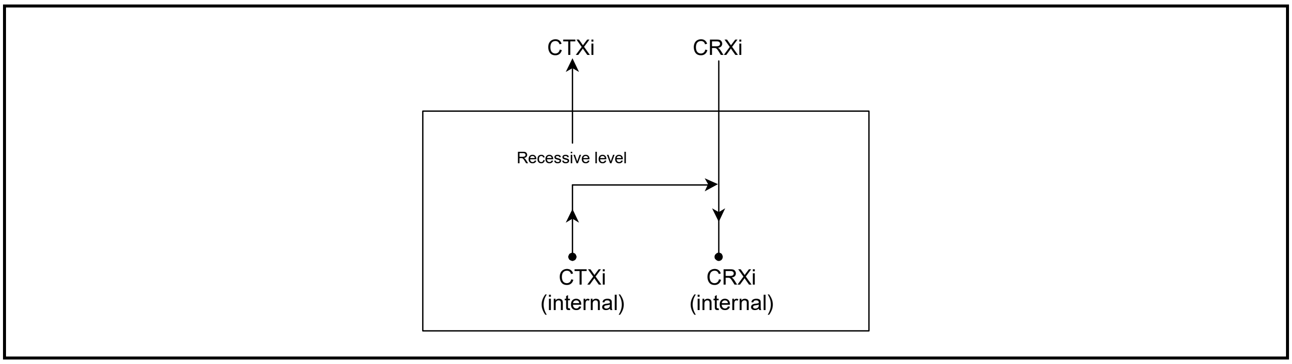


Figure 37.6 Connection when listen-only mode is selected (i = 0, 1)

(2) Self-test mode 0 (external loopback)

Self-test mode 0 is provided for CAN transceiver tests. In this mode, the protocol module treats its own transmitted messages as those received by the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol module generates the ACK bit.

Connect the CTXi and CRXi pins to the transceiver.

Figure 37.7 shows the connection when self-test mode 0 is selected.

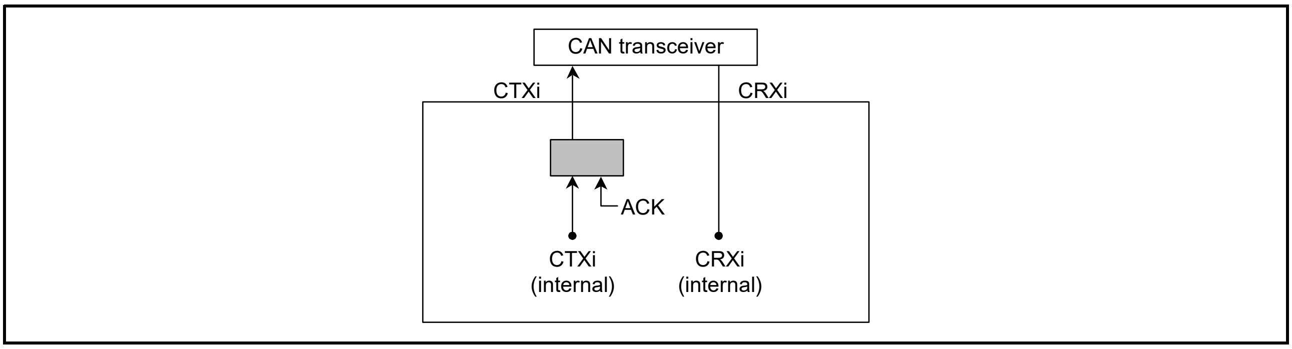

Figure 37.7 Connection when self-test mode 0 is selected (i = 0, 1)

(3) Self-test mode 1 (internal loopback)

Self-test mode 1 is provided for self-test functions.

In self-test mode 1, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CTXi pin to the internal CRXi pin. The input value of the external CRXi pin is ignored. The external CTXi pin outputs only recessive bits. The CTXi and CRXi pins are not required to be connected to the CAN bus or any external device.

Figure 37.8 shows the connection when self-test mode 1 is selected.

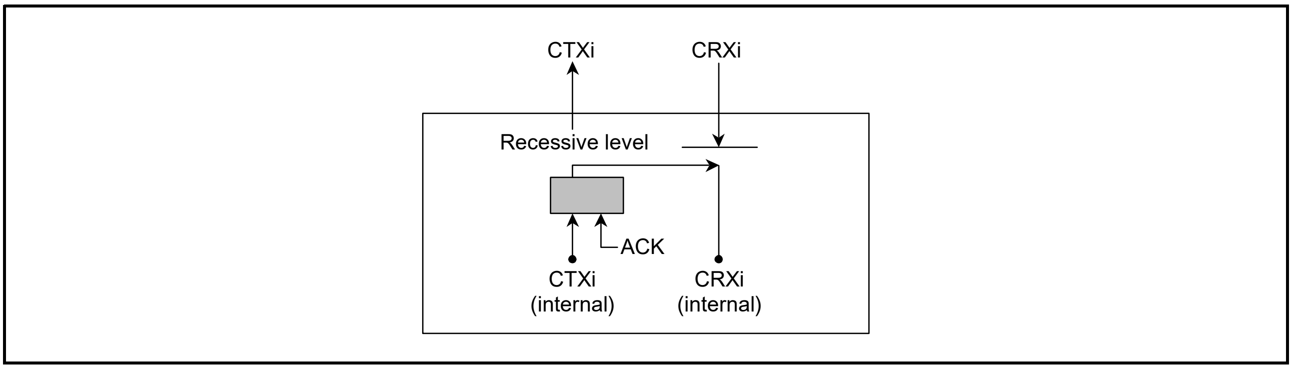

Figure 37.8 Connection when self-test mode 1 is selected (i = 0, 1)

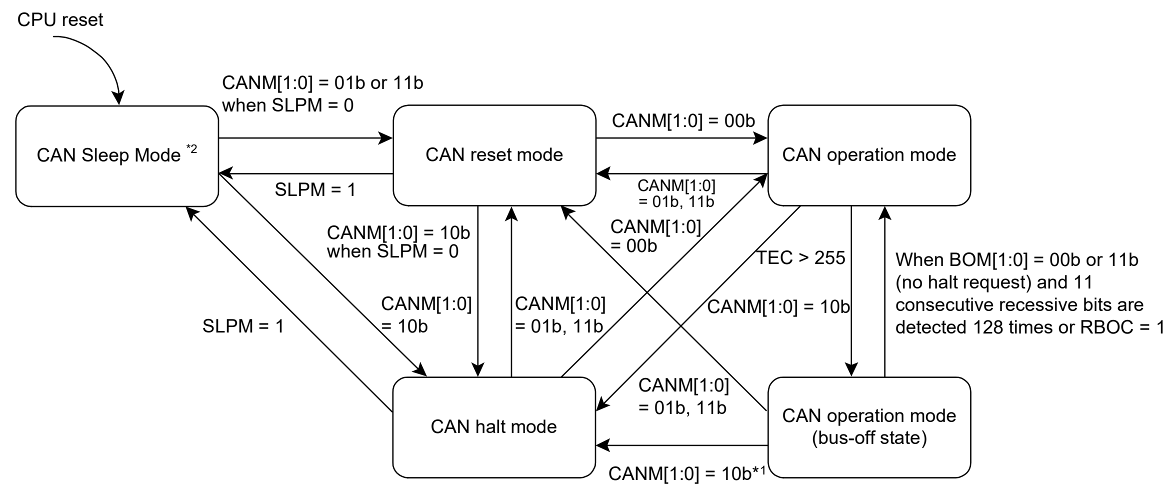
37.3 Operation Modes

The CAN module operation modes include:

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode.

Figure 37.9 shows the transitions between the operation modes.



CANM, SLPM, BOM, RBOC: Bits in CTLR

Note 1. The transition timing from the bus-off state to CAN halt mode depends on the setting of the CTLR.BOM[1:0] bits.
When the CTLR.BOM[1:0] bits are 01b, the state transition occurs immediately after entering the bus-off state.
When the CTLR.BOM[1:0] bits are 10b, the state transition occurs at the end of the bus-off state.
When the CTLR.BOM[1:0] bits are 11b, the state transition occurs at the setting of the CTLR.CANM[1:0] bits to 10b (CAN halt mode).

Note 2. Change the CTLR.SLPM bit to set or cancel CAN Sleep mode.

Figure 37.9 Transition between different operation modes

37.3.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration. When the CTLR.CANM[1:0] bits are set to 01b or 11b, the CAN module enters CAN reset mode. The STR.RSTST bit then is set to 1. Do not change the CTLR.CANM[1:0] bits until the RSTST bit is 1. Set BCR before exiting CAN reset mode to any other modes.

The following registers are initialized to their reset values after entering CAN reset mode, and their initial values are saved during CAN reset mode:

- MCTL_TXj and MCTL_RXj
- STR (except for the SLPST and TFST bits)
- EIFR
- RECR
- TECR
- TSR
- MSSR
- MSMR
- RFCR
- TFCR
- TCR
- ECSR (except for the EDPM bit).

The following registers retain their previous values even after entering CAN reset mode:

- CTLR
- STR (only the SLPST and TFST bits)
- MIER and MIER_FIFO
- EIER
- BCR
- CSSR
- ECSR (only the EDPM bit)
- MBj_ID, MBj_DL, MBj_Dm and MBj_TS
- MKRk
- FIDCR0 and FIDCR1
- MKIVLR
- AFSR
- RFPCR
- TFPCR.

37.3.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CTLR.CANM[1:0] bits are set to 10b, CAN halt mode is selected. Then the STR.HLTST bit is set to 1. Do not change the CTLR.CANM[1:0] bits until the HLTST bit is 1.

See Table 37.8 for the state transition conditions when transmitting or receiving.

All registers except for the RSTST, HLTST, and SLPST bits in STR remain unchanged when the CAN enters CAN halt mode.

Do not change CTLR (except for the CANM[1:0] and SLPM bits) and EIER in CAN halt mode. BCR can be changed in CAN halt mode only when listen-only mode is selected for automatic baud rate detection.

Table 37.8 Operation in CAN reset and halt modes

Operation mode	Receiver	Transmitter	Bus-off
CAN reset mode (forced transition) CANM[1:0] = 11b	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode without waiting for the end of message transmission.	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.
CAN reset mode CANM[1:0] = 01b	CAN module enters CAN reset mode without waiting for the end of message reception.	CAN module enters CAN reset mode after waiting for the end of message transmission.*1,*4	CAN module enters CAN reset mode without waiting for the end of bus-off recovery.
CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception.*2,*3	CAN module enters CAN halt mode after waiting for the end of message transmission.*1,*4	When the BOM[1:0] bits are 00b: A halt request from software is accepted only after bus-off recovery. When the BOM[1:0] bits are 01b: CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery, regardless of a halt request from the software. When the BOM[1:0] bits are 10b: CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery, regardless of a halt request from software. When the BOM[1:0] bits are 11b: CAN module enters CAN halt mode without waiting for the end of bus-off recovery, if a halt is requested by software during bus-off.

BOM[1:0] bits: Bits in CTLR

Note 1. If transmission of multiple messages is requested, a mode transition occurs on completion of the first transmission. If the CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.

Note 2. If the CAN bus is locked at the dominant level, the program can detect this state by monitoring the BLIF bit in EIFR.

Note 3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module transitions to CAN halt mode.

Note 4. If a CAN bus error or arbitration-lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module transits to the requested CAN mode.

37.3.3 CAN Sleep Mode

CAN sleep mode reduces power consumption by stopping the clock supply to the CAN module. After a reset from an MCU pin or a software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in CTLR is set to 1, the CAN module enters CAN sleep mode. Then the SLPST bit in STR is set to 1. Do not change the value of the SLPM bit until the SLPST bit is 1. The other registers remain unchanged when the CAN module enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except for the SLPM bit) during CAN sleep mode. Read operation is still allowed.

When the SLPM bit is set to 0, the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

37.3.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM[1:0] bits in CTLR are set to 00b, the CAN module enters CAN operation mode. Then the RSTST and HLTST bits in STR set to 0. Do not change the value of the CANM[1:0] bits until the RSTST and HLTST bits are 0.

If 11 consecutive recessive bits are detected after entering CAN operation mode, the following occurs:

- The CAN module becomes an active node on the network, which enables transmission and reception of CAN messages

- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module might be in one of the following three sub-modes, depending on the status of the CAN bus.

- Idle mode: No transmission or reception occurs
- Receive mode: A CAN message sent by another node is being received
- Transmit mode: A CAN message is being transmitted. The CAN module receives a message transmitted by the local node simultaneously when self-test mode 0 (TSTM[1:0] bits in TCR = 10b) or self-test mode 1 (TSTM[1:0] bits = 11b) is selected.

Figure 37.10 demonstrates the sub-modes in CAN operation mode.

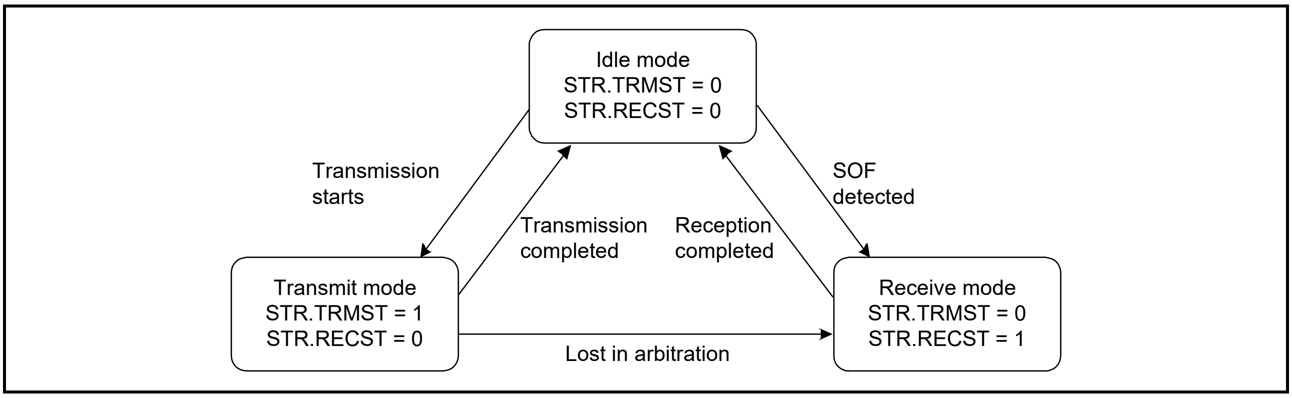


Figure 37.10 Sub-modes of CAN operation mode

37.3.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state based on the incrementing decrementing rules for the transmit and error counters defined in the CAN Specifications. The following cases apply when the CAN module is recovering from the bus-off state. When the CAN module is in the bus-off state, the values of the CAN-related registers remain unchanged, except for those in STR, EIFR, RECR, TECR, and TSR.

(1) When CTLR.BOM[1:0] = 00b (normal mode)

The CAN module enters the error-active state after it completes recovery from the bus-off state and CAN communication is enabled. The BORIF flag in EIFR is set to 1 (bus-off recovery detected) at this time.

(2) When CTLR.RBOC = 1 (forced return from bus-off)

The CAN module enters the error-active state when it is in the bus-off state and the RBOC bit is 1. CAN communication is enabled again after 11b consecutive recessive bits are detected. The BORIF bit does not set to 1 at this time.

(3) When CTLR.BOM[1:0] = 01b (automatic transition to CAN halt mode on bus-off)

The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF flag does not set to 1 at this time.

(4) When CTLR.BOM[1:0] = 10b (automatic transition to CAN halt mode on bus-off end)

The CAN module enters CAN halt mode when it completes recovery from bus-off. The BORIF flag is set to 1 at this time.

(5) When CTLR.BOM[1:0] = 11b (automatic transition to CAN halt mode through software) and CTLR.CANM[1:0] = 10b (CAN halt mode) during bus-off state

The CAN module enters CAN halt mode when it is in the bus-off state and the CANM[1:0] bits are set to 10b (CAN halt mode). The BORIF flag does not set to 1 at this time.

If the CANM[1:0] bits are not set to 10b during bus-off, the same behavior as (1) applies.

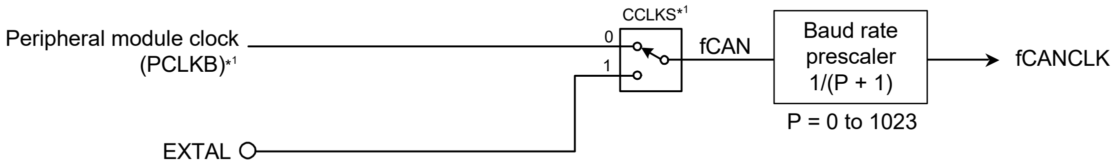
37.4 Data Transfer Rate Configuration

This section describes how to configure the data transfer rate.

37.4.1 Clock Setting

The CAN module has a CAN clock generator that can be set by the CCLKS and the BRP[9:0] bits in the BCR register.

Figure 37.11 shows a block diagram of the CAN clock generator.



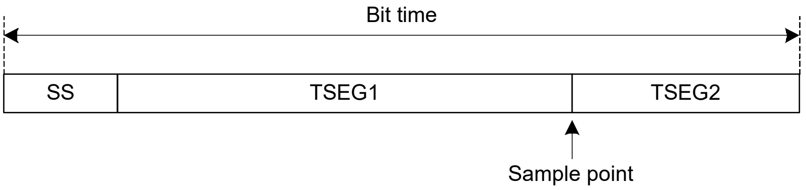
CCLKS:	Bit in the BCR register
fCAN:	CAN system clock
P:	Value selected in BRP[9:0] bits in BCR (P = 0 to 1023)
fCANCLK:	CAN communication clock (fCANCLK = fCAN/(P + 1))

Note 1. See section 9, Clock Generation Circuit. When using the CAN module while the CCLKS bit is cleared to 0, PLL must be selected as the source of the peripheral module clock.

Figure 37.11 Block diagram of CAN clock generator

37.4.2 Bit Timing Setting

The bit time consists of the following three segments shown in Figure 37.12.



The range of each segment: Bit time = 8 Tq to 25 Tq
SS = 1 Tq
TSEG1 = 4 Tq to 16 Tq
TSEG2 = 2 Tq to 8 Tq
SJW = 1 Tq to 4 Tq
Setting of TSEG1 and TSEG2: TSEG1 > TSEG2 ≥ SJW

Figure 37.12 Bit timing

37.4.3 Data Transfer Rate

The data transfer rate depends on the division value of fCAN (CAN system clock), the division value of the baud rate prescaler, and the Tq count for 1 bit time.

$$\text{Data transfer rate (bps)} = \frac{\text{fCAN}}{\text{Baud rate prescaler division value}^{*1} \times \text{number of Tq of 1 bit time}} = \frac{\text{fCANCLK}}{\text{Tq count for 1 bit time}}$$

Note 1. Division value of baud rate prescaler = P + 1 (P: 0 to 1023), where P is the BRP[9:0] setting in BCR.

Table 37.9 lists data transfer rate examples.

Table 37.9 Data transfer rate examples

fCAN	50 MHz		48 MHz		40 MHz		32 MHz	
Data transfer rate	Tq count	P + 1	Tq count	P + 1	Tq count	P + 1	Tq count	P + 1
1 Mbps	10 Tq 25 Tq	5 2	8 Tq 12 Tq 16 Tq	6 4 3	10 Tq 20 Tq	4 2	8 Tq 16 Tq	4 2

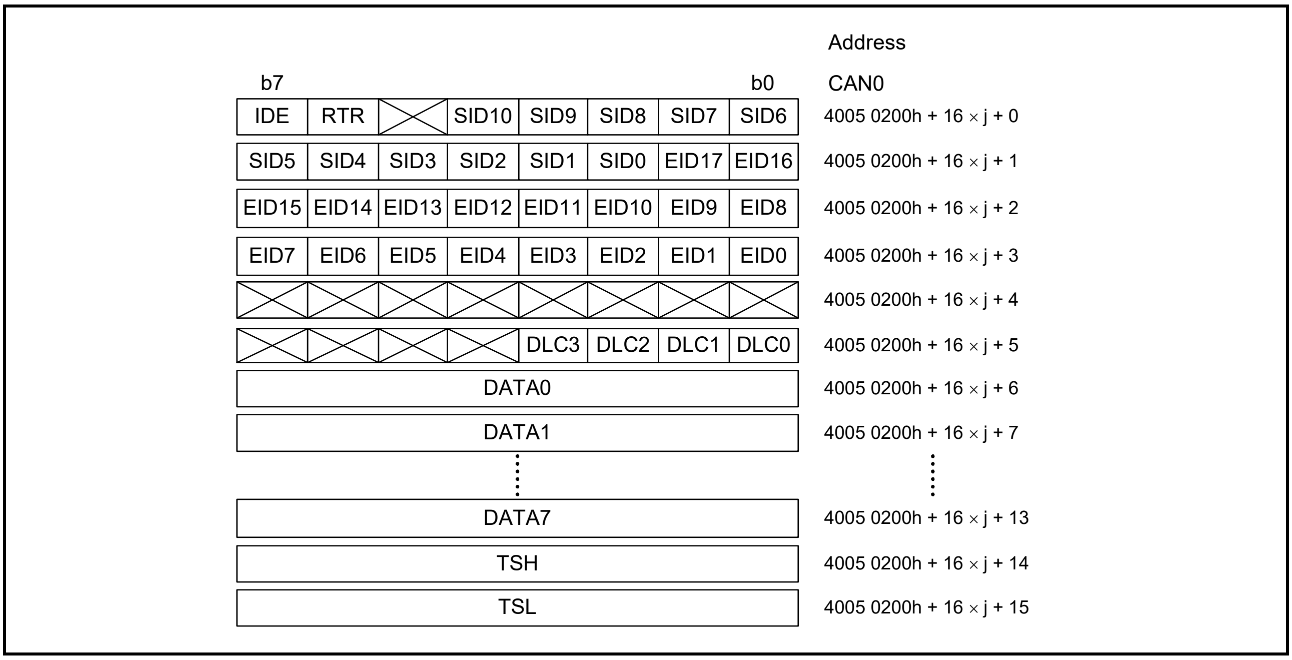
37.5 Mailbox and Mask Register Structure

Figure 37.13 shows the structure of the 32 mailbox registers: MBj_ID, MBj_DL, MBj_Dm, and MBj_TS.



b7							b0	Address CAN0
IDE	RTR		SID10	SID9	SID8	SID7	SID6	4005 0200h + 16 × j + 0
SID5	SID4	SID3	SID2	SID1	SID0	EID17	EID16	4005 0200h + 16 × j + 1
EID15	EID14	EID13	EID12	EID11	EID10	EID9	EID8	4005 0200h + 16 × j + 2
EID7	EID6	EID5	EID4	EID3	EID2	EID1	EID0	4005 0200h + 16 × j + 3
								4005 0200h + 16 × j + 4
				DLC3	DLC2	DLC1	DLC0	4005 0200h + 16 × j + 5
DATA0								4005 0200h + 16 × j + 6
DATA1								4005 0200h + 16 × j + 7
⋮								⋮
DATA7								4005 0200h + 16 × j + 13
TSH								4005 0200h + 16 × j + 14
TSL								4005 0200h + 16 × j + 15

Figure 37.13 Structure of the mailbox registers (j = 0 to 31)

Figure 37.14 shows the structure of the eight mask registers: MKRk.

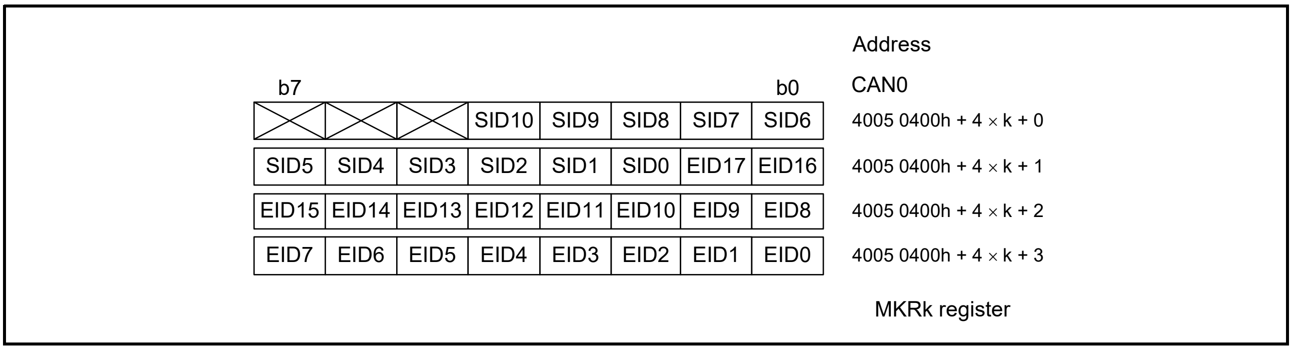


Figure 37.14 Structure of the MKRk registers (k = 0 to 7)

Figure 37.15 shows the structure of the two FIFO receive ID compare registers: FIDCR0 and FIDCR1.

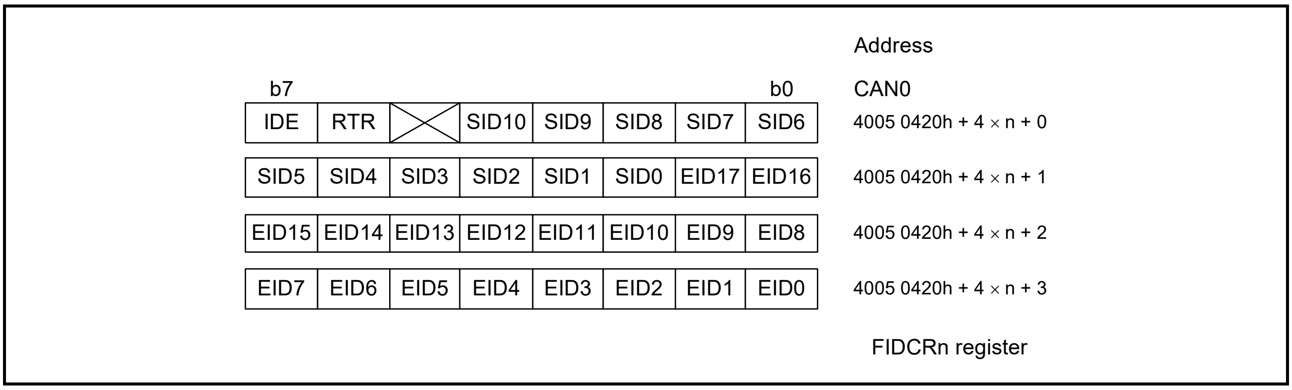

Figure 37.15 Structure of the FIDCRn registers (n = 0, 1)

37.6 Acceptance Filtering and Masking Functions

The acceptance filtering and masking functions allow you to select and receive messages with multiple IDs for mailboxes within a specified range.

The MKRk registers can mask the standard ID and the extended ID for 29 bits.

- MKR0 controls mailboxes 0 to 3
- MKR1 controls mailboxes 4 to 7
- MKR2 controls mailboxes 8 to 11
- MKR3 controls mailboxes 12 to 15
- MKR4 controls mailboxes 16 to 19
- MKR5 controls mailboxes 20 to 23
- MKR6 controls mailboxes 24 to 27 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode
- MKR7 controls mailboxes 28 to 31 in normal mailbox mode and the receive FIFO mailboxes 28 to 31 in FIFO mailbox mode.

MKIVLR disables acceptance filtering independently for each mailbox.

The IDE bit in MBj_ID is valid when the IDFM[1:0] bits in CTLR are 10b (mixed ID mode).

The RTR bit in MBj_ID selects a data or remote frame.

In FIFO mailbox mode, the normal mailboxes (0 to 23) use one associated register from MKR0 to MKR5 for acceptance filtering. The receive FIFO mailboxes (28 to 31) use two registers, MKR6 and MKR7, for acceptance filtering.

The receive FIFO also uses two registers, FIDCR0 and FIDCR1, for ID comparison. The EID[17:0], SID[10:0], RTR, and IDE bits in mailbox28 to mailbox31 for the receive FIFO are disabled. As acceptance filtering depends on the result of two logic OR operations, two ranges of IDs can be received into the receive FIFO.

MKIVLR is disabled for the receive FIFO.

If different standard ID and extended ID values are set in the IDE bits in FIDCR0 and FIDCR1, both ID formats are received.

If different data frame and remote frame values are set in the RTR bits in FIDCR0 and FIDCR1, both data and remote frames are received.

When a combination of two ranges of IDs is not necessary, set the same mask value and the same ID into both the FIFO ID and mask registers.

Figure 37.16 shows the associations between the mask registers and mailboxes. Figure 37.17 shows the acceptance filtering.

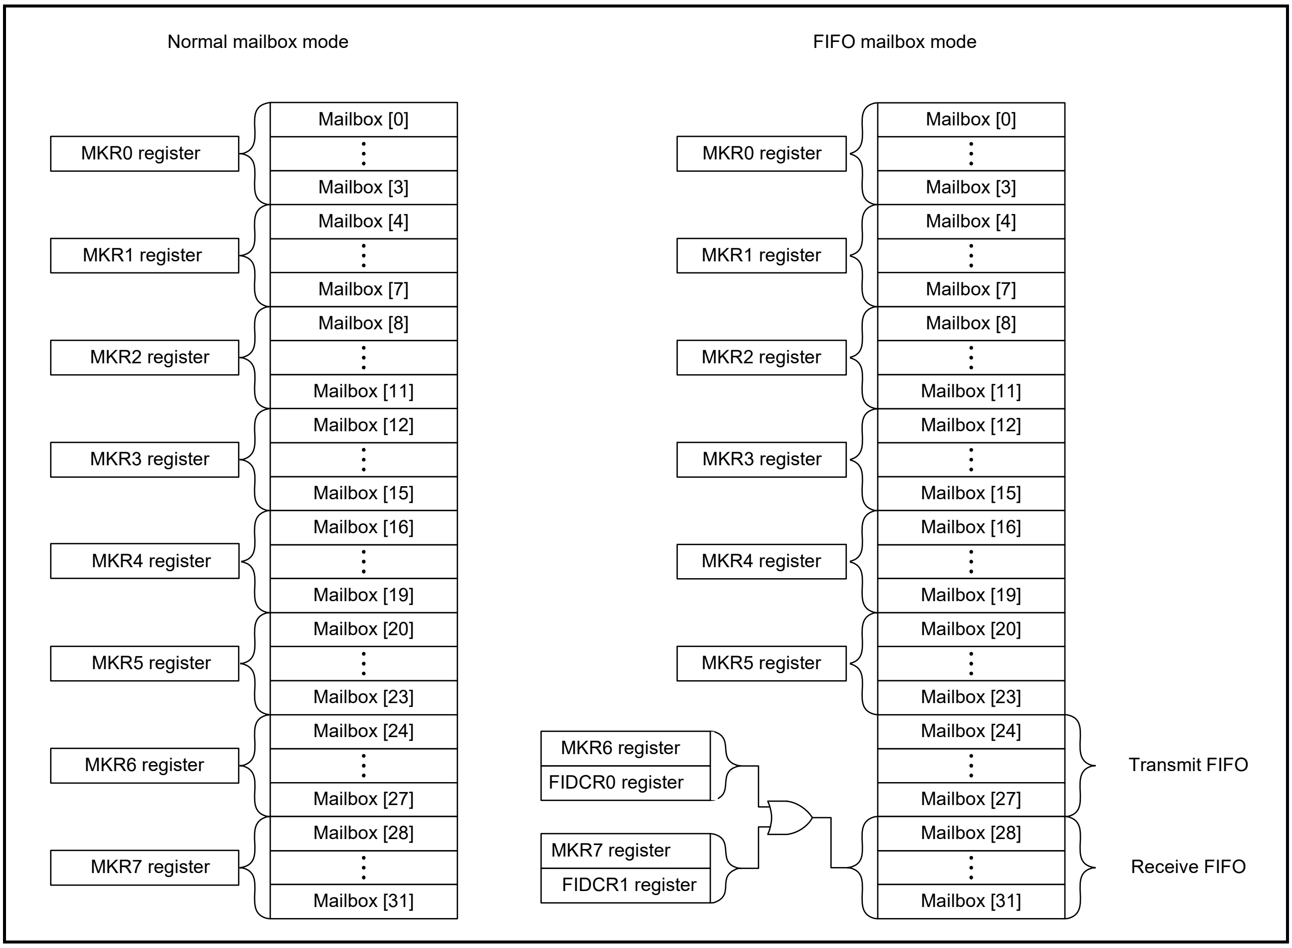

Figure 37.16 Associations between mask registers and mailboxes

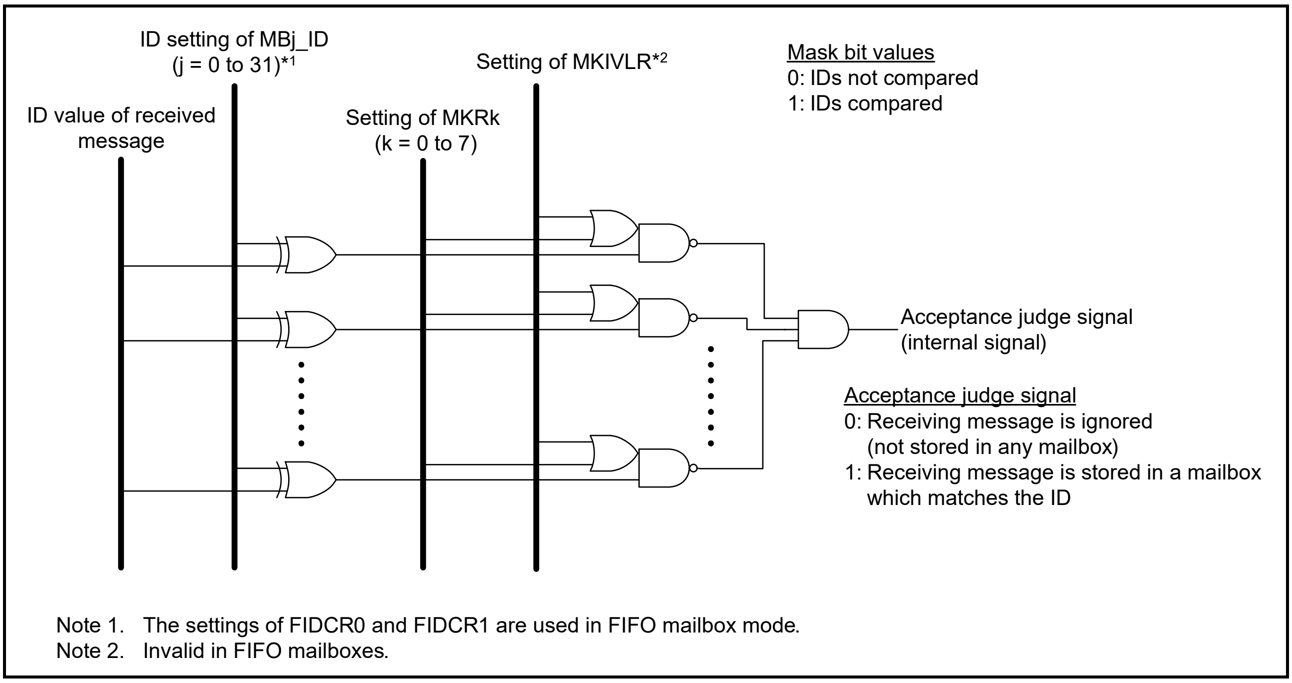

Note 1. The settings of FIDCR0 and FIDCR1 are used in FIFO mailbox mode.
Note 2. Invalid in FIFO mailboxes.

Figure 37.17 Acceptance filtering

37.7 Reception and Transmission

Table 37.10 lists the CAN communication mode settings.

Table 37.10 Settings for CAN receive and transmit modes

MCTL_TXj.TRMREQ and MCTL_RXj.TRMREQ	MCTL_TXj.RECREQ and MCTL_RXj.RECREQ	MCTL_TXj.ONESHOT and MCTL_RXj.ONESHOT	Mailbox communication mode
0	0	0	Mailbox disabled or transmission being aborted
0	0	1	Can be configured only when transmission or reception from a mailbox programmed in one-shot mode is aborted
0	1	0	Configured as a receive mailbox for a data or remote frame
0	1	1	Configured as a one-shot receive mailbox for a data or remote frame.
1	0	0	Configured as a transmit mailbox for a data or remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data or remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

j = 0 to 31

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, the following restrictions apply:

- Before configuring the mailbox, set MCTL_RXj to 00h.
- A received message is stored in the first mailbox that matches the condition resulting from the receive mode settings and acceptance filtering. The matching mailbox with the smallest number takes priority for storing the received message.
- In CAN operation mode, the CAN module does not receive its own transmitted data even if the ID is a match. In self-test mode, however, the CAN module receives its own transmitted data and returns ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, the following constraint applies:

- Before configuring a mailbox, ensure that MCTL_TXj is 00h and that there is no pending abort process.

37.7.1 Reception

Figure 37.18 shows an operation example of data frame reception in overwrite mode. The example shows the overwriting of the first message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL_RXj (j = 0 to 31).

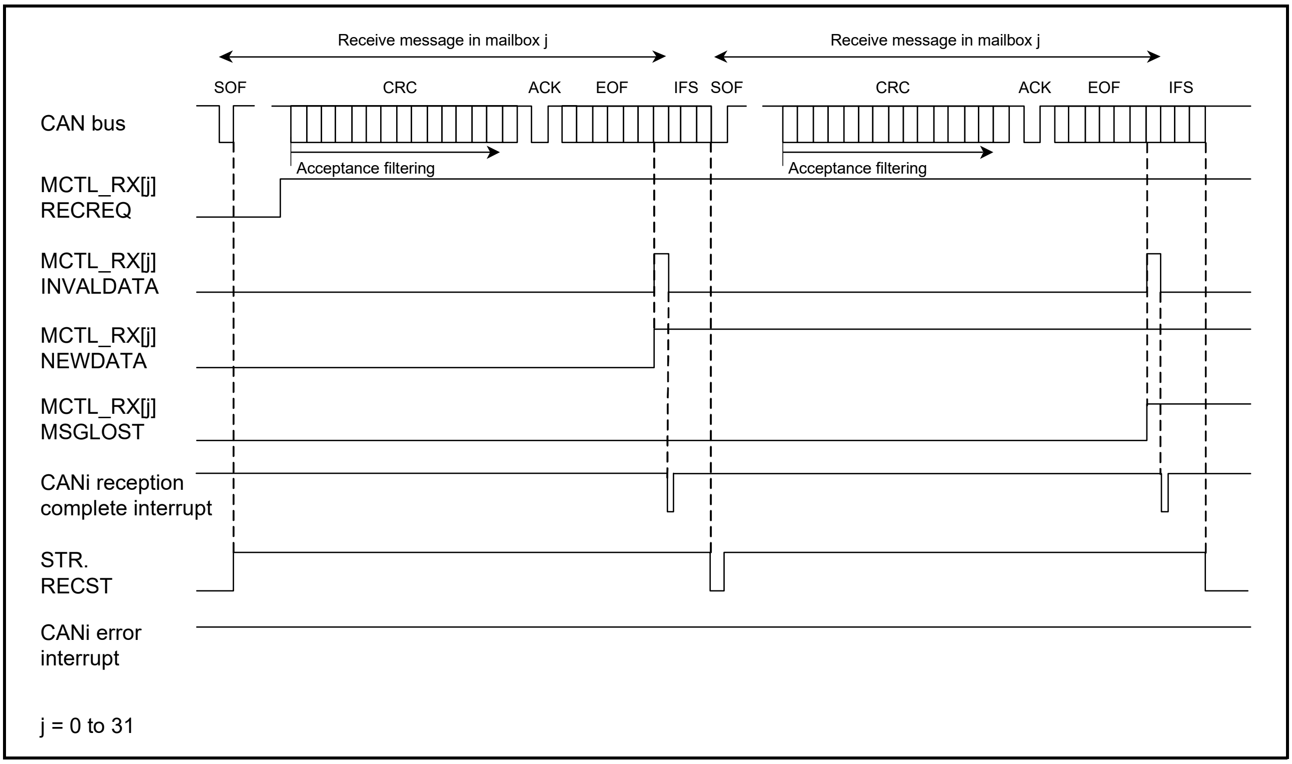

Figure 37.18 Operation example of data frame reception in overwrite mode

1. When an SOF is detected on the CAN bus, the RECST bit in STR is set to 1 (reception in progress) if the CAN module has no message ready to start transmission.
2. Acceptance filtering starts at the beginning of the CRC field to select the receive mailbox.
3. After a message is received, the NEWDATA flag in MCTL_RXj for the receive mailbox is set to 1 (new message is being stored or was stored in the mailbox). The INVALDATA flag in MCTL_RXj is set to 1 (message is being updated) at the same time, and then the INVALDATA flag is set to 0 (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in MIER for the receive mailbox is 1 (interrupt enabled), the INVALDATA flag is set to 0, which triggers a CAN0 reception complete interrupt request.
5. After reading the message from the mailbox, the NEWDATA flag must be set to 0 by software.
6. In overwrite mode, if the next CAN message is received while the NEWDATA flag in MCTL_RXj is set to 1, the MSGLOST flag in MCTL_RXj is set to 1 (message was overwritten). The new received message is transferred to the mailbox. The CAN0 reception complete interrupt request occurs the same as in step 4.

Figure 37.19 shows an operation example of data frame reception in overrun mode. The example shows the overrunning of the second message when the CAN module receives two consecutive CAN messages that match the receiving conditions in MCTL_RXj (j = 0 to 31).

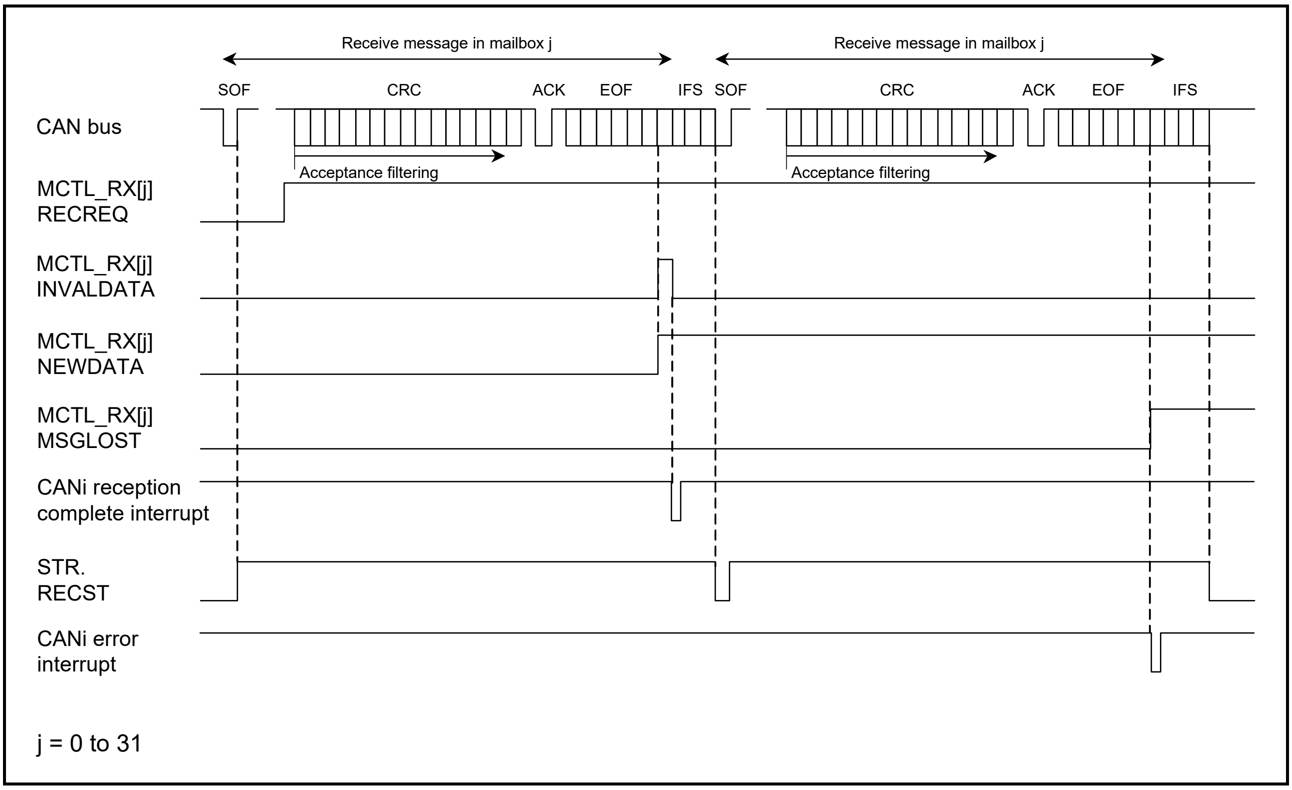

Figure 37.19 Operation example of data frame reception in overrun mode

Steps 1 to 5 are the same as in overwrite mode.

6. In overrun mode, if the next CAN message is received before the NEWDATA flag in MCTL_RXj is set to 0, the MSGLOST flag in MCTL_RXj is set to 1 (message overrun). The new received message is discarded and a CANi error interrupt request occurs if the associated interrupt enable bit in EIER is set to 1 (interrupt enabled).

37.7.2 Transmission

Figure 37.20 shows an operation example of data frame transmission.

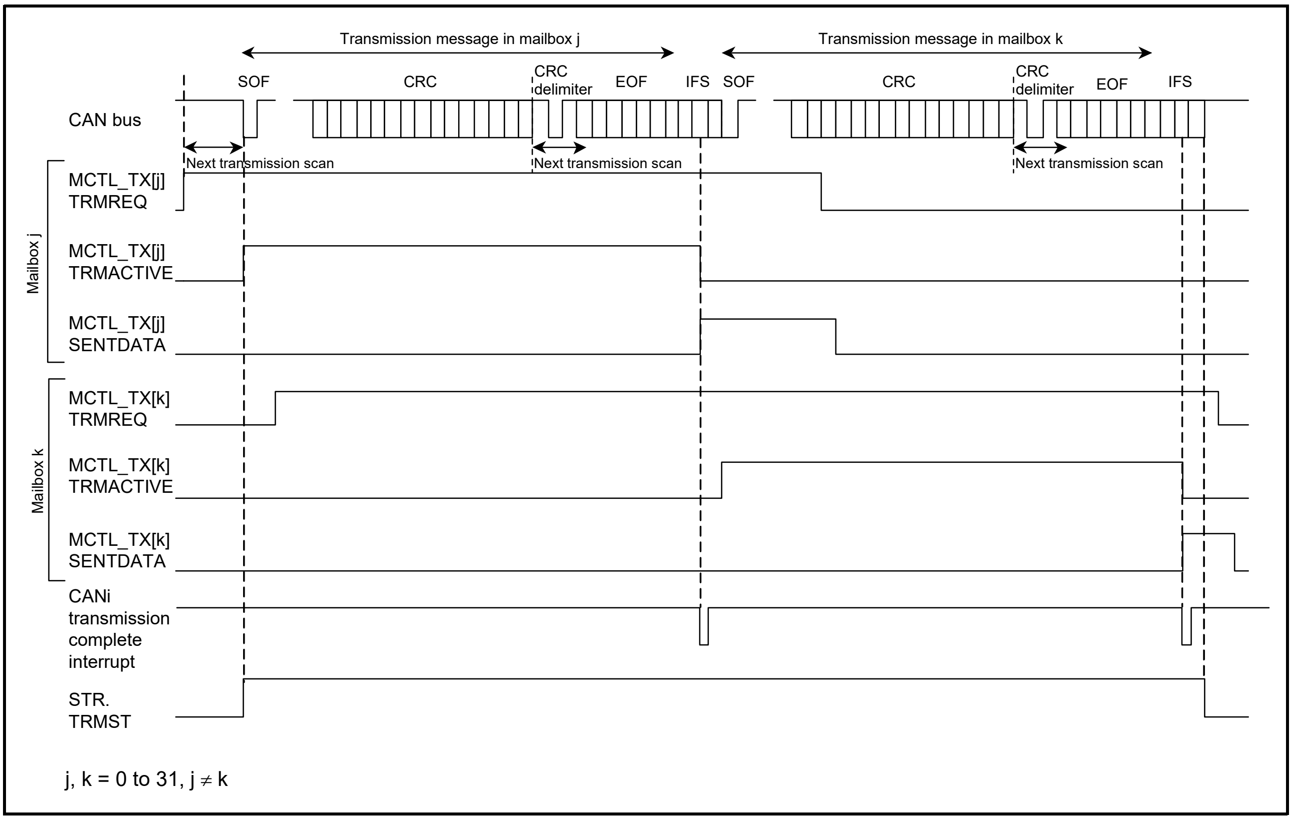

Figure 37.20 Operation example of data frame transmission

1. When a TRMREQ bit in MCTL_TXj (j = 0 to 31) is set to 1 (transmit mailbox) in the bus-idle state, mailbox scanning starts to decide the highest-priority mailbox for transmission. When the transmit mailbox is decided, the TRMACTIVE flag in MCTL_TXj is set to 1 (from acceptance of transmission request to completion of transmission, or error or arbitration-lost), the TRMST bit in STR is set to 1 (transmission in progress), and the CAN module starts transmission.*1
2. If other TRMREQ bits are set, the transmission scanning starts with the CRC delimiter for the next transmission.
3. If transmission is completed without losing arbitration, the SENTDATA flag in MCTL_TXj is set to 1 (transmission complete) and the TRMACTIVE flag is set to 0 (transmission is pending or transmission is not requested). If the interrupt enable bit in MIER is 1 (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set the SENTDATA flag and TRMREQ bit to 0, and then set the TRMREQ bit to 1 after checking that the SENTDATA flag and TRMREQ bit are set to 0.

Note 1. If arbitration is lost after the CAN module starts transmission, the TRMACTIVE flag is set to 0. Transmission scanning is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following arbitration-lost, transmission scanning is performed again to search for the highest-priority transmit mailbox from the start of the error delimiter.

37.8 Interrupts

The CAN module provides the following interrupts for each channel. Table 37.11 lists the CAN interrupts.

- CANi reception complete interrupt for mailboxes 0 to 31 (CANi_RXM)
- CANi transmission complete interrupt for mailboxes 0 to 31 (CANi_TXM)
- CANi receive FIFO interrupt (CANi_RXF)
- CANi transmit FIFO interrupt (CANi_TXF)
- CANi error interrupt (CANi_ERS).

Eight interrupt sources are available for CANi error interrupts. Check EIFR to determine whether these sources were triggered:

- Bus error
- Error-warning
- Error-passive
- Bus-off entry
- Bus-off recovery
- Receive overrun
- Overload frame transmission
- Bus lock.

Table 37.11 CAN interrupts

Module	Interrupt name	Interrupt source	Source flag
CANi i = 0, 1	CANi_ERS	Bus lock detected	EIFR.BLIF
		Overload frame transmission detected	EIFR.OLIF
		Overrun detected	EIFR.ORIF
		Bus-off recovery detected	EIFR.BORIF
		Bus-off entry detected	EIFR.BOEIF
		Error-passive detected	EIFR.EPIF
		Error-warning detected	EIFR.EWIF
		Bus error detected	EIFR.BEIF
	CANi_RXF	Receive FIFO message received (MIER_FIFO.MB29 = 0)	RFCR.RFUST[2:0]
		Receive FIFO warning (MIER_FIFO.MB29 = 1)	
	CANi_TXF	Transmit FIFO message transmission completed (MIER_FIFO.MB25 = 0)	TFCR.TFUST[2:0]
		FIFO last message transmission completed (MIER_FIFO.MB25 = 1)	
	CANi_RXM	Mailbox 0 to 31 message received	MCTL_RX0.NEWDATA to MCTL_RX31.NEWDATA
	CANi_TXM	Mailbox 0 to 31 message transmission completed	MCTL_TX0.SENTDATA to MCTL_TX31.SENTDATA

37.9 Usage Notes

37.9.1 Settings for the Module-Stop Function

CAN operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The CAN module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

37.9.2 Settings for the Operating Clock

The settings for the operating clock can be made as follows:

- The following clock constraint must be satisfied for the CAN module when the CCLKS bit is 1:

  fPCLKB ≥ fCANMCLK

- The source of the peripheral module clock must be PLL for the CAN module when the CCLKS bit is 0.

38. Serial Peripheral Interface (SPI)

38.1 Overview

The MCU provides two independent channels for the Serial Peripheral Interface (SPI). The SPI channels are capable of high-speed, full-duplex, synchronous serial communications with multiple processors and peripheral devices. Table 38.1 lists the SPI specifications, Figure 38.1 shows a block diagram, and Table 38.2 lists the I/O pins.

In this section, *n* indicates A or B, and *i* indicates 0 or 1. A lower-case letter *i* in pin and signal names indicates a value from 0 to 3, and a lower-case letter *m* in SPI Command Register m (SPCMDm) indicates a value from 0 to 7.

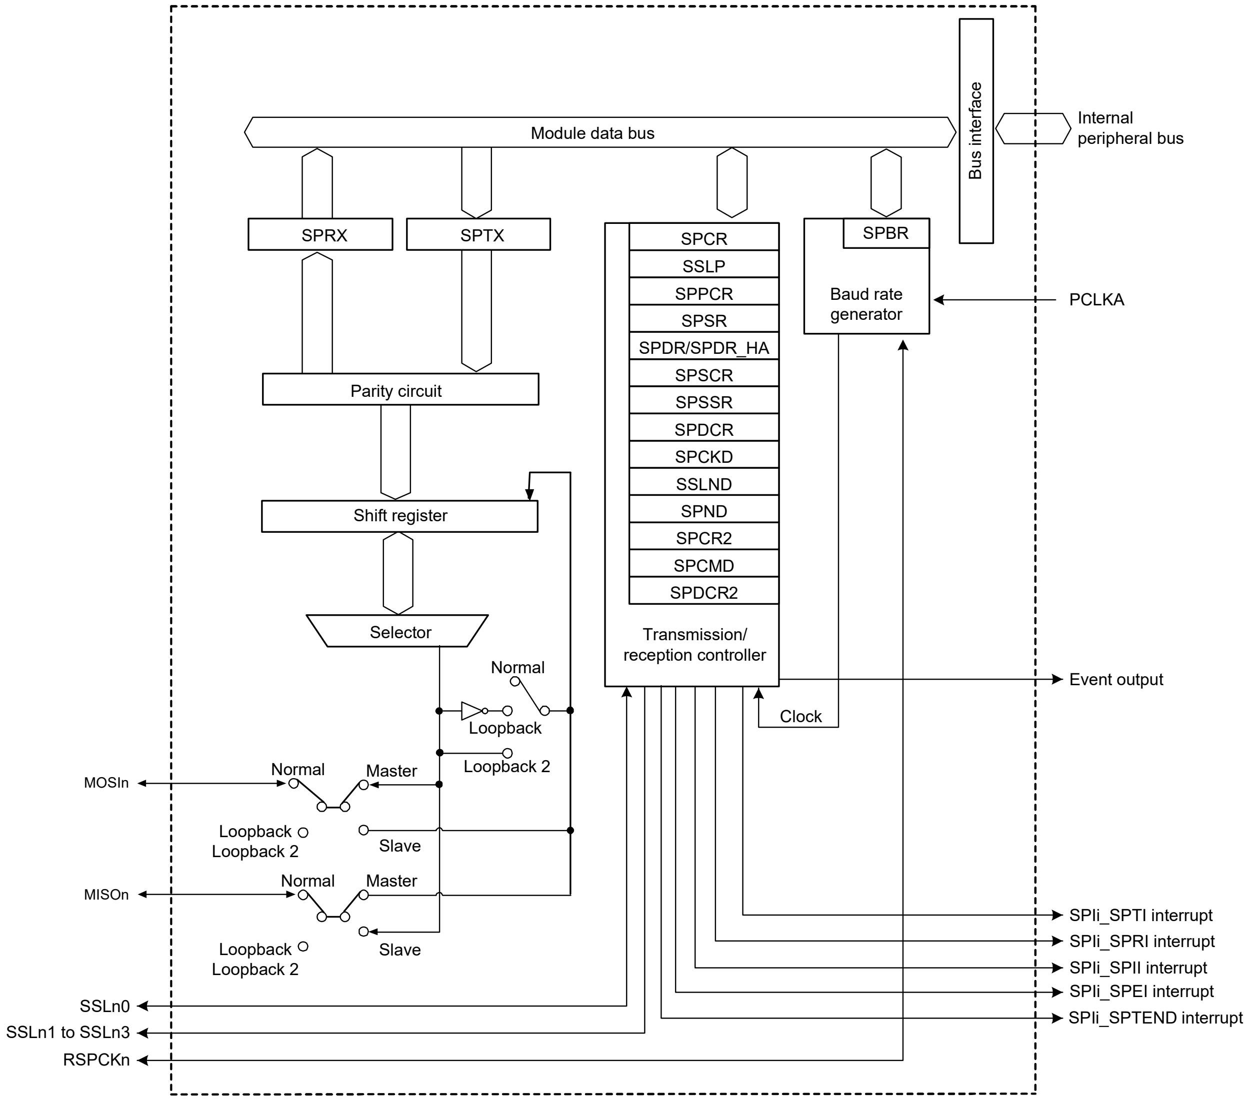
Table 38.1 SPI specifications (1 of 2)

Parameter	Specifications
Number of channels	Two channels
SPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method) • Transmit-only operation available • Communication mode selectable to full-duplex or transmit-only • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB-first or LSB-first selectable • Transfer bit length selectable to 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits • 128-bit transmit and receive buffers • Up to four frames transferrable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLKA (the division ratio ranges from divided by 2 to divided by 4096) • In slave mode, the minimum PCLKA clock divided by 4 can be input as RSPCK (PCLKA divided by 4 is the maximum RSPCK frequency) Width at high level: 2 PCLKA cycles; width at low level: 2 PCLKA cycles
Buffer configuration	• Double buffer configuration for the transmit and receive buffers • 128 bits for the transmit and receive buffers
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection^{*1} • Parity error detection
SSL control function	• Four SSL pins (SSLn0 to SSLn3) for each channel • In single master mode, SSLn0 to SSLn3 pins are output. • In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused • In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Control in master transfer	• Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, MSB- or LSB-first, burst, RSPCK delay, SSL negation delay, and next-access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function
Interrupt sources	Interrupt sources: • Receive buffer full interrupt • Transmit buffer empty interrupt • SPI error interrupt (mode fault, overrun, parity error) • SPI idle interrupt (SPI idle) • Transmission-complete interrupt

Table 38.1 SPI specifications (2 of 2)

Parameter	Specifications
Event link function (output)	The following events can be output to the Event Link Controller (ELC): • Receive buffer full signal • Transmit buffer empty signal • Mode fault, underrun, overrun, or parity error signal • SPI idle signal • Transmission-complete signal
Other functions	• Switching between CMOS output and open-drain output • SPI initialization function • Loopback mode
Module-stop function	Module-stop state can be set to reduce power consumption

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.



SPCR:	SPI Control Register
SPCR2:	SPI Control Register 2
SSLP:	SPI Slave Select Polarity Register
SPPCR:	SPI Pin Control Register
SPSR:	SPI Status Register
SPDR/SPDR_HA:	SPI Data Register
SPSCR:	SPI Sequence Control Register
SPSSR:	SPI Sequence Status Register
SPDCR:	SPI Data Control Register
SPCKD:	SPI Clock Delay Register

SPDCR2:	SPI Data Control Register 2

Figure 38.1 SPI block diagram

Table 38.2 lists the I/O pins used in the SPI. The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see section 38.3.2, Controlling the SPI Pins.

Table 38.2 SPI I/O pins

Channel	Pin name	I/O	Function
SPI0	RSPCKA	I/O	Clock input/output
	MOSIA	I/O	Master transmit data input/output
	MISOA	I/O	Slave transmit data input/output
	SSLA0	I/O	Slave selection input/output
	SSLA1	Output	Slave selection output
	SSLA2	Output	Slave selection output
	SSLA3	Output	Slave selection output
SPI1	RSPCKB	I/O	Clock input/output
	MOSIB	I/O	Master transmit data input/output
	MISOB	I/O	Slave transmit data input/output
	SSLB0	I/O	Slave selection input/output
	SSLB1	Output	Slave selection output
	SSLB2	Output	Slave selection output
	SSLB3	Output	Slave selection output

38.2 Register Descriptions

38.2.1 SPI Control Register (SPCR)

Address(es): SPI0.SPCR 4007 2000h, SPI1.SPCR 4007 2100h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODF EN	TXMD	SPMS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SPMS	SPI Mode Select	0: Select SPI operation (4-wire method) 1: Select clock synchronous operation (3-wire method).	R/W
b1	TXMD	Communications Operating Mode Select	0: Select full-duplex synchronous serial communications 1: Select serial communications with transmit-only.	R/W
b2	MODFEN	Mode Fault Error Detection Enable	0: Disable detection of mode fault errors 1: Enable detection of mode fault errors.	R/W
b3	MSTR	SPI Master/Slave Mode Select	0: Select slave mode 1: Select master mode.	R/W
b4	SPEIE	SPI Error Interrupt Enable	0: Disable SPI error interrupt requests 1: Enable SPI error interrupt requests.	R/W
b5	SPTIE	Transmit Buffer Empty Interrupt Enable	0: Disable transmit buffer empty interrupt requests 1: Enable transmit buffer empty interrupt requests.	R/W
b6	SPE	SPI Function Enable	0: Disable SPI function 1: Enable SPI function.	R/W
b7	SPRIE	SPI Receive Buffer Full Interrupt Enable	0: Disable SPI receive buffer full interrupt requests 1: Enable SPI receive buffer full interrupt requests.	R/W

If the SPCR.MSTR, SPCR.MODFEN, or SPCR.TXMD bit is changed while the SPCR.SPE bit is 1, do not perform subsequent operations.

SPMS bit (SPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISOn pins handle communications. For clock synchronous operation in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. For clock synchronous operation in slave mode (SPCR.MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0).

TXMD bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and not receive operations (see section 38.3.6, Data Transfer Modes), and receive buffer full interrupt requests cannot be used.

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault errors (see section 38.3.8, Error Detection). In addition, the SPI determines the I/O direction of the SSLn0 to SSLn3 pins based on combination of the MODFEN and MSTR bits (see section 38.3.2, Controlling the SPI Pins).

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISOn, and SSLn0 to SSLn3 pins.

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1.

For details, see section 38.3.8, Error Detection.

SPTIE bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

SPE bit (SPI Function Enable)

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see section 38.3.8, Error Detection.

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see section 38.3.9, Initializing the SPI. In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

38.2.2 SPI Slave Select Polarity Register (SSLP)

Address(es): SPI0.SSLP 4007 2001h, SPI1.SSLP 4007 2101h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SSL0P	SSL0 Signal Polarity Setting	0: Set SSL0 signal to active low 1: Set SSL0 signal to active high.	R/W
b1	SSL1P	SSL1 Signal Polarity Setting	0: Set SSL1 signal to active low 1: Set SSL1 signal to active high.	R/W
b2	SSL2P	SSL2 Signal Polarity Setting	0: Set SSL2 signal to active low 1: Set SSL2 signal to active high.	R/W
b3	SSL3P	SSL3 Signal Polarity Setting	0: Set SSL3 signal to active low 1: Set SSL3 signal to active high.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the contents of SSLP are changed while the SPCR.SPE bit is 1, do not perform subsequent operations.

38.2.3 SPI Pin Control Register (SPPCR)

Address(es): SPI0.SPPCR 4007 2002h, SPI1.SPPCR 4007 2102h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SPLP	SPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission).	R/W
b1	SPLP2	SPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission).	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	MOIFV	MOSI Idle Fixed Value	0: Set level output on MOSIn pin during MOSI idling to correspond to low 1: Set level output on MOSIn pin during MOSI idling to correspond to high.	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: Set MOSI output value to equal final data from previous transfer 1: Set MOSI output value to equal value set in the MOIFV bit.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the contents of SPPCR are changed while the SPCR.SPE bit is 1, do not perform subsequent operations.

SPLP bit (SPI Loopback)

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the input path and output path for the shift register (loopback mode).

SPLP2 bit (SPI Loopback 2)

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the

SPCR.MSTR bit is 0. The SPI then connects the input path and output path for the shift register (loopback mode).

MOIFV bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIn pin output value during the SSL negation period, including the SSL retention period during a burst transfer.

MOIFE bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period, including the SSL retention period during a burst transfer. When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

38.2.4 SPI Status Register (SPSR)

Address(es): SPI0.SPSR 4007 2003h, SPI1.SPSR 4007 2103h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRF	—	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	OVRF	Overrun Error Flag	0: No overrun error occurred 1: Overrun error occurred.	R/(W)*1
b1	IDLNF	SPI Idle Flag	0: SPI is in the idle state 1: SPI is in the transfer state.	R
b2	MODF	Mode Fault Error Flag	0: No mode fault or underrun error occurred 1: Mode fault error or underrun error occurred.	R/(W)*1
b3	PERF	Parity Error Flag	0: No parity error occurred 1: Parity error occurred.	R/(W)*1
b4	UDRF	Underrun Error Flag	0: Mode fault error occurred (MODF = 1) 1: Underrun error occurred (MODF = 1). This bit is invalid when MODF flag is 0.	R/W*1,*2
b5	SPTEF	SPI Transmit Buffer Empty Flag	0: Data is in the transmit buffer 1: No data is in the transmit buffer.	R/(W)*3
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	SPRF	SPI Receive Buffer Full Flag	0: No valid data is in SPDR/SPDR_HA 1: Valid data is in SPDR/SPDR_HA.	R/(W)*3

Note 1. Only 0 can be written to clear the flag after reading 1.
Note 2. The UDRF flag clears at the same time that the software clears the MODF flag.
Note 3. The write value should be 1.

OVRF flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (SPCR.MSTR bit = 1) and when the RSPCK clock auto-stop function is enabled (SPCR2.SCKASE bit = 1), overrun errors do not occur. This flag does not set to 1. For details, see section 38.3.8.1, Overrun errors.

[Setting condition]

- When the next serial transfer ends while the SPCR.TXMD bit is 0 and the receive buffer is full.

[Clearing condition]

- When 0 is written to the OVRF flag after the OVRF flag is confirmed to be 1 by a read of SPSR.

IDLNF flag (SPI Idle Flag)

The IDLNF flag indicates the transfer status of the SPI.

[Setting conditions]

Master mode

- When conditions 1. and 2. in the master mode [Clearing conditions] are not satisfied.

Slave mode

- When the SPCR.SPE bit is 1, enabling the SPI function.

[Clearing conditions]

Master mode

- When condition 1. OR conditions 2., 3., and 4. are satisfied.

1. The SPCR.SPE bit is 0, indicating the SPI is initialized.
2. The transmit buffer (SPTX) is empty, indicating that data for the next transfer is not set.
3. The SPSSR.SPCP[2:0] bits are 000b, indicating the beginning of sequence control.
4. The SPI internal sequencer enters the idle state, indicating that operations up to the next-access delay are complete.

Slave mode

- When condition 1. is satisfied.

MODF flag (Mode Fault Error Flag)

The MODF flag indicates the occurrence of a mode fault error or an underrun error. Use the UDRF flag to identify which error occurred.

[Setting conditions]

Multi-master mode

- When the input level of the SSLni pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled). The SPI detects a mode fault error.

Slave mode

- When condition 1. OR 2. is satisfied.

1. The SSLni pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled). The SPI detects a mode fault error.
2. The serial transfer begins while the SPCR.MSTR bit is 0 (slave mode), the SPCR.SPE bit is 1, and the transmission data is not prepared. The SPI detects an underrun error.

The active level of the SSLni signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting bit).

[Clearing condition]

- When 0 is written to the MODF flag after the MODF flag is confirmed to be 1 by a read of SPSR.

PERF flag (Parity Error Flag)

The PERF flag indicates the occurrence of a parity error.

[Setting condition]

- When a serial transfer ends while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The SPI detects a parity error.

[Clearing condition]

- When 0 is written to the PERF flag after the PERF flag is confirmed to be 1 by a read of SPSR.

UDRF flag (Underrun Error Flag)

The UDRF flag indicates the occurrence of an underrun error.

[Setting condition]

- When the serial transfer begins while the SPCR.MSTR bit is 0 (slave mode), the SPCR.SPE bit is 1, and the transmission data is not prepared. The SPI detects an underrun error.

[Clearing condition]

- When 0 is written to the UDRF flag after the UDRF flag is confirmed to be 1 by a read of SPSR.

SPTEF flag (SPI Transmit Buffer Empty Flag)

The SPTEF flag indicates the status of the transmit buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting conditions]

- When condition 1. OR 2. is satisfied.

1. The SPCR.SPE bit is 0 (the SPI is initialized).
2. Transmit data was transferred from the transmit buffer to the shift register.

[Clearing condition]

- When data written to SPDR/SPDR_HA equals the number of frames set in the SPFC[1:0] bits in the SPI Data Control Register (SPDCR).

Data can only be written to SPDR/SPDR_HA when the SPTEF flag is 1. If data is written to the transmit buffer of SPDR/SPDR_HA when the SPTEF flag is 0, the data in the transmit buffer is not updated.

SPRF flag (SPI Receive Buffer Full Flag)

The SPRF flag indicates the status of the receive buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting condition]

- When a serial transfer ends while the communication operating mode select bit (TXMD) in the SPI Control Register (SPCR) is 0, the SPRF flag is 0, and the SPI transfers the receive data from the shift register to SPDR/SPDR_HA. However, when the OVRF flag is 1, the SPRF flag does not change from 0 into 1.

[Clearing condition]

- When received data is read from the SPDR/SPDR_HA.

38.2.5 SPI Data Register (SPDR/SPDR_HA)

Address(es): SPI0.SPDR 4007 2004h, SPI1.SPDR 4007 2104h

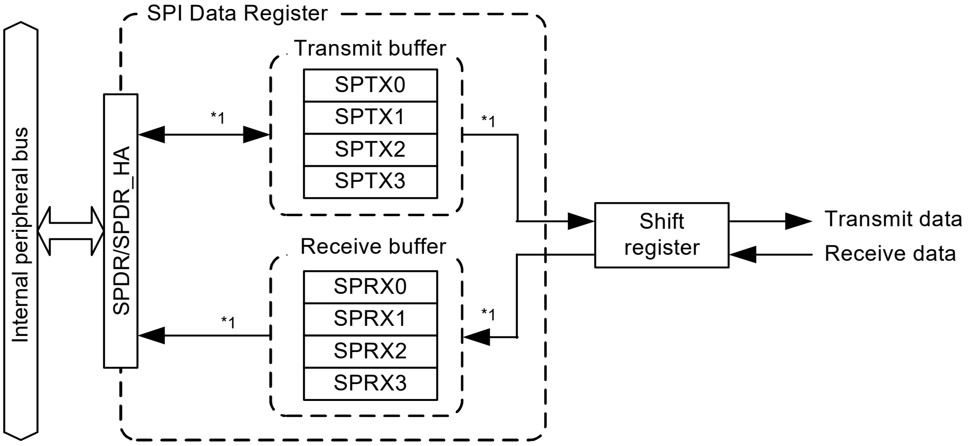
Address(es): SPI0.SPDR_HA 4007 2004h, SPI1.SPDR_HA 4007 2104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPDR/SPDR_HA is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words (the SPLW bit is 1), access SPDR. When accessing it in halfwords (the SPLW bit is 0), access SPDR_HA.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR_HA. Figure 38.2 shows the configuration.



Note 1. The destination buffer and stage for access is automatically switched by the hardware.

Figure 38.2 Configuration of SPDR/SPDR_HA

The transmit and receive buffers each have four stages. The number of stages to be used is selectable in the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The eight stages of the buffer are all mapped to the single address of SPDR/SPDR_HA.

Data written to SPDR/SPDR_HA is written to a transmit-buffer stage (SPTXn) (n = 0 to 3) and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is other than 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the associated bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRXn[8:0] bits, and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus interface

SPDR/SPDR_HA is an interface with 32-bit wide transmit and receive buffers, each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for SPDR/SPDR_HA. Additionally, the unit of access for SPDR/SPDR_HA is selected by the SPI word access/halfword access specification bit in the SPI Data Control Register (SPDCR.SPLW). Other case, make an access to SPDR with the access size specified by the SPI byte access bit in the SPI Data Control Register (SPDCR.SPBYT).

Flush transmission data at the LSB end of the register, and store received data at the LSB end.

This section describes the operations involved in writing to and reading from SPDR/SPDR_HA.

(a) Writing

Data written to SPDR/SPDR_HA is written to a transmit buffer (SPTXn). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR_HA. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR_HA.

Figure 38.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR.

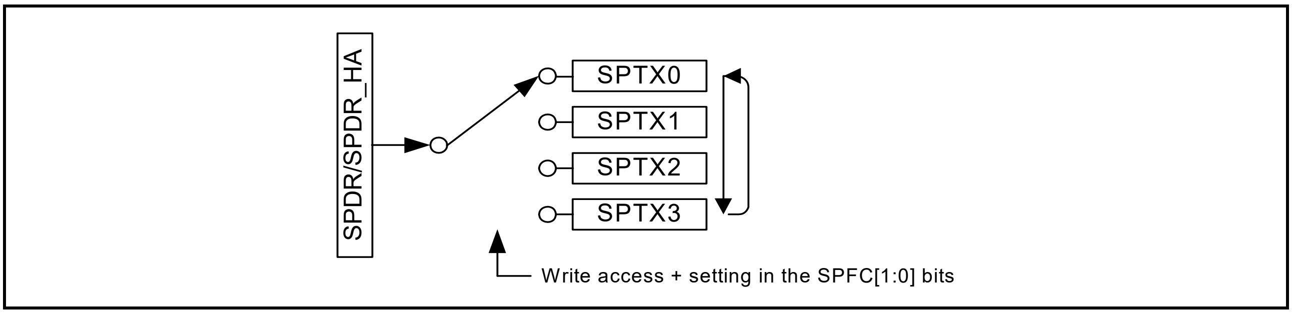


Figure 38.3 Configuration of SPDR/SPDR_HA for write access

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching among SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When 1 is written to the SPI function enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 0, SPTX0 is the destination the next time writing proceeds.

When writing to the transmit buffer (SPTXn) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before the next transmit buffer empty interrupt is generated (when SPTEF is 0).

(b) Reading

SPDR/SPDR_HA can be accessed to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting in the SPI receive/transmit data select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR_HA register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 38.4 shows the configuration of the bus interface with the receive and transmit buffers for a read from SPDR/SPDR_HA.

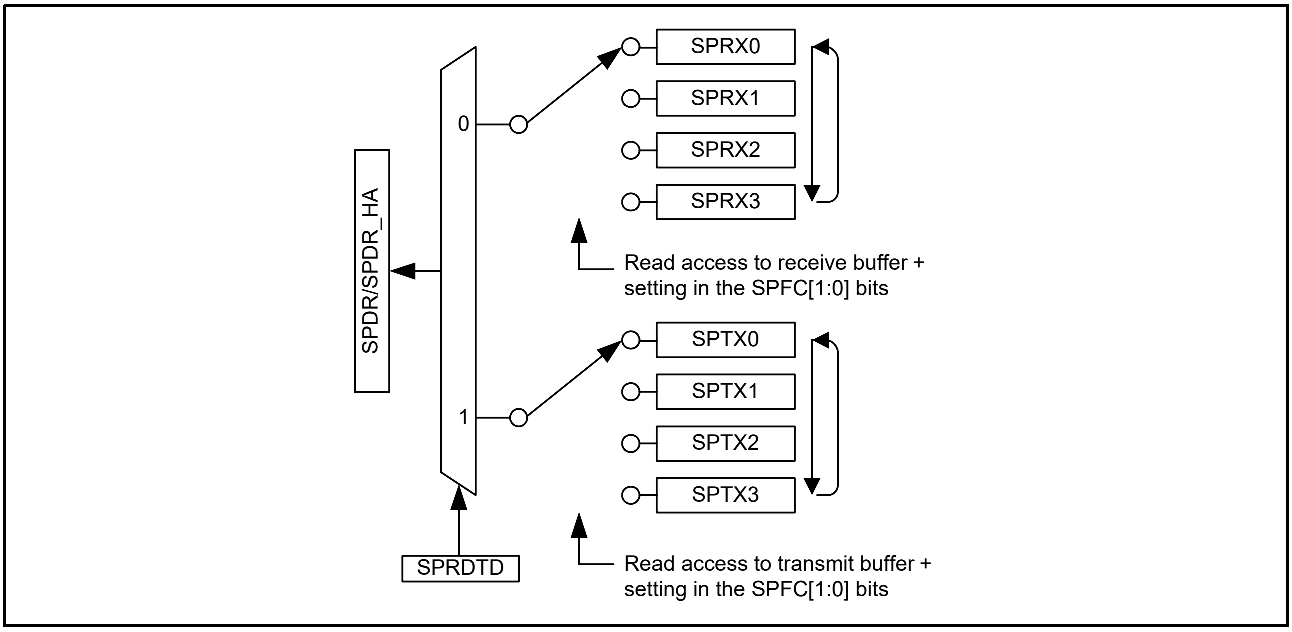

Figure 38.4 Configuration of SPDR/SPDR_HA for read access

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI function enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer the next time reading proceeds.

The transmit buffer read pointer is updated when writing to SPDR/SPDR_HA, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR_HA is read. However, after generation of the transmit buffer empty interrupt, the values read from the transmit buffer are all 0s in the interval after completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits and before generation of the next buffer empty interrupt (when SPTEF is 0).

38.2.6 SPI Sequence Control Register (SPSCR)

Address(es): SPI0.SPSCR 4007 2008h, SPI1.SPSCR 4007 2108h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	SPSLN[2:0]	SPI Sequence Length Specification	b2 b0 Sequence Length Referenced SPCMD0 to SPCMD7 (No.) 0 0 0: 1 0→0→… 0 0 1: 2 0→1→0→… 0 1 0: 3 0→1→2→0→… 0 1 1: 4 0→1→2→3→0→… 1 0 0: 5 0→1→2→3→4→0→… 1 0 1: 6 0→1→2→3→4→5→0→… 1 1 0: 7 0→1→2→3→4→5→6→0→… 1 1 1: 8 0→1→2→3→4→5→6→7→0→… The sequence length that is set in these bits determines the order in which the SPCMD0 to SPCMD07 registers are referenced. The setting defines the relationship between the sequence length and the SPCMD0 to SPCMD7 registers referenced by the SPI. In slave mode, the SPI references SPCMD0.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPSCR specifies the sequence length when the SPI operates in master mode. Before changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, always check that the SPSR.IDLNF flag is 0.

SPSLN[2:0] bits (SPI Sequence Length Specification)

The SPSLN[2:0] bits specify the sequence length when the SPI in master mode performs sequential operations. The SPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced, and the order in which they are referenced is based on this sequence length setting. In slave mode, SPCMD0 is referenced.

38.2.7 SPI Sequence Status Register (SPSSR)

Address(es): SPI0.SPSSR 4007 2009h, SPI1.SPSSR 4007 2109h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	SPCP[2:0]	SPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7.	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	SPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7.	R
b7	—	Reserved	This bit is read as 0.	R

SPSSR indicates the sequence control status when the SPI operates in master mode. Any writes to SPSSR are ignored.

SPCP[2:0] bits (SPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is referenced to by the pointer during sequence control by the SPI. For the SPI sequence control, see section 38.3.10.1, Master mode operation.

SPECM[2:0] bits (SPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the SPI error detection function, see section 38.3.8, Error Detection. For the SPI sequence control, see section 38.3.10.1, Master mode operation.

38.2.8 SPI Bit Rate Register (SPBR)

Address(es): SPI0.SPBR 4007 200Ah, SPI1.SPBR 4007 210Ah

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

SPBR sets the bit rate in master mode. If the contents of SPBR are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

When the SPI is used in slave mode, the bit rate depends on the bit rate of the input clock regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings. The equation for calculating the bit rate is as follows:

$$\text{Bit rate} = \frac{f\,(\text{PCLKA})}{2 \times (n + 1) \times 2^N}$$

In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

Table 38.3 lists examples of the relationship among the SPBR settings, the BRDV[1:0] settings, and bit rates.

Table 38.3 Relationship among SPBR settings, BRDV[1:0] settings, and bit rates

SPBR (n)	BRDV[1:0] bits (N)	Division ratio	Bit rate							
			PCLKA = 32 MHz	PCLKA = 36 MHz	PCLKA = 40 MHz	PCLKA = 50 MHz	PCLKA = 60 MHz	PCLKA = 80 MHz	PCLKA = 100 MHz	PCLKA = 120 MHz
0	0	2	16.0 Mbps	18.0 Mbps	20.0 Mbps	25.0 Mbps	30.0 Mbps	Not supported

b4	SPRDTD	SPI Receive/Transmit Data Select	0: Read SPDR/SPDR_HA values from receive buffer 1: Read SPDR/SPDR_HA values from transmit buffer, but only if the transmit buffer is empty.	R/W
b5	SPLW	SPI Word Access/Halfword Access Specification	0: Set SPDR_HA to valid for halfword access 1: Set SPDR to valid for word access.	R/W
b6	SPBYT	SPI Byte Access Specification	0: SPDR is accessed in halfword or word (SPLW is valid) 1: SPDR is accessed in byte (SPLW is invalid).	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits.

When changing the SPDCR.SPFC[1:0] bits while the SPCR.SPE bit is 1, always check that the SPSR.IDLNF flag is 0.

SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

Table 38.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (1 of 2)

Setting	SPSLN[2:0]	SPFC[1:0]	Number of frames in a single sequence	Number of frames at which transmission or receive buffer is filled

4	011b	11b	4	4
5	100b	00b	5	1

Table 38.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (2 of 2)

Setting	SPSLN[2:0]	SPFC[1:0]	Number of frames in a single sequence	Number of frames at which transmission or receive buffer is filled
6	101b	00b	6	1
7	110b	00b	7	1
8	111b	00b	8	1

SPRDTD bit (SPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR/SPDR_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the value written to SPDR/SPDR_HA register immediately beforehand is read. When reading the transmit buffer, do so before writing of the number of frames set in the SPFC[1:0] bits is finished and after generation of the transmit buffer empty interrupt (when SPSR.SPTEF is 1).

For details, see section 38.2.5, SPI Data Register (SPDR/SPDR_HA).

SPLW bit (SPI Word Access/Halfword Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPCMDm.SPB[3:0] bits (SPI data length setting) from 8 to 16 bits. Do not perform any operations when 20, 24, or 32 bits is specified.

SPBYT bit (SPI Byte Access Specification)

This bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register n (SPCMDn) to 0 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bit, subsequent operation is not guaranteed.

38.2.10 SPI Clock Delay Register (SPCKD)

Address(es): SPI0.SPCKD 4007 200Ch, SPI1.SPCKD 4007 210Ch

Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPCKD specifies the RSPCK delay, the period from the beginning of SSLni signal assertion to RSPCK oscillation, when the SPCMDm.SCKDEN bit is 1. If the contents of SPCKD are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

SCKDL[2:0] bits (RSPCK Delay Setting)

The SCKDL[2:0] bits specify an RSPCK delay value when the SPCMDm.SCKDEN bit is 1. When using the SPI in slave mode, set the SCKDL[2:0] bits to 000b.

38.2.11 SPI Slave Select Negation Delay Register (SSLND)

Address(es): SPI0.SSLND 4007 200Dh, SPI1.SSLND 4007 210Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SSLND specifies the SSL negation delay, the period from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the SPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

SLNDL[2:0] bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits specify an SSL negation delay value when the SPI is in master mode. When using the SPI in slave mode, set the SLNDL[2:0] bits to 000b.

38.2.12 SPI Next-Access Delay Register (SPND)

Address(es): SPI0.SPND 4007 200Eh, SPI1.SPND 4007 210Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	SPNDL[2:0]	SPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 2 PCLKA 0 0 1: 2 RSPCK + 2 PCLKA 0 1 0: 3 RSPCK + 2 PCLKA 0 1 1: 4 RSPCK + 2 PCLKA 1 0 0: 5 RSPCK + 2 PCLKA 1 0 1: 6 RSPCK + 2 PCLKA 1 1 0: 7 RSPCK + 2 PCLKA 1 1 1: 8 RSPCK + 2 PCLKA.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPND specifies the next-access delay, the non-active period of the SSLni signal after termination of a serial transfer, when the SPCMDm.SPNDEN bit is 1. If the contents of SPND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

SPNDL[2:0] bits (SPI Next-Access Delay Setting)

The SPNDL[2:0] bits specify a next-access delay when the SPCMDm.SPNDEN bit is 1. When using the SPI in slave mode, set the SPNDL[2:0] bits to 000b.

38.2.13 SPI Control Register 2 (SPCR2)

Address(es): SPI0.SPCR2 4007 200Fh, SPI1.SPCR2 4007 210Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SCKASE	PTE	SPIIE	SPOE	SPPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SPPE	Parity Enable	0: Do not add parity bit to transmit data and do not check parity bit of receive data 1: When SPCR.TXMD = 0: Add parity bit to transmit data and check parity bit of receive data When SPCR.TXMD = 1: Add parity bit to transmit data but do not check parity bit of receive data.	R/W
b1	SPOE	Parity Mode	0: Select even parity for transmission and reception 1: Select odd parity for transmission and reception.	R/W
b2	SPIIE	SPI Idle Interrupt Enable	0: Disable idle interrupt requests 1: Enable idle interrupt requests.	R/W
b3	PTE	Parity Self-Testing	0: Disable self-diagnosis function of the parity circuit 1: Enable self-diagnosis function of the parity circuit.	R/W
b4	SCKASE	RSPCK Auto-Stop Function Enable	0: Disable RSPCK auto-stop function 1: Enable RSPCK auto-stop function.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

If the SPPE, SPOE, or SCKASE bit in SPCR2 is changed while the SPCR.SPE bit is 1, do not perform subsequent operations.

SPPE bit (Parity Enable)

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data but parity checking is not performed for receive data.

SPOE bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears to 0.

PTE bit (Parity Self-Testing)

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs when data is received in master mode. For details, see section 38.3.8.1, Overrun errors.

38.2.14 SPI Command Registers 0 to 7 (SPCMD0 to SPCMD7)

Address(es): SPI0.SPCMD0 4007 2010h, SPI0.SPCMD1 4007 2012h, SPI0.SPCMD2 4007 2014h, SPI0.SPCMD3 4007 2016h, SPI0.SPCMD4 4007 2018h, SPI0.SPCMD5 4007 201Ah, SPI0.SPCMD6 4007 201Ch, SPI0.SPCMD7 4007 201Eh, SPI1.SPCMD0 4007 2110h, SPI1.SPCMD1 4007 2112h, SPI1.SPCMD2 4007 2114h, SPI1.SPCMD3 4007 2116h, SPI1.SPCMD4 4007 2118h, SPI1.SPCMD5 4007 211Ah, SPI1.SPCMD6 4007 211Ch, SPI1.SPCMD7 4007 211Eh

b12	LSBF	SPI LSB First	0: MSB first 1: LSB first.	R/W
b13	SPNDEN	SPI Next-Access Delay Enable	0: Select next-access delay of 1 RSPCK + 2 PCLKA 1: Select next-access delay equal to the setting in the SPI Next-Access Delay Register (SPND).	R/W
b14	SLNDEN	SSL Negation Delay Setting Enable	0: Select SSL negation delay of 1 RSPCK 1: Select SSL negation delay equal to the setting in the SPI Slave Select Negation Delay Register (SSLND).	R/W
b15	SCKDEN	RSPCK Delay Setting Enable	0: Select RSPCK delay of 1 RSPCK 1: Select RSPCK delay equal to the setting in the SPI Clock Delay Register (SPCKD).	R/W

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPI Command Registers (SPCMD0 to SPCMD7). Some of the bits in the SPCMD0 register are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the

SPSCR.SPSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm register.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm register is referenced.

The SPCMDm register referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. If the contents of SPCMDm are changed while the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1, do not perform subsequent operations.

CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate. The bit rate is determined by the combination of the settings in the BRDV[1:0] bits and SPBR (see section 38.2.8, SPI Bit Rate Register (SPBR)). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMDm registers. This enables execution of serial transfers at different bit rates for each command.

SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see section 38.3.10.1, Master mode operation. When using the SPI in slave mode, set the SSLKP bit to 0.

SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode. When the SPLW bit is 0, set these bits from 8 to 16 bits.

LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay in accordance with the SPND setting.

When using the SPI in slave mode, set the SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSLni signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay determined by the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSLni signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at the RSPCK delay determined by the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

38.2.15 SPI Data Control Register 2 (SPDCR2)

Address(es): SPI0.SPDCR2 4007 2020h, SPI1.SPDCR2 4007 2120h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BYSW
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	BYSW	Byte Swap Operating Mode Select	0: Byte Swap OFF 1: Byte Swap ON	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPI Data Control Register2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units. When a data of transmit buffers copies to a shift register, it is to swap in byte units. When a data of shift register copies to a receive buffers, it is to swap in byte units.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32bit (SPB[3:0] = 0010 or 0011)

  Before swap: [31:24] [23:16] [15:8] [7:0]

  After swap: [7:0] [15:8] [23:16] [31:24]

- Length data 16bit (SPB[3:0] = 1111)

  Before swap: [31:24] [23:16]

  After swap: [23:16] [31:24].

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

38.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

38.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation).

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 38.5 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 38.5 Relationship between SPCR settings and SPI modes (1 of 2)

Mode	Slave (SPI operation)	Single master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
RSPCKn signal	Input	Output	Output/Hi-Z	Input	Output
MOSIn signal	Input	Output	Output/Hi-Z	Input	Output
MISOn signal	Output/Hi-Z	Input	Input	Output	Input
SSLn0 signal	Input	Output	Input	Hi-Z*1	Hi-Z*1
SSLn1 to SSLn3 signals	Hi-Z*1	Output	Output/Hi-Z	Hi-Z*1	Hi-Z*1
SSL polarity change function	Supported	Supported	Supported	-	-
Max transfer rate	PCLKA/4	PCLKA/2	PCLKA/2	PCLKA/4	PCLKA/2
Clock source	RSPCKn input	On-chip baud rate generator	On-chip baud rate generator	RSPCKn input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two	Two	Two	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transfer data length	8 to 16, 20, 24, 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	-	-
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer trigger	SSL input active or RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported				
Receive buffer full detection	Supported*2				
Overrun error detection	Supported*2	Supported*2, *4	Supported*2, *4	Supported*2	Supported*2
Parity error detection	Supported*2,*3				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported

Table 38.5 Relationship between SPCR settings and SPI modes (2 of 2)

Mode	Slave (SPI operation)	Single master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
Underrun error detection	Supported	Not supported	Not supported	Supported	Not supported

Note 1. This function is not supported in this mode.
Note 2. When the SPCR.TXMD bit is 1, receiver buffer full detection, overrun error detection, and parity error detection are not performed.
Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection is not performed.

38.3.2 Controlling the SPI Pins

The SPI can switch pin states based on the settings in the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for the I/O ports. Table 38.6 lists the relationship between the pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects CMOS output. Setting it to 1 selects open-drain output. The I/O port settings must follow this relationship.

Table 38.6 Relationship between pin states and bit settings

Mode	Pin	Pin state*2 PmnPFS.NCODR bit for I/O ports = 0	 PmnPFS.NCODR bit for I/O ports = 1
Single master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3	CMOS output	Open-drain output
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLn0	Input	Input
	SSLn1 to SSLn3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOn	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKn	Input	Input
	SSLn0	Input	Input
	SSLn1 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input
Slave mode (clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKn	Input	Input
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. When SSLn0 is at the active level, the pin state is Hi-Z.
Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z.
Note 5. These pins are available for use as I/O port pins.

The SPI in single master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and

MOIFV bit settings in SPPCR, as listed in Table 38.7.

Table 38.7 MOSI signal value determination during SSL negation

MOIFE bit	MOIFV bit	MOSIn signal value during SSL negation
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

38.3.3 SPI System Configuration Examples

38.3.3.1 Single master and single slave with the MCU as a master

Figure 38.5 shows a single-master and single-slave SPI system configuration example where the MCU is a master. In the single-master/single-slave configuration, the SSLn0 to SSLn3 outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal cannot be fixed to the active level for some slave devices. In situations where the SSL signal cannot be fixed, the SSLni output of the MCU must be connected to the SSL input of the slave device.

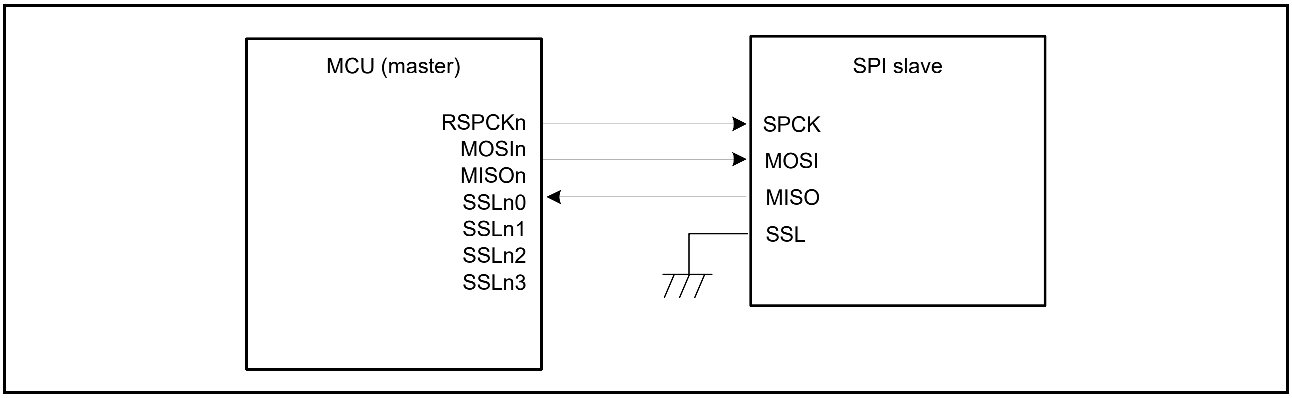

Figure 38.5 Single-master/single-slave configuration example with the MCU as a master

38.3.3.2 Single master and single slave with the MCU as a slave

Figure 38.6 shows a single-master/single-slave SPI system configuration example where the MCU is a slave. When the MCU is a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) stays selected. This enables serial transfer execution (Figure 38.7).

Note 1. When SSLn0 is at the non-active level, the pin state is Hi-Z.

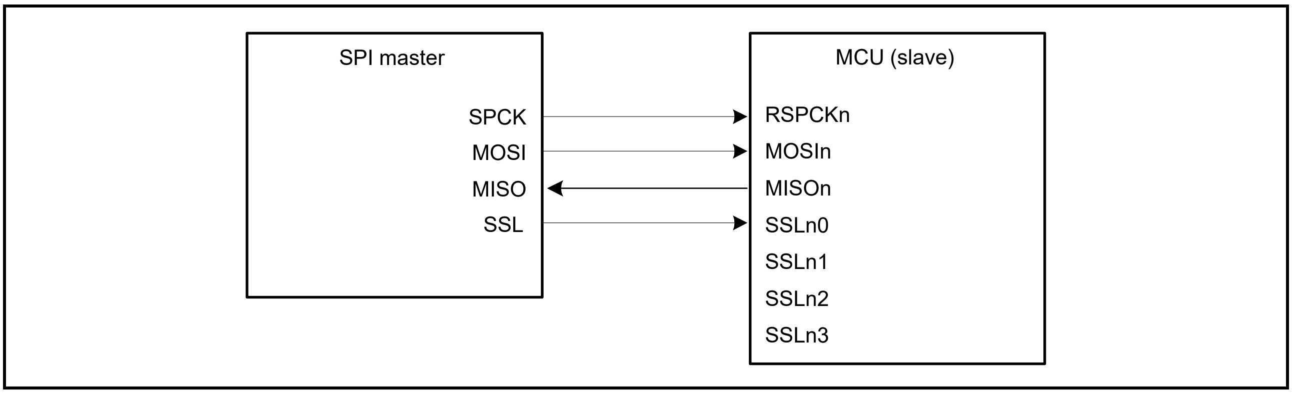

Figure 38.6 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0

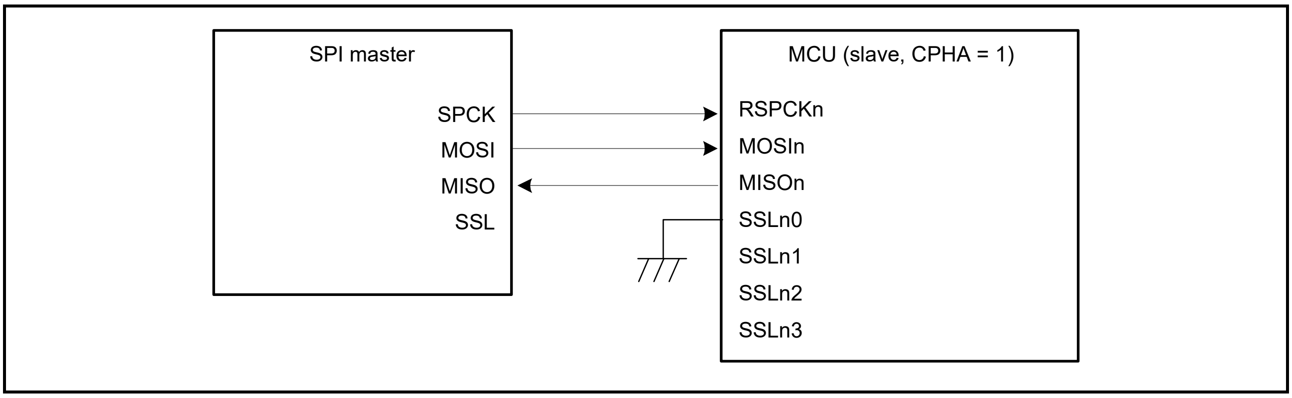

Figure 38.7 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1

38.3.3.3 Single master and multi slave with the MCU as a master

Figure 38.8 shows a single-master/multi-slave SPI system configuration example where the MCU is a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

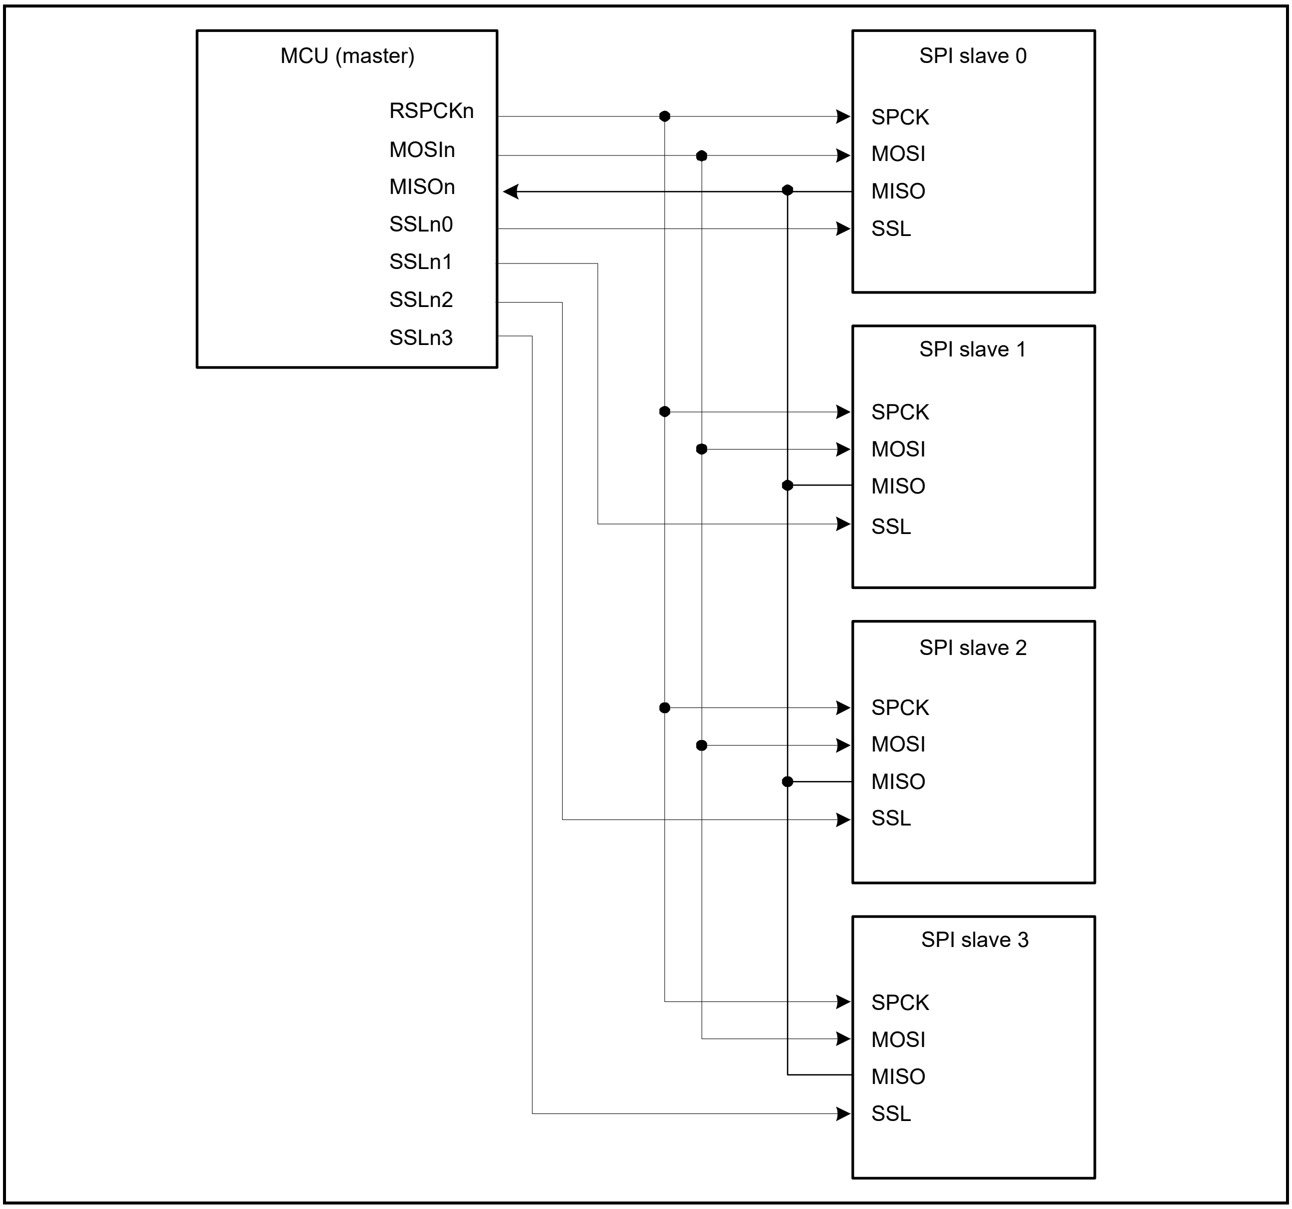

Figure 38.8 Single master/multi-slave configuration example with the MCU as a master

38.3.3.4 Single master and multi slave with the MCU as a slave

Figure 38.9 shows a single-master and multi-slave SPI system configuration example where the MCU is a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

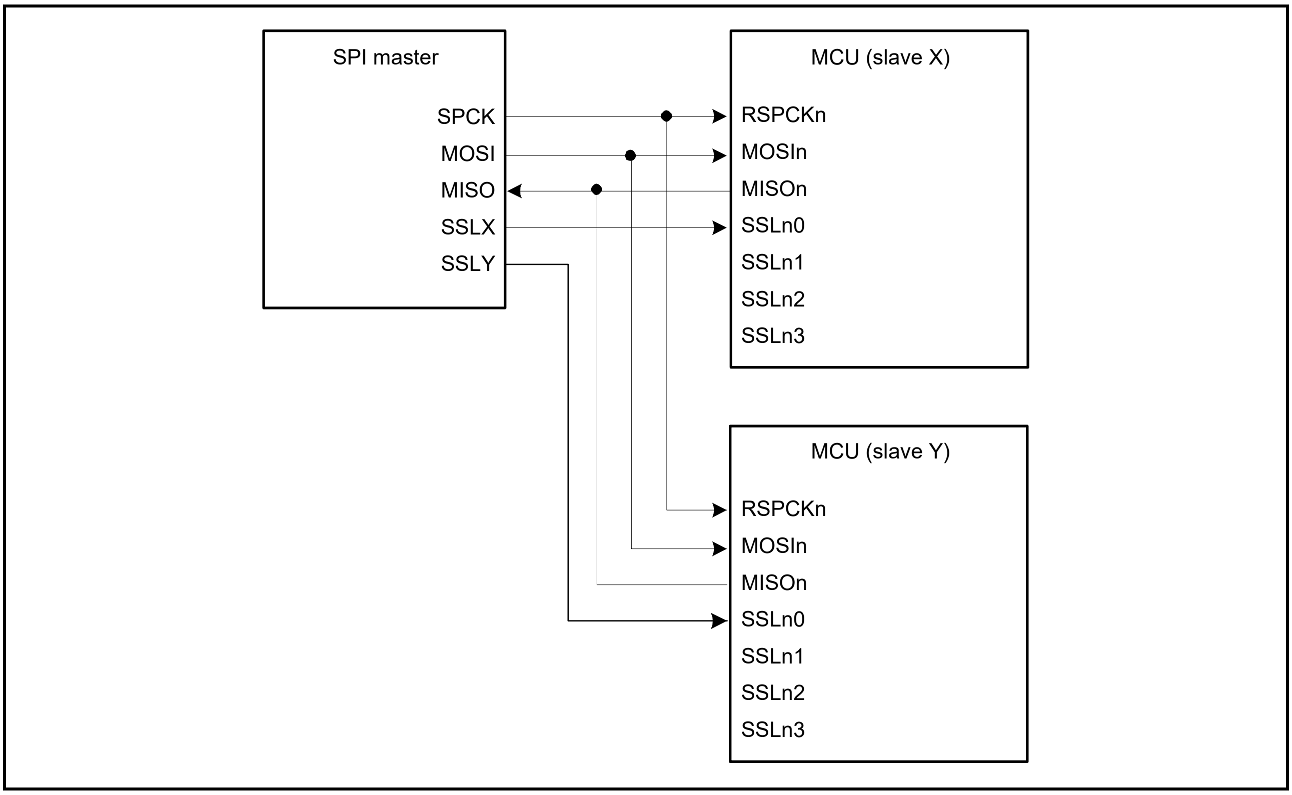

Figure 38.9 Single-master/multi-slave configuration example with the MCU as a slave

38.3.3.5 Multi master and multi slave with the MCU as a master

Figure 38.10 shows a multi-master/multi-slave SPI system configuration example where the MCU is a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

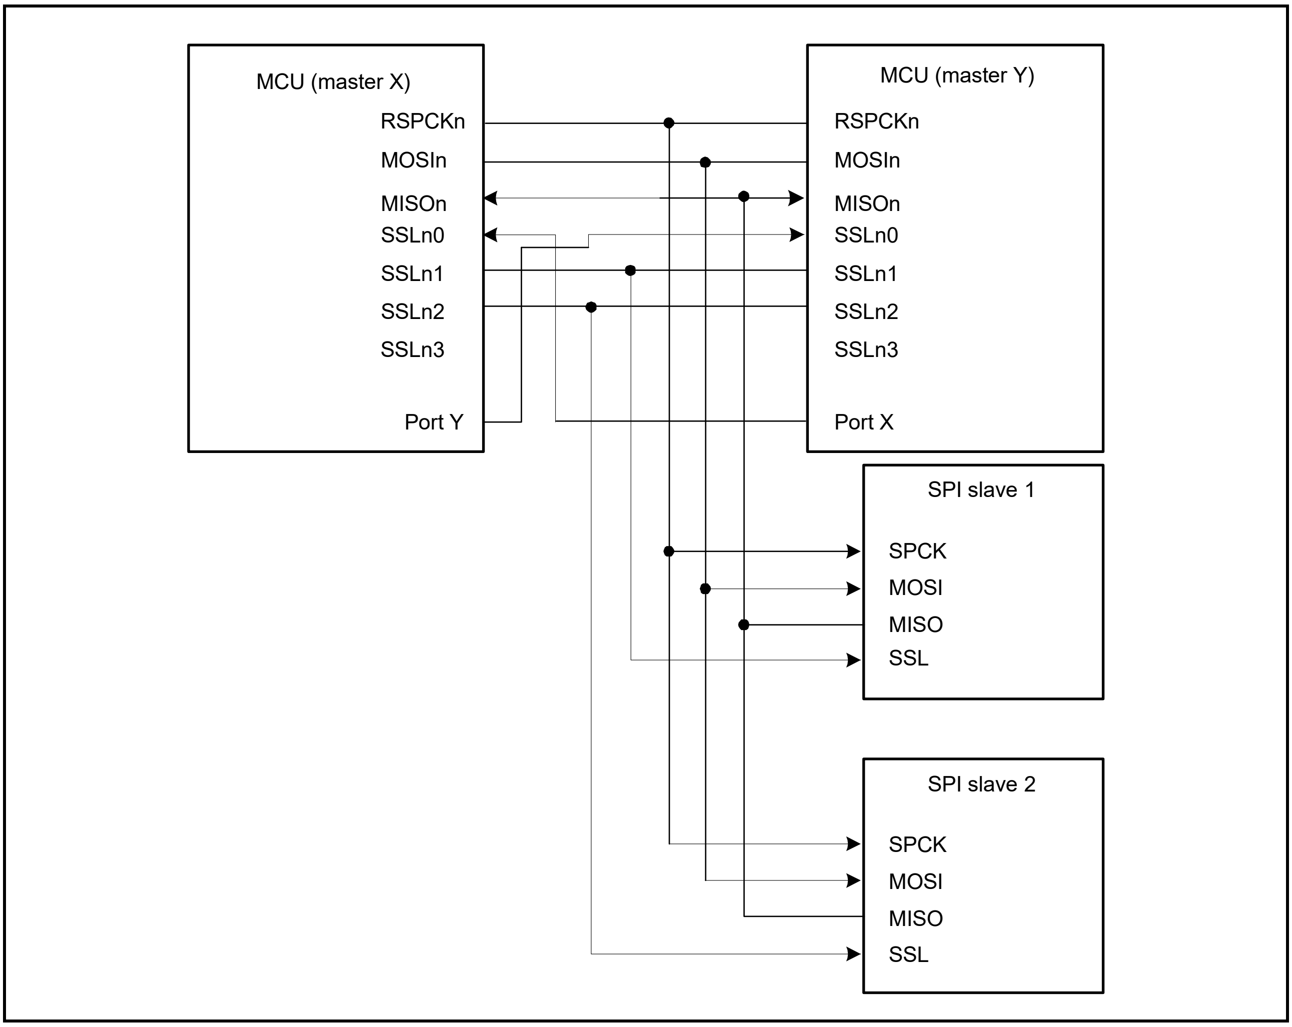

Figure 38.10 **Multi-master/multi-slave configuration example with the MCU as a master**

38.3.3.6 Master and slave in clock synchronous mode with the MCU as a master

Figure 38.11 shows master and slave in clock synchronous mode where the MCU is a master. In this configuration, SSLn0 to SSLn3 of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

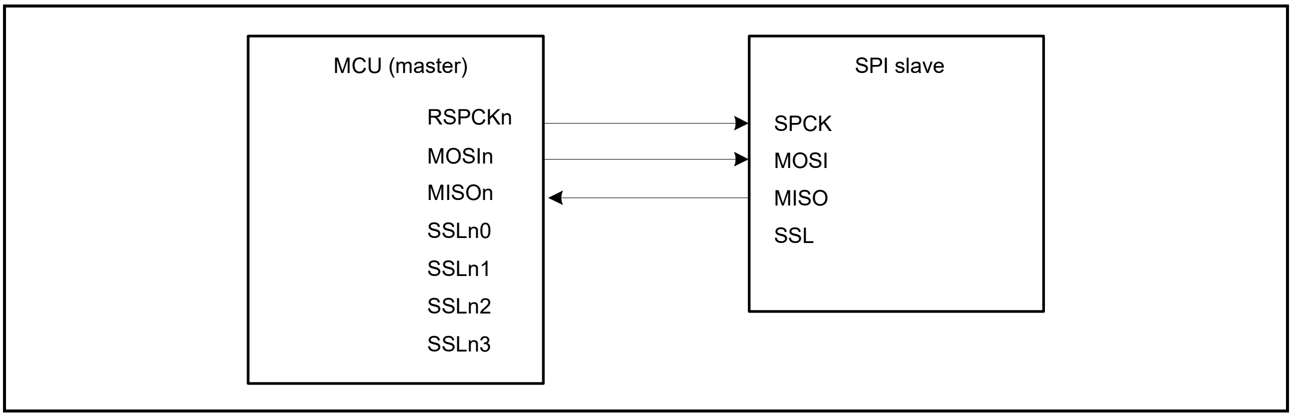

Figure 38.11 **Configuration example of master/slave in clock synchronous mode with the MCU as a master**

38.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 38.12 shows a master and slave in clock synchronous mode configuration where the MCU is a slave. When the MCU operates as a slave in clock synchronous mode, the MCU (slave) drives the MISOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single slave configuration when the SPCMDm.CPHA bit is set to 1.

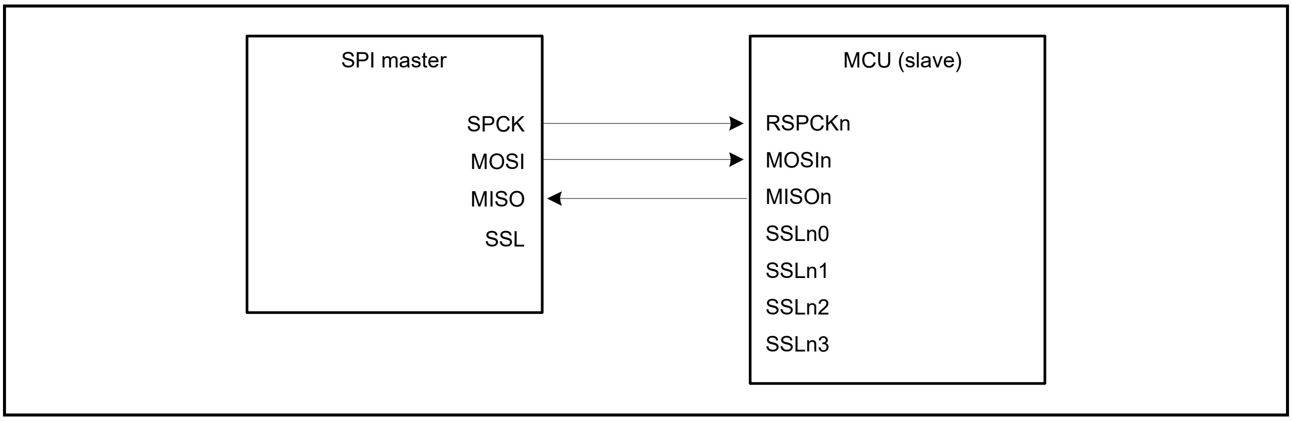

Figure 38.12 Configuration example of master and slave in clock synchronous mode with the MCU as a slave and CPHA = 1

38.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) (m = 0 to 7) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR_HA) to the bit corresponding to the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

(a) Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]).

(b) Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

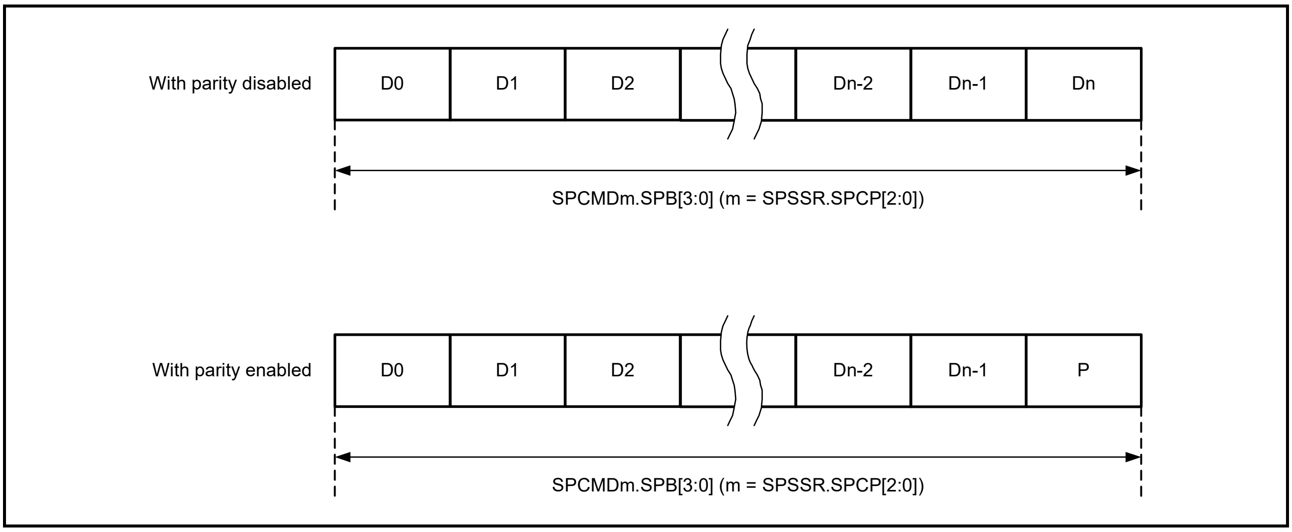

Figure 38.13 Data format with parity disabled and enabled

38.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)

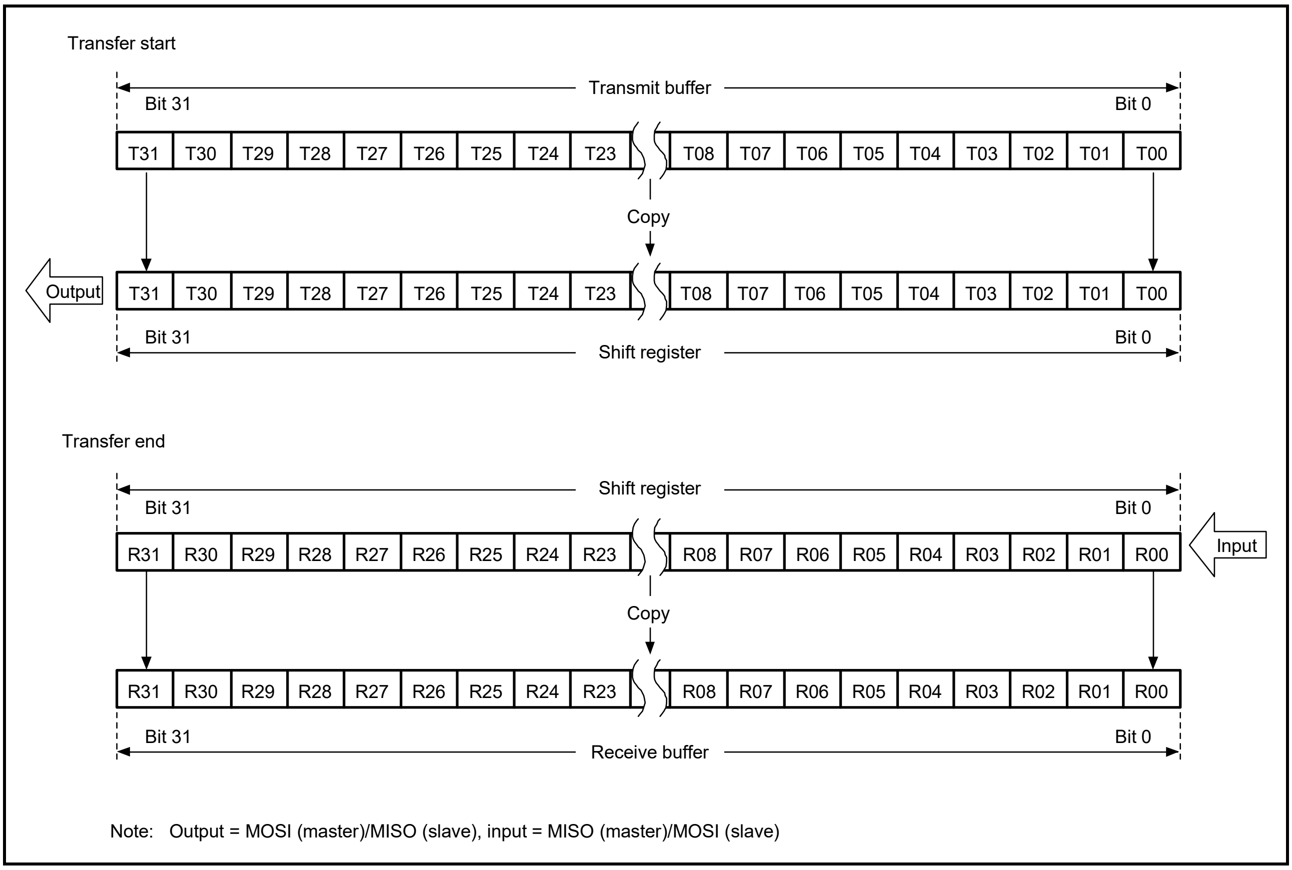
When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 38.14 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity disabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00, in that order.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

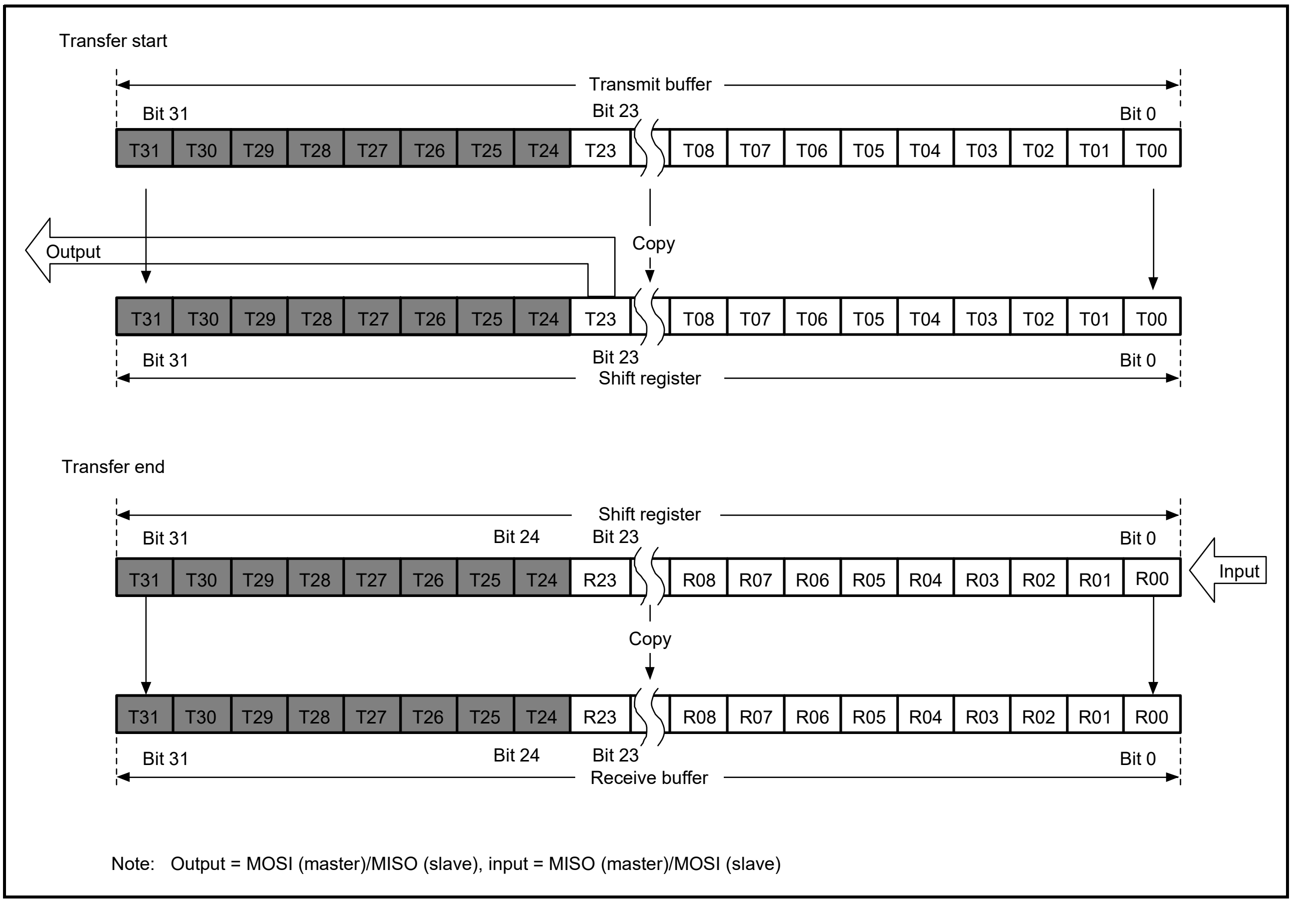
Figure 38.14 MSB-first transfer with 32-bit data and parity disabled

(2) MSB-first transfer with 24-bit data

Figure 38.15 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity disabled, an SPI data length of 24 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00, in that order.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the upper 8 bits of the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

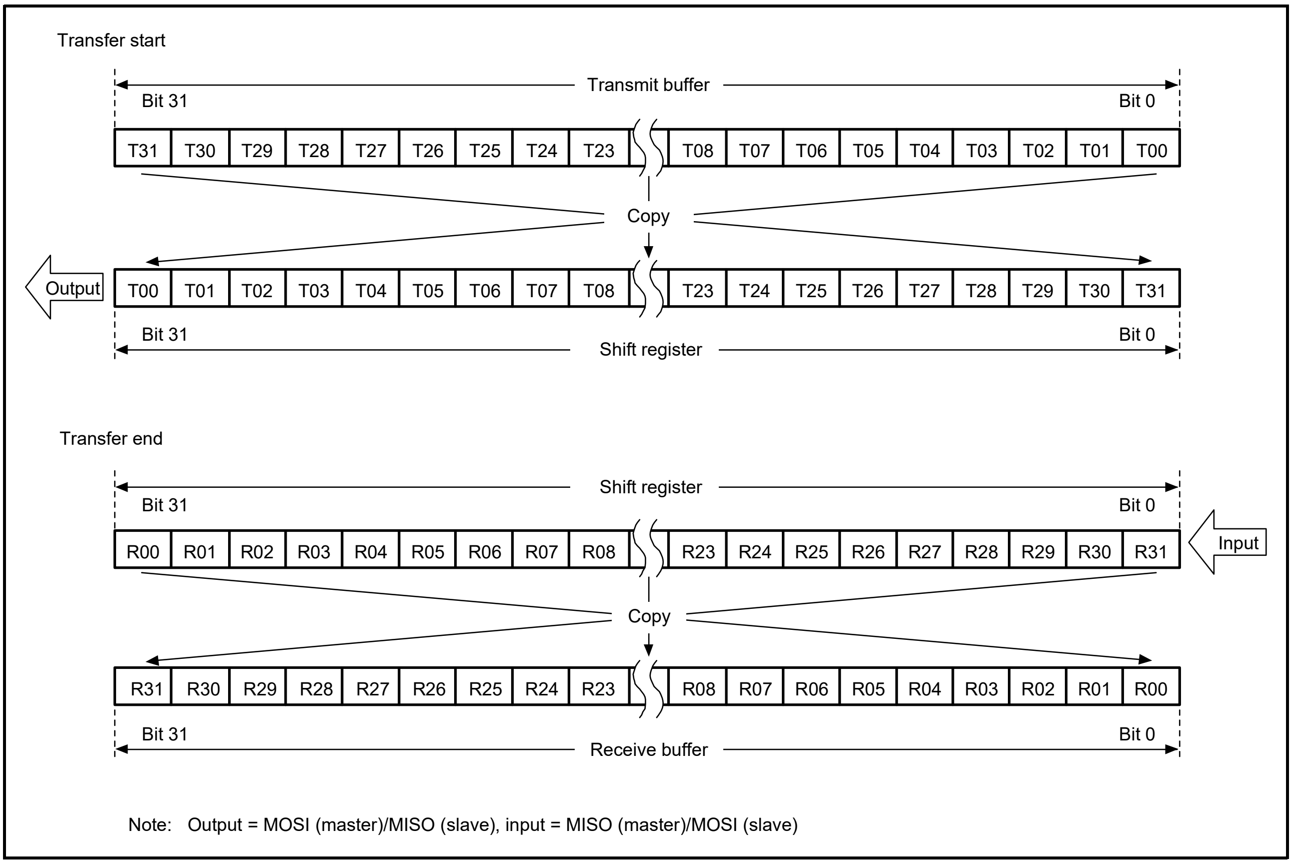
Figure 38.15 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 38.16 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T31, in that order.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 38.16 LSB-first transfer with 32-bit data and parity disabled

(4) LSB-first transfer with 24-bit data

Figure 38.17 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity disabled, an SPI data length of 24 bits, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23, in that order.

In reception, received data is shifted in bit-by-bit through bit [8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the upper 8 bits of the receive buffer.

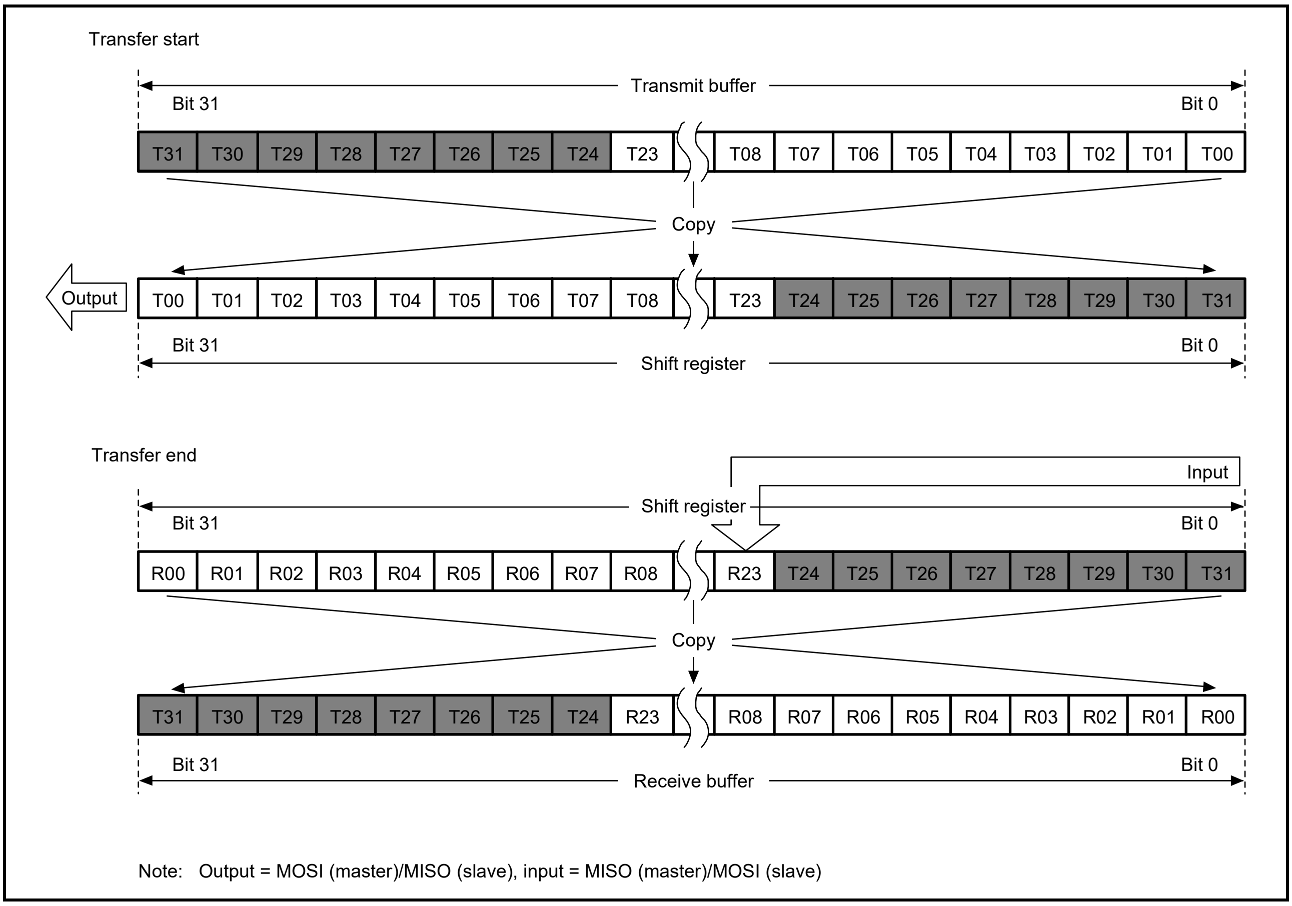


Figure 38.17 LSB-first transfer with 24-bit data and parity disabled

38.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)

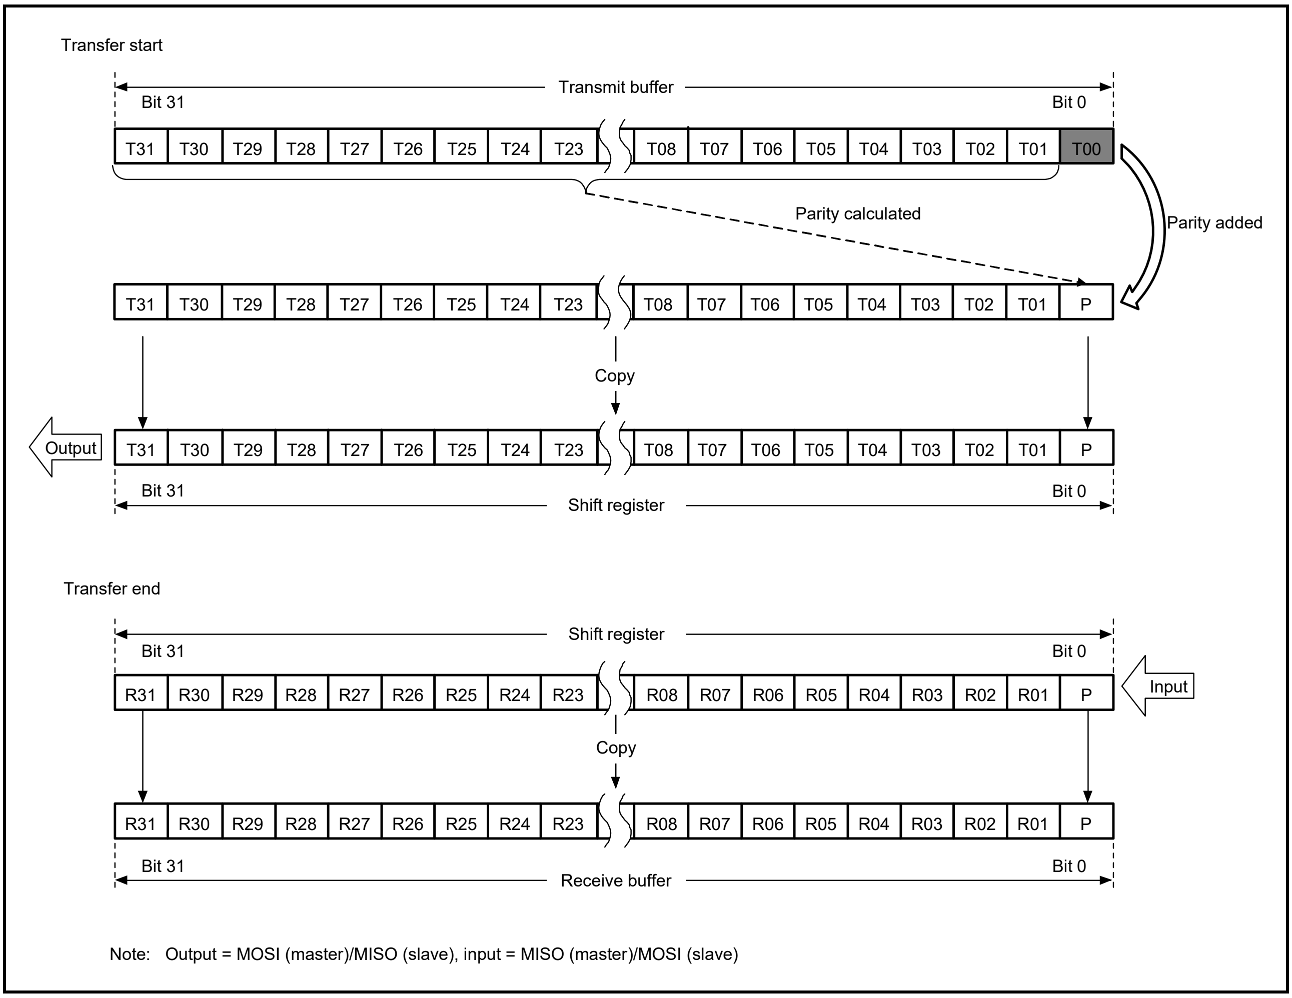
When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 38.18 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, data from R31 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

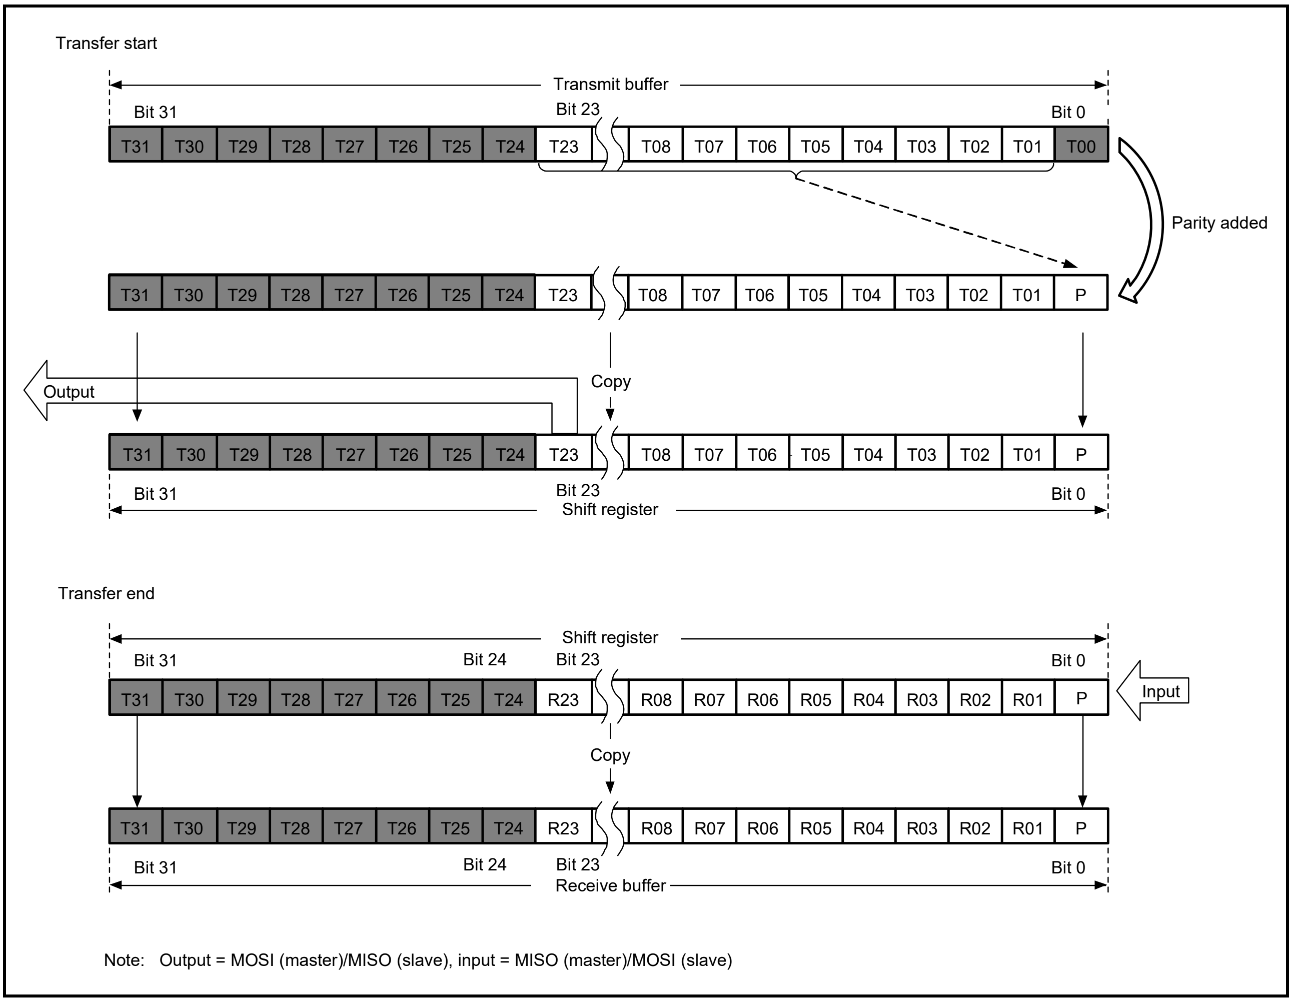
Figure 38.18 MSB-first transfer with 32-bit data and parity enabled

(2) MSB-first transfer with 24-bit data

Figure 38.19 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity enabled, an SPI data length of 24 bits and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data is transmitted in the order T23, T22, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, data from R23 to P is checked for parity. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the upper 8 bits of the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 38.19 MSB-first transfer with 24-bit data and parity enabled

(3) LSB-first transfer with 32-bit data

Figure 38.20 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data is transmitted in the order T00, T01, …, T30, and P.

In reception, received data is shifted in bit-by-bit through bit [0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, data from R00 to P is checked for parity.

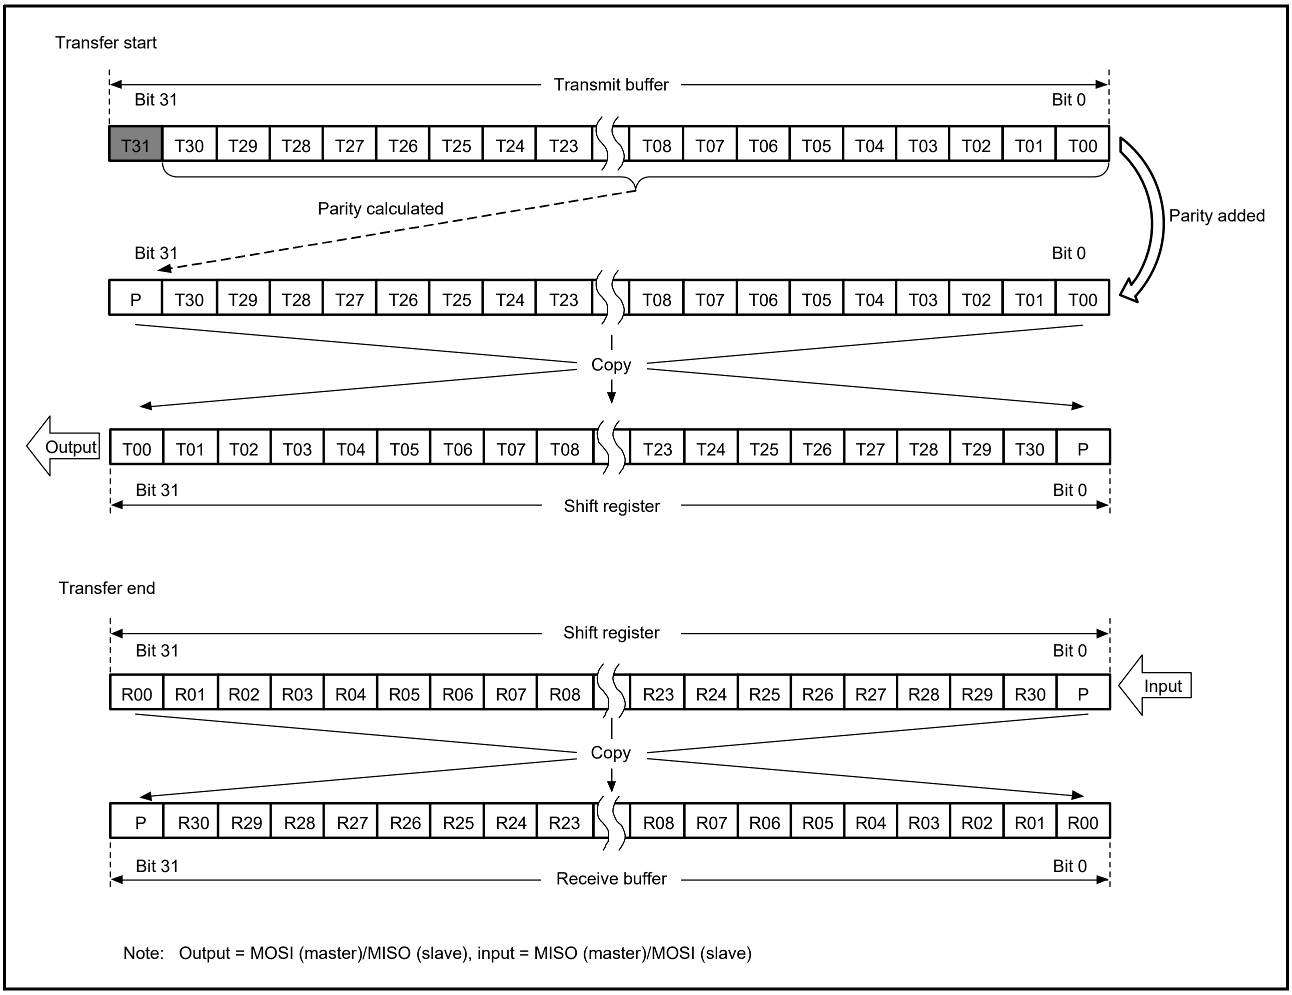


Figure 38.20 LSB-first transfer with 32-bit data and parity enabled

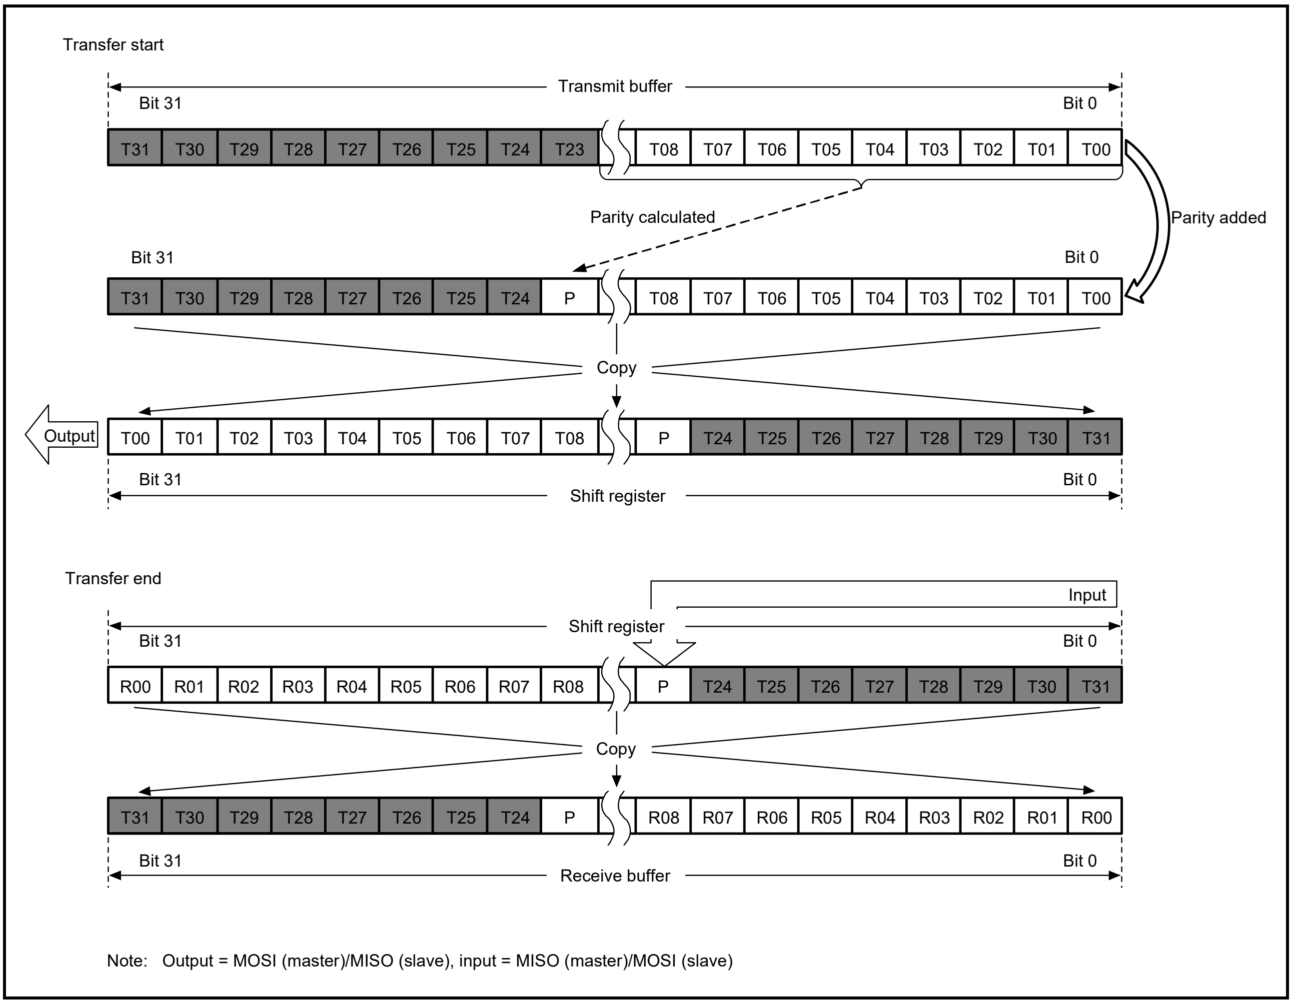
(4) LSB-first transfer with 24-bit data

Figure 38.21 shows the transfer operations of the SPI Data Register (SPDR) and the shift register with parity enabled, an SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data is transmitted in the order T00, T01, …, T22, and P.

In reception, received data is shifted in bit-by-bit through bit [8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, data from R00 to P is checked for parity. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the upper 8 bits of the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 38.21 LSB-first transfer with 24-bit data and parity enabled

38.3.5 Transfer Formats

38.3.5.1 Transfer format when CPHA = 0

Figure 38.22 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In the figure, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 38.3.2, Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals commences on an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCK cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the period from an SSLni signal assertion to RSPCKn oscillation (RSPCK delay). t2 denotes the period from the termination of RSPCKn oscillation to an SSLni signal negation (SSL negation delay). t3 denotes the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 38.3.10.1, Master mode operation.

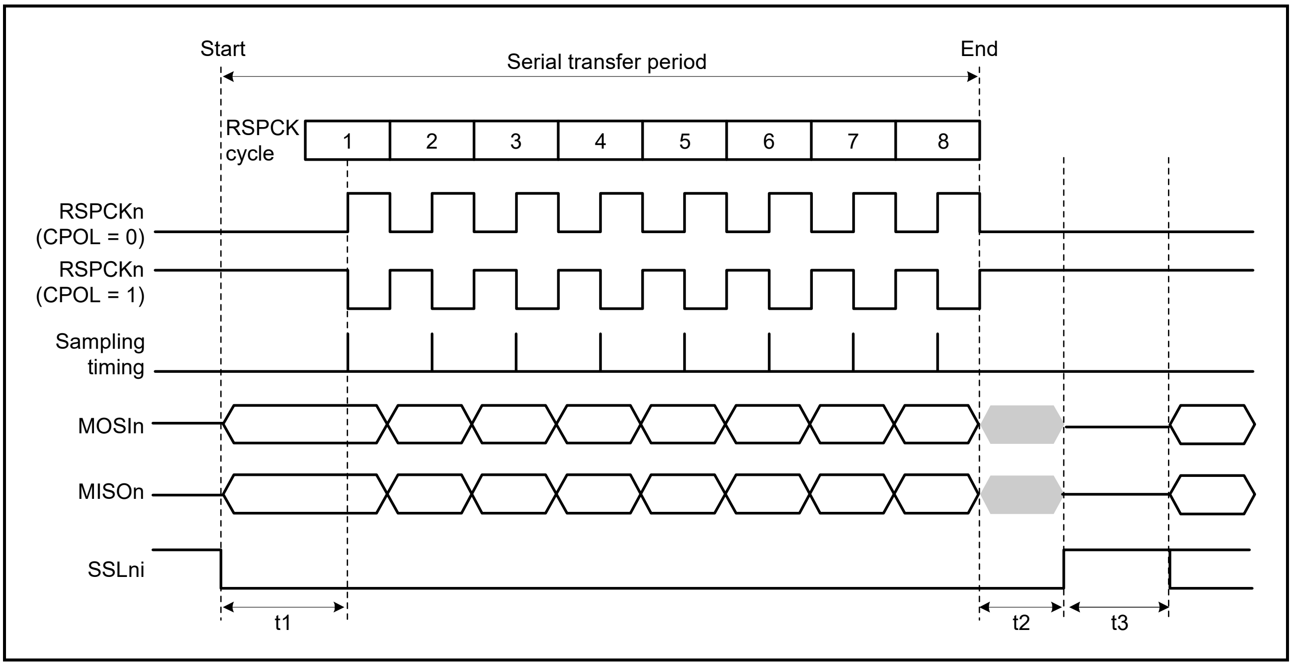


Figure 38.22 SPI transfer format when CPHA = 0

38.3.5.2 When CPHA = 1

Figure 38.23 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 38.23, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0; RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave). For details, see section 38.3.2, Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal commences on an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals commences at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 38.3.10.1, Master mode operation.

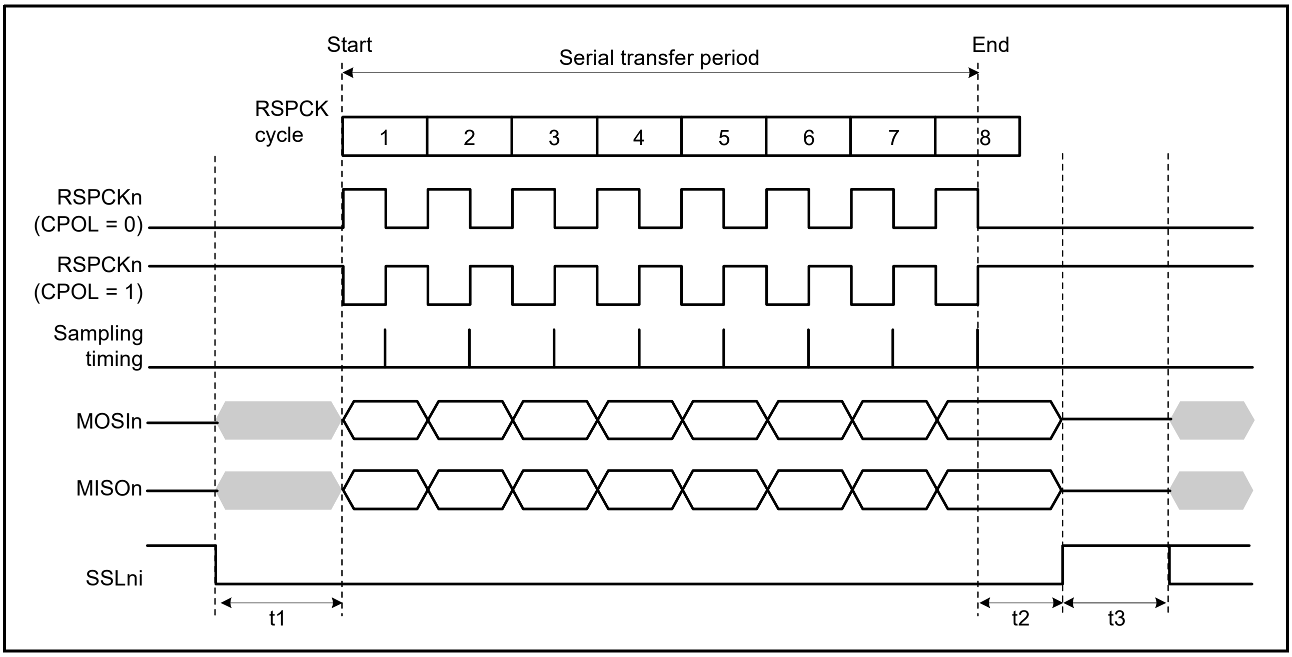

Figure 38.23 SPI transfer format when CPHA = 1

38.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the communications operating mode select bit (SPCR.TXMD). The SPDR/SPDR_HA access shown in Figure 38.24 and Figure 38.25 indicate the condition of access to the register, where W denotes a write cycle.

38.3.6.1 Full-duplex synchronous serial communications (SPCR.TXMD = 0)

Figure 38.24 shows an example of operation where the communications operating mode select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, indicating the number of transferred bits.

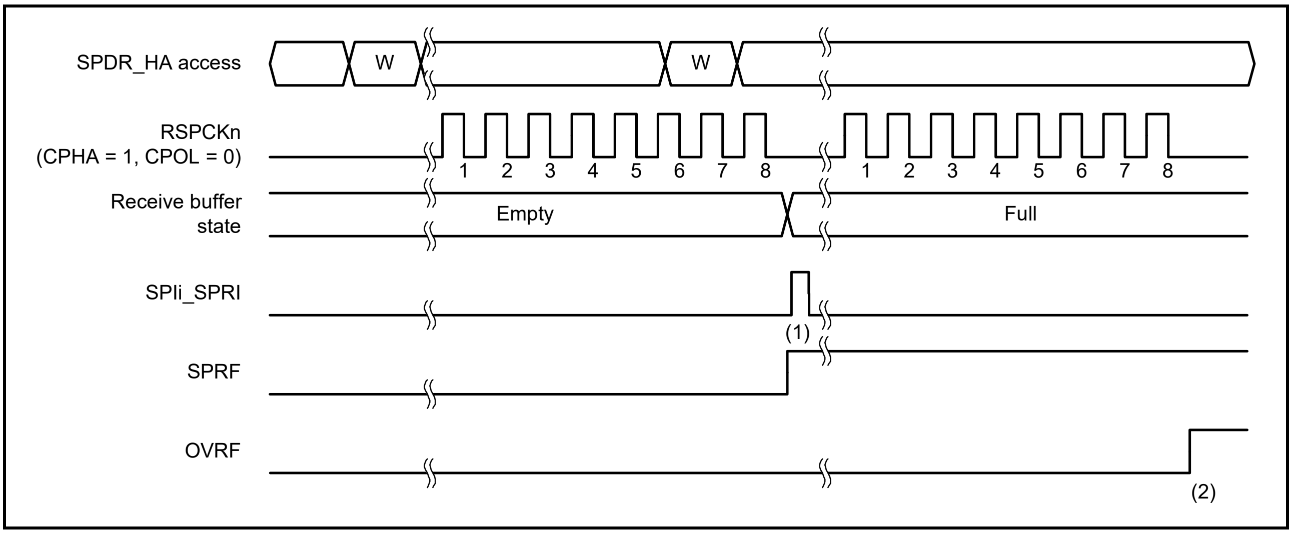

Figure 38.24 Operation example when SPCR.TXMD = 0

The operation of the flags at times (1) and (2) in the figure is as follows:

1. When a serial transfer ends with the receive buffer of SPDR_HA empty, the SPI generates a receive buffer full interrupt request (SPIi_SPRI) (the SPI sets the SPSR.SPRF flag to 1) and copies the received data in the shift

register to the receive buffer.

2. When a serial transfer ends with the receive buffer of SPDR_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

38.3.6.2 Transmit operations only (SPCR.TXMD = 1)

Figure 38.25 shows an example of operation where the communications operating mode select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, indicating the number of transferred bits.

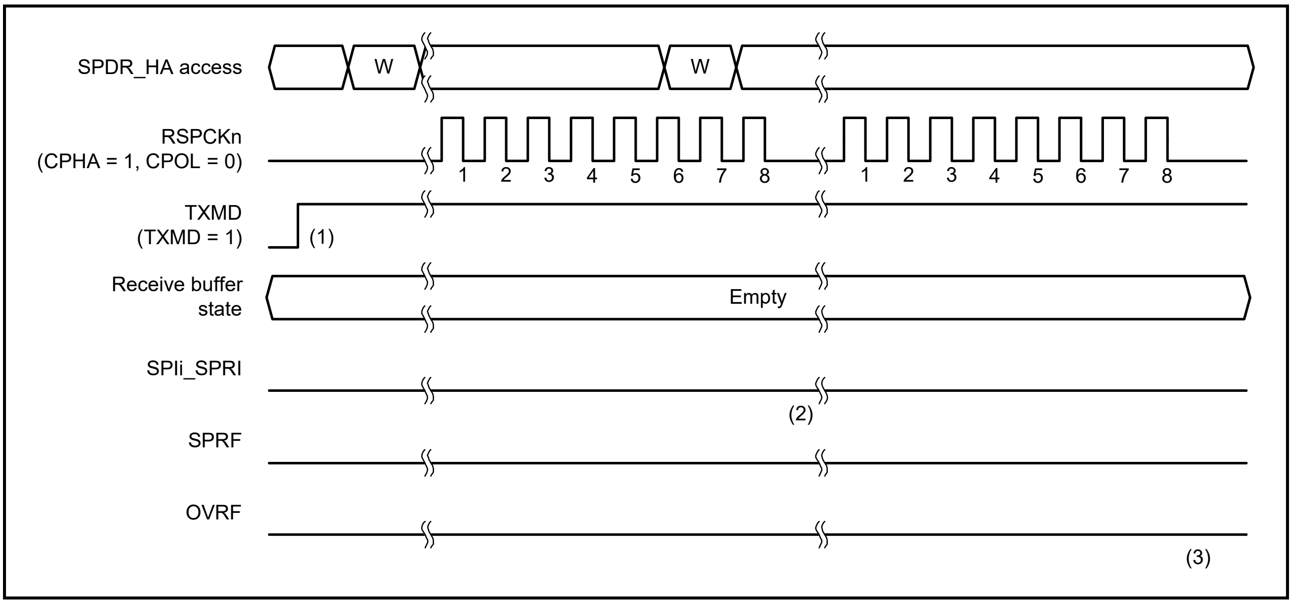

Figure 38.25 Operation example when SPCR.TXMD = 1

The operation of the flags at times (1) to (3) in the figure is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR_HA empty, if the transmit-only mode is selected (SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at times (1) to (3).

38.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 38.26 and Figure 38.27 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI) and the receive buffer full interrupt (SPIi_SPRI). The SPDR_HA register accesses shown in these figures indicate the condition of access to the register, where W denotes a write cycle and R a read cycle. In the example in Figure 38.26, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In the example in Figure 38.27, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, indicating the number of transferred bits.

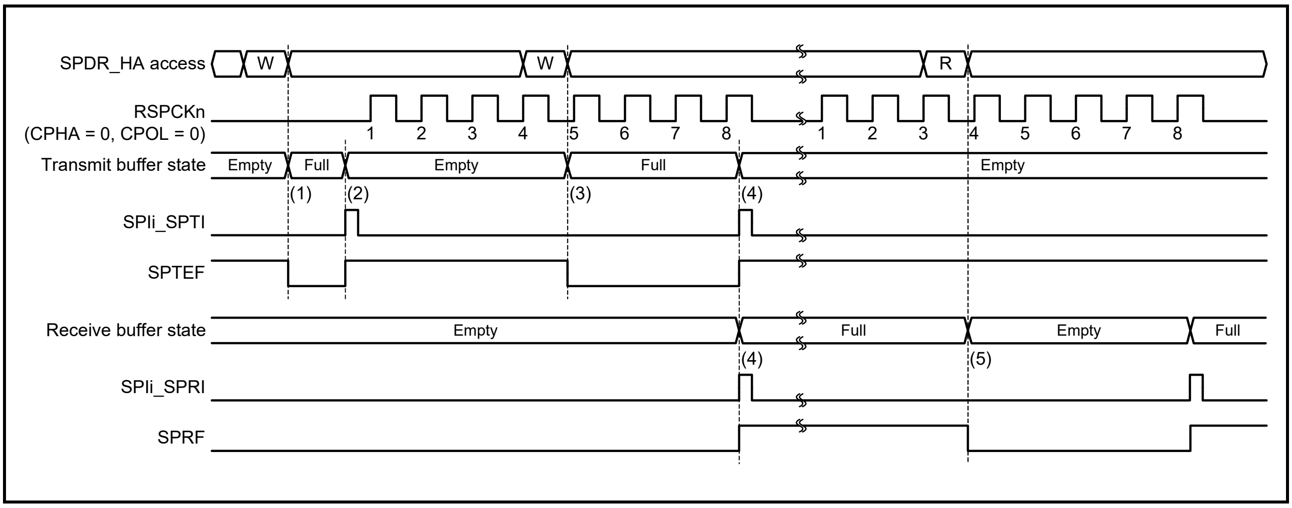

Figure 38.26 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 0 and CPOL = 0

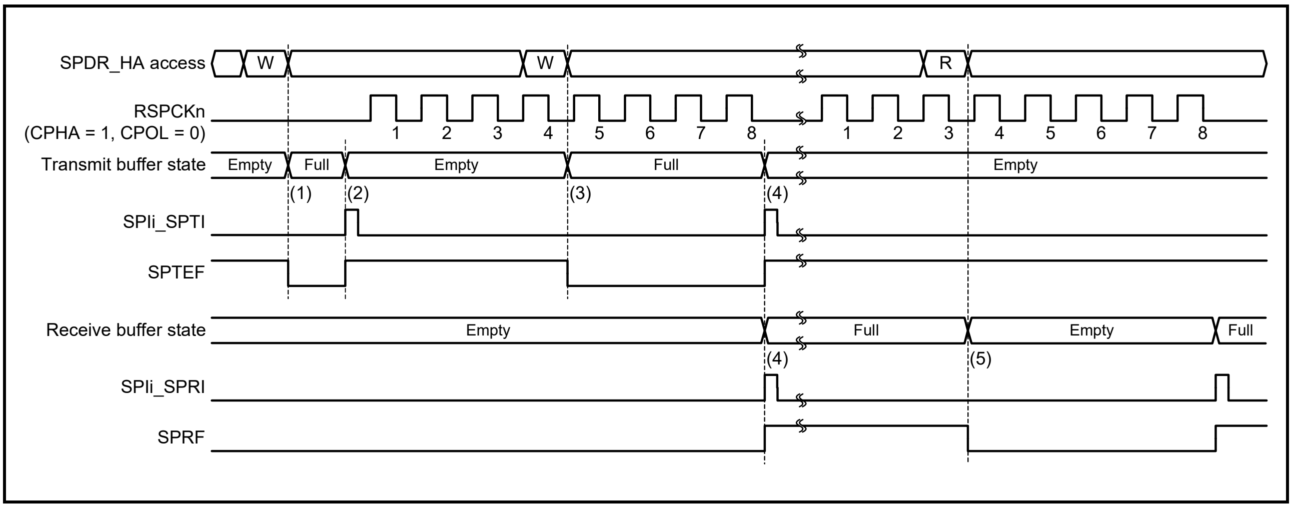

Figure 38.27 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 1 and CPOL = 0

The operation of the SPI at times (1) to (5) in the figure is as follows:

1. When transmit data is written to SPDR_HA and when the transmit buffer of SPDR_HA is empty (data for the next transfer is not set), the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the SPI. For details, see section 38.3.10, SPI Operation, and section 38.3.11, Clock Synchronous Operation.
3. When transmit data is written to SPDR_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty state using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends and the receive buffer of SPDR_HA is empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, when the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full state using the SPRF flag, the receive data can be read.

If SPDR_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 38.3.8, Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 14, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

38.3.8 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR_HA. In some cases non-normal transfers can be executed when SPDR/SPDR_HA is accessed, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If a non-normal transfer operation occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 38.8 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 38.8 Relationship between non-normal transfer operations and SPI error detection

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR/SPDR_HA is written when the transmit buffer is full.	• Keeps the contents of the transmit buffer • Missing write data.	None
2	SPDR/SPDR_HA is read when the receive buffer is empty.	Outputs the contents of the receive buffer and previously received data.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Suspends serial transfer • Missing transmit and receive data • Stops driving of the MISOA output signal • Disables the SPI function.	Underrun error
4	Serial transfer terminates when the receive buffer is full.	• Keeps the contents of the receive buffer • Missing receive data.	Overrun error
5	An incorrect parity bit is received when performing full-duplex synchronous serial communications with the parity function enabled.	Asserts the parity error flag.	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Stops driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals • Disables the SPI function.	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Suspends serial transfer • Missing transmit and receive data • Stops driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals • Disables the SPI function.	Mode fault error
8	The SSLn0 input signal is negated during serial transfer in slave mode.	• Suspends serial transfer • Missing transmit and receive data • Stops driving of the MISOn output signal • Disables the SPI function.	Mode fault error

In operation 1 described in Table 38.8, the SPI does not detect an error. To prevent data omission during the writing to SPDR/SPDR_HA, write operations to SPDR/SPDR_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR_HA read operations must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For the other errors in the figure, see the following sections:

- Underrun error (operation 3): section 38.3.8.4, Underrun errors
- Overrun error (operation 4): section 38.3.8.1, Overrun errors
- Parity error (operation 5): section 38.3.8.2, Parity errors
- Mode fault error (operations 6 to 8): section 38.3.8.3, Mode fault errors.

For the transmit and receive interrupts, see section 38.3.7, Transmit Buffer Empty and Receive Buffer Full Interrupts.

38.3.8.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

Figure 38.28 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR_HA accesses shown in the figure indicate the condition of access to the register, where W denotes a write cycle and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, indicating the number of transferred bits.

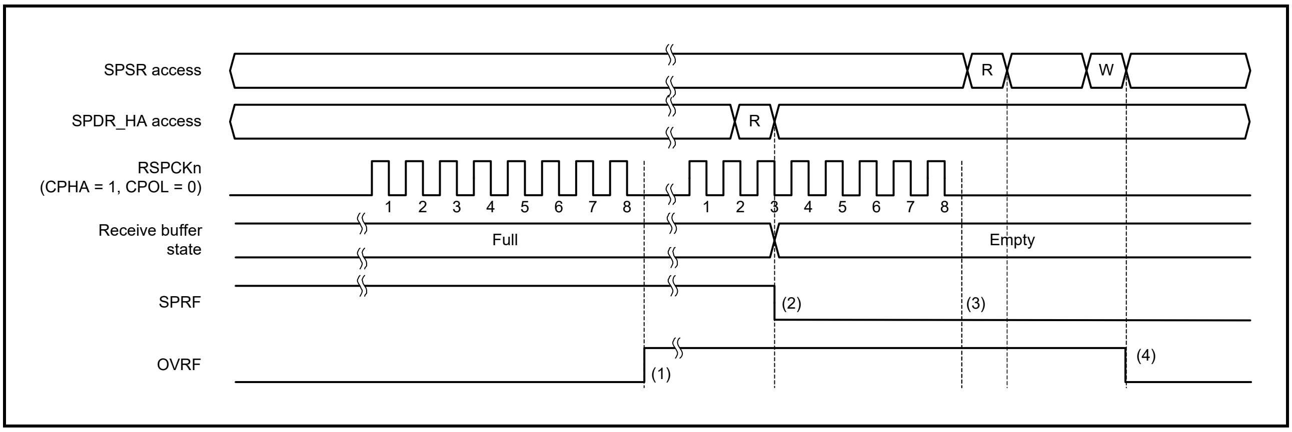

Figure 38.28 Operation example of the OVRF and SPRF flags

The operation of the flags at times (1) to (4) in the figure is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected. In master mode, the SPI copies the value of the SPCMDm pointer to the SPSSR.SPECM[2:0] bits.
2. When SPDR_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In master mode, the SPI does not update the SPSSR.SPECM[2:0] bits. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR_HA is read. In master mode, the value of the SPCMDm pointer at the error occurrence can be checked by reading the SPSSR.SPECM[2:0] bits.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is cleared to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 38.29 and Figure 38.30 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

t2: SPI Slave Select Negation Delay Register (SSLND)
t3: SPI Next-Access Delay Register (SPND)

Figure 38.30 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)

The operation of the flags at times (1) and (2) in the figure is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag clears to 0).

38.3.8.2 Parity errors

When full-duplex synchronous serial communication is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, the SPI checks for parity errors when serial transfer ends. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag sets to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 38.31 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 38.31 indicates the condition of access to the register, where W denotes a write cycle and R a read cycle. In this example, full-duplex synchronous serial communication is performed while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, meaning the number of transferred bits.

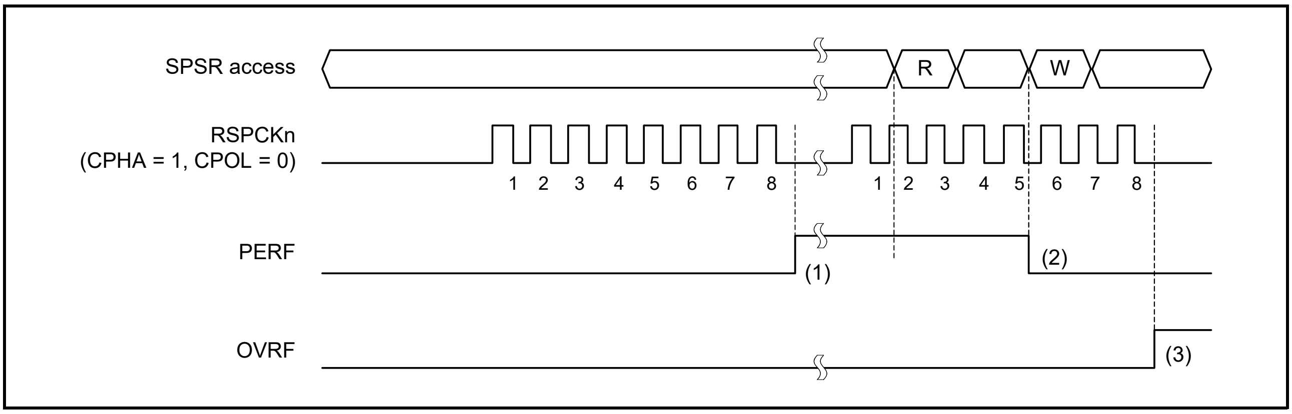

Figure 38.31 Operation example of the PERF flag

The operation of the flags at times (1) to (3) in the figure is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this timing and sets the PERF flag to 1 if a parity error is detected. In master mode, the SPI copies the value of the SPCMDm pointer to the SPSSR.SPECM[2:0] bits.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag clears to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

38.3.8.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the SPCMDm pointer to the SPSSR.SPECM[2:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

On detecting a mode fault error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 38.3.9, Initializing the SPI). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. SPSR polling is required for detecting mode fault errors if the SPI error interrupt is not used. When using the SPI in master mode, the value of the SPCMDm pointer at the error occurrence can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

38.3.8.4 Underrun errors

When the serial transfer begins while the SPCR.MSTR bit is 0 (slave mode), SPCR.SPE bit is 1 and the transmission data not prepared, the SPI detects an underrun error. Then, SPI sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 38.3.9, Initializing the SPI).

The occurrence of an underrun error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. SPSR polling is required for detecting underrun errors if the SPI error interrupt is not used.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be cleared to 0.

38.3.9 Initializing the SPI

If 0 is written to the SPCR.SPE bit or the SPI sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

38.3.9.1 Initialization by clearing of the SPE bit

When the SPCR.SPE bit is set to 0, the SPI performs the following initialization:

- Suspends any serial transfer that is being executed
- Stops the driving of output signals (Hi-Z) in slave mode
- Initializes the internal state of the SPI
- Initializes the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1).

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the status of error occurrence during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit at the same time as writing 0 to the SPE bit.

38.3.9.2 System reset

An initialization by a system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 38.3.9.1, Initialization by clearing of the SPE bit.

38.3.10 SPI Operation

38.3.10.1 Master mode operation

The only difference between single- and multi-master mode operation lies in mode fault error detection (see section

38.3.8, Error Detection). The SPI does not detect mode fault errors in single master mode and does in multi-master mode. This section explains operations that are the same for single- and multi-master modes.

(1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR_HA) and the SPI transmit buffer is empty (data for the next transfer is not set and the SPSR.SPTEF flag is 1). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SSLP register settings. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit setting. The polarity of the SSLni output pin depends on the SSLP register settings. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following Parameters are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced.

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

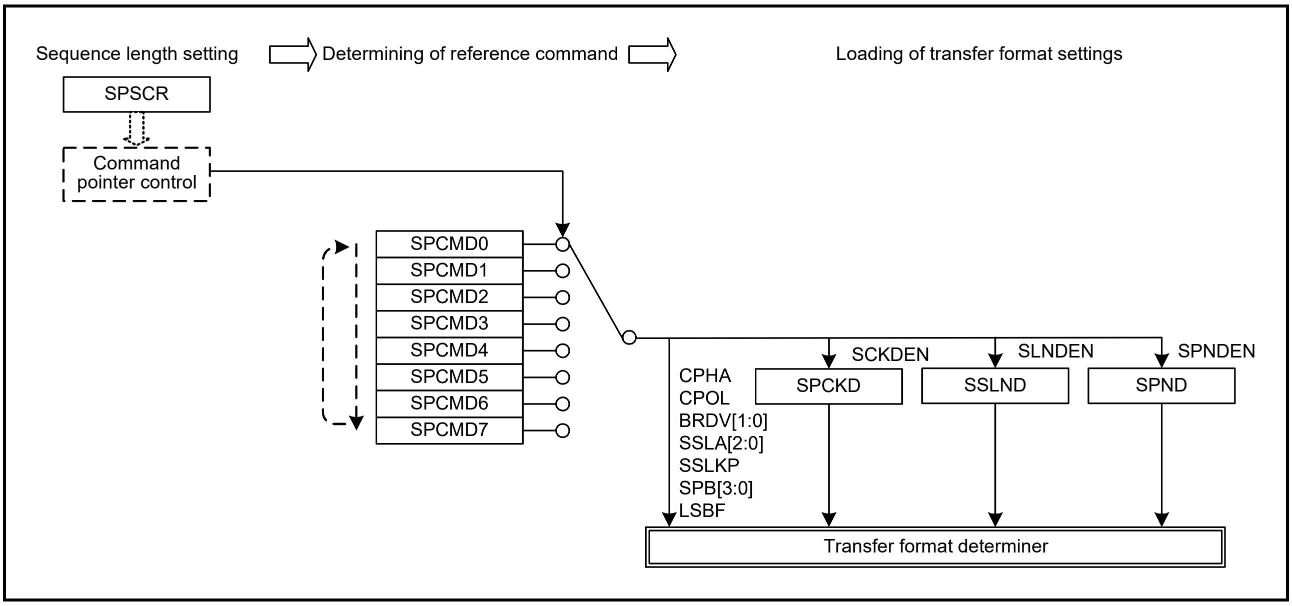

Figure 38.32 Procedure for determining the form of a serial transfer in master mode

In this section, a frame is the combination of the data in SPDR/SPDR_HA and the settings in SPCMDm.

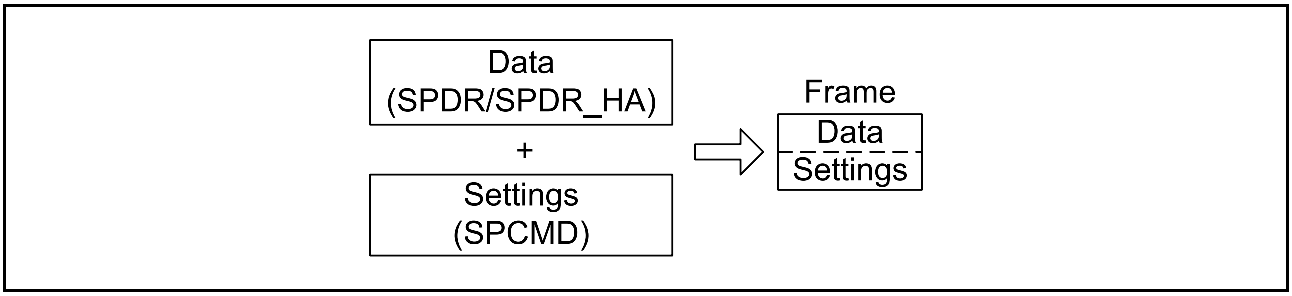

Figure 38.33 Conceptual diagram of frames

Figure 38.34 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings in Table 38.4.

	1st frame	2nd frame	3rd frame	4th frame	5th frame	6th frame	7th frame	8th frame
Setting 1-1	SPTX0/SPRX0 SPCMD0 Only 1 frame							
Setting 1-2	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD0						
Setting 1-3	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD0	SPTX2/SPRX2 SPCMD0					
Setting 1-4	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD0	SPTX2/SPRX2 SPCMD0	SPTX3/SPRX3 SPCMD0				
Setting 2-1	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD1						
Setting 2-2	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD1	SPTX2/SPRX2 SPCMD0	SPTX3/SPRX3 SPCMD1				
Setting 3	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD1	SPTX2/SPRX2 SPCMD2					
Setting 4	SPTX0/SPRX0 SPCMD0	SPTX1/SPRX1 SPCMD1	SPTX2/SPRX2 SPCMD2	SPTX3/SPRX3 SPCMD3				
Setting 5	SPTX0/SPRX0 SPCMD0	SPTX0/SPRX0 SPCMD1	SPTX0/SPRX0 SPCMD2	SPTX0/SPRX0 SPCMD3	SPTX0/SPRX0 SPCMD4			
Setting 6	SPTX0/SPRX0 SPCMD0	SPTX0/SPRX0 SPCMD1	SPTX0/SPRX0 SPCMD2	SPTX0/SPRX0 SPCMD3	SPTX0/SPRX0 SPCMD4	SPTX0/SPRX0 SPCMD5		
Setting 7	SPTX0/SPRX0 SPCMD0	SPTX0/SPRX0 SPCMD1	SPTX0/SPRX0 SPCMD2	SPTX0/SPRX0 SPCMD3	SPTX0/SPRX0 SPCMD4	SPTX0/SPRX0 SPCMD5	SPTX0/SPRX0 SPCMD6	
Setting 8	SPTX0/SPRX0 SPCMD0	SPTX0/SPRX0 SPCMD1	SPTX0/SPRX0 SPCMD2	SPTX0/SPRX0 SPCMD3	SPTX0/SPRX0 SPCMD4	SPTX0/SPRX0 SPCMD5	SPTX0/SPRX0 SPCMD6	SPTX0/SPRX0 SPCMD7

Figure 38.34 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Burst transfers

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

Figure 38.35 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (7) shown in Figure 38.35.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

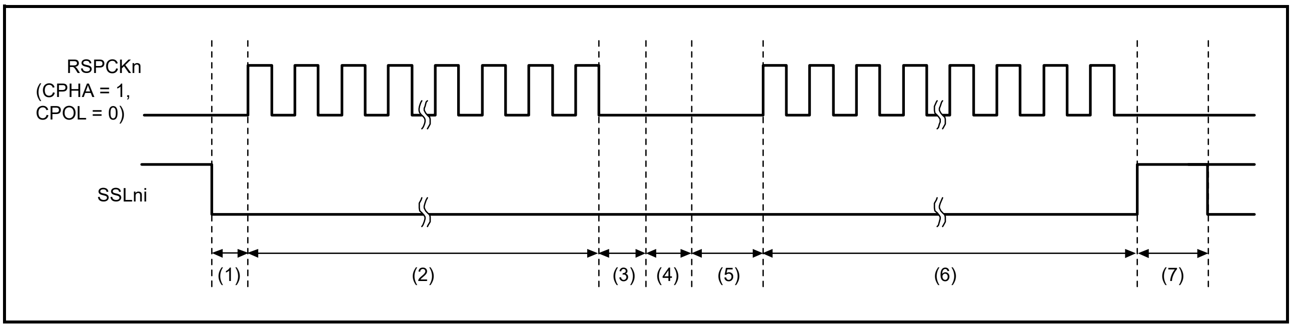

Figure 38.35 Example of burst transfer operation using the SSLKP bit

The SPI operation at times (1) to (7) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 38.35. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines the RSPCK delay value by using the SPCMDm.SCKDEN bit and SPCKD, as listed in Table 38.9. For a definition of the RSPCK delay, see section 38.3.5, Transfer Formats.

Table 38.9 Relationship among the SCKDEN bit, SPCKD register, and RSPCK delay (1 of 2)

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay
0	000b to 111b	1 RSPCK

Table 38.9 Relationship among the SCKDEN bit, SPCKD register, and RSPCK delay (2 of 2)

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines the SSL negation delay by using the SPCMDm.SLNDEN bit and SSLND, as listed in Table 38.10. For a definition of the SSL negation delay, see section 38.3.5, Transfer Formats.

Table 38.10 Relationship among the SLNDEN bit, SSLND, and SSL negation delay

SPCMDm.SLNDEN bit	SSLND.SLNDL[2:0] bits	SSL negation delay
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND register setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines the next-access delay during serial transfer by using the SPCMDm.SPNDEN bit and SPND, as listed in Table 38.11. For a definition of the next-access delay, see section 38.3.5, Transfer Formats.

Table 38.11 Relationship among the SPNDEN bit, SPND, and next-access delay

SPCMDm.SPNDEN bit	SPND.SPNDL[2:0] bits	Next-access delay
0	000b to 111b	1 RSPCK + 2 PCLKA
1	000b	1 RSPCK + 2 PCLKA
	001b	2 RSPCK + 2 PCLKA
	010b	3 RSPCK + 2 PCLKA
	011b	4 RSPCK + 2 PCLKA
	100b	5 RSPCK + 2 PCLKA
	101b	6 RSPCK + 2 PCLKA
	110b	7 RSPCK + 2 PCLKA
	111b	8 RSPCK + 2 PCLKA

(8) Initialization flow

Figure 38.36 shows an example of initialization flow for SPI operation when the SPI is used in master mode. For a description of how to set up the Interrupt Controller Unit (ICU), DMAC, and I/O ports, see the descriptions given in the individual blocks.

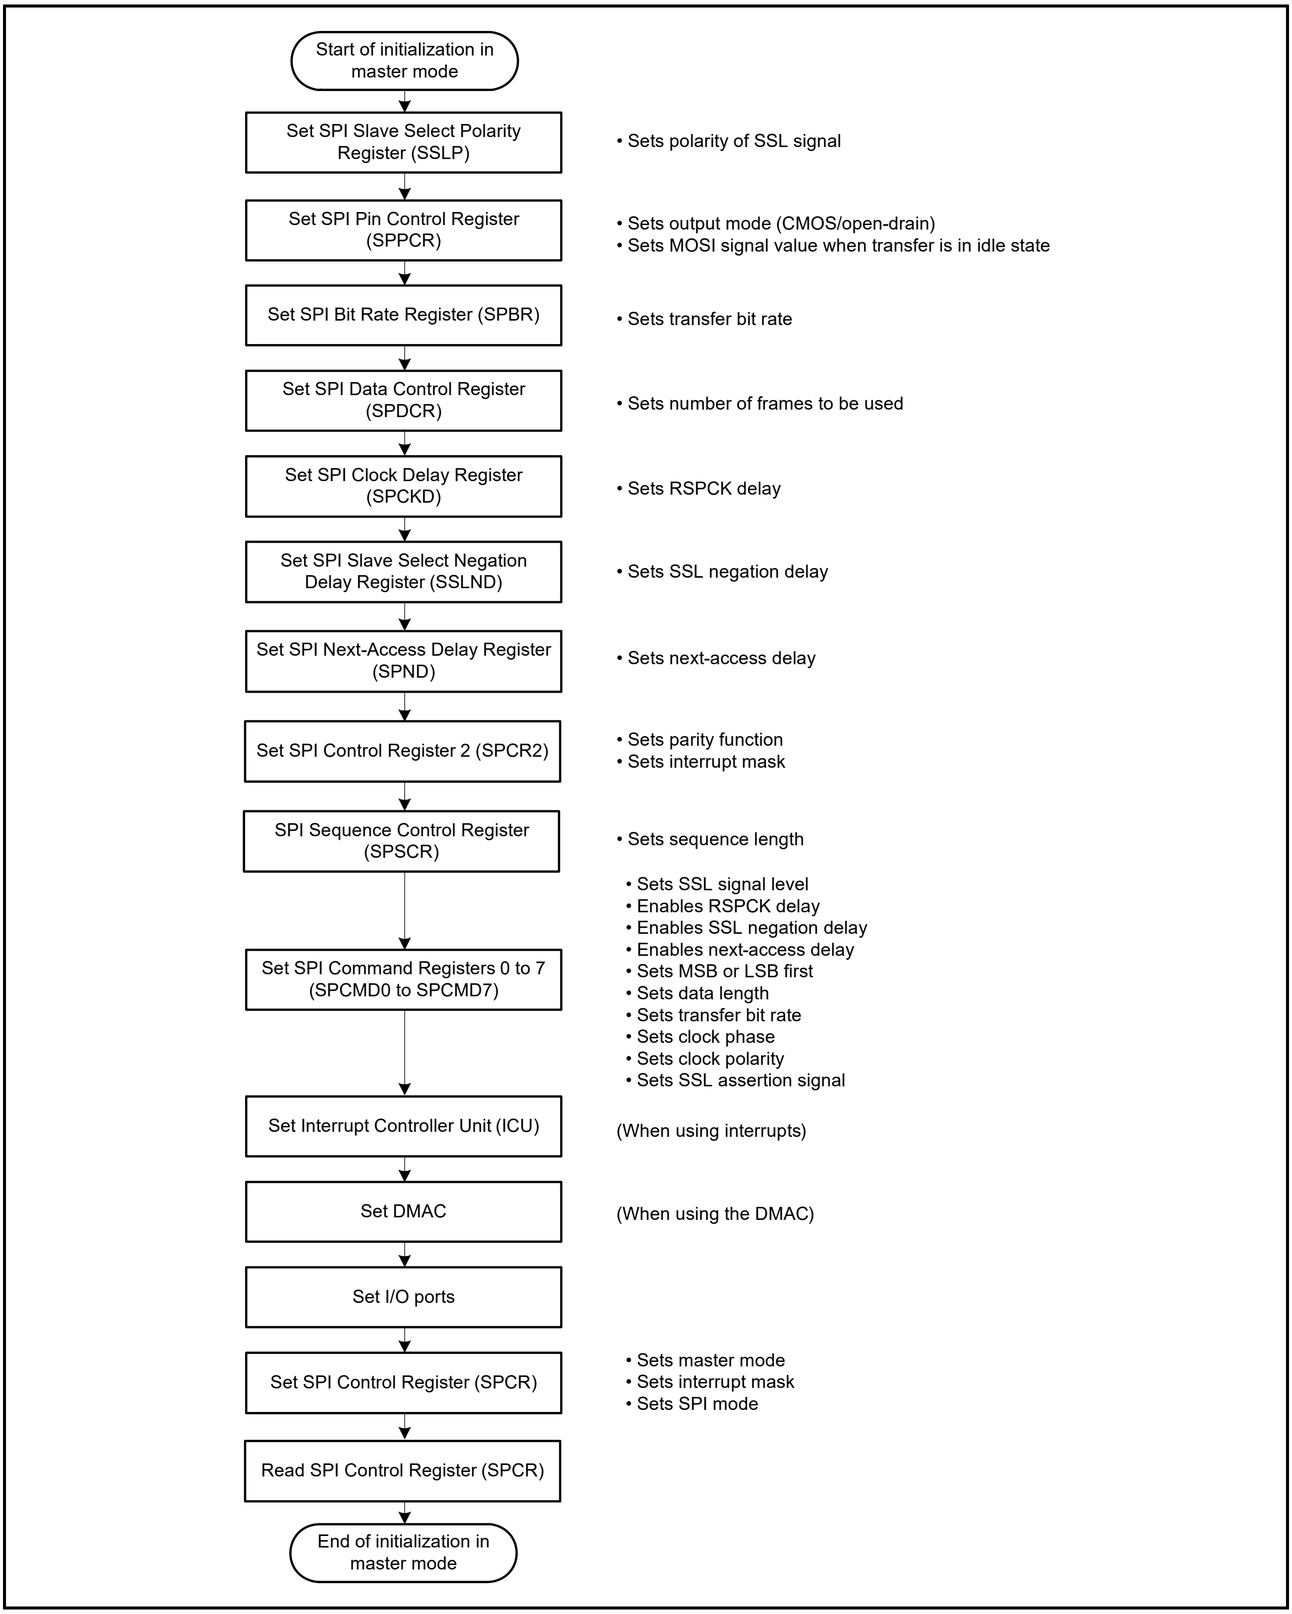

Figure 38.36 Example of initialization flow in master mode for SPI operation

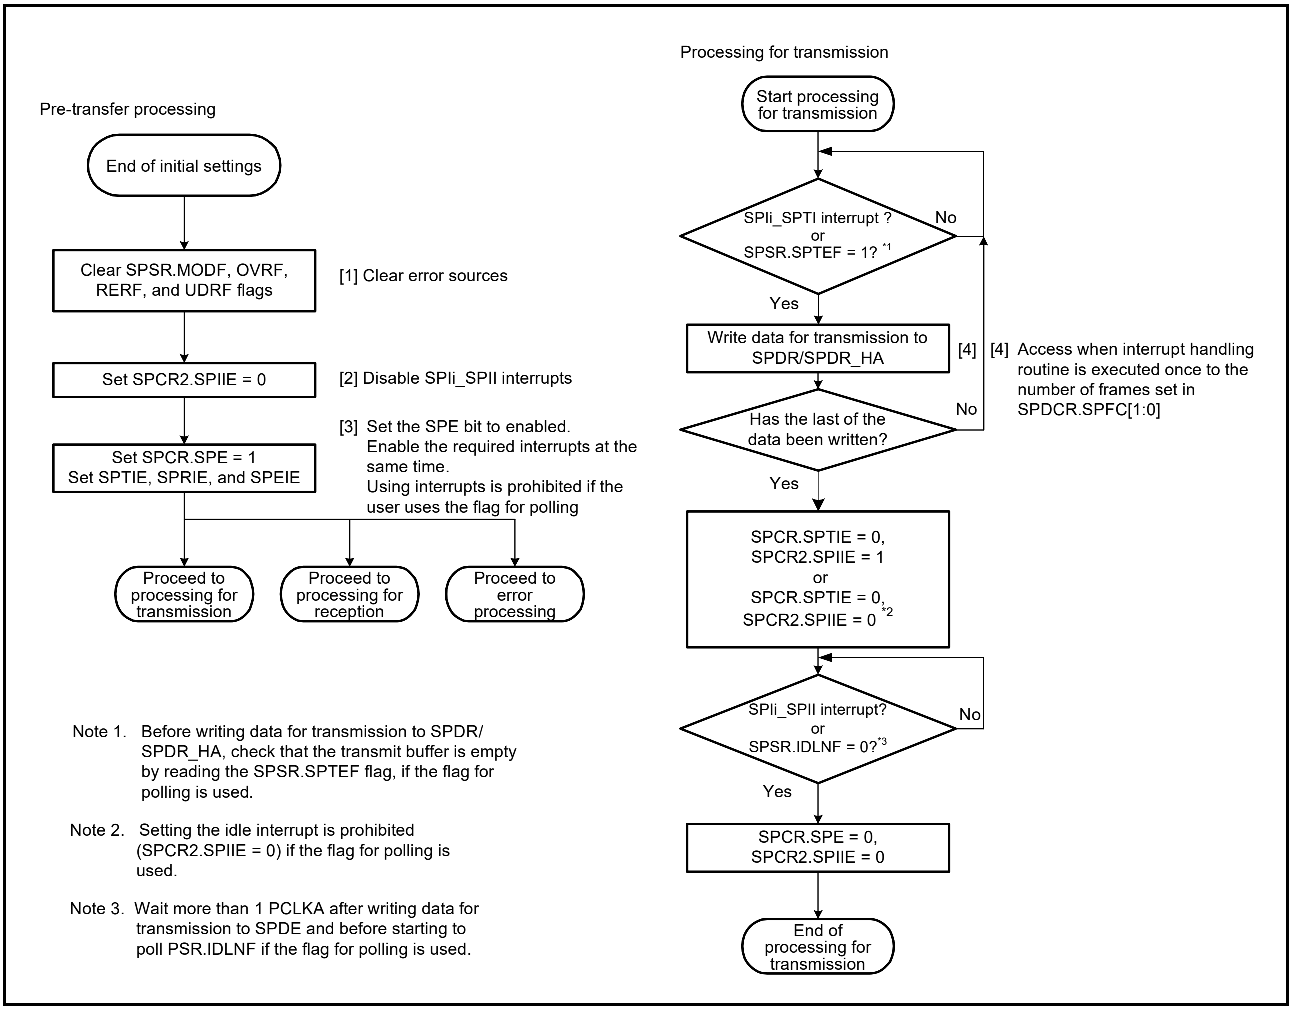
(9) Software processing flow

Figure 38.37 to Figure 38.39 show examples of the software processing flow.

(a) Transmit processing flow

When transmitting data and when the SPIi_SPII interrupt is enabled, the CPU is notified of the completion of data transmission after the last writing of data for transmission.



Note 1. Before writing data for transmission to SPDR/SPDR_HA, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.

Note 2. Setting the idle interrupt is prohibited (SPCR2.SPIIE = 0) if the flag for polling is used.

Note 3. Wait more than 1 PCLKA after writing data for transmission to SPDE and before starting to poll PSR.IDLNF if the flag for polling is used.

Figure 38.37 Transmission flow in master mode transmission

(b) Receive processing flow

The SPI does not handle receive-only operation, so processing for transmission is required.

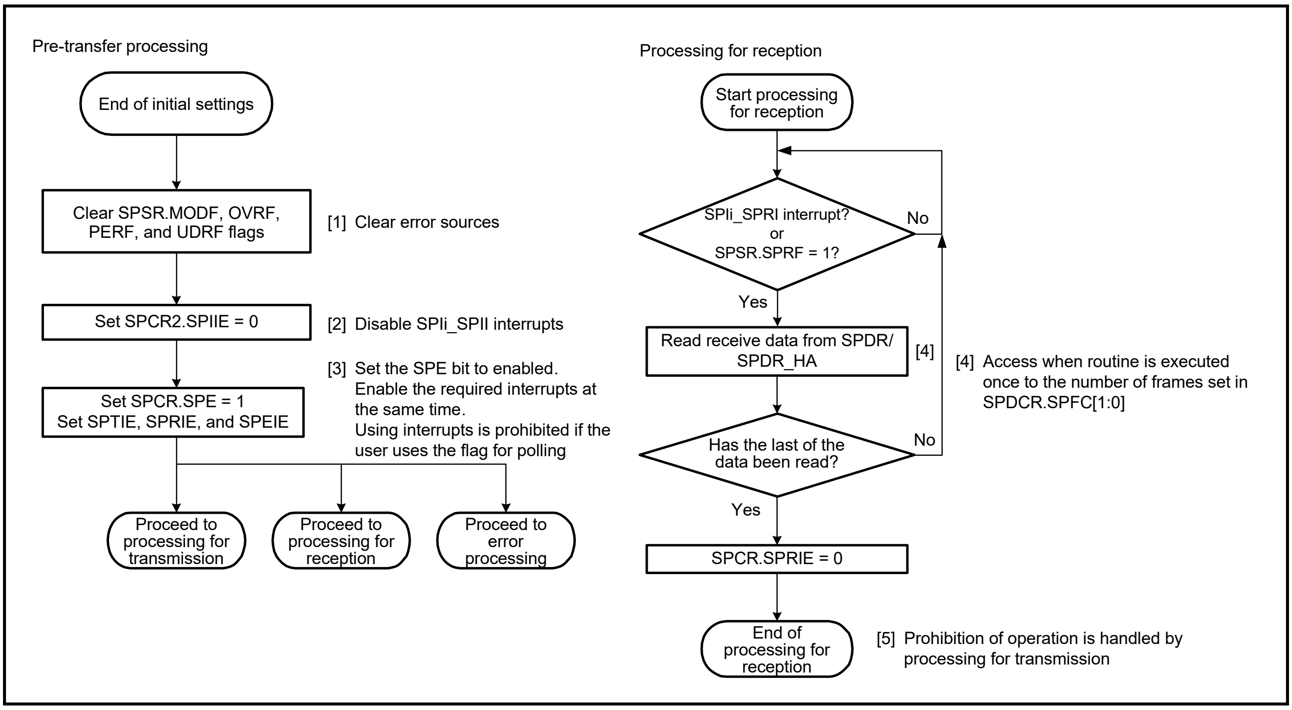


Figure 38.38 Reception flow in master mode

(c) Error processing flow

The SPI detects mode fault errors, underrun errors, overrun errors, and parity errors. When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSSR.SPECM[2:0] bits.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

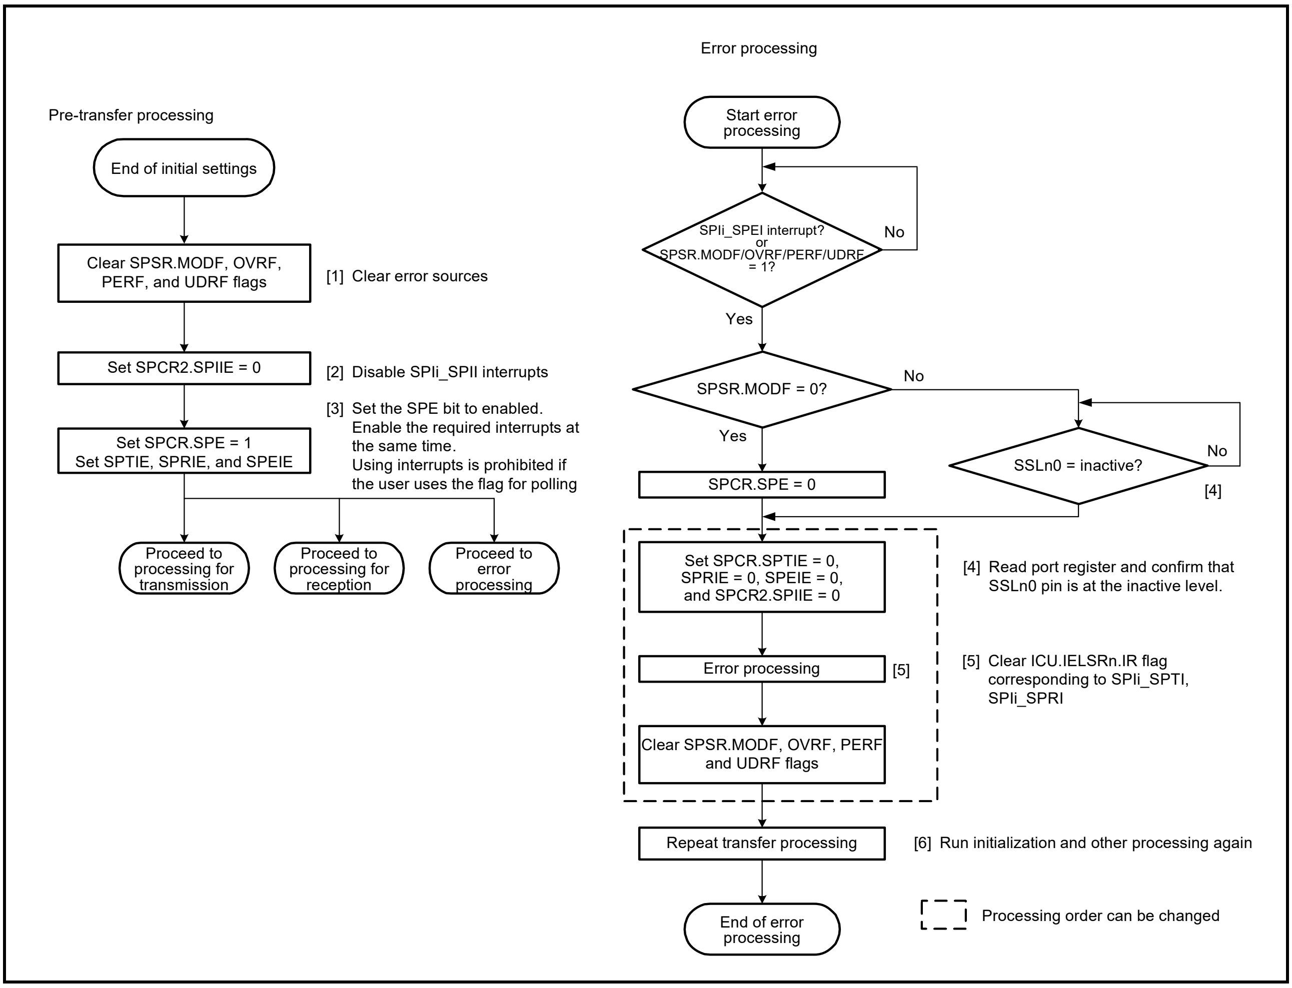

Figure 38.39 Error processing flow for master mode

38.3.10.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 38.3.5, Transfer Formats. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 38.3.8, Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bit setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(3) Notes on single slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the type of configuration shown in Figure 38.7, for example, if the SPI is used in single slave mode, the SSLn0 signal is fixed at the active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. To correctly execute transmit and receive operations by the SPI in slave mode when the SSLn0 input signal is fixed at the active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

(4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization flow

Figure 38.40 shows an example of initialization flow for SPI operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC, and I/O ports, see the descriptions given in the individual blocks.

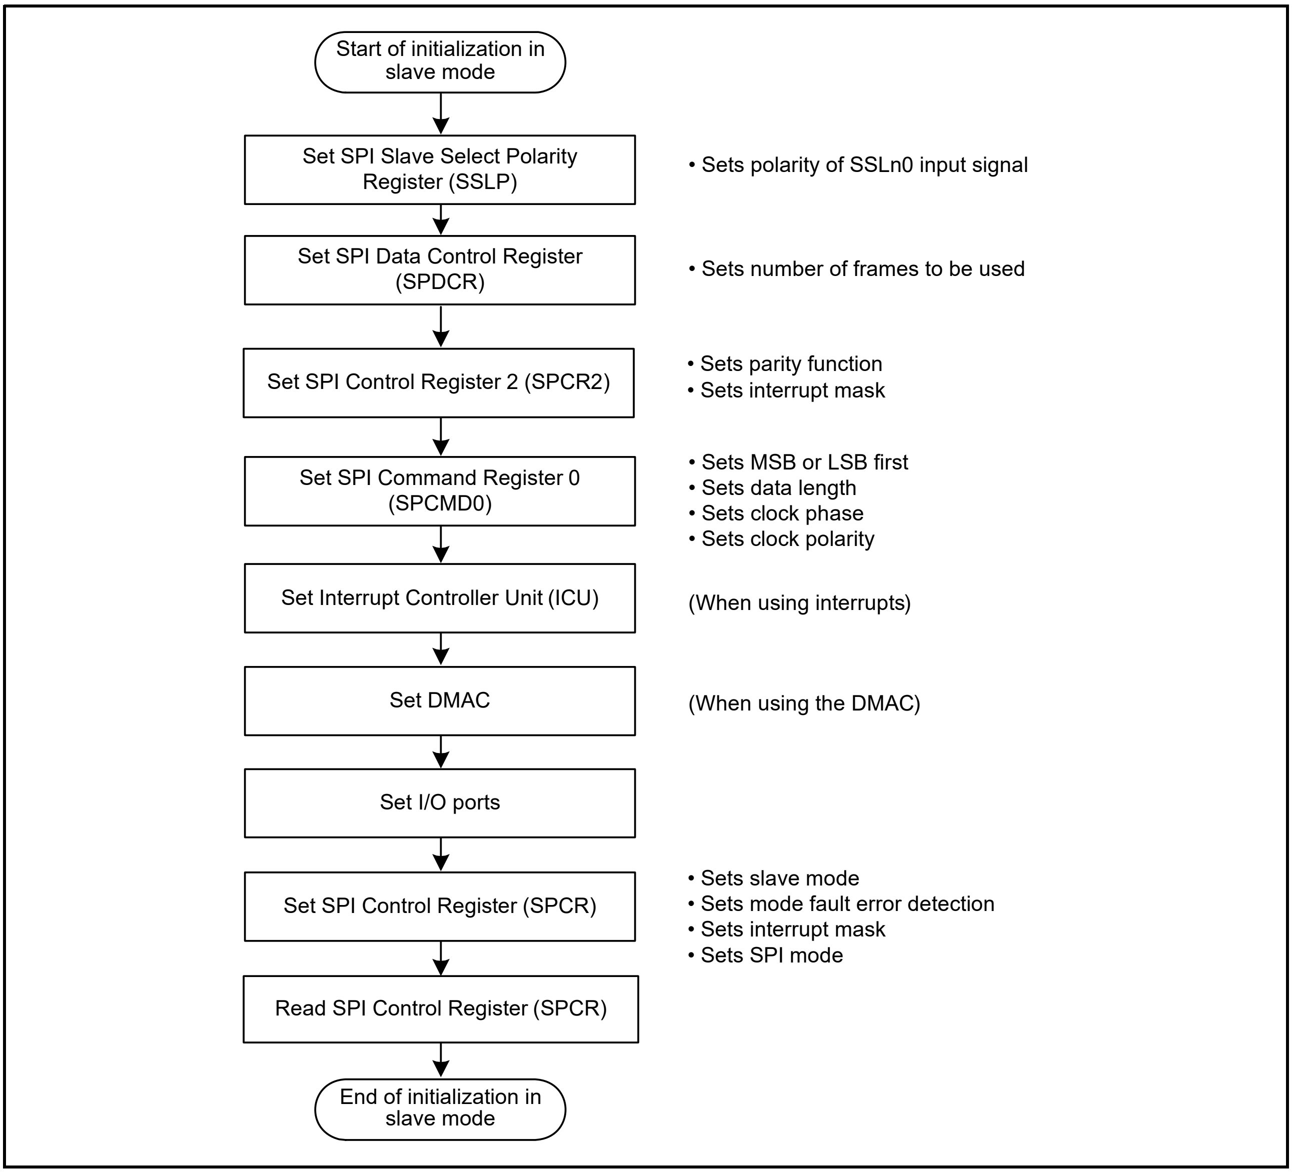

Figure 38.40 Example initialization flow in slave mode for SPI operation

(6) Software processing flow

Figure 38.41 to Figure 38.43 show examples of the flow of software processing.

(a) Transmit processing flow

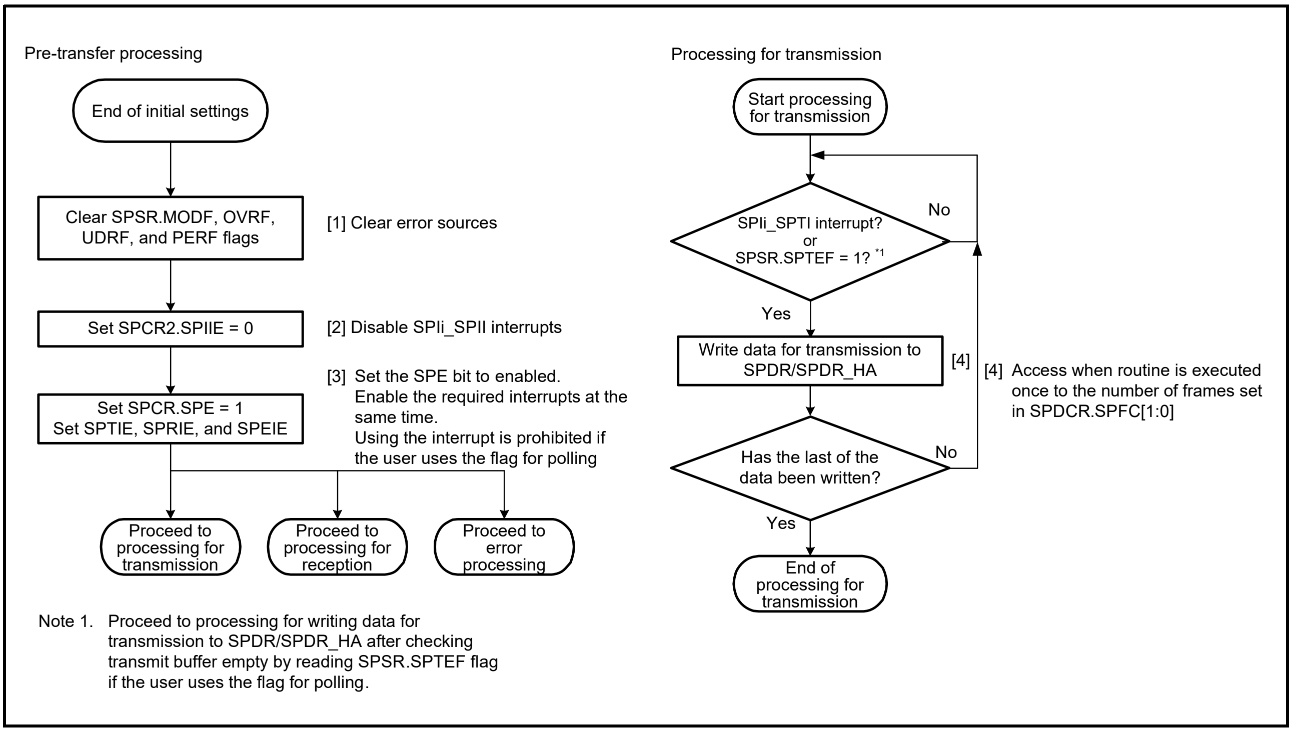

Figure 38.41 Transmission flow in slave mode

(b) Receive processing flow

The SPI does not handle receive-only operation, so processing for transmission is required.

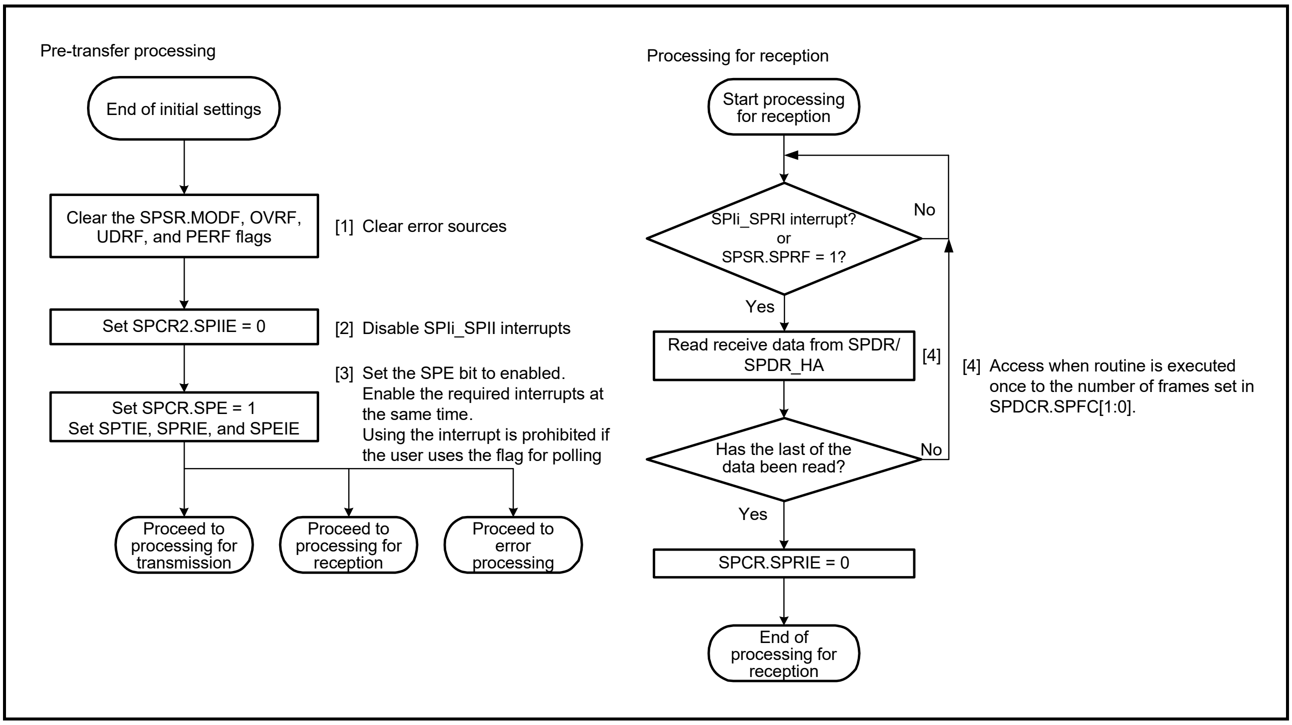

Figure 38.42 Reception flow in slave mode

(c) Error processing flow

In slave operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

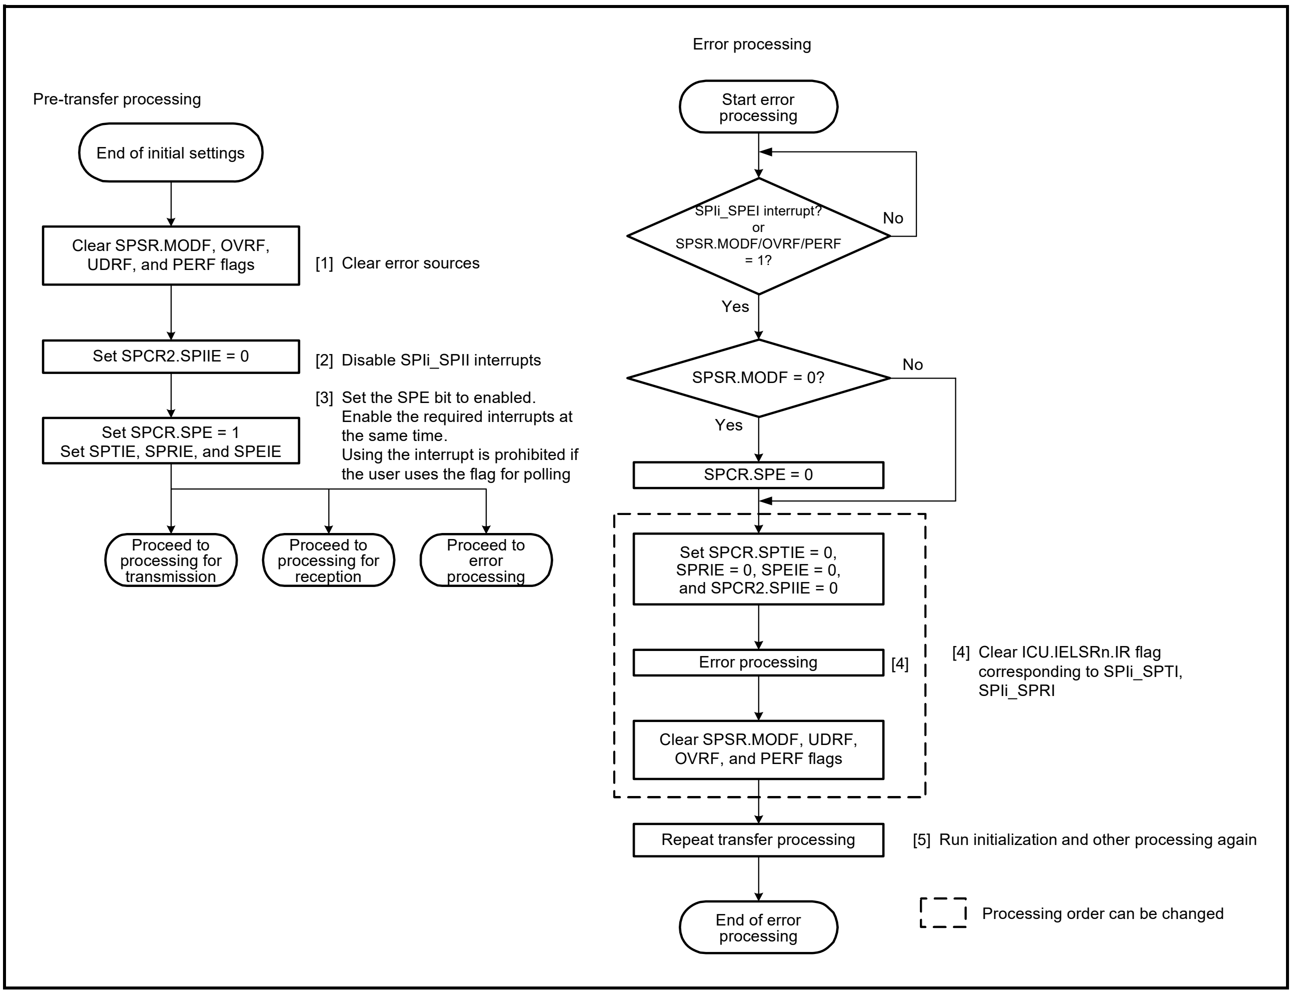

Figure 38.43 Error processing flow for slave mode

38.3.11 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master and slave operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

38.3.11.1 Master mode operation

(1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR_HA when data is written to the SPDR/SPDR_HA register and the transmit buffer is empty (data for the next transfer is not set and the SPSR.SPTEF flag is 1). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced.

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

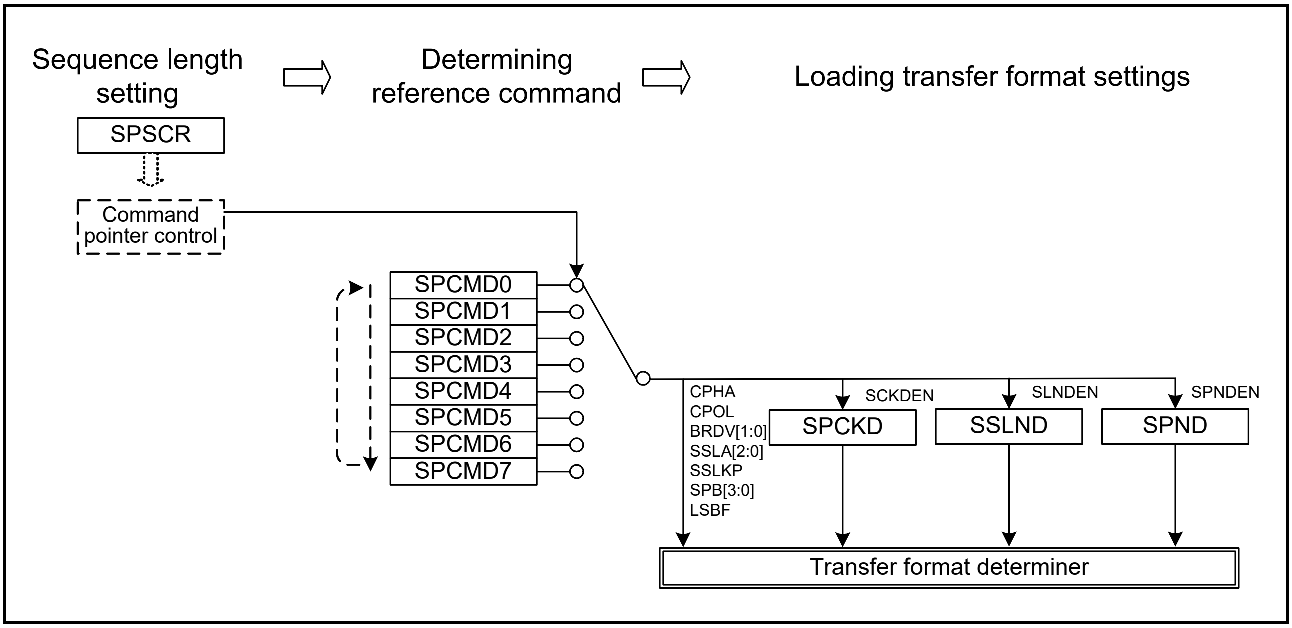

Figure 38.44 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR/SPDR_HA) and the settings (SPCMDm).

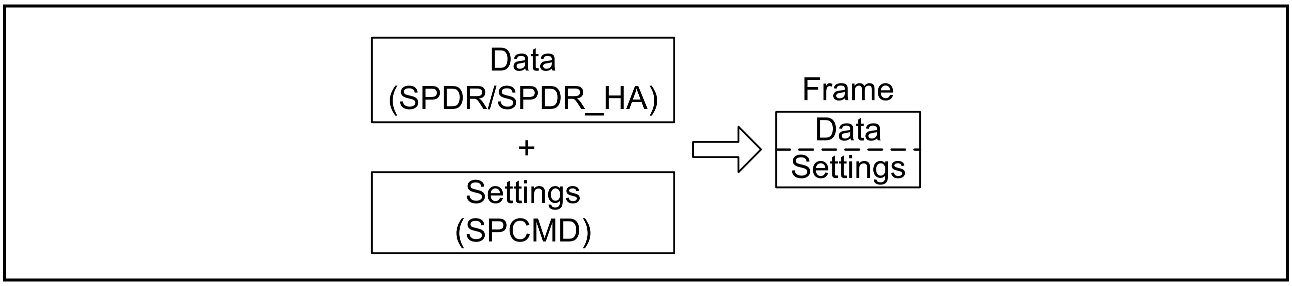

Figure 38.45 Conceptual diagram of frames

Figure 38.46 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 38.4.

(4) Initialization flow

Figure 38.47 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For a description of how to set up the ICU, DMAC, and I/O ports, see the descriptions given in the individual blocks.

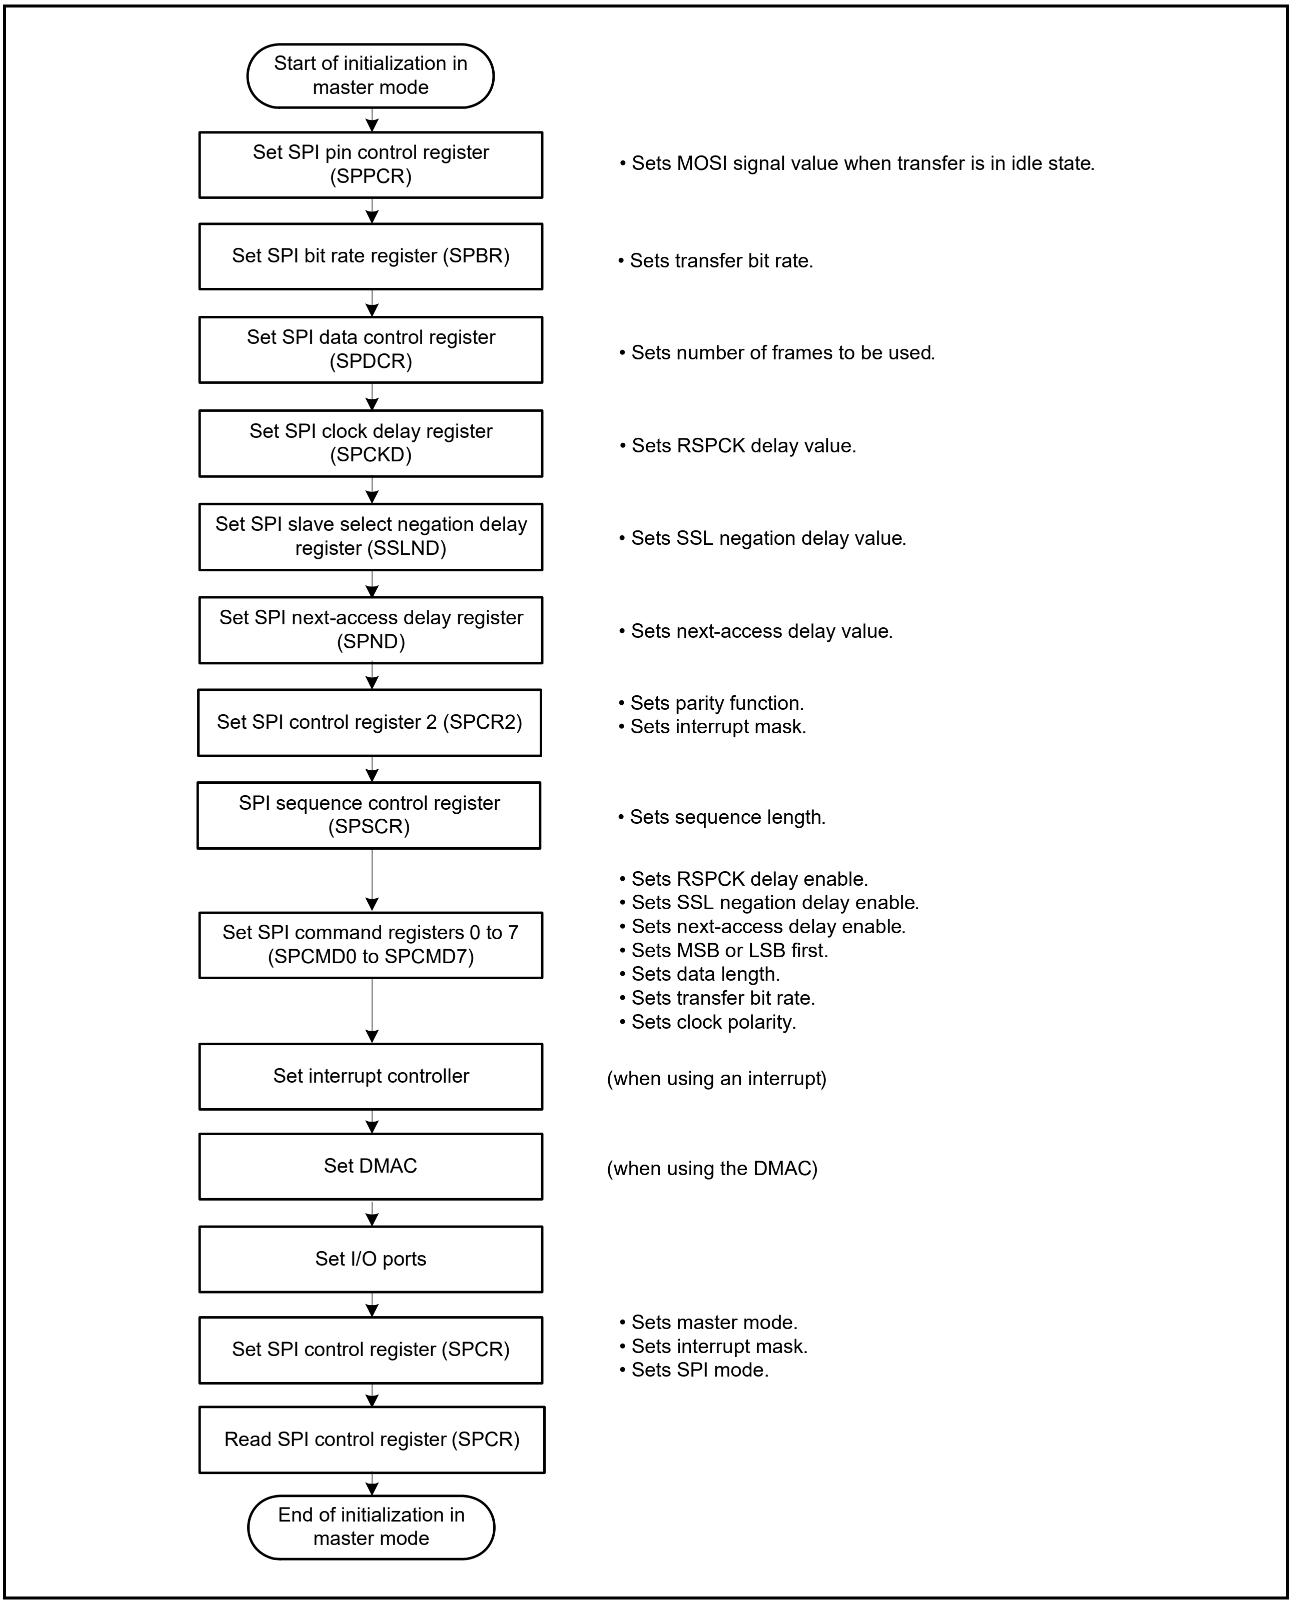

Figure 38.47 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see section 38.3.10.1, (9) Software processing flow. Mode fault errors do not occur in clock synchronous operation.

38.3.11.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSLn0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bit setting. For details on the SPI transfer format, see section 38.3.5, Transfer Formats.

(3) Initialization flow

Figure 38.48 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC, and I/O ports, see the descriptions given in the individual blocks.

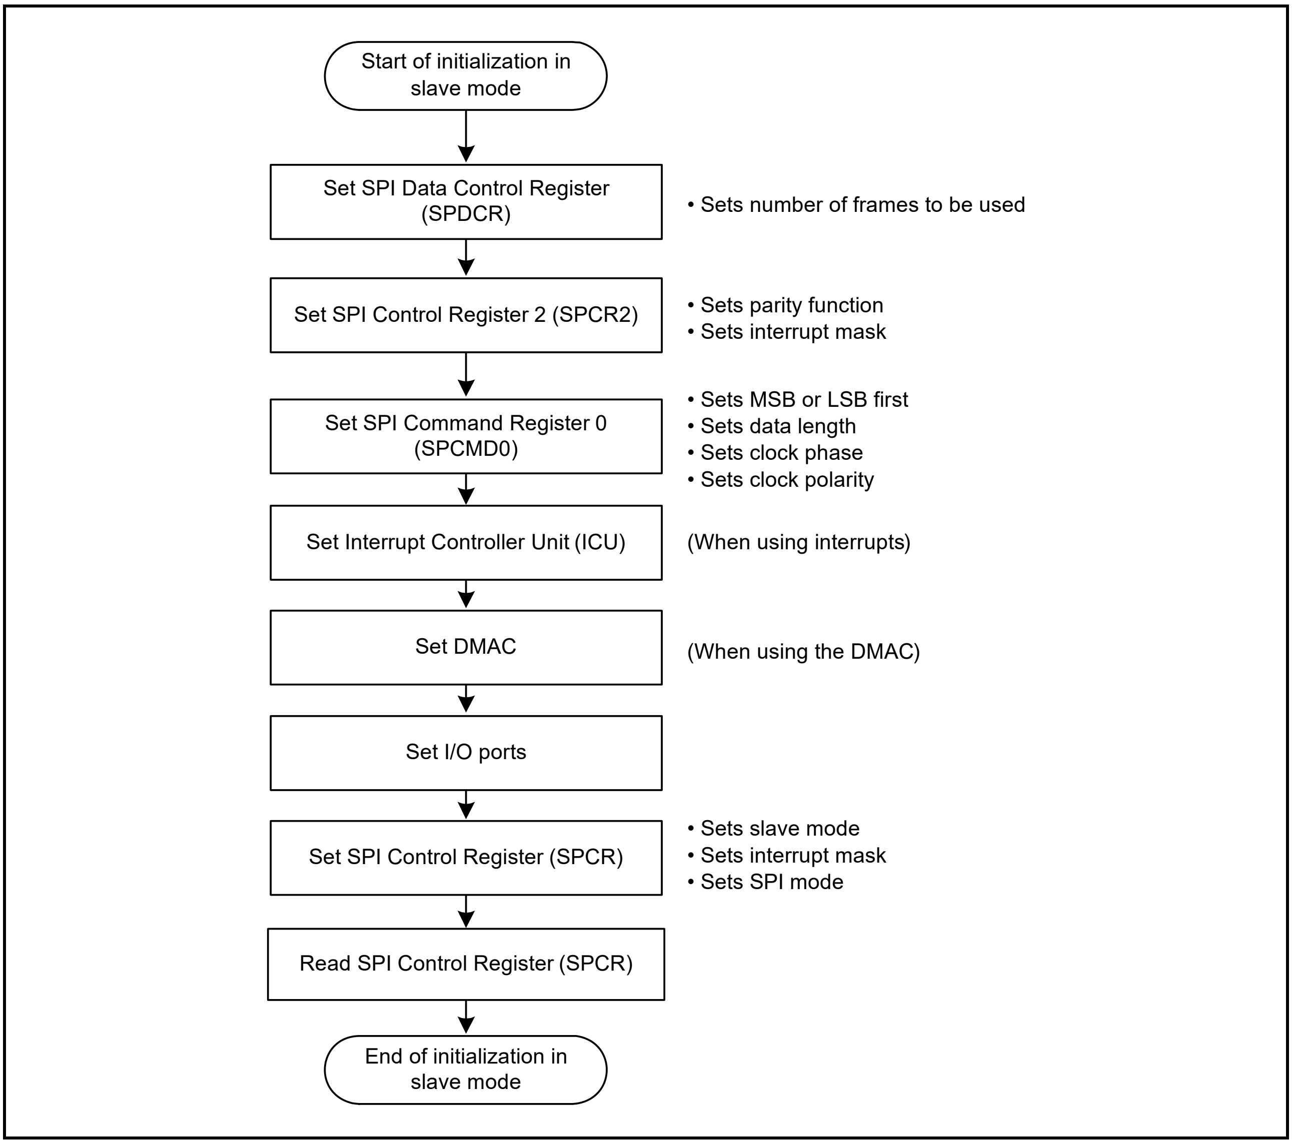

Figure 38.48 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see section 38.3.10.2, (6) Software processing flow. Mode fault errors do not occur in clock synchronous mode.

38.3.12 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 38.12 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 38.49 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPPCR.SPLP2 = 1, SPPCR.SPLP = 0 or 1).

Table 38.12 SPLP2 and SPLP bit settings and received data

SPPCR.SPLP2 bit	SPPCR.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

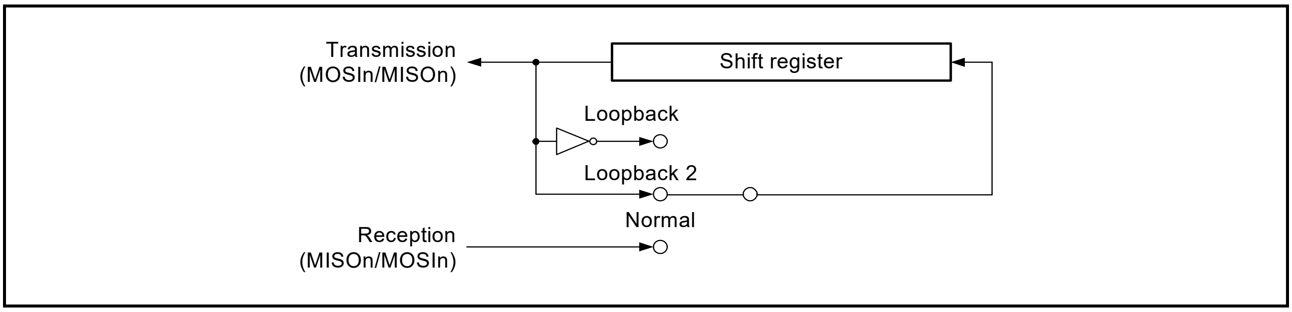

Figure 38.49 Configuration of Shift register I/O paths in loopback mode for master mode

38.3.13 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flow shown in Figure 38.50.

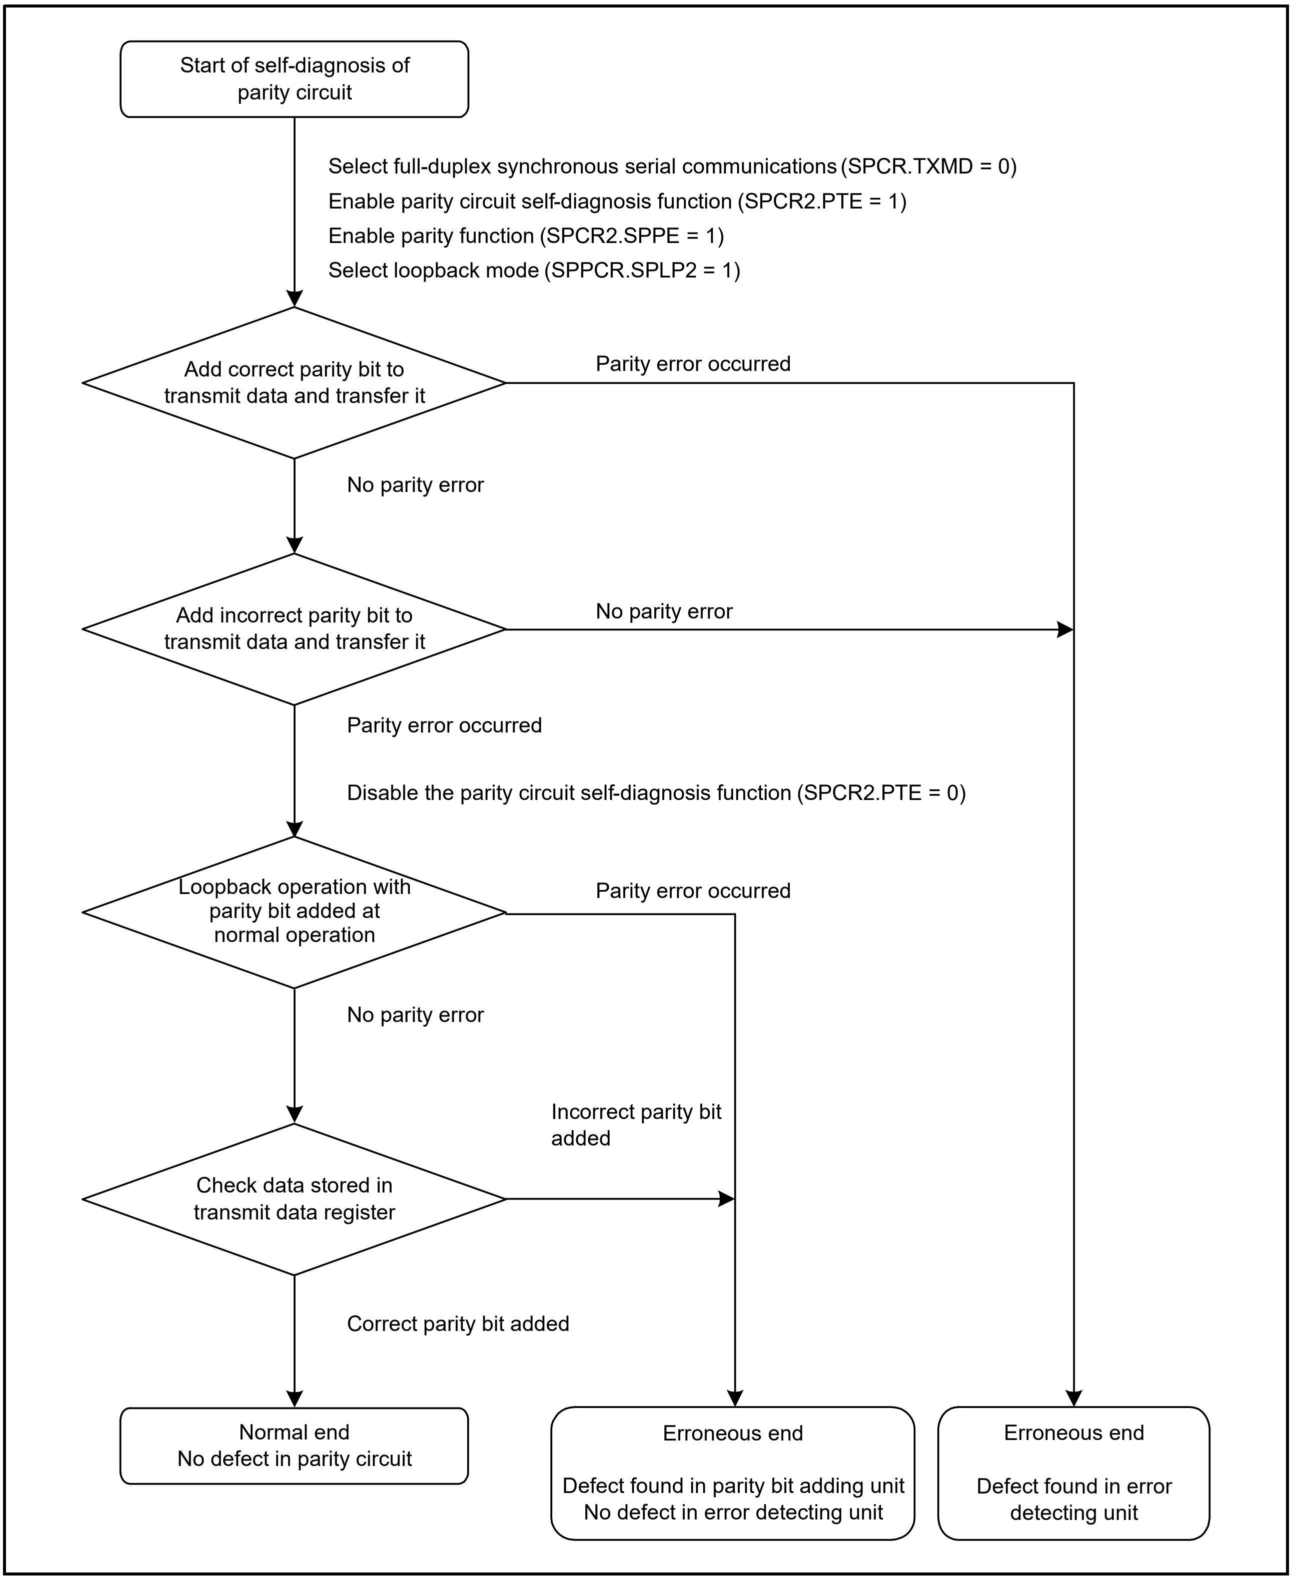

Figure 38.50 Self-diagnosis flow for parity circuit

38.3.14 Interrupt Sources

The SPI interrupt sources include:

- Receive buffer full
- Transmit buffer empty

- SPI error (mode fault, underrun, overrun, or parity error)
- SPI idle
- Transmission-complete

The DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 38.13. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 38.13. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DTC or DMAC to perform data transmission and reception, the DTC or DMAC must be set up first to a transfer-enabled status before making the SPI settings. For information on setting up the DTC or DMAC, see section 17, DMA Controller (DMAC), or section 18, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag clears to 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 38.13 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DMAC or DTC activation
Receive buffer full	SPIi_SPRI	Receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1	Possible
Transmit buffer empty	SPIi_SPTI	Transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode fault, underrun, overrun, or parity error)	SPIi_SPEI	SPSR.MODF, OVRF, PERF, or UDRF flag sets to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	SPSR.IDLNF flag clears to 0 while the SPCR2.SPIIE bit is 1	Impossible
Transmission-complete	SPIi_SPTEND	• Master mode: Interrupt is generated when the IDLNF flag (SPI idle flag) changes from 1 to 0 • Slave mode: interrupt occurs on conditions shown in Table 38.15	Impossible

38.4 Output to the Event Link Controller (ELC)

The ELC can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output.

The event link output signal is output regardless of the interrupt enable bit setting.

38.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR_HA on completion of serial transfer.

38.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

38.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode fault, underrun, overrun, or parity error is detected. See section 38.5.4, Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output if using this event signal.

(1) Mode-fault

Table 38.14 lists the conditions for occurrence of a mode-fault event.

Table 38.14 Conditions for mode fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR bit = 0)	1	Not active	Event is output only when the pin is deactivated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag sets to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

38.4.4 SPI Idle Event Output

(1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

38.4.5 Transmission-Completed Event Output

During both SPI operation and clock synchronous operation in master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. Table 38.15 lists the conditions for occurrence of a transmission-completed event.

Table 38.15 Conditions for generation of transmission-complete event in slave mode

SPI mode	Transmit buffer state	Shift register state	Other
SPI operation (SPMS = 0)	Empty	Empty	Negation of SSLn0 input
Clock synchronous operation (SPMS = 1)	Empty	Empty	Edge detection of the last RSPCKn

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit in transmission or the SPCR.SPE bit is cleared by the mode-fault error or the underrun error.

38.5 Usage Notes

38.5.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

38.5.2 Constraint on Low Power Functions

When using the module-stop function and entering a low power mode other than Sleep, set the SPCR.SPE bit to 0 before completing communication.

38.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally saved, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE or SPCR.SPRIE) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE or SPCR.SPRIE) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

38.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

38.5.5 Constraints on the SPRF and SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, interrupt usage is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

39. Quad Serial Peripheral Interface (QSPI)

39.1 Overview

The Quad Serial Peripheral Interface (QSPI) module is a memory controller for connecting serial ROM that has an SPI-compatible interface. This includes nonvolatile memory, such as a serial flash memory, serial EEPROM, or serial FeRAM. Table 39.1 lists the QSPI specifications, Figure 39.1 shows a block diagram, and Table 39.2 lists the I/O pins.

Table 39.1 QSPI specifications

Parameter	Specifications
Number of channels	1 channel
SPI	• Support for Extended SPI, Dual SPI, and Quad SPI protocols • Configurable to SPI mode 0 and SPI mode 3 • Address width selectable to 8, 16, 24, or 32 bits.
Timing adjustment function	Configurable to support a wide range of serial flash
Flash read function	• Support for Read, Fast Read, Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, and Fast Read Quad I/O instructions • Substitutable instruction code • Adjustable number of dummy cycles • Prefetch function • Polling processing • SPI bus cycle extension function.
Direct communication function	Flexible support for a wide variety of serial flash instructions and functions through software control, including erase, write, ID read, and power-down control
Interrupt source	Error interrupts
Module-stop function	Module-stop state can be set to reduce power consumption

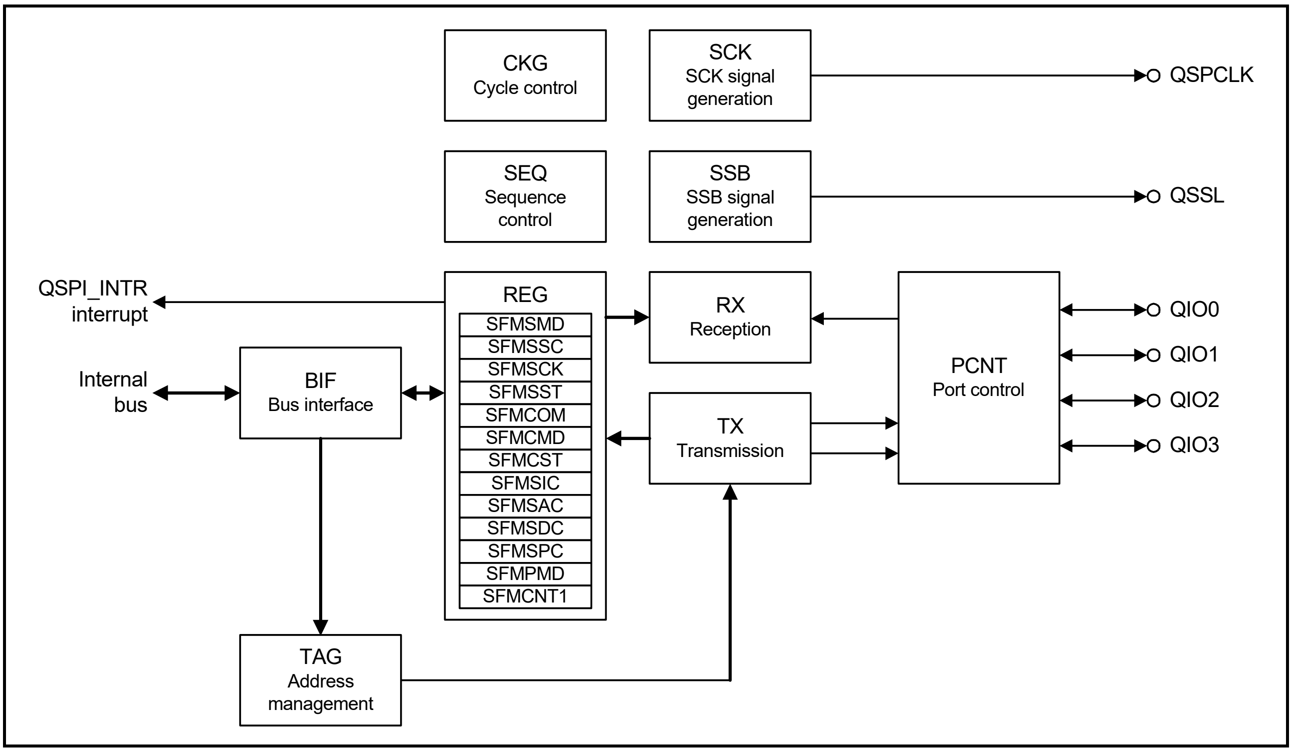

Figure 39.1 QSPI block diagram

Table 39.2 QSPI I/O pins

Pin name	I/O	Function
QSPCLK	Output	QSPI clock output pin
QSSL	Output	QSPI slave select pin
QIO0	I/O	Data 0 input/output
QIO1	I/O	Data 1 input/output
QIO2	I/O	Data 2 input/output
QIO3	I/O	Data 3 input/output

39.2 Register Descriptions

39.2.1 Transfer Mode Control Register (SFMSMD)

Address(es): QSPI.SFMSMD 6400 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	Symbol	Bit name	Description	R/W
b25 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b26	QSPI_EXT[5:0]	Bank switching address	When accessing from 6000 0000h to 63FF FFFFh, the address bus is set from QSPI_EXT[5:0] to the upper 6 bits of the internal bus address.	R/W

39.3 Memory Map

39.3.1 Internal Bus Space

The locations of the serial flash and control registers in the AHB space are determined by the address range of the configured area.

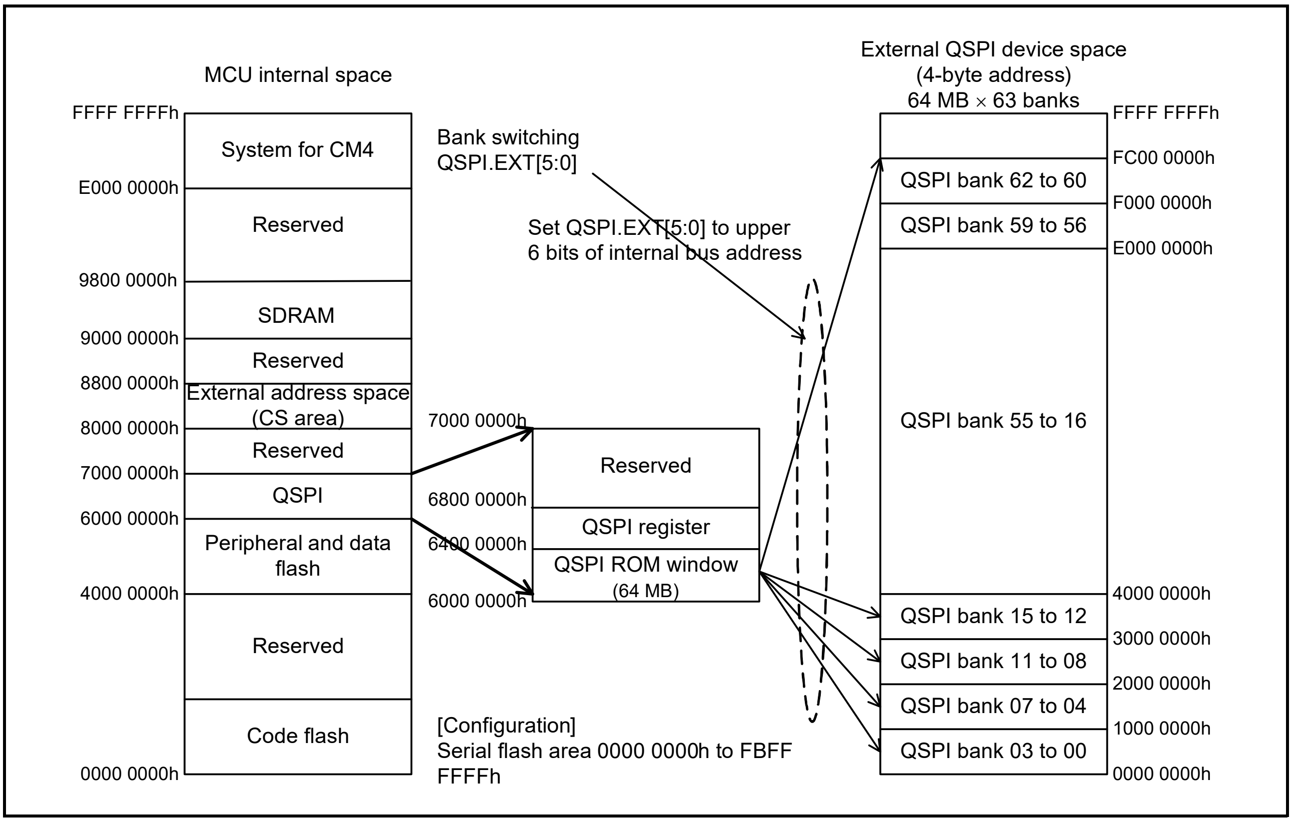

Figure 39.2 Default area setting and AHB space memory map

39.3.2 Address Width of the SPI Space and SPI Bus

The SPI space has a 32-bit address width for referencing the serial flash. When the SPI space is accessed for a read, an SPI bus cycle starts automatically, and data read from the serial flash is returned.

The address width of the SPI space is fixed at 32 bits. However, the address width of the SPI bus is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register. If 8, 16, or 24 bits is selected as the address width of the SPI bus, only the lower part of the address used to access the SPI space is posted to the serial flash through the SPI bus. As a result, the mirror image of the serial flash corresponding to the address width of the SPI bus repeatedly appears in the SPI space.

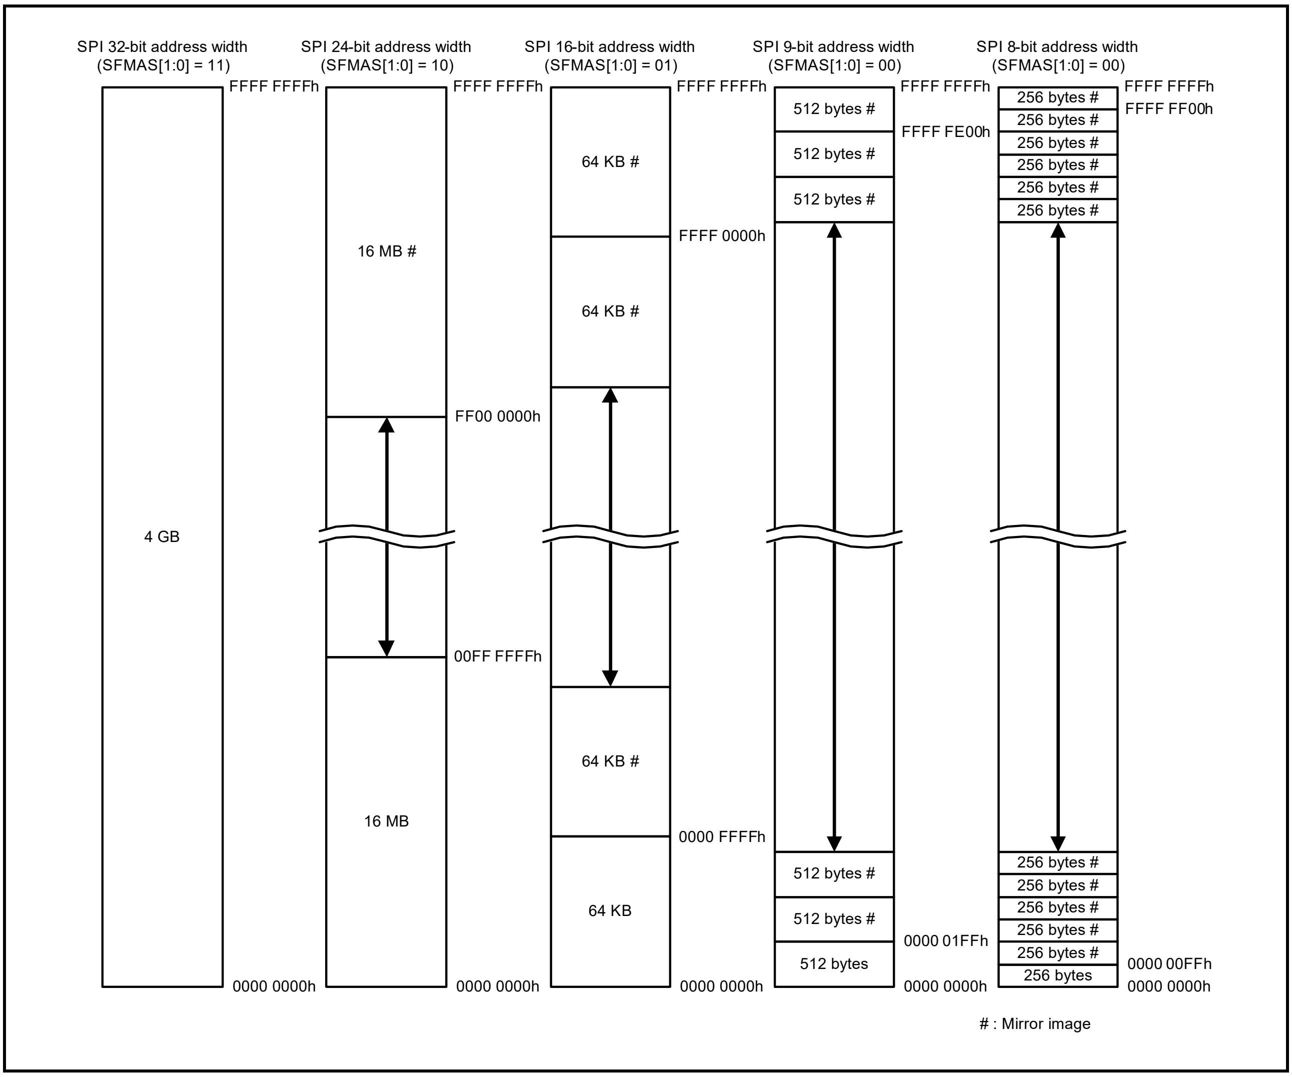

Figure 39.3 Memory map of SPI space

Note: The SPI bus address width is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register. When an 8-bit address width is selected, the address information of the ninth bit can be embedded in the Read instruction code. The address map in the figures is for the SPI 9-bit address width. For details on the Read instruction, see section 39.6.2, Standard Read Instruction.

39.4 SPI Bus

39.4.1 SPI Protocol

The QSPI supports Extended SPI, Dual SPI, and Quad SPI, in addition to the SPI protocol used for serial flash connection. The initial state is Extended SPI. To change the protocol, set the SFMSPI bit in the SFMSPC register. The Extended SPI protocol always outputs instruction codes from a single QIO0 pin. It performs subsequent address and data

I/O operations using one to four pins, depending on the instruction code format.

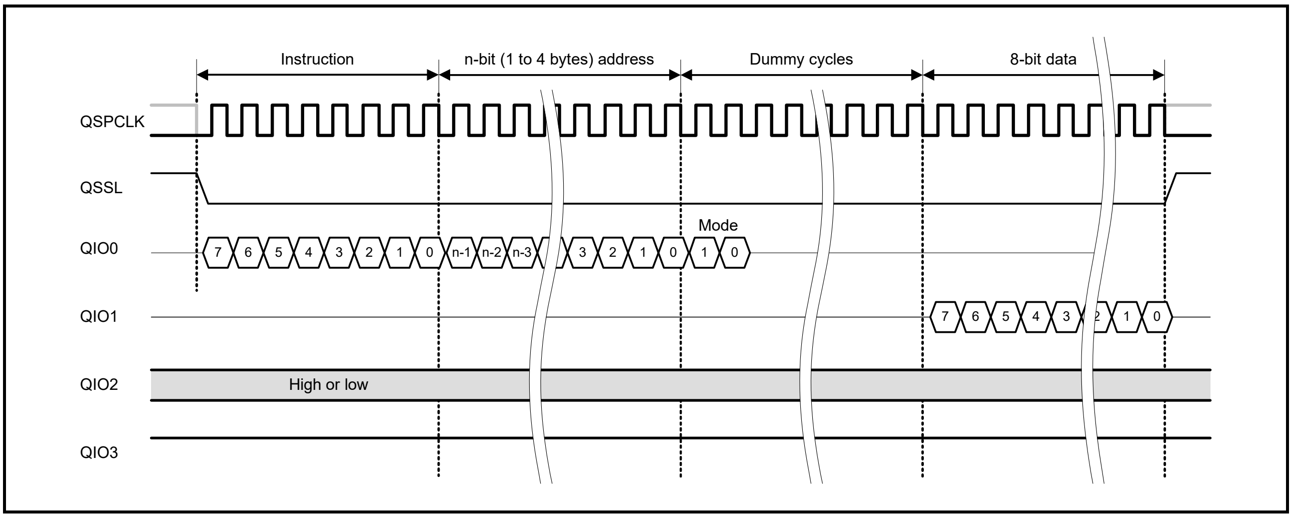

Figure 39.4 Extended SPI protocol example 1 for Fast Read

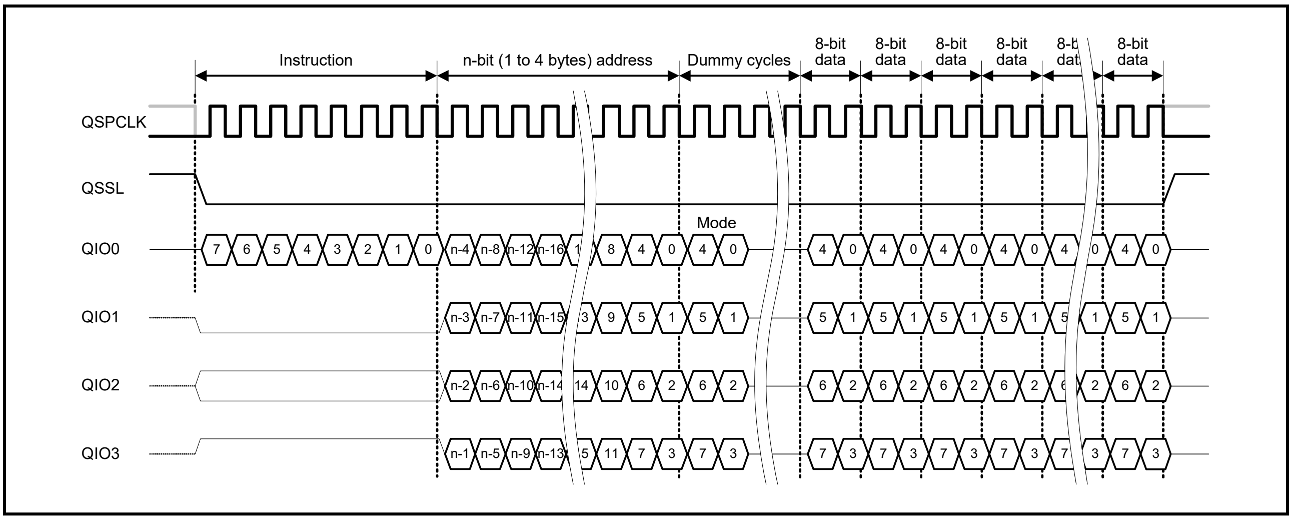

Figure 39.5 Extended SPI protocol example 2 for Fast Read Quad I/O

The Dual SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using two pins, QIO0 and QIO1.

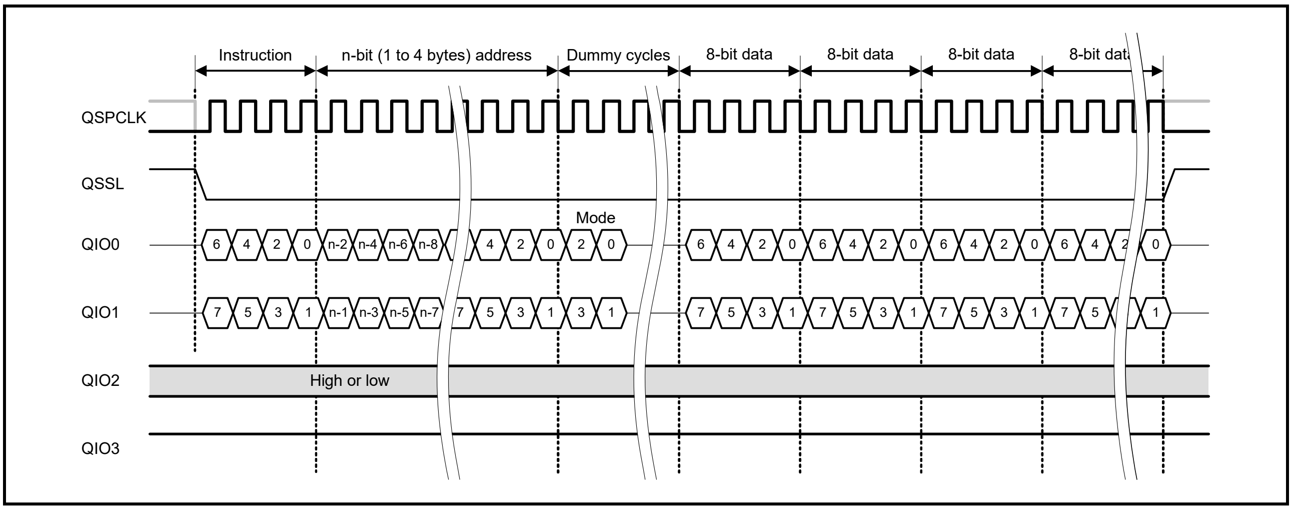

Figure 39.6 Dual SPI protocol example for Fast Read

The Quad SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using four pins, QIO0, QIO1, QIO2, and QIO3.

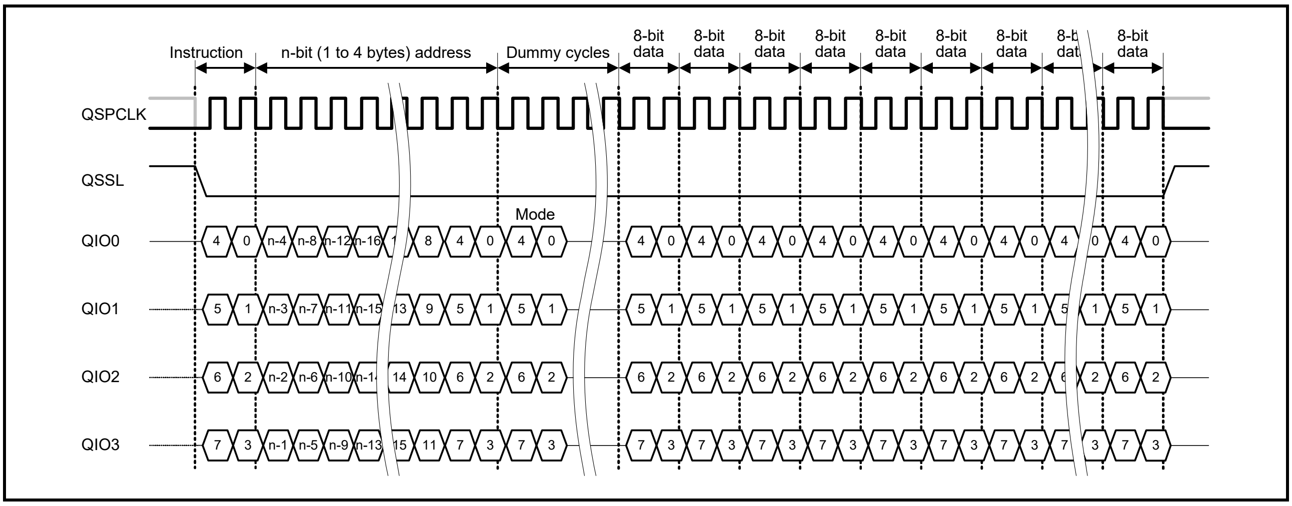

Figure 39.7 Quad SPI protocol example for Fast Read

39.4.2 SPI Mode

The initial SPI mode is set to SPI mode 0 or 3 by the CFGMD3 pin. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and 3 is the standby level of the QSPCLK signal. The standby level of the QSPCLK signal in SPI mode 0 is low, and high in SPI mode 3.

Serial data is output from the QSPI on a falling edge of the serial clock and is read into the external flash on a rising edge of the serial clock. Serial data is output from the external flash on a falling edge of the serial clock and is read into the QSPI on the next falling edge of the serial clock.

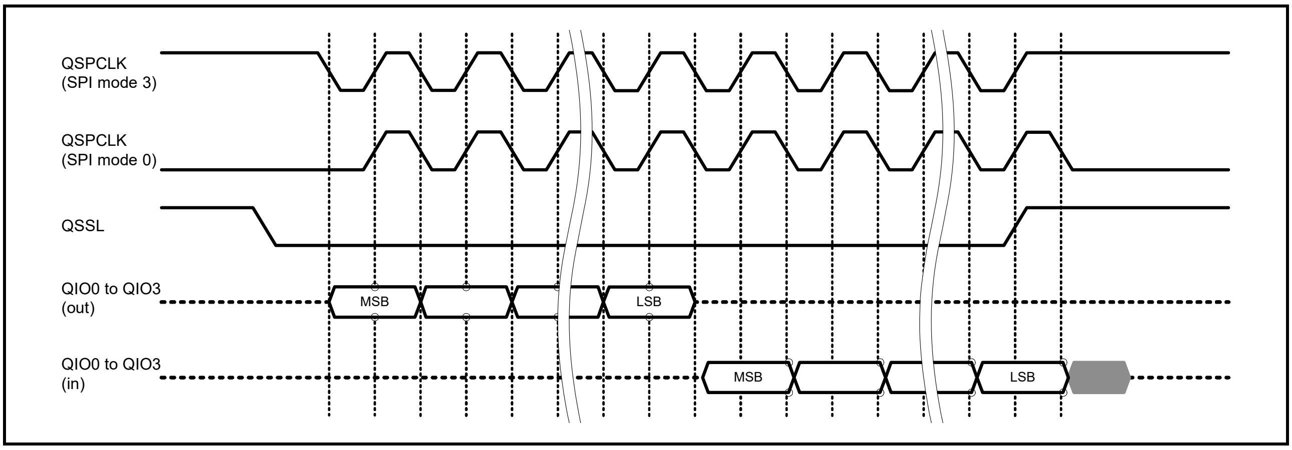

Figure 39.8 Basic serial interface timing

39.5 SPI Bus Timing Adjustment

The timing of the SPI bus signal can be adjusted in the registers. The configured timing is applied to all SPI bus accesses, for both ROM access and direct communication.

39.5.1 SPI Bus Reference Cycles

The SPI bus operates on reference cycles obtained by multiplying PCLKA by an integer. The reference cycles are selectable within the range of PCLKA multiplied by 2 to 48 in the SFMDV[4:0] bits in the SFMSKC register.

Table 39.3 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (1 of 2)

SFMDV[4:0]	Cycle multiplier	PCLKA frequency (MHz)
		120
11111	48	2.50
11110	46	2.61
11101	44	2.73
11100	42	2.86
11011	40	3.00
11010	38	3.16
11001	36	3.33
11000	34	3.53
10111	32	3.75
10110	30	4.00
10101	28	4.29
10100	26	4.62
10011	24	5.00
10010	22	5.45
10001	20	6.00
10000	18	6.67
01111	17	7.06
01110	16	7.50
01101	15	8.00
01100	14	8.57
01011	13	9.23
01010	12	10.00

Table 39.3 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (2 of 2)

SFMDV[4:0]	Cycle multiplier	PCLKA frequency (MHz)
		120
01001	11	10.91
01000	10	12.00
00111	9	13.33
00110	8	15.00
00101	7	17.14
00100	6	20.00
00011	5	24.00
00010	4	30.00
00001	3	40.00
00000	2	60.00

39.5.2 QSPCLK Signal Duty Ratio

When the reference clock is configured as PCLKA multiplied by an even number, the high- and low-level widths of the QSPCLK signal match each other. When PCLKA is multiplied by an odd number, however, the high-level width is longer than the low-level width by 1 PCLKA.

To make the duty ratio of the QSPCLK signal close to 50% when PCLKA multiplied by an odd number is the reference clock, set the SFMDTY bit in the SFMSKC register to 1. With this setting, the rising edge of the QSPCLK output signal is delayed by one-half PCLKA cycle to perform an interface operation equivalent to a duty ratio of 50%.

When the reference clock is PCLKA multiplied by an even number, the SFMDTY setting in the SFMSKC register is ignored.

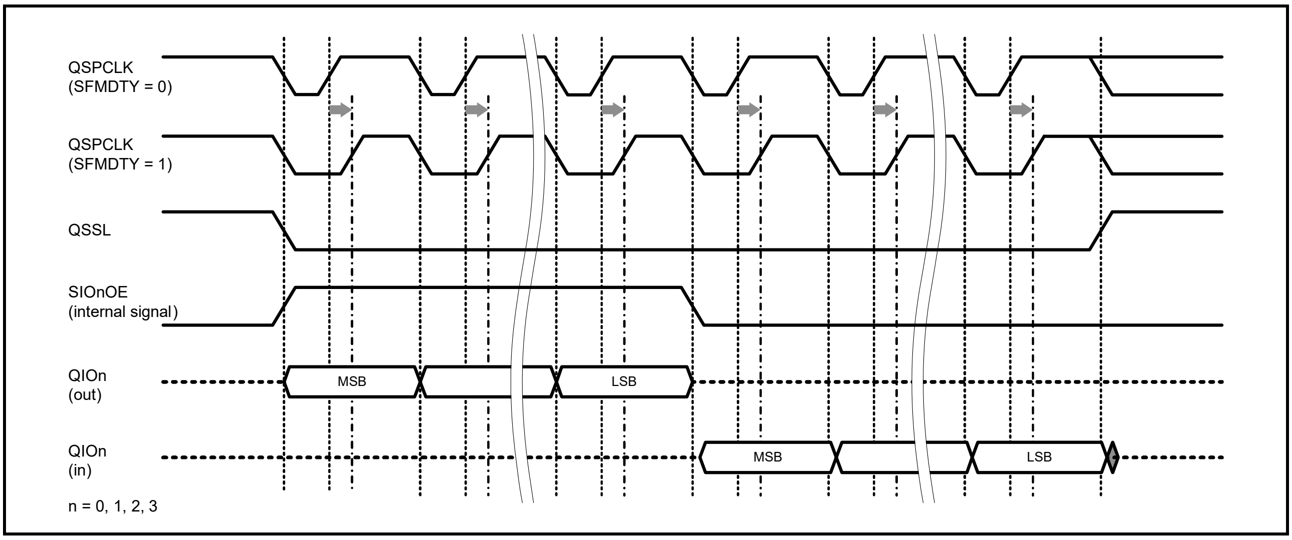

Figure 39.9 Example correction of the QSPCLK signal duty ratio using the SFMDTY bit, when PCLKA is multiplied by 3

39.5.3 Minimum High-Level Width for the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to satisfy the deselect time required by the serial flash. The minimum high-level width of the QSSL output signal is selectable as the reference cycle multiplied by an integer from 1 to 16 in the SFMSW[3:0] bits in the SFMSSC register.

39.5.4 QSSL Signal Setup Time

When the QSPCLK signal first rises after the QSSL signal is driven low, the QSSL signal setup time can be configured to satisfy the serial flash requirements. The setup time can be selectable as 0.5 QSPCLK or 1.5 QSPCLK in the SFMSLD bit in the SFMSSC register.

The SFMSLD setting in the SFMSSC register is also applied to the allocate a setup time from the output of the serial data output enable signal (QIO0OE, QIO1OE, QIO2OE, or QIO3OE) until the first rising edge of the QSPCLK signal. Set a value that meets the most constrained timing condition for your application.

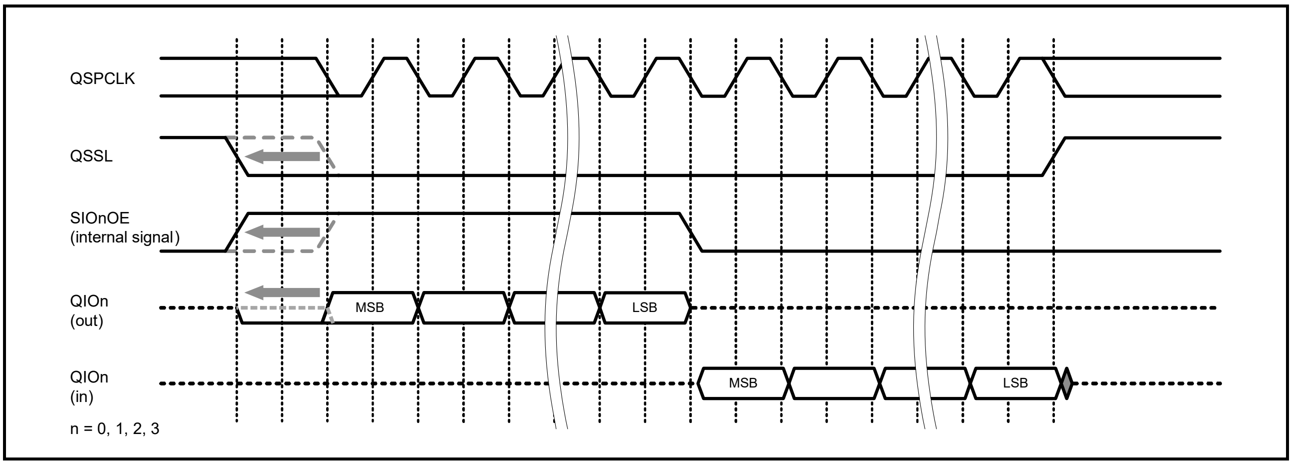

Figure 39.10 Setup time adjustment for the QSSL signal using the SFMSLD bit

39.5.5 QSSL Signal Hold Time

When the QSSL signal is driven high after the last rising edge of the QSPCLK signal, the QSSL signal hold time can be configured to satisfy the device requirements. The hold time is selectable as 0.5 QSPCLK or 1.5 QSPCLK in the SFMSHD bit in the SFMSSC register.

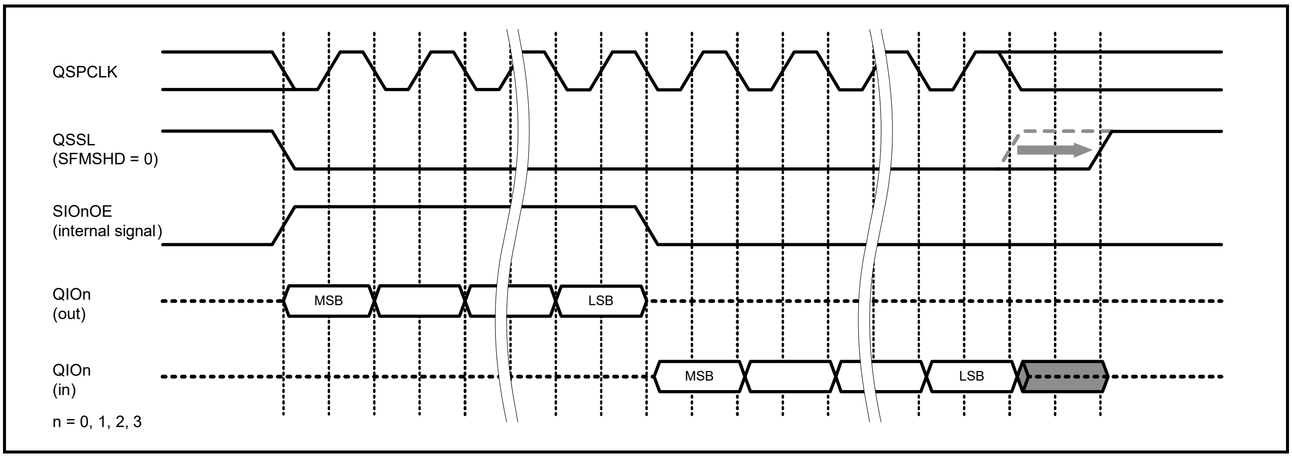

Figure 39.11 Hold time adjustment for the QSSL signal using the SFMSHD bit

39.5.6 Hold Time of the Serial Data Output Enable

The buffer output enable of the QIO0, QIO1, QIO2, or QIO3 pin can be extended by 1 QSPCLK using the SFMOEX bit in the SFMSMD register. The target extension signals include only the output enable signals: QIO0E, QIO1OE, QIO2OE, and QIO3OE. They do not include the output data signals: QIO0O, QIO1O, QIO2O, or QIO3O.

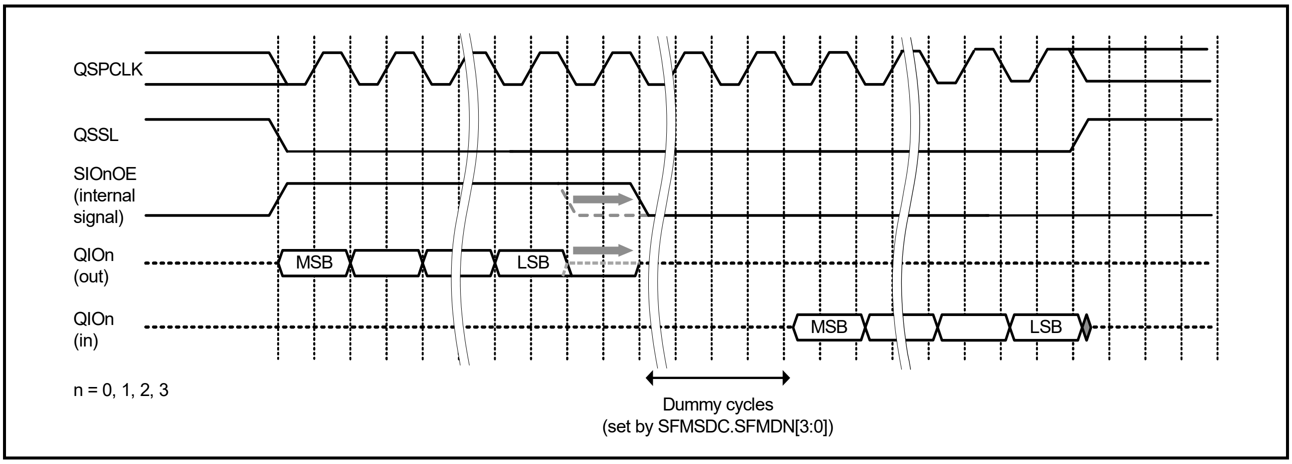

Figure 39.12 Hold time adjustment for output enable using the SFMOEX bit

39.5.7 Setup Time for Serial Data Output

When a command or address is transmitted to the serial flash, the setup time begins on serial data output and ends when the QSPCLK signal rises. If this setup time is insufficient, it can be extended by 1 PCLKA using the SFMOSW bit in the SFMSMD register. When SFMOSW is 1, the low-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

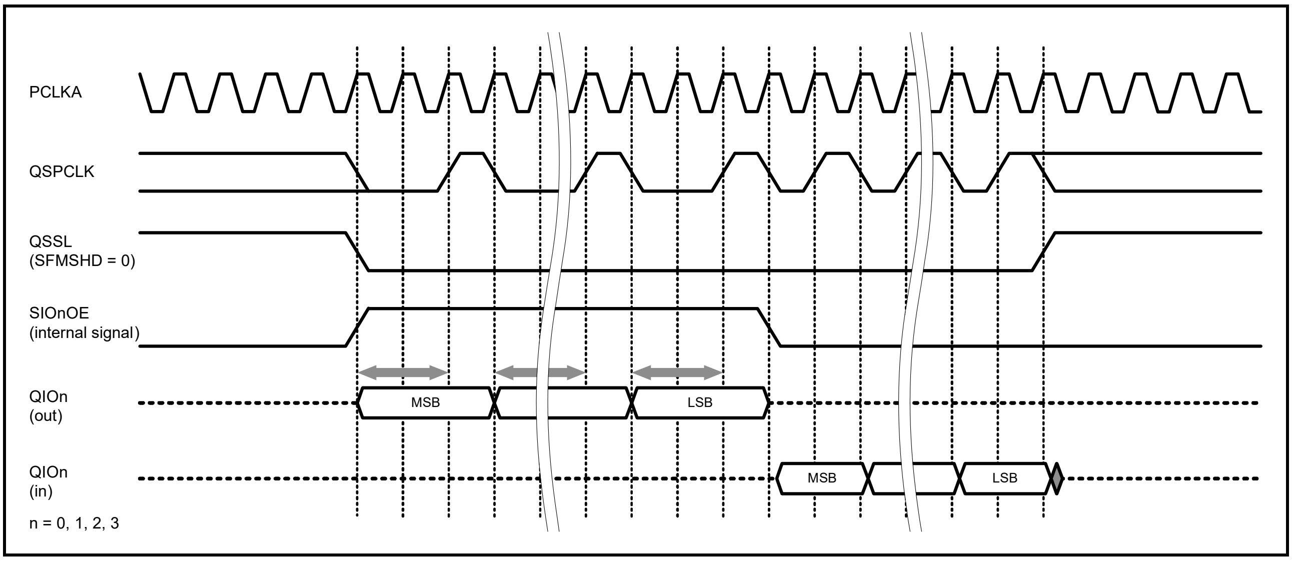

Figure 39.13 Setup time adjustment for serial data output using the SFMOSW bit

39.5.8 Hold Time for Serial Data Output

When a command or address is transmitted to the serial flash, the hold time begins on the rising edge of QSPCLK and ends when the serial data makes another transmission. If this hold time is insufficient, it can be extended by 1 PCLKA using the SFMOHW bit in the SFMSMD register. When SFMOSW is 1, the high-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

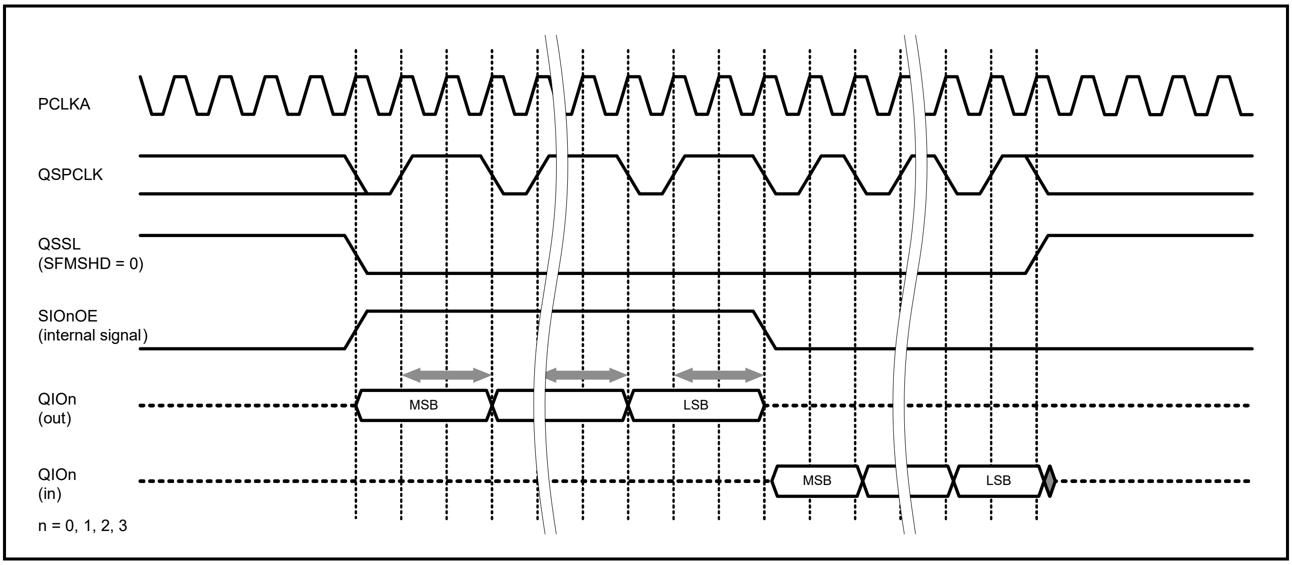

Figure 39.14 Hold time adjustment for serial data output using the SFMOHW bit

39.5.9 Serial Data Receiving Latency

The serial flash outputs data in synchronization with the falling edge of the QSPCLK signal. The QSPI receives that data in synchronization with the falling edge of the subsequent QSPCLK signal. The delay from when the serial flash starts outputting data until the QSPI receives that data is called the receiving latency. The QSPI adds a latency adjustment cycle immediately before the first data reception cycle in the SPI bus cycle. From the serial flash side, this is seen as an increase in the number of data reception cycles. This added latency adjustment cycle is not generated in the SPI bus cycle without accompanying data reception.

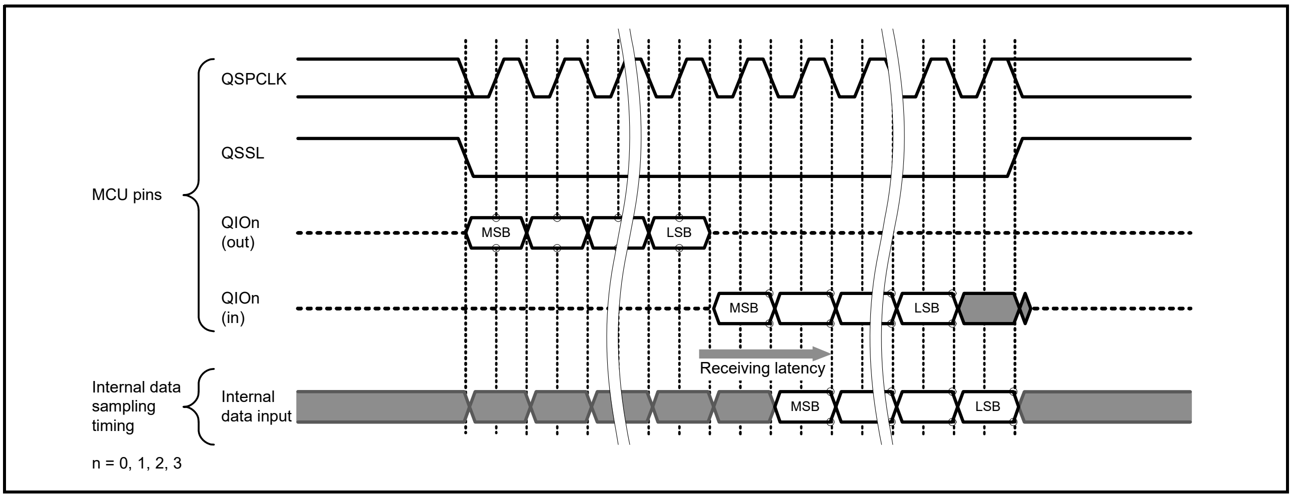

Figure 39.15 Receiving latency

39.6 SPI Instruction Set Used for Flash Access

39.6.1 SPI Instructions That Are Automatically Generated

When the serial flash is accessed, an SPI bus cycle using one of the instructions described in Table 39.4 to Table 39.8 is automatically generated based on the settings in the SFMAS[1:0] bits in the SFMSAC register and in the SFMSMD register.

Table 39.4 SPI instructions automatically generated when SFMAS[1:0] = 00b

Instruction format	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h[*1]	1	—	1 to ∞	Required: SFMRM[2:0] = 000, A8 = 0
	0Bh[*1]	1	—	1 to ∞	Required: SFMRM[2:0] = 000, A8 = 1

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Table 39.5 SPI instructions automatically generated when SFMAS[1:0] = 01b

Instruction format	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h[*1]	2	—	1 to ∞	Required: SFMRM[2:0] = 000

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Table 39.6 SPI instructions automatically generated when SFMAS[1:0] = 10b

Instruction format	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h[*1]	3	—	1 to ∞	Required: SFMRM[2:0] = 000
Fast Read	0Bh[*1]	3	8[*2]	1 to ∞	Selectable: SFMRM[2:0] = 001

Fast Read Dual I/O	BCh*1	4	4*2	1 to ∞	Selectable: SFMRM[2:0] = 011
Fast Read Quad Output	6Ch*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 100
Fast Read Quad I/O	ECh*1	4	6*2	1 to ∞	Selectable: SFMRM[2:0] = 101
Write Enable	06h	—	—	—	Selectable: ENEX4B[1:0] = 10
Enter 4-Byte Mode	B7h	—	—	—	Selectable: ENEX4B[1:0] = 01,10

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable in SFMSDC.SFMDN[3:0].

39.6.2 Standard Read Instruction

The standard Read instruction is a common read instruction supported by most serial flash. When an SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (03h/13h)*1 is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted. Data is then received.

This standard Read instruction is selected in the initial QSPI settings.

Note 1. Many 4-Kb serial flash devices have an address field not larger than 1 byte (A7-A0) to minimize the overhead and to receive A8 information from bit 3 of the Read instruction code. To support these devices, the QSPI only outputs A8 (address bit 8) to bit [3] of the standard Read instruction code when an address width of 1 byte is specified (SFMAS[1:0] = 00). This means that 0Bh might be output instead of 03h as the standard Read instruction code. This code duplicates the Fast Read instruction code. However, for most of the 2-Kb or smaller serial flash devices, with an address width of 1 byte, bit 3 of a command is designed to be excluded from decoding as a don’t-care bit, so such a Read instruction code is recognized correctly as the standard Read instruction code. In rare cases, some serial flash devices allow bit 3 to be decoded. When such a serial flash is connected, configure your application to avoid access resulting in A8 = 1.

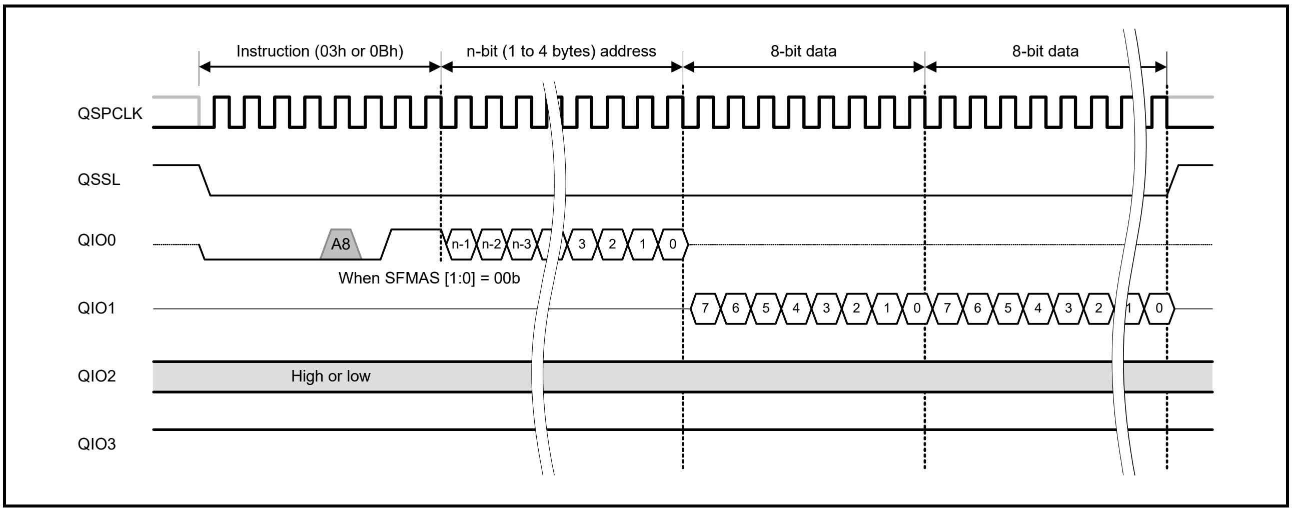

Figure 39.16 Standard Read bus cycle

39.6.3 Fast Read Instruction

The Fast Read instruction is a read instruction that supports a higher communication clock speed than the standard Read instruction. When an SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0Bh/0Ch) is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in SFMSAC, and a certain number of dummy cycles, specified in the SFMSDC register, are transmitted. Data is then received.

The first two dummy cycles are used to select or deselect the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 39.8, XIP Control.

Switching to the Fast Read instruction is controlled in the SFMSMD register.

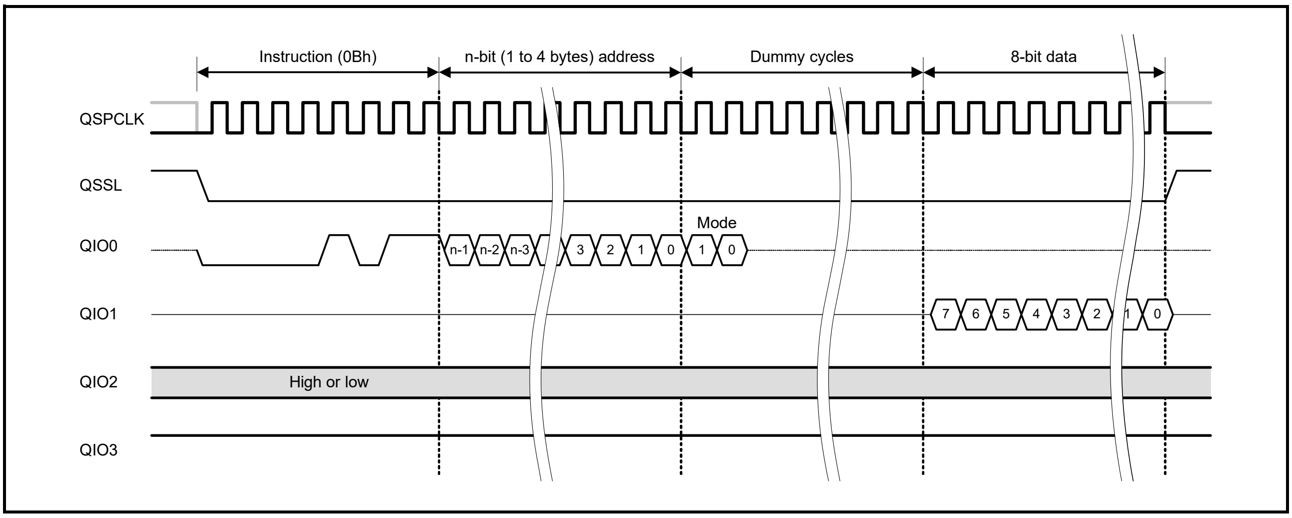

Figure 39.17 Fast Read bus cycle

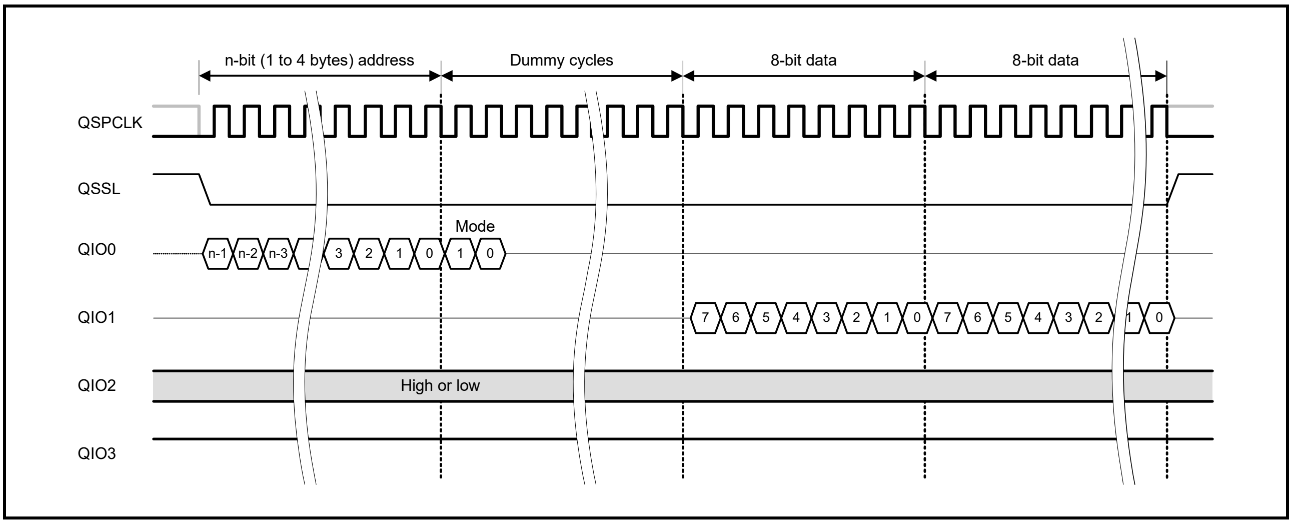

Figure 39.18 Fast Read bus cycle in XIP mode

Note: To use the Fast Read instruction, a serial flash device that supports Fast Read transfers is required.

39.6.4 Fast Read Dual Output Instruction

The Fast Read Dual Output instruction is a read instruction that uses two signal lines to receive data. When the SPI bus cycle starts, the serial flash select signal is asserted. The instruction code (3Bh/3Ch) and an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, are transmitted from the QIO0 pin. Next, a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then received through the QIO0 and QIO1 pins. Even bit data is received from the QIO0 pin and odd bit data is received from the QIO1 pin.

The first two dummy cycles are used to select or deselect the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 39.8, XIP Control.

Switching to Fast Read Dual Output is controlled in the SFMSMD register.

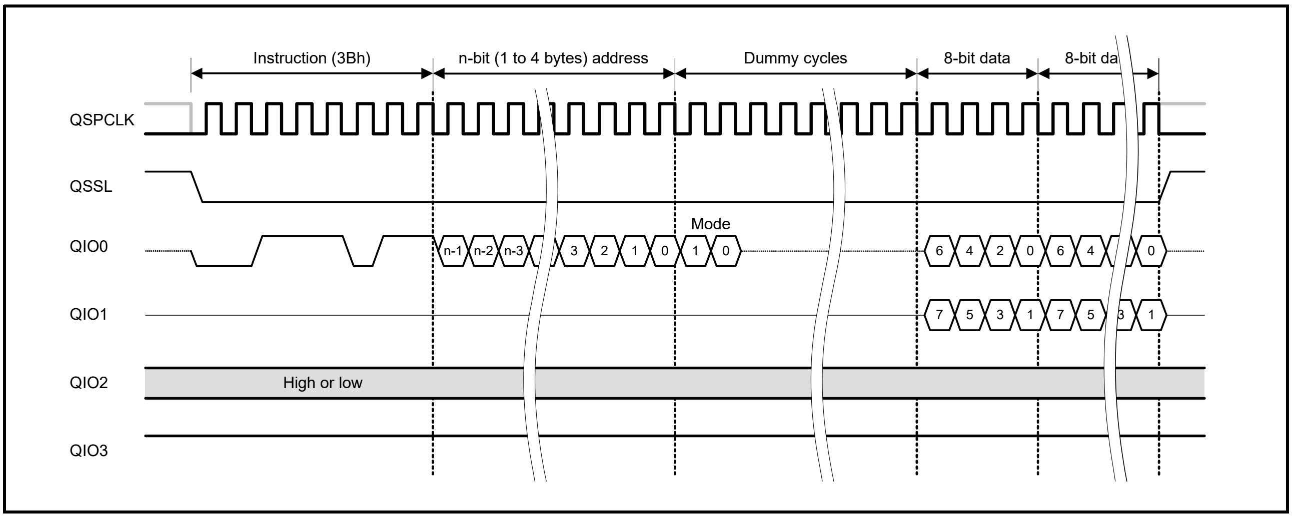

Figure 39.19 Fast Read Dual Output bus cycle

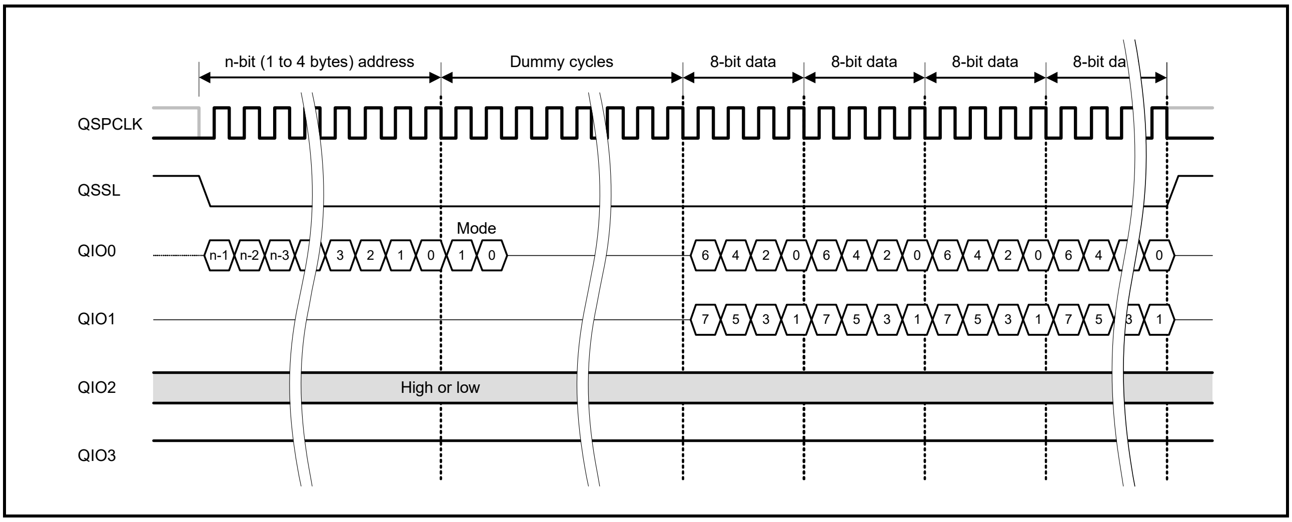

Figure 39.20 Fast Read Dual Output bus cycle in XIP mode

Note: To use the Fast Read Dual Output instruction, a serial flash device that supports Fast Read Dual Output transfers is required.

39.6.5 Fast Read Dual I/O Instruction

The Fast Read Dual I/O instruction is a read instruction that uses two signal lines to transmit an address and receive data. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (BBh/BCh) is output from the QIO0 pin. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0 and QIO1 pins, and a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then is received through the QIO0 and QIO1 pins. Address and dummy cycle transmission and data reception are performed through the QIO0 pin for even bits and through the QIO1 pin for odd bits.

The first two dummy cycles are used to select or deselect the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 39.8, XIP Control.

Switching to Fast Read Dual I/O is controlled in the SFMSMD register.

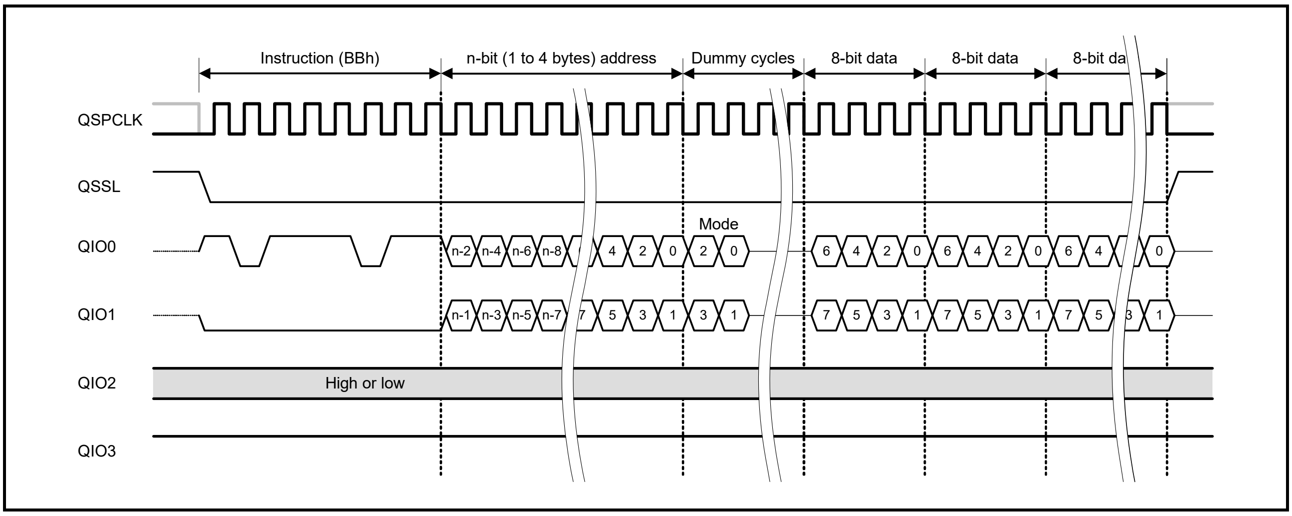

Figure 39.21 Fast Read Dual I/O bus cycle

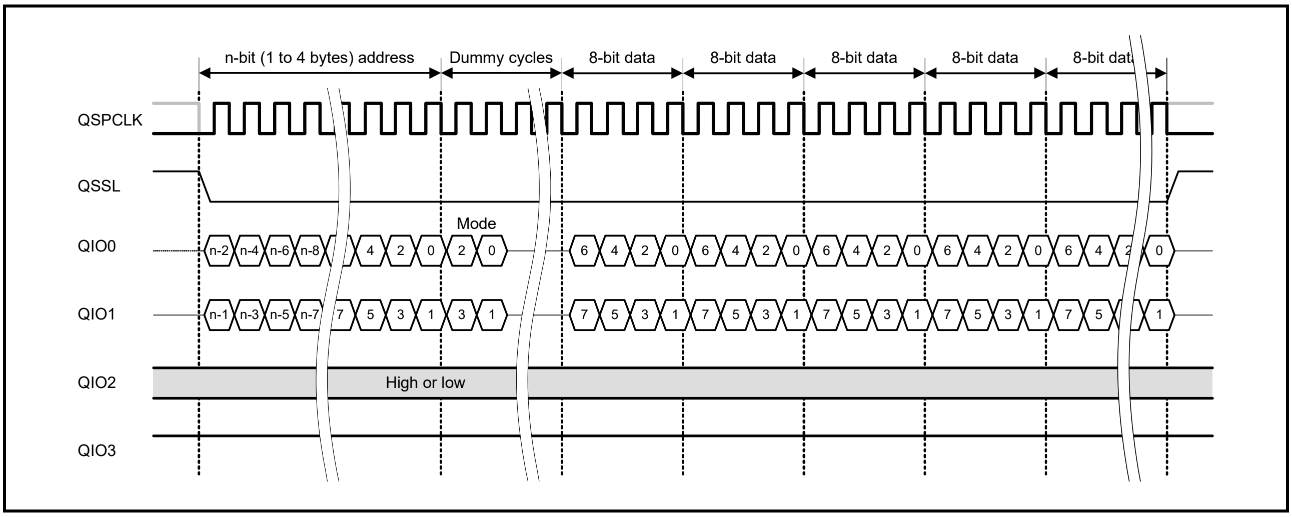

Figure 39.22 Fast Read Dual I/O bus cycle in XIP mode

Note: To use the Fast Read Dual I/O instruction, a serial flash device that supports Fast Read Dual I/O transfers is required.

39.6.6 Fast Read Quad Output Instruction

The Fast Read Quad Output instruction is a read instruction that uses four signal lines to receive data. When the SPI bus cycle starts, the serial flash select signal is asserted. The instruction code (6Bh/6Ch) and an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, are output from the QIO0 pin. Next, a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSMD register, are generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select or deselect the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 39.8, XIP Control.

Switching to Fast Read Quad Output is controlled in the SFMSMD register.

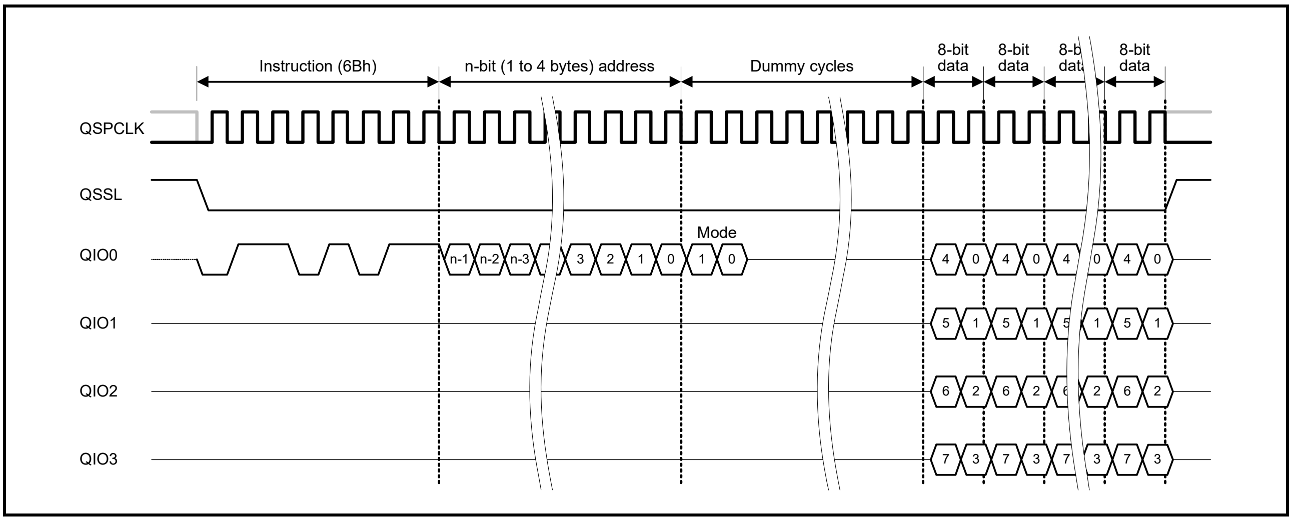

Figure 39.23 Fast Read Quad Output bus cycle

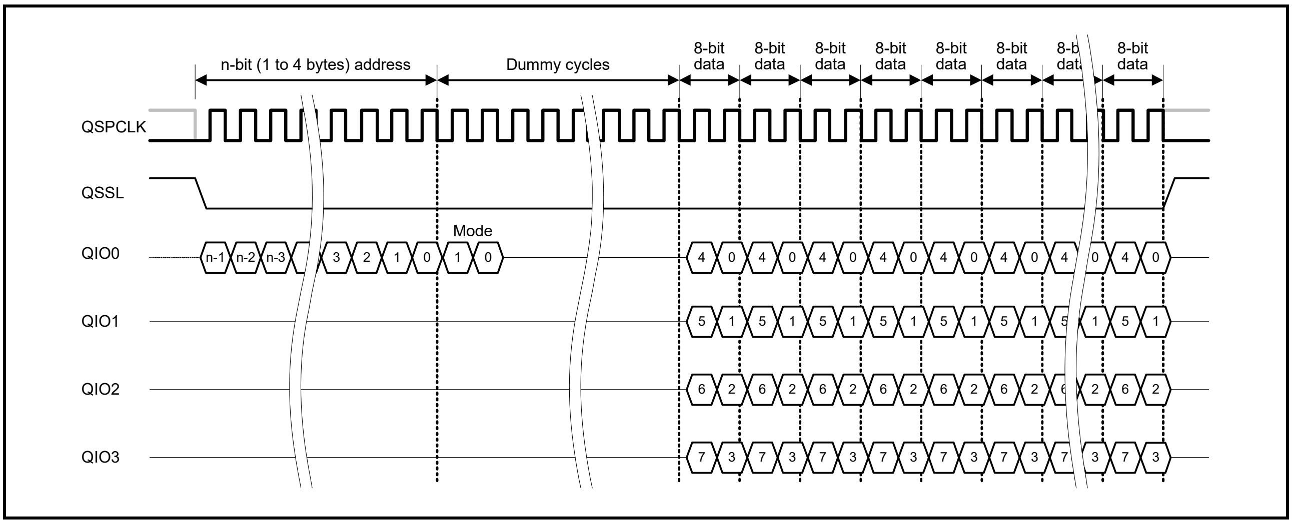

Figure 39.24 Fast Read Quad Output bus cycle in XIP mode

Note: To use Fast Read Quad Output, a serial flash that supports Fast Read Quad Output transfer is required.

39.6.7 Fast Read Quad I/O Instruction

The Fast Read Quad I/O instruction is a read instruction that uses four signal lines to transmit an address and receive data. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (EBh/ECh) is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0, QIO1, QIO2, and QIO3 pins, and a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSMD register, is generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select or deselect the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 39.8, XIP Control.

Switching to Fast Read Quad I/O is controlled in the SFMSMD register.

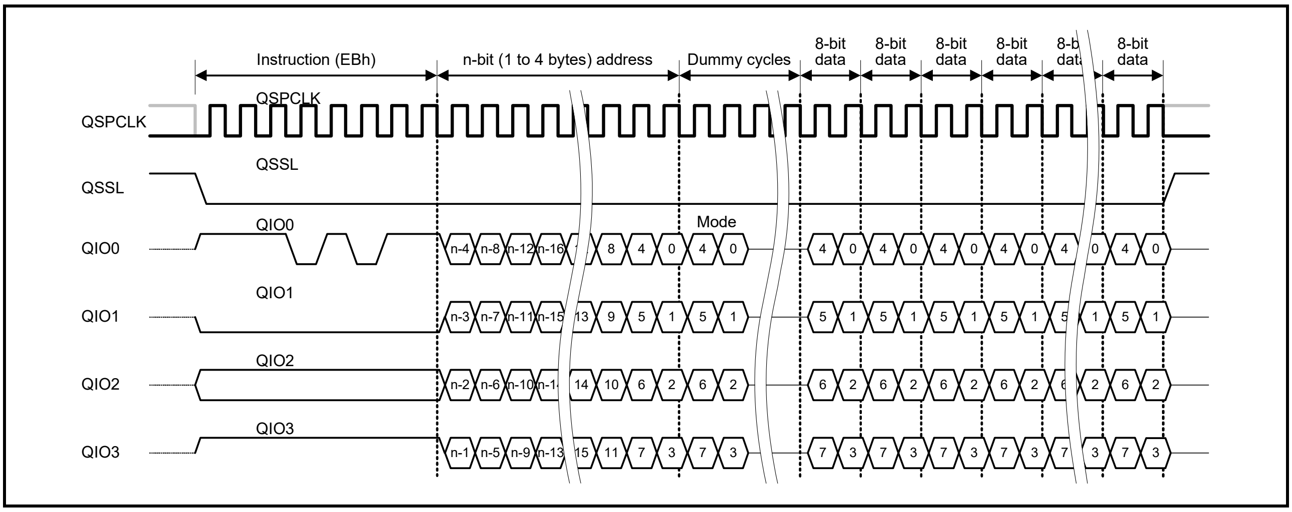

Figure 39.25 Fast Read Quad I/O bus cycle

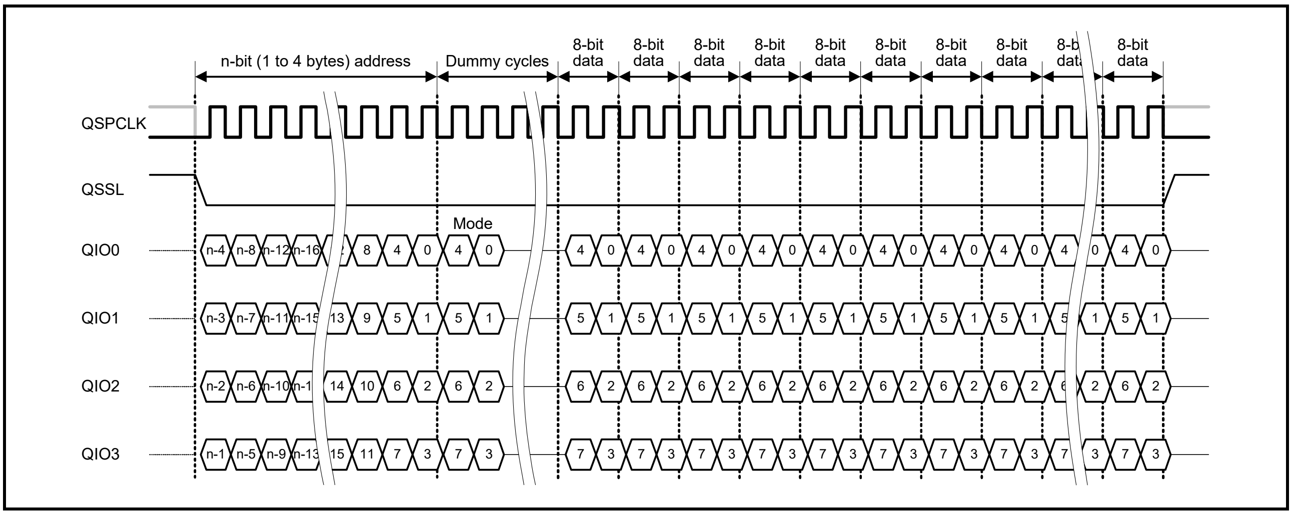

Figure 39.26 Fast Read Quad I/O bus cycle in XIP mode

Note: To use the Fast Read Quad I/O instruction, a serial flash device that supports Fast Read Quad I/O transfers is required.

39.6.8 Enter 4-Byte Mode Instruction

The Enter 4-Byte Mode instruction sets the serial flash address width to 4 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (B7h) is output.

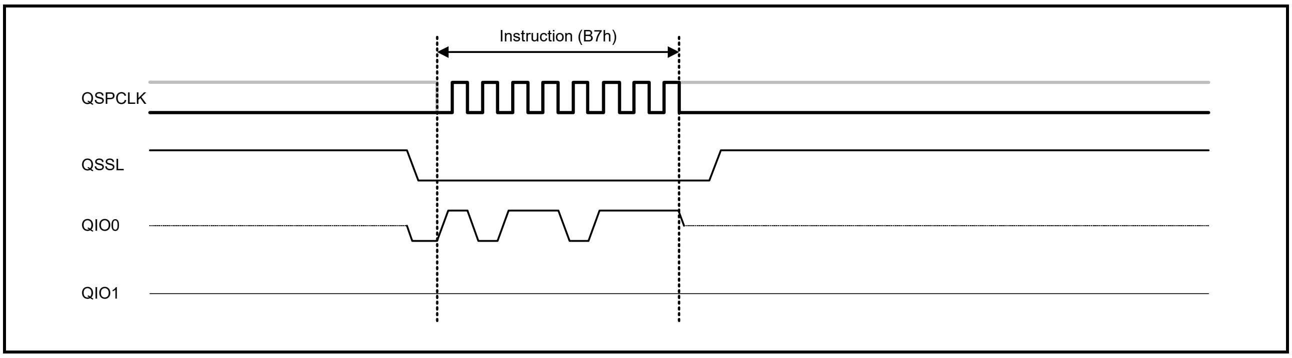

Figure 39.27 Enter 4-Byte Mode bus cycle

Note: The Enter 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

39.6.9 Exit 4-Byte Mode Instruction

The Exit 4-Byte Mode instruction sets the serial flash address width to 3 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (E9h) is output.

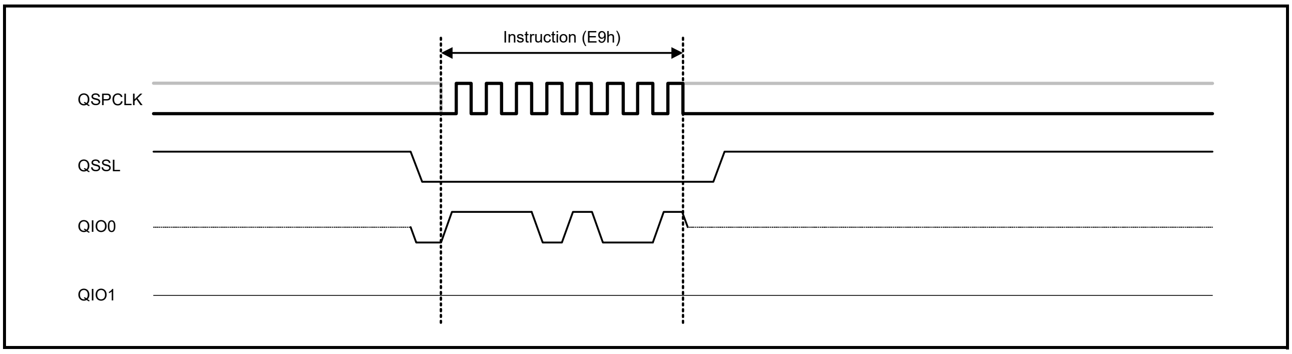

Figure 39.28 Exit 4-Byte Mode bus cycle

Note: The Exit 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

39.6.10 Write Enable Instruction

The Write Enable instruction enables changing of the serial flash address width. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (06h) is output.

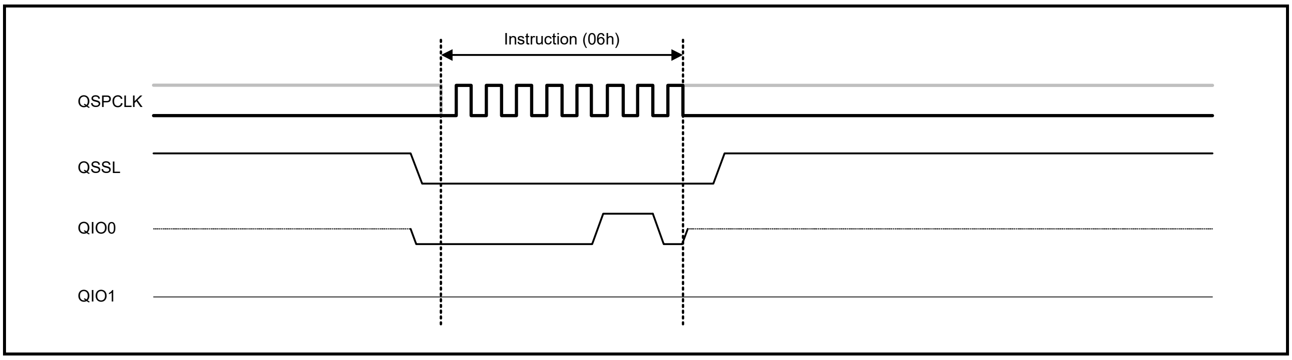

Figure 39.29 Write Enable bus cycle

39.7 SPI Bus Cycle Arrangement

39.7.1 Flash Read Based on Individual Conversion

ROM read internal bus cycles are individually converted to SPI bus cycles on a one-to-one basis. When a ROM read bus cycle is detected, the QSSL signal is asserted, and an SPI bus cycle starts. When data is received from the serial flash, the QSSL signal is deasserted, and the SPI bus cycle is complete.

When another ROM read bus cycle is detected, the QSSL signal is reasserted after ensuring the minimum high-level width of the QSSL signal is reached. Then another SPI bus cycle starts.

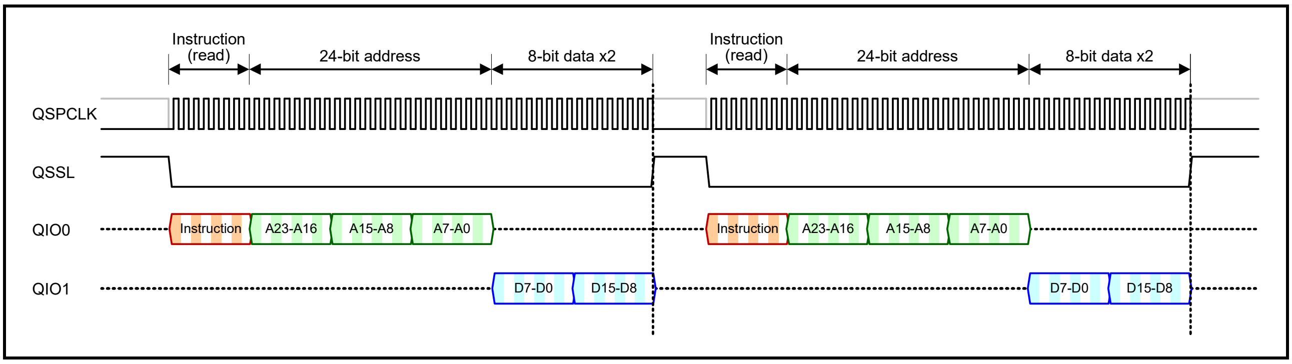

Figure 39.30 **Successive data read operations based on individual conversion**

39.7.2 Flash Read Using the Prefetch Function

In operations such as CPU instruction execution and block data transfer, data is often read in ascending order from contiguous flash addresses. Serial flash provides the ability to repeat data reception without reissuing an instruction code and address. However, if bus cycles issued by the MCU are individually converted, SPI bus cycles are separated from each other, resulting in a failure to take advantage of this feature of serial flash. The QSPI contains a prefetch function to ensure the use of this capability.

To enable the prefetch function, set the SFMPFE bit in the SFMSMD register to 1. When the prefetch function is enabled, data is received continuously and stored in the buffer, without waiting for another flash read request. When the MCU performs a flash read operation, an address check is made. If an address match is confirmed, the data in the buffer is passed to the MCU. If an address mismatch is found, the data in the buffer is discarded, and a new SPI bus cycle is issued.

The buffer for prefetching is 18 bytes long. When this buffer is full, the SPI bus cycle is ended. When the buffer data is read to create free space, a new SPI bus cycle is automatically started to resume prefetching.

The prefetch function allows for efficient transfer operations when data is read in ascending order from contiguous addresses, as in instruction fetch and block data transfer.

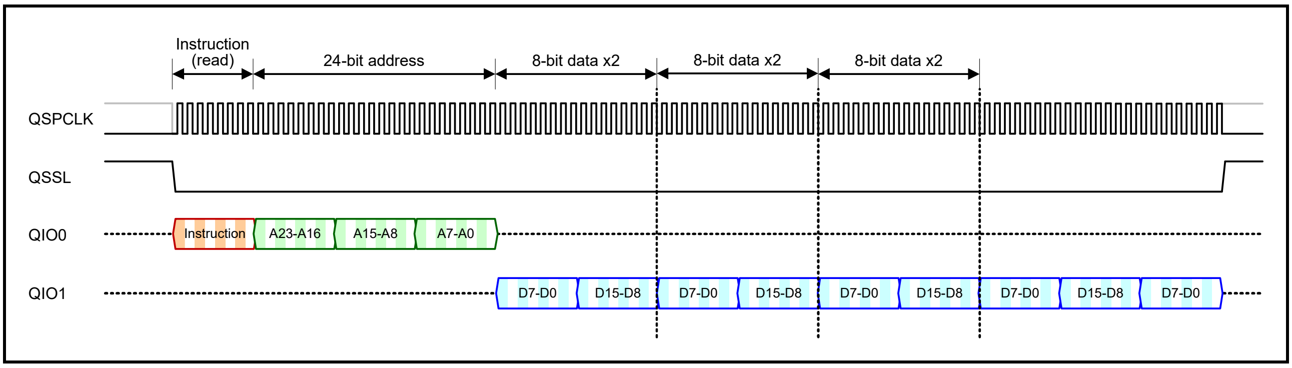

Figure 39.31 **Successive data read operations using the prefetch function**

39.7.3 Halt of Prefetching

If a ROM read bus cycle for reading from another address occurs during a serial transfer for prefetching, the unnecessary serial transfer being made is halted and a new SPI bus cycle is started. Usually, such a halt of serial transfer occurs on data reception byte boundaries. However, if the SFMPAE bit in the SFMSMD register is set to 1, the halt can occur on locations other than byte boundaries. To use this function, the serial flash device must support halts not on byte boundaries.

39.7.4 Direct Specification of Prefetch Destination

When the SFMPFE bit is set and the QSPI receives internal bus write access to the QSPI window area, the system obtains it as a prefetch address and starts to prefetch. Internal bus write access to the QSPI window area can only be used to obtain prefetch address data. Writes to serial flash cannot be performed.

Combining this function with the prefetch state polling function described in section 39, Prefetch State Polling, can reduce the load on the internal bus when data is read from a low-speed serial flash.

Note: When writing to the QSPI window area to indicate a prefetch destination, write to the first byte of the address where prefetching is to be started. Writes to the QSPI window area with a data size of 2 bytes or more return an ERROR response.

39.7.5 Prefetch State Polling

Reading data from a low-speed serial flash increases system load, because the internal bus enters a wait state until the SPI reception bus cycle is complete. The prefetch state polling function is provided to reduce this load.

The PFOFF bit in the SFMSST register indicates the state of the prefetch function, and the PFCNT[4:0] bits in the SFMSST register indicate the number of data bytes already prefetched. This allows the prefetch status to be determined with a single CPU operation.

```
//
// copy 1K byte (32bit x 256 word) data from serial flash to SDRAM
//
unsigned long *sptr;                    // pointer for the serial flash
unsigned long *dptr;                    // pointer for the SDRAM
int i;

SFMSMD |= 0x0040;                        // set SFMPFE bit to enable prefetch
*( (volatile unsigned char *) sptr ) = 0;    // make the TAG valid to start prefetch

for ( i = 0 ; i < 256 ; i++ ){
while ( ( SFMSST & 0x00FF ) < 0x04 ){};   // waiting for 4-byte data to be received
*(dptr++) = *(sptr++);
}
```

Note: When executing a polling program, place the program outside of the serial flash or enable the instruction cache. If the polling program is executed when the program is on the serial flash or is executed without using the instruction cache, the prefetch target frequently switches to an instruction code. This eliminates the effect of polling, and an infinite loop can result because the prefetch buffer is not filled.

39.7.6 Flash Read Using the SPI Bus Cycle Extension Function

If the SFMSE[1:0] bits in the SFMSMD register are set to a value other than 00b, the QSPI waits for next flash read, suspending the SPI bus cycle, while stopping the QSPCLK signal and holding the QSSL signal low even after data is obtained from the serial flash.

If the address of the next flash read is contiguous in ascending order, the toggling of the QSPCLK signal is restarted to continue reception of subsequent data. If the address of the next flash read is not contiguous in ascending order, the QSSL signal is driven high once to end the SPI bus cycle being suspended. A new SPI bus cycle is then started.

When data is read intermittently from ascending order contiguous addresses, this function enables an efficient transfer operation to be performed by reducing the overhead for instruction code and address transmission.

The SPI bus cycle extension time is selectable in the SFMSE[1:0] bits in the SFMSMD register. When the specified extension time elapses, the QSSL signal returns to the high level to automatically end the SPI bus cycle being suspended. If the SFMSE[1:0] bits are set to 11b, QSSL is extended infinitely. This increases the power consumption of the serial flash, so the system must be designed accordingly.

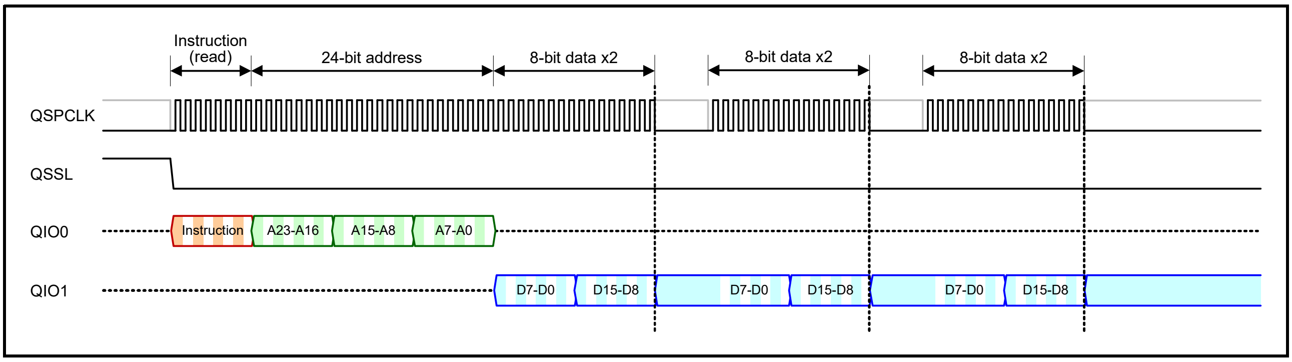

Figure 39.32 Successive data read operations using the SPI bus cycle extension

39.8 XIP Control

Some serial flash devices allow latencies to be reduced by skipping instruction code reception for flash reads. This instruction code skip function is selected in mode data received during the dummy cycle period of the previous serial bus cycle.

In the dummy cycle of the Fast Read instructions, the QSPI controls the XIP mode of the serial flash by using the serial data signal to send the mode data set in the SFMXD[7:0] bits in the SFMSDC register during the first 2 cycles, as shown in Figure 39.33.

The mode data to enable the XIP mode differs for each serial flash. Accordingly, set the appropriate mode data in the SFMXD[7:0] bits.

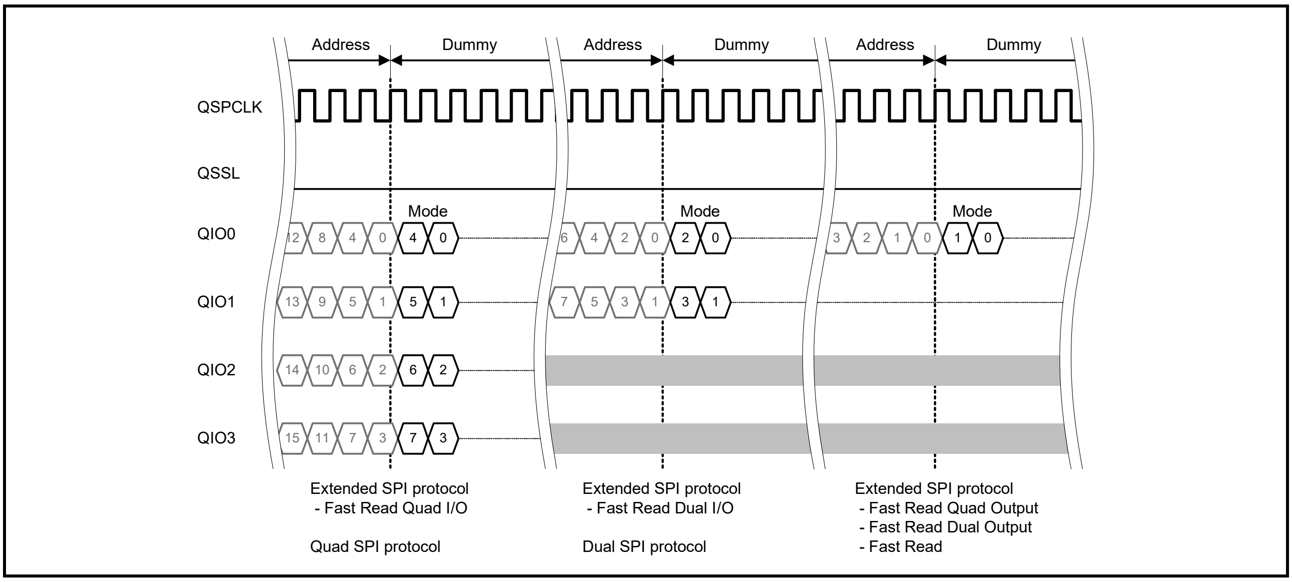

Figure 39.33 XIP mode control data

39.8.1 Selecting the XIP Mode

To select the XIP mode, specify the XIP mode configuration for the serial flash device in the SFMXD[7:0] bits in the SFMSDC register, and set the SFMXEN bit to 1. In the dummy cycle of the next Fast Read instruction, the mode data specified in the SFMXD[7:0] bits is transferred to the serial flash device. From that point, the XIP mode is enabled in both the serial flash controller and the serial flash device. To confirm completion of the XIP mode select procedure, read 1 from the SFMXST bit in the SFMSDC register.

Note: Set the SFMXD[7:0] bits in the SFMSDC register to the XIP mode setting data specified for the actual serial flash device. The XIP mode of the serial flash controller is only enabled in the SFMXEN bit, regardless of the SFMXD[7:0] setting in the SFMSDC register.

39.8.2 Releasing the XIP Mode

To release the XIP mode, specify the release configuration for the serial flash in the SFMXD[7:0] bits in the SFMSDC register, and clear the SFMXEN bit to 0. In the dummy cycle of the next Fast Read instruction, the mode data specified in the SFMXD[7:0] bits is transferred to the serial flash during the first two-cycle period. From that point, the XIP mode is disabled in both the QSPI and the serial flash device. To confirm completion of the XIP mode release procedure, read 0 from the SFMXST bit in the SFMSDC register

Note: Set the SFMXD[7:0] bits in the SFMSDC register to the XIP mode setting data specified for the actual serial flash device. The XIP mode of the serial flash controller is only disabled in the SFMXEN bit, regardless of the SFMXD[7:0] setting in the SFMSDC register.

39.9 QIO2 and QIO3 Pin States

The QIO2 and QIO3 pin states depend on the serial interface read mode specified in the SFMRM[2:0] bits in the SFMSMD register.

Table 39.9 QIO2 and QIO3 pin states

SFMSMD.SFMRM[2:0] bits	QIO2 pin state[1]	QIO3 pin state[2]	Remarks
111	Setting prohibited		
110			
101	Input or output as a serial data signal (standby level is Hi-Z)	Input or output as serial data signal (standby level is Hi-Z)	Fast Read Quad I/O
100			Fast Read Quad Output
011	Output SFMWPL bit variable of SFMPMD register (initial output variable is low level)	Output high level	Fast Read Dual I/O
010			Fast Read Dual Output
001			Fast Read
000			Read (Initial State)

Note 1. The serial flash can also use the QIO2 pin for the WP function.
Note 2. The serial flash can also use the QIO3 pin for the HOLD or RESET function.

39.10 Direct Communication Mode

39.10.1 About Direct Communication

The QSPI can read the serial flash contents by automatically converting a ROM read bus cycle to an SPI bus cycle. However, serial flash devices have many different functions in addition to memory data read, including ID information read, erase, programming, and status information read. There is no standardized instruction set for using these functions, and more functions are being added rapidly by different vendors to different devices. It is difficult to support these functions by hardware control.

The QSPI flexibly supports these serial flash devices by providing a means for the software to directly communicate with the serial flash, so that the software can create any SPI bus cycle required.

39.10.2 Using Direct Communication Mode

To communicate directly with serial flash, transition to direct communication mode by setting the DCOM bit in the SFMCMD register to 1. While direct communication mode is selected, ordinary flash read operation is disabled. For ordinary flash access after direct communication, terminate direct communication mode by setting the DCOM bit in the SFMCMD register to 0.

Note: If the QSPI is set to the XIP mode, you must terminate the XIP mode before starting direct communication mode.

39.10.3 Generating the SPI Bus Cycle during Direct Communication

The SPI bus cycle in direct communication starts on the first access to the SFMCOM port and ends with a write to the SFMCMD register, after a series of I/O operations is performed through the SFMCOM port. At that point, a write to the SFMCOM port is converted to a one-byte transmission to the SPI bus, and a read from the SFMCOM port is converted to a one-byte reception from the SPI bus.

During the period from the first access to the SFMCOM port to the last write operation to the SFMCMD register, the serial flash select signal is held active to notify the serial flash that a series of SPI bus cycles is in progress.

Note: In direct communication mode, all writes to registers other than SFMCMD (including SFMSMD, SFMSSC, SFMSKC, SFMSST, SFMCST, SFMSIC, SFMSAC, SFMSDC, SFMSPC, and SFMPMD) are disabled. With this circuit configuration, writing to a register area other than the SFMCOM port terminates the SPI bus cycle. However, do not write to a register area other than SFMCMD as a way to terminate the SPI bus cycle. This operation is not guaranteed as a normal function.

The following is an example program for direct communication.

```
//### CAUTION! ### This code must be outside the serial flash that is going to be controlled.

// Define specific instruction codes of the target serial flash device.
#define  Instruction_FREAD  0x0B // Fast Read
#define  Instruction_RDSR   0x05 // Read Status register
#define  Instruction_RDID   0x9F // Read Identification
#define  Instruction_WREN   0x06 // Write Enable
#define  Instruction_CERA   0xC7 // Chip Erase

unsigned char  mfid, mtype, mcap, data, temp;

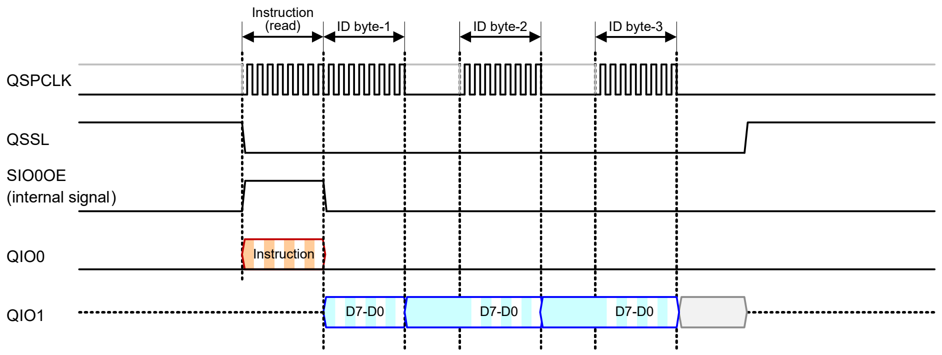
SFMCMD = 0x01; // Enable direct operation

// Get the device identification assigned by JEDEC.
SFMCOM = Instruction_RDID; // put “Read Identification” instruction (open SPI bus cycle)
mfid   = (unsigned char) SFMCOM; // get “Manufacturer Identification”
mtype  = (unsigned char) SFMCOM; // get “Memory Type”
mcap   = (unsigned char) SFMCOM; // get “Memory Capacity”
SFMCMD = 0x01h; // close SPI bus cycle

// Get one byte from the address 0x012345h.
SFMCOM = Instruction_FREAD; // put “Fast Read” instruction (open SPI bus cycle)
SFMCOM = 0x01; // put upper byte of the address 0x012345
SFMCOM = 0x23; // put middle byte of the target address 0x012345
SFMCOM = 0x45; // put lower byte of the target address 0x012345
temp   = (unsigned char) SFMCOM; // get one byte dummy code for FAST READ transaction
data   = (unsigned char) SFMCOM; // get the data
SFMCMD = 0x01; // close SPI bus cycle

// Erase All contents.
SFMCOM = Instruction_WREN; // put “Write Enable” instruction (open SPI bus cycle)
SFMCMD = 0x01; // close SPI bus cycle
SFMCOM = Instruction_CERA; // put “Chip Erase” instruction (open SPI bus cycle)
SFMCMD = 0x01; // close SPI bus cycle
SFMCOM = Instruction_RDSR; // put “Read Status Register” instruction (open SPI bus cycle)
while (SFMCOM & 0x01){}; // Polling “Write Progress Bit” until completion
SFMCMD = 0x01; // close SPI bus cycle

SFMCMD = 0x00; // Disable direct operation
```



```
(1)  SFMCMD = 01h;                    // Enable direct operation
                                      // Get the device identification assigned by JEDEC
(2)  SFMCOM = Instruction_RDID;       // Put “Read Identification” instruction (open the transaction)
(3)  mfid = (unsigned char) SFMCOM;   // Get ID byte-1 “Manufacturer Identification”
(4)  mtype = (unsigned char)          // Get ID byte-2 “Memory Type”
     SFMCOM;
(5)  mcap = (unsigned char) SFMCOM;   // Get ID byte-3 “Memory Capacity”
(6)  SFMCMD = 01h;                    // Close the transaction
(7)  SFMCMD = 00h;                    // Disable direct operation
```

Figure 39.34 Example of direct communication timing for ID read

Note: When Extended SPI protocol is used in direct communication mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial flash. The QSPI does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O transfers in this configuration. When these high-speed read operations are required, use ordinary flash access.

39.11 Operation

39.11.1 Procedure for Changing Settings in Multiple Control Registers

The settings of the QSPI control registers can be changed dynamically during system operation. However, when the settings of multiple control registers are changed sequentially, an SPI bus cycle might occur before all of the registers are updated. The register setting sequence must be carefully designed so that the SPI bus timing specification is satisfied at all stages of register setting changes.

```
//
// Making QSPCLK faster
//
SFMSMD = 0x0041; // SFMPAE: 0 SFMPFE: 1 SFMSE:00 SFMRM:01 (prefetch enable fast read)
SFMSSC = 0x04; // SFMSLD: 0 SFMSHD: 0 SFMSW:4 (minimum QSSL high width = 5 sck)
SFMSKC = 0x00; // SFMDTY: 0 SFMDV: 0 (1/2 mode)  ### switch clock speed last ###

//
// Making QSPCLK slower
//
SFMSKC = 0x06; // SFMDTY: 0 SFMDV:6 (1/8 mode)  ### switch clock speed first ###
SFMSSC = 0x01; // SFMSLD: 0 SFMSHD:0 SFMSW: 1 (minimum QSSL high width = 2 sck)
SFMSMD = 0x0040; // SFMPAE: 0 SFMPFE:1 SFMSE: 00 SFMRM:00 (prefetch enable, standard read)
```

39.12 Interrupts

When the EROMR bit in the SFMCST register sets to 1, the QSPI requests an interrupt. The EROMR bit sets to 1 when a ROM read access is detected in direct communication mode. Interrupt requests are retained until the EROMR bit is cleared by a 0 write. For details, see section 14, Interrupt Controller Unit (ICU).

39.13 Usage Notes

39.13.1 Settings for the Module-Stop Function

QSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The QSPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

40. Cyclic Redundancy Check (CRC) Calculator

40.1 Overview

The Cyclic Redundancy Check (CRC) calculator generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB- or MSB-first communication. Additionally, various CRC generation polynomials are available for your application. The snoop function allows monitoring of reads from and writes to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 40.1 lists the CRC calculator specifications and Figure 40.1 shows a block diagram.

Table 40.1 CRC calculator specifications

Parameter	Specifications for 8-bit data	Specifications for 32-bit data
Data size	8-bit	32-bit
Data for CRC calculation[*1]	CRC code generated for data in 8n-bit units (where n is a whole number)	CRC code generated for data in 32n-bit units (where n is a whole number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials selectable [8-bit CRC] • $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] • $X^{16} + X^{15} + X^2 + 1$ (CRC-16) • $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials selectable [32-bit CRC] • $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) • $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB- or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
CRC snoop	Monitor reads from and writes to a certain register address	—

Note 1. The circuit cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

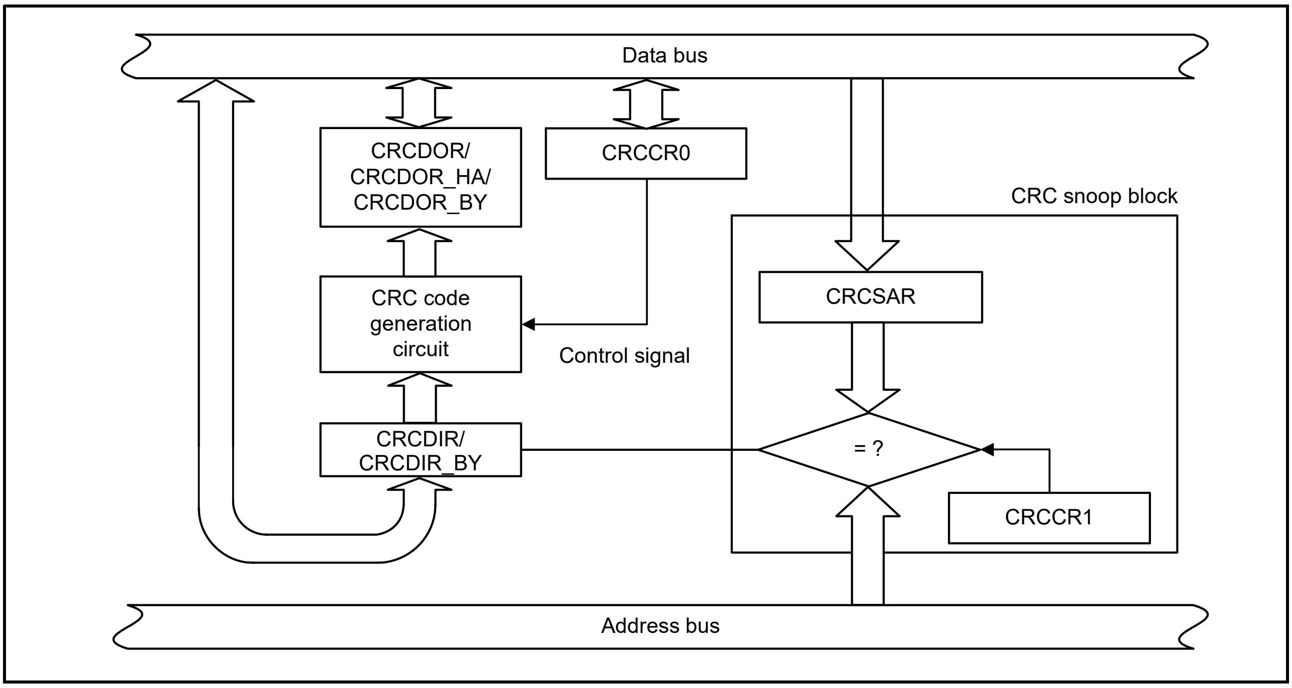


Figure 40.1 CRC calculator block diagram

40.2 Register Descriptions

40.2.1 CRC Control Register 0 (CRCCR0)

Address(es): CRC.CRCCR0 4007 4000h

	b7	b6	b5	b4	b3	b2	b1	b0
	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	GPS[2:0]	CRC Generating Polynomial Switching	b2 b0 0 0 0: Do not calculate 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Other: Do not calculate.	R/W
b5 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	LMS	CRC Calculation Switching	0: Generate CRC for LSB-first communication 1: Generate CRC for MSB-first communication.	R/W
b7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear	1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register. This bit is read as 0.	W*1

Note 1. This bit must always be set to 1 when writing to this register.

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY)

Write 1 to the DORCLR bit to clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0000_0000h. This bit is read as 0. Only 1 can be written.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower-order byte of the CRC code first for LSB-first communication and the higher-order byte first for MSB-first communication. For details on transmitting and receiving CRC code, see section 40.3, Operation.

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

40.2.2 CRC Control Register 1 (CRCCR1)

Address(es): CRC.CRCCR1 4007 4001h

	b7	b6	b5	b4	b3	b2	b1	b0
	CRCSEN	CRCSWR	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	CRCSWR	Snoop-On-Write/Read Switch	0: Snoop-on-read 1: Snoop-on-write.	R/W

Bit	Symbol	Bit name	Description	R/W
b7	CRCSEN	Snoop Enable	0: Disabled 1: Enabled.	R/W

CRCSWR bit (Snoop-On-Write/Read Switch)

The CRCSWR bit selects the direction of the access in the address monitoring function. When the bit is set to 0 (initial value), the CRC snoop operation to read a specific register address is enabled. When the bit is set to 1, the CRC snoop operation to write to a specific register address is enabled.

CRCSEN bit (Snoop Enable)

When the CRCSEN bit is set to 1, CRC snoop operation is enabled. When the bit is set to 0, CRC snoop operation is disabled.

40.2.3 CRC Data Input Register (CRCDIR/CRCDIR_BY)

Address(es): CRC.CRCDIR/CRCDIR_BY 4007 4004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CRCDIR is a 32-bit read/write register to write data to for CRC-32 or CRC-32C calculation. CRCDIR_BY is an 8-bit read/write register to write data to for CRC-8, CRC-16, or CRC-CCITT calculation.

40.2.4 CRC Data Output Register (CRCDOR/CRCDOR_HA/CRCDOR_BY)

Address(es): CRC.CRCDOR/CRCDOR_HA/CRCDOR_BY 4007 4008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CRCDOR is a 32-bit read/write register for CRC-32 or CRC-32C. CRCDOR_HA is a 16-bit read/write register for CRC-16 or CRC-CCITT. CRCDOR_BY is an 8-bit read/write register for CRC-8. Because its initial value is 0000_0000h, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value.

Data written to the CRCDIR/CRCDIR_BY register is CRC-calculated, and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following transferred data and the result is 0000_0000h, there is no CRC error.

When an 8-bit CRC ($X^8 + X^2 + X + 1$ polynomial) is in use, the valid CRC code is obtained in CRCDOR_BY.

When a 16-bit CRC ($X^{16} + X^{15} + X^2 + 1$ or $X^{16} + X^{12} + X^5 + 1$ polynomial) is in use, the valid CRC code is obtained in CRCDOR_HA.

40.2.5 Snoop Address Register (CRCSAR)

Address(es): CRC.CRCSAR 4007 400Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CRCSA[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b13 to b0	CRCSA[13:0]	Register Snoop Address	These bits store the TDR or RDR address in the SCI module to snoop.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CRCSA[13:0] bits (Register Snoop Address)

The CRCSA[13:0] bits specify the lower 14 bits of the register address monitored by the CRC snoop operation. Only the following addresses can be used for the CRCSA[13:0] bits:

- 4007 0003h: SCI0.TDR, 4007 0005h: SCI0.RDR
- 4007 0023h: SCI1.TDR, 4007 0025h: SCI1.RDR
- 4007 0043h: SCI2.TDR, 4007 0045h: SCI2.RDR
- 4007 0063h: SCI3.TDR, 4007 0065h: SCI3.RDR
- 4007 0083h: SCI4.TDR, 4007 0085h: SCI4.RDR
- 4007 00A3h: SCI5.TDR, 4007 00A5h: SCI5.RDR
- 4007 00C3h: SCI6.TDR, 4007 00C5h: SCI6.RDR
- 4007 00E3h: SCI7.TDR, 4007 00E5h: SCI7.RDR
- 4007 0103h: SCI8.TDR, 4007 0105h: SCI8.RDR
- 4007 0123h: SCI9.TDR, 4007 0125h: SCI9.RDR
- 4007 000Fh: SCI0.FTDRL, 4007 0011h: SCI0.FRDRL
- 4007 002Fh: SCI1.FTDRL, 4007 0031h: SCI1.FRDRL
- 4007 004Fh: SCI2.FTDRL, 4007 0051h: SCI2.FRDRL
- 4007 006Fh: SCI3.FTDRL, 4007 0071h: SCI3.FRDRL
- 4007 008Fh: SCI4.FTDRL, 4007 0091h: SCI4.FRDRL
- 4007 00AFh: SCI5.FTDRL, 4007 00B1h: SCI5.FRDRL
- 4007 00CFh: SCI6.FTDRL, 4007 00D1h: SCI6.FRDRL
- 4007 00EFh: SCI7.FTDRL, 4007 00F1h: SCI7.FRDRL
- 4007 010Fh: SCI8.FTDRL, 4007 0111h: SCI8.FRDRL
- 4007 012Fh: SCI9.FTDRL, 4007 0131h: SCI9.FRDRL.

40.3 Operation

40.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB- or MSB-first transfers.

The following examples illustrate CRC code generation for input data (F0h) using the 16-bit CRC-CCITT-generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When an 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

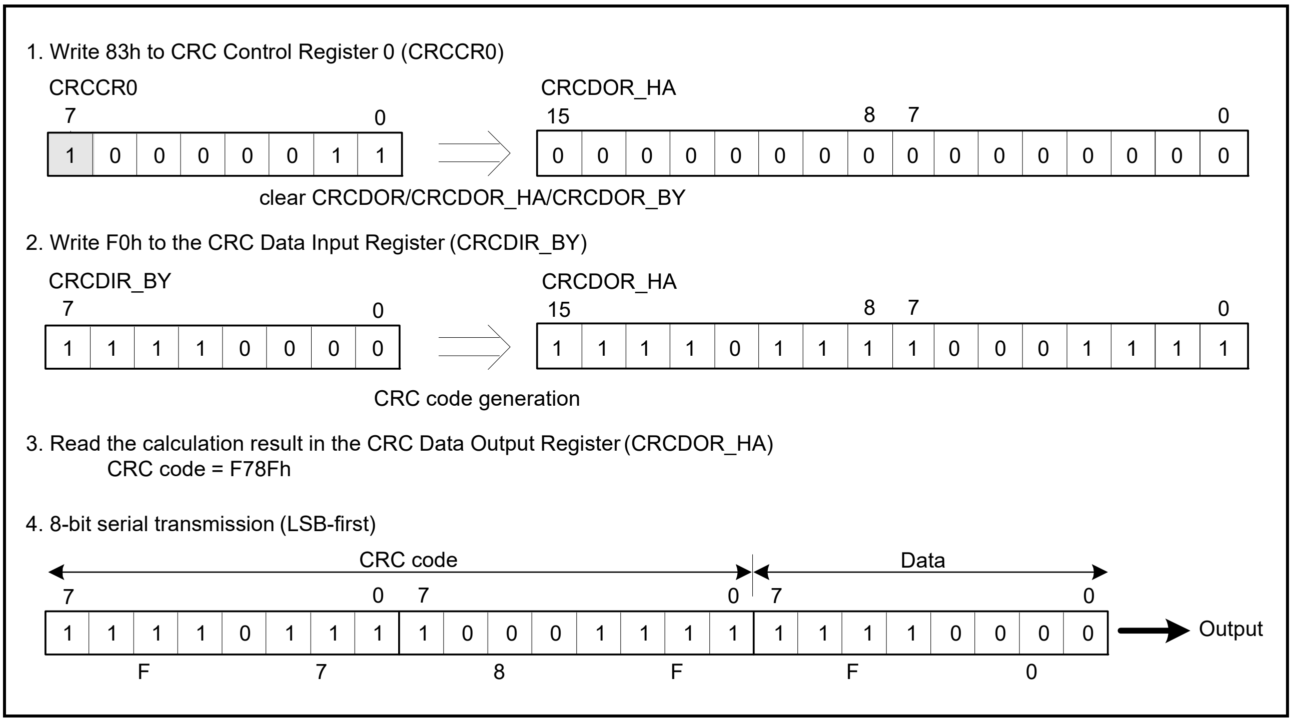

Figure 40.2 LSB-first data transmission

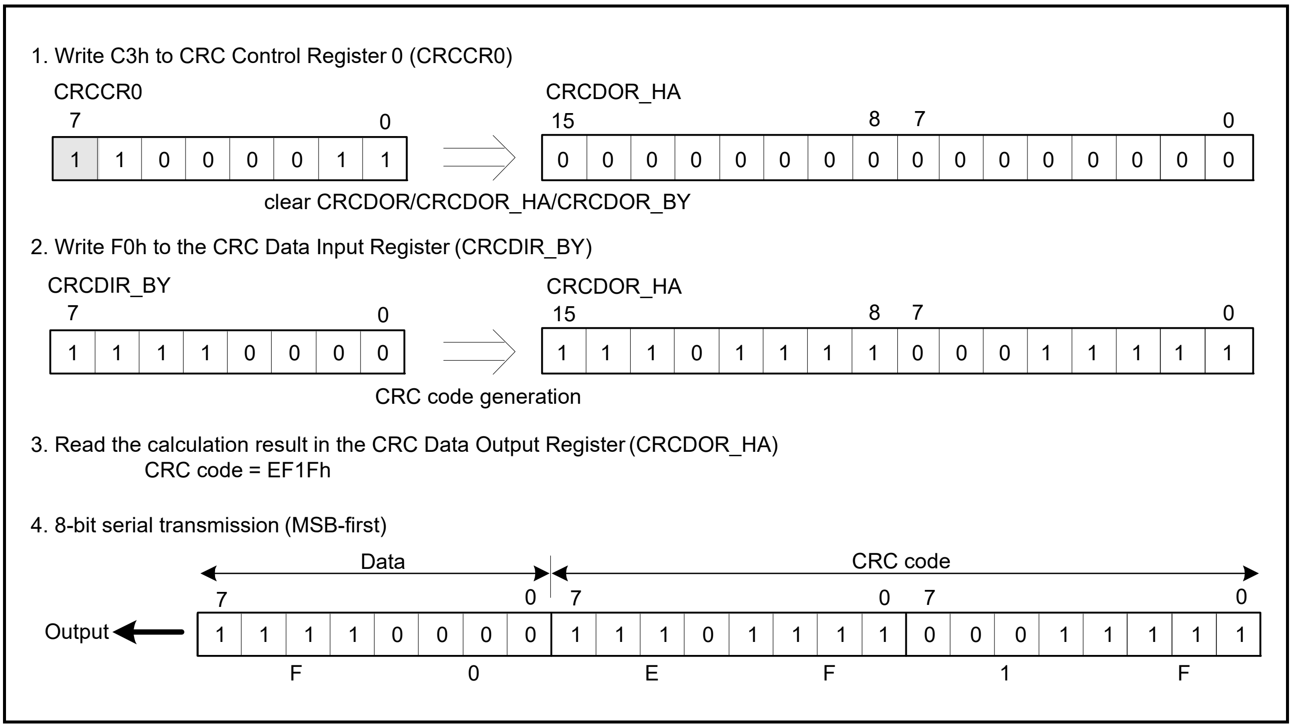

Figure 40.3 MSB-first data transmission

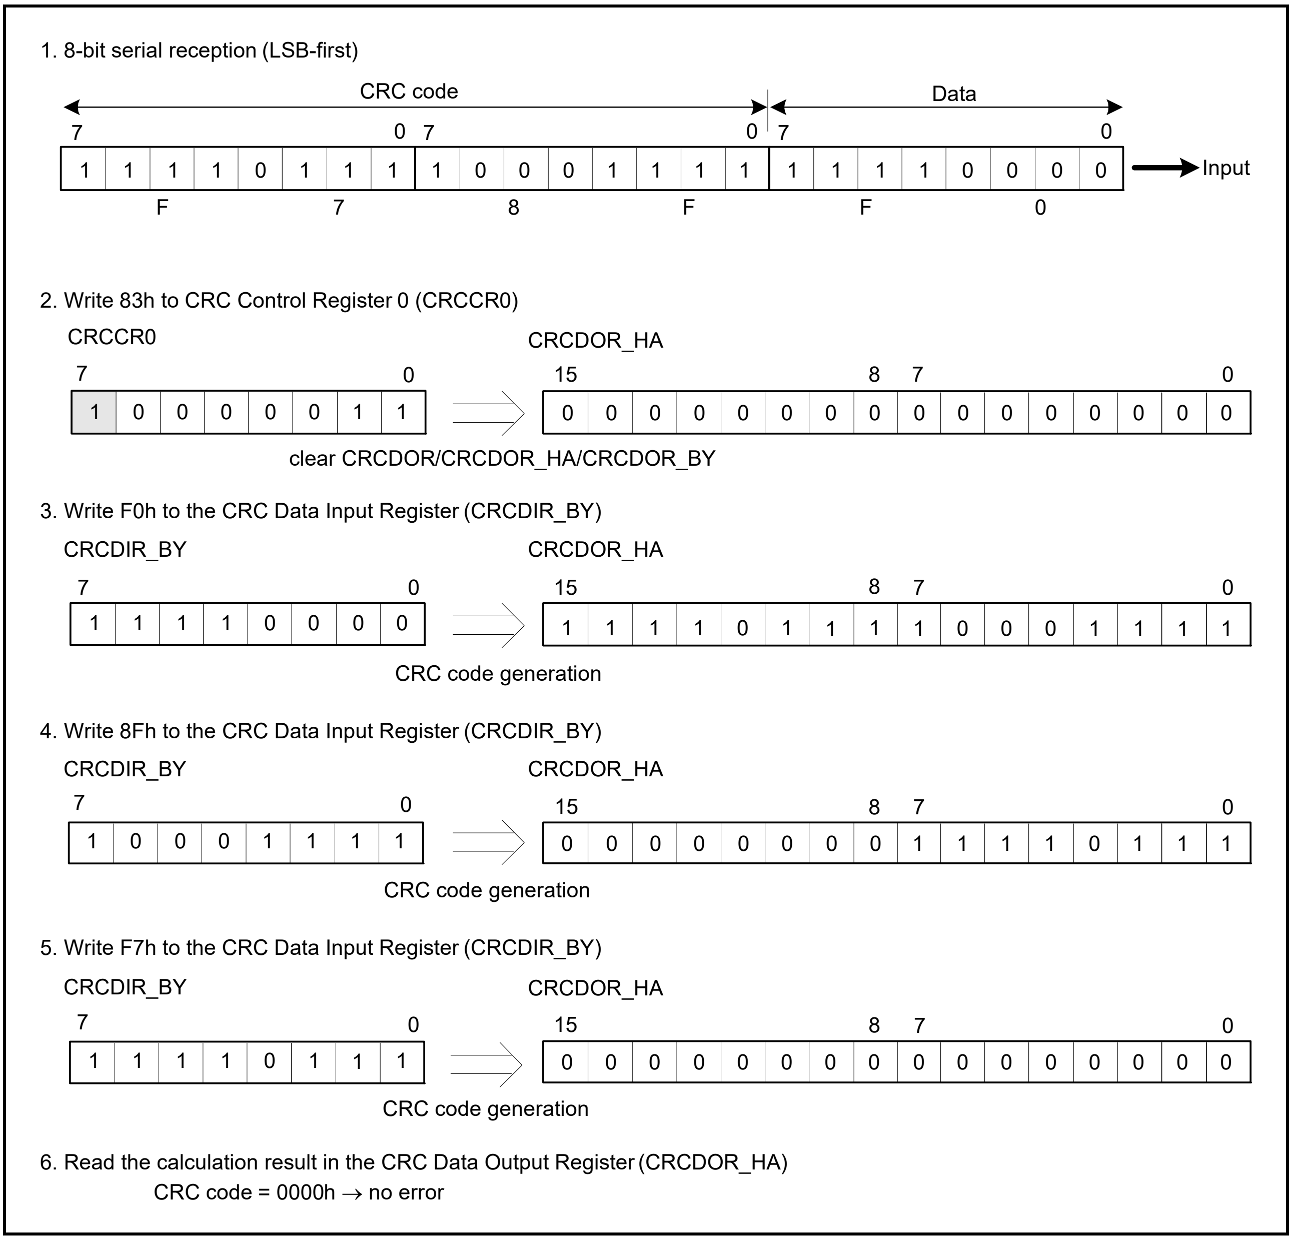

Figure 40.4 LSB-first data reception

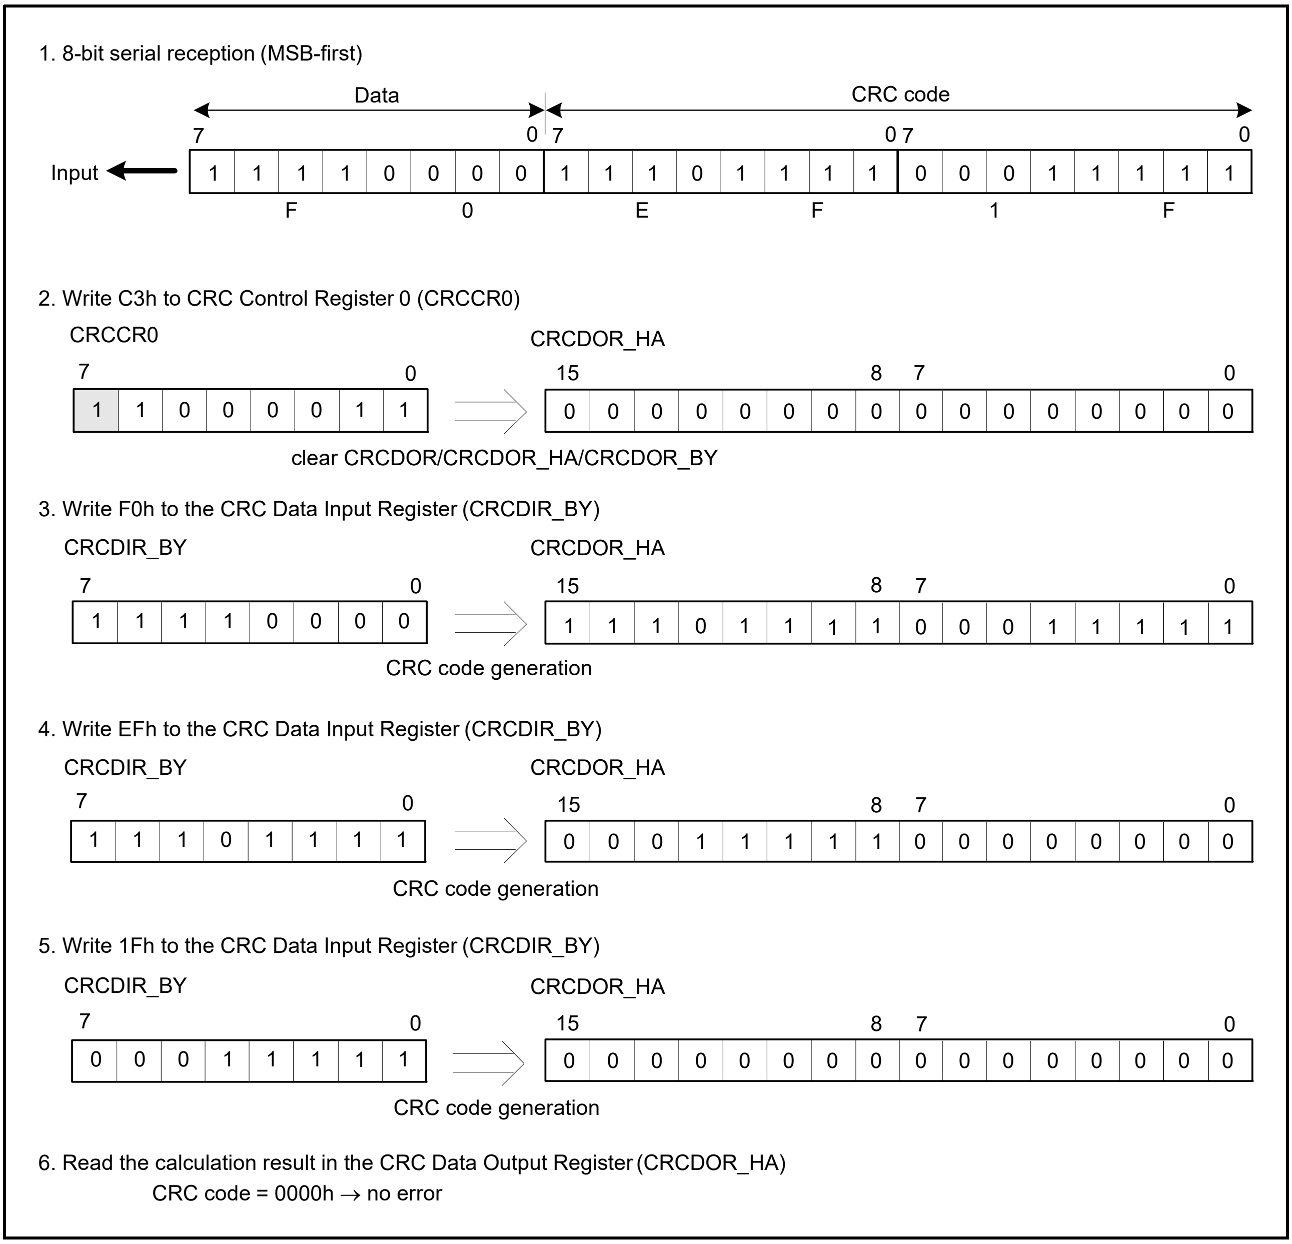

Figure 40.5 MSB-first data reception

40.3.2 CRC Snoop

The CRC snoop function monitors reads from and writes to a specified I/O register address and performs CRC calculation on the data read from and written to the register address automatically. Because the CRC snoop recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, writing data to the CRCDIR_BY register is not required. All I/O register addresses specified in section 40.2.5, Snoop Address Register (CRCSAR) are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the serial transmit buffer, and reads from the serial receive buffer.

To use this function, write a target I/O register address to the CRCSA13 to CRCSA0 bits in the CRCSAR register, and set the CRCSEN bit in the CRCCR1 register to 1. Then set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target address, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target address.

When both the CRCSEN and CRCSWR bits are set to 1 and data is written to a target I/O register address in a bus master module (including the CPU, DMAC, and DTC), the CRC calculator stores the data in the CRCDIR_BY register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1 and the CRCSWR bit to 0, and data is read from a target I/O register address in a bus master module (including the CPU, DMAC, and DTC), the CRC calculator stores the data in the CRCDIR_BY register and performs CRC calculation.

CRC calculation is performed 1 byte at a time. When the target I/O register address is accessed in words (16 bits) or long words (32 bits), CRC code is generated on the lower byte (1 byte) of data.

40.4 Usage Notes

40.4.1 Settings for the Module-Stop Function

CRC calculator operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The CRC calculator is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

40.4.2 Note on Transmission

The transmission sequence for the CRC code differs depending on whether transmission is LSB-first or MSB-first.

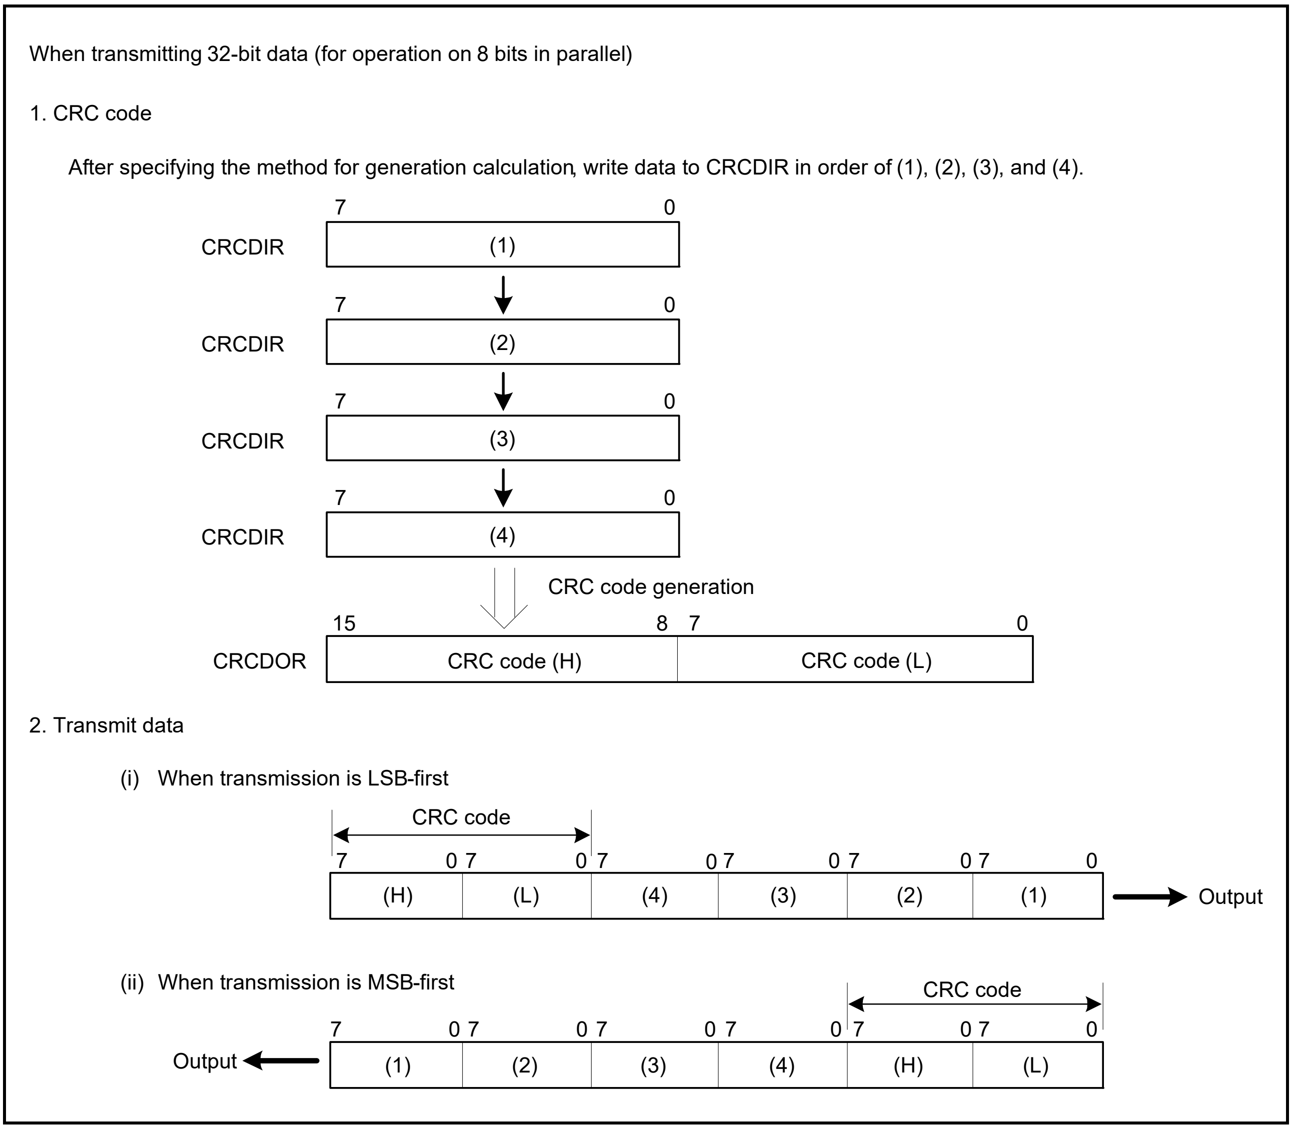

Figure 40.6 LSB-first and MSB-first data transmission

41. Serial Sound Interface Enhanced (SSIE)

41.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as I^2S, monaural, and TDM.

41.2 Features

Table 41.1 Features of SSIE

Parameter		Description
Number of channels		Two channels, SSIE0 and SSIE1
Communication mode		• Master/slave • Transmission/reception(SSIE0 full-duplex communication) • Transmission/reception(SSIE1 half-duplex communication)
Communication format		• I^2S format • Monaural format • TDM format
Serial data		• MSB first • Data can be left-justified or right-justified. • Data delay (1 clock cycle) or no delay selectable for the period from SSILRCK/SSIFS to SSITXD0/SSIRXD0/SSIDATA1 • System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: 8, 16, 18, 20, 22, 24, or 32 bits • Padding polarity: Low or high
Bit clock (SSIBCK)	In master mode	• Two clock sources available (AUDIO_CLK/GPT output (GTIOC1A)) • Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. • Supply/stop is selectable while communication is halted.
	In master/slave mode	• Polarity (rising edge or falling edge) selectable
LR clock/frame synchronization (SSILRCK/SSIFS)	In master mode	• Polarity (low level or high level) selectable • Supply/stop is selectable while communication is halted.
Transmit data (SSITXD0/SSIDATA1) and receive data (SSIRXD0/SSIDATA1)	Transmission	• Muting method (transmission of transmit FIFO data or transmission of data fixed to 0) selectable
FIFO	Capacity	• Transmit FIFO/receive FIFO: 4 bytes × 32 stages
	Data alignment	• Data alignment method (left-justification or right-justification) selectable for the data transfer between FIFO and shift register
Interrupt	Interrupt output	• Communication error/idle mode • Receive data full • Transmit data empty
Low power consumption function		• Whether to supply the audio clock selectable in master mode
Module stop function		• Module stop state can be set to reduce power consumption.

The following table lists and defines the terms used for the communication formats SSIE can use:

Table 41.2 Definition of terms

Term	Definition
Start trigger	First edge of the signal on the SSILRCK/SSIFS pin when the signal is set to the value specified in LRCKP to enable communication
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame

Table 41.2 Definition of terms

Term	Definition
Frame word number	Number of sound channels per frame
System word length	Number of bits per channel
Data word length	Number of significant bits per channel
Control bits for communication formats	• SSICR register: FRM, DWL, SWL, LRCKP, SPDP, SDTA, PDTA, and DEL bits • SSIFCR register: BSW bit • SSIOFR register: OMOD bit • SSISCR register: TDES and RDFS bits

</table>

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

TEN and REN bits (Transmission and Reception Enable)

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK/SSIFS signal. For details, see section 41.8.2 to section 41.8.4. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

MUEN bit (Mute Enable)

This bit sets/clears the mute function for the data output from the SSITXD0/SSIDATA1 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

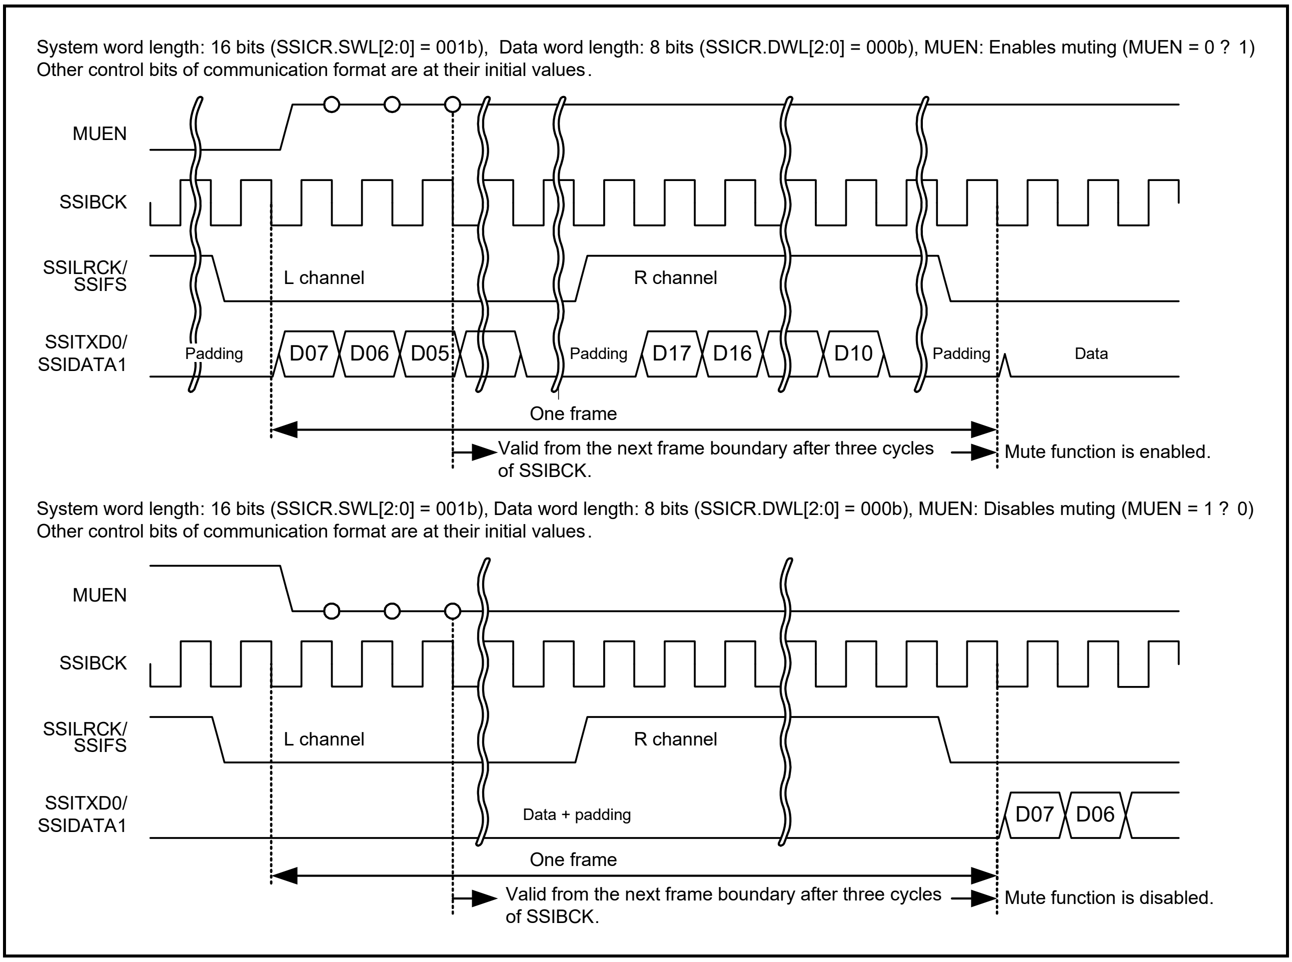

Figure 41.5 Transmit data with the mute function set

CKDV[3:0] bits (Selects Bit Clock Division Ratio)

These bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in SSIFCR.

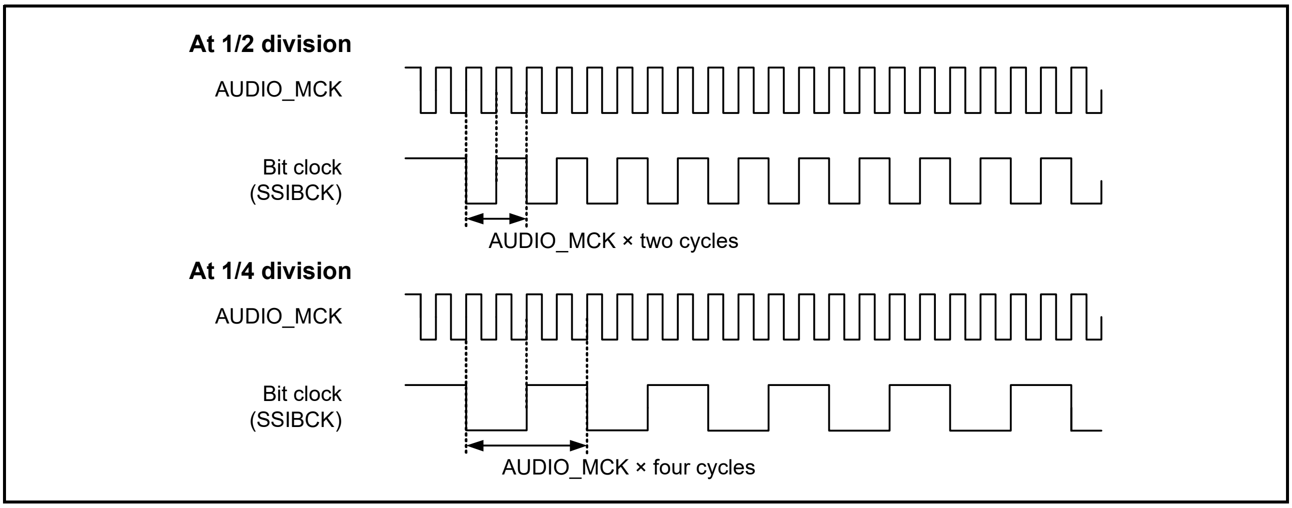

Figure 41.6 Sampling frequencies in master-mode communication

DEL bit (Selects Serial Data Delay)

This bit sets whether or not there will be a delay between SSILRCK/SSIFS and SSITXD0/SSIRXD0/SSIDATA1.

For the I^{2}S or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCK/SSIFS. For details, see section 41.5.2, Monaural Format. When using a compatible communication format, specify a setting of this bit that enables communication.

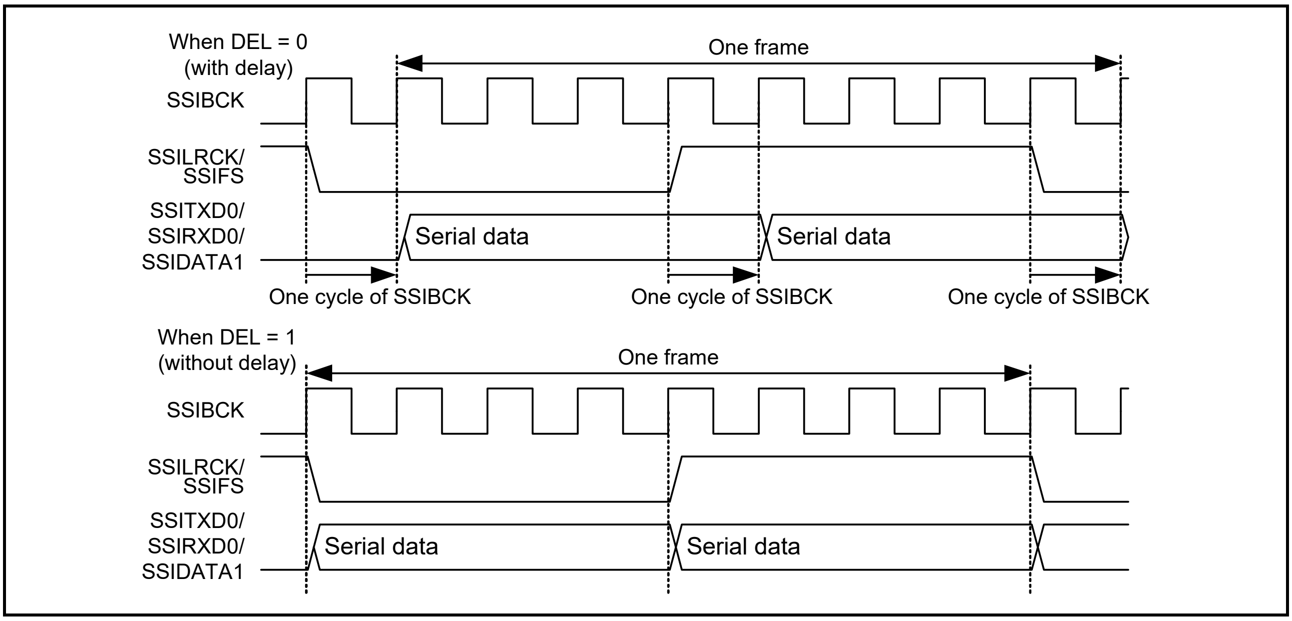

Figure 41.7 Setting of delay in serial data

PDTA bit (Selects Placement Data Alignment)

This bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see Figure 41.8.

111 (Setting prohibited)			

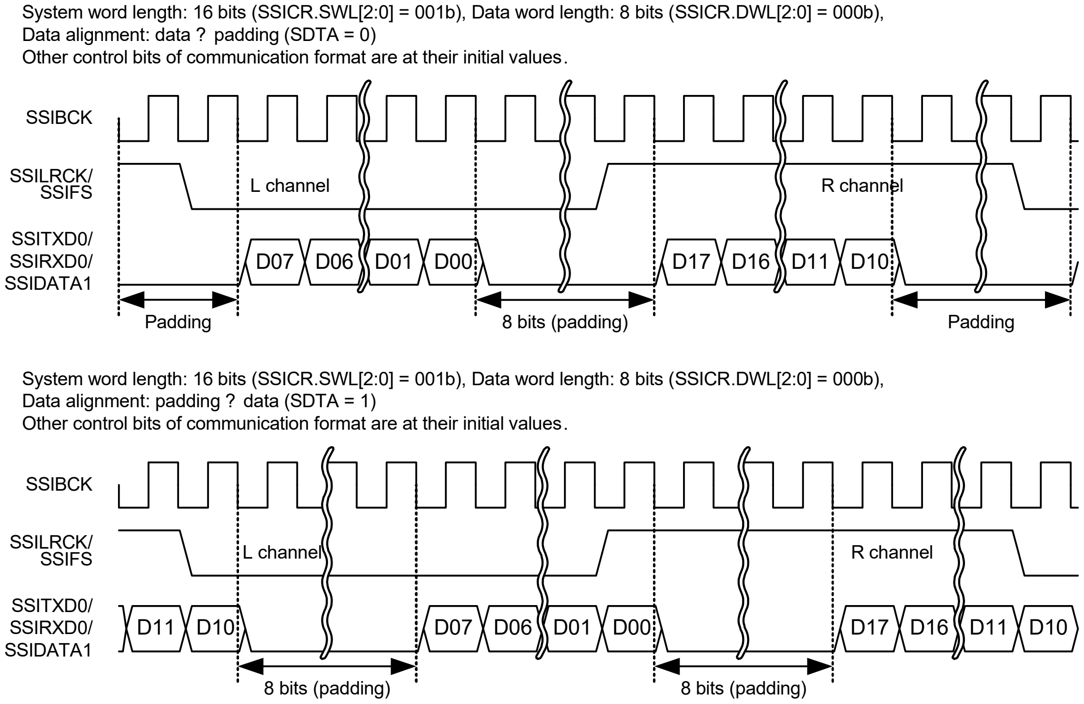
Figure 41.9 Alignment of placement data at reception

SDTA bit (Selects Serial Data Delay)

This bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.



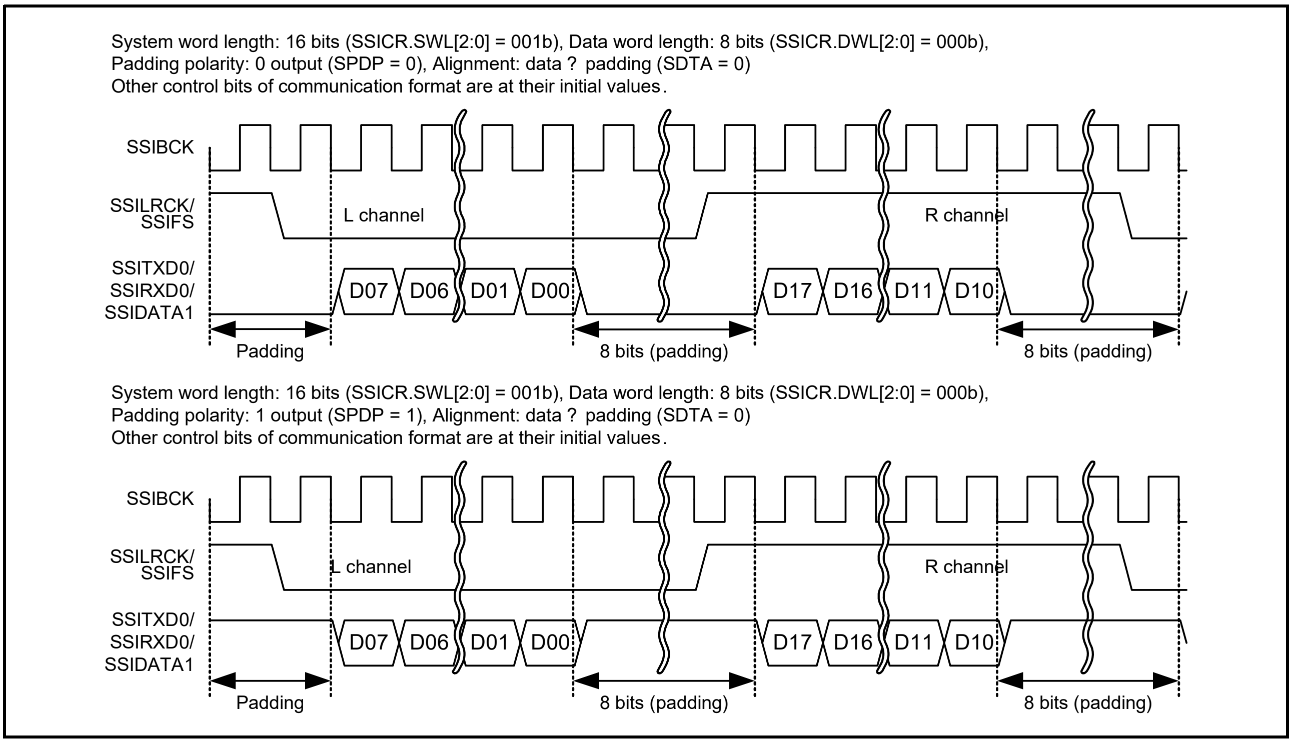
System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Data alignment: data ? padding (SDTA = 0)
Other control bits of communication format are at their initial values.

System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Data alignment: padding ? data (SDTA = 1)
Other control bits of communication format are at their initial values.

Figure 41.10 Alignment setting of serial data with padding bits

SPDP bit (Selects Serial Padding Polarity)

This bit sets polarity of padding bits.



System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Padding polarity: 0 output (SPDP = 0), Alignment: data ? padding (SDTA = 0)
Other control bits of communication format are at their initial values.

System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Padding polarity: 1 output (SPDP = 1), Alignment: data ? padding (SDTA = 0)
Other control bits of communication format are at their initial values.

Figure 41.11 Padding bit polarity

LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

This bit sets the initial value and polarity of SSILRCK/SSIFS. Set this bit according to the communication format to be used in SSIE. See Table 41.3 Initial output value and polarity of SSILRCK/SSIFS pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in SSIOFR.

Table 41.3 Initial output value and polarity of SSILRCK/SSIFS pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I^{2}S	High	0
Monaural	Low	1
TDM	Low	1

Note: When the format to be used is compatible with the I^{2}S, monaural, or TDM format, specify settings to enable communication with the respective formats.

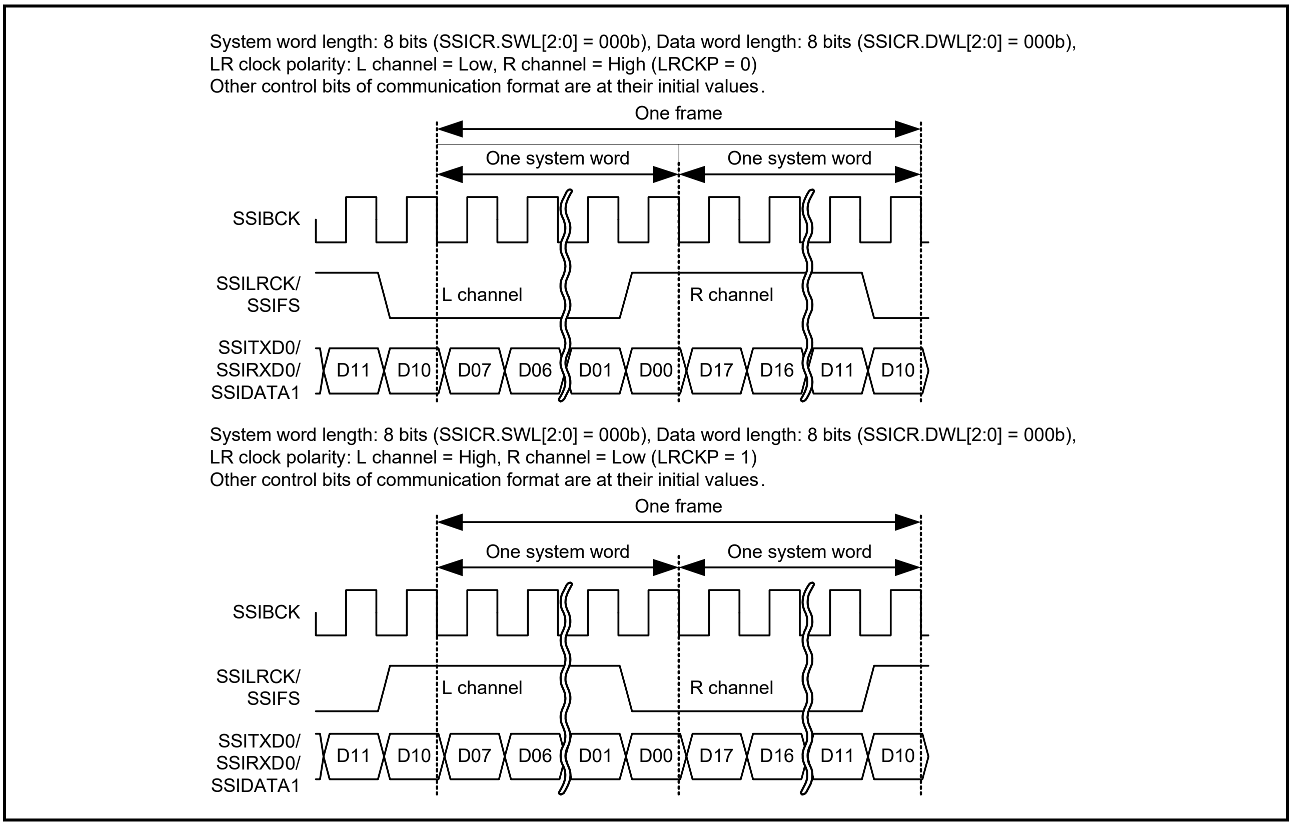


Figure 41.12 LR clock/frame synchronization polarity setting

BCKP bit (Selects Bit Clock Polarity)

This bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 41.4.3, FIFO Control Register (SSIFCR).

Table 41.4 Bit clock polarity

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCK/SSIFS sampling	SSIBCK rising edge	SSIBCK falling edge
	Master/slave	At SSIRXD0/SSIDATA1 sampling	SSIBCK rising edge	SSIBCK falling edge
Transmission	Master	At change of SSILRCK/SSIFS output	SSIBCK falling edge	SSIBCK rising edge
	Master/slave	At change of SSITXD0/SSIDATA1 output	SSIBCK falling edge	SSIBCK rising edge

MST bit (Master Enable)

This bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 41.4.3, FIFO Control Register (SSIFCR).

SWL[2:0] bits (Selects System Word Length)

These bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See Table 41.11 for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 41.4.7, Audio Format Register (SSIOFR).

DWL[2:0] bits (Selects Data Word Length)

These bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see Table 41.11.

FRM[1:0] bits (Selects Frame Word Number)

These bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in SSIOFR.

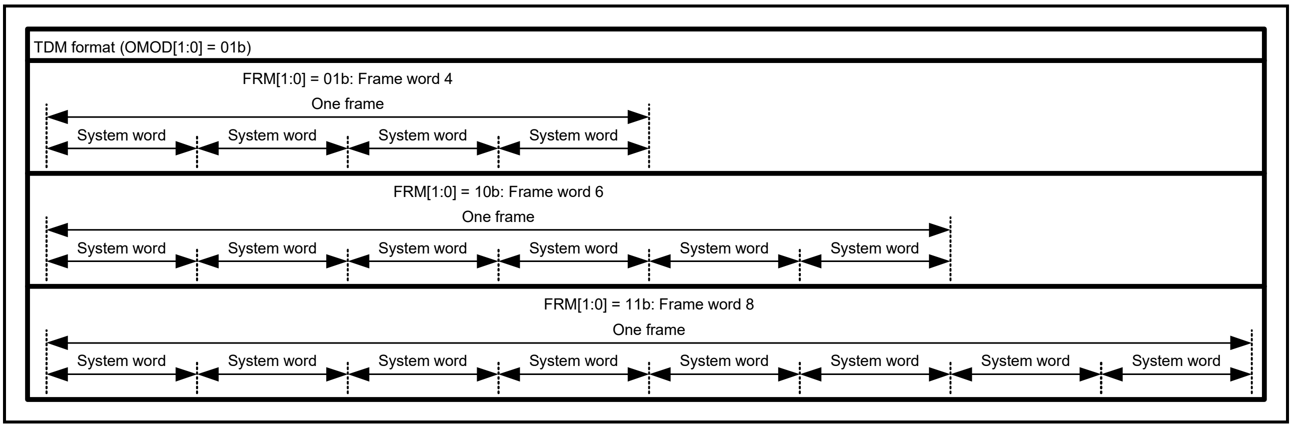

Figure 41.13 Frame word number

IIEN bit (Idle Mode Interrupt Output Enable)

This bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

ROIEN bit (Receive Overflow Interrupt Output Enable)

This bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

RUIEN bit (Receive Underflow Interrupt Output Enable)

This bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

TOIEN bit (Transmit Overflow Interrupt Output Enable)

This bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

TUIEN bit (Transmit Underflow Interrupt Output Enable)

This bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

CKS bit (Selects an Audio Clock for Master-mode Communication)

This bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in SSIFCR.

41.4.2 Status Register (SSISR)

Address(es): SSIE0.SSISR 4004 E004h, SSIE1.SSISR 4004 E104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b24 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25	IIRQ	Idle Mode Status Flag	0: In the communication state 1: In the idle state.	R
b26	ROIRQ	Receive Overflow Error Status Flag	0: No receive overflow error is generated 1: A receive overflow error is generated.	R/W
b27	RUIRQ	Receive Underflow Error Status Flag	0: No receive underflow error is generated 1: A receive underflow error is generated.	R/W
b28	TOIRQ	Transmit Overflow Error Status Flag	0: No transmit overflow error is generated 1: A transmit overflow error is generated.	R/W
b29	TUIRQ	Transmit Underflow Error Status flag	0: No transmit underflow error is generated 1: A transmit underflow error is generated.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is configured with status flags that indicate SSIE operational state.

IIRQ bit (Idle Mode Status Flag)

This is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see Figure 41.14 and Figure 41.15.

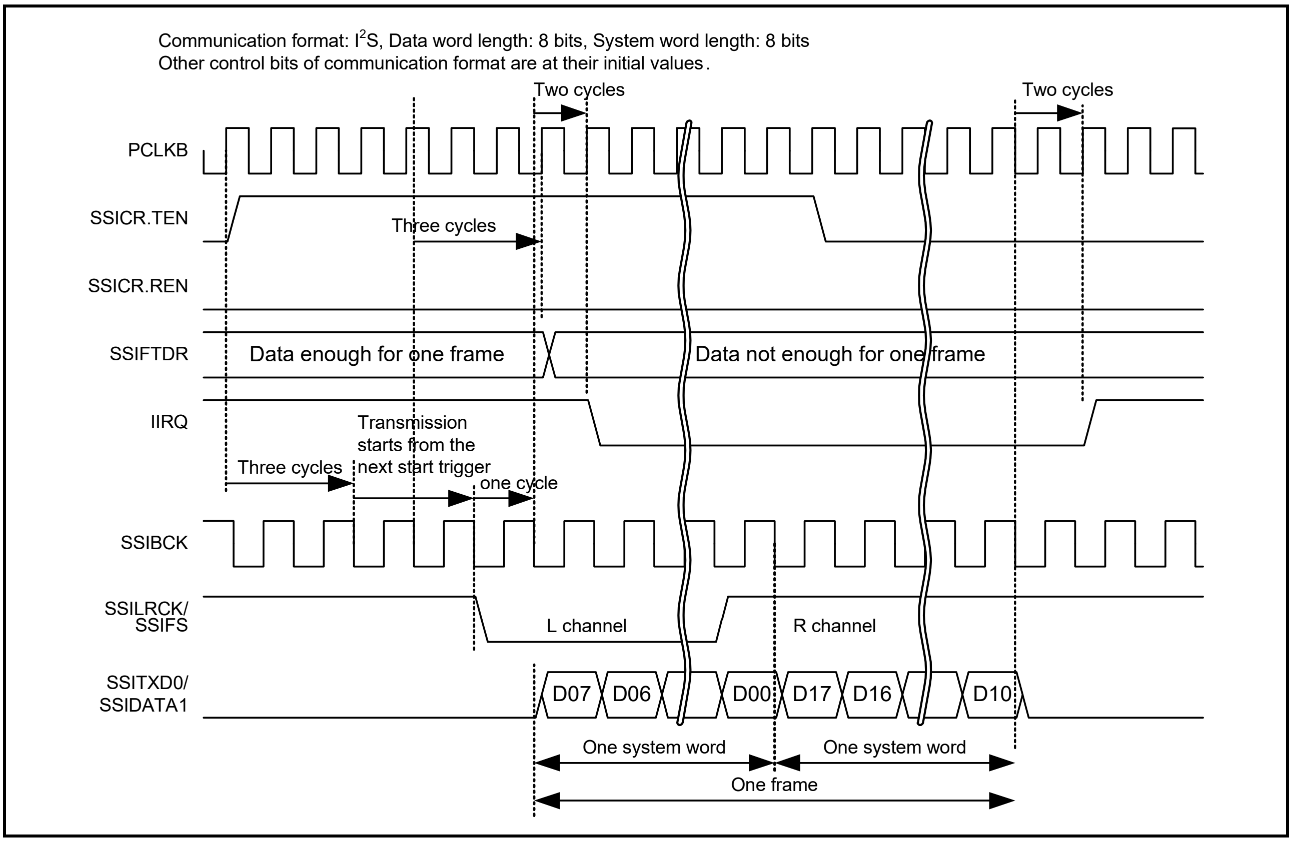

Figure 41.14 IIRQ setting timing (transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

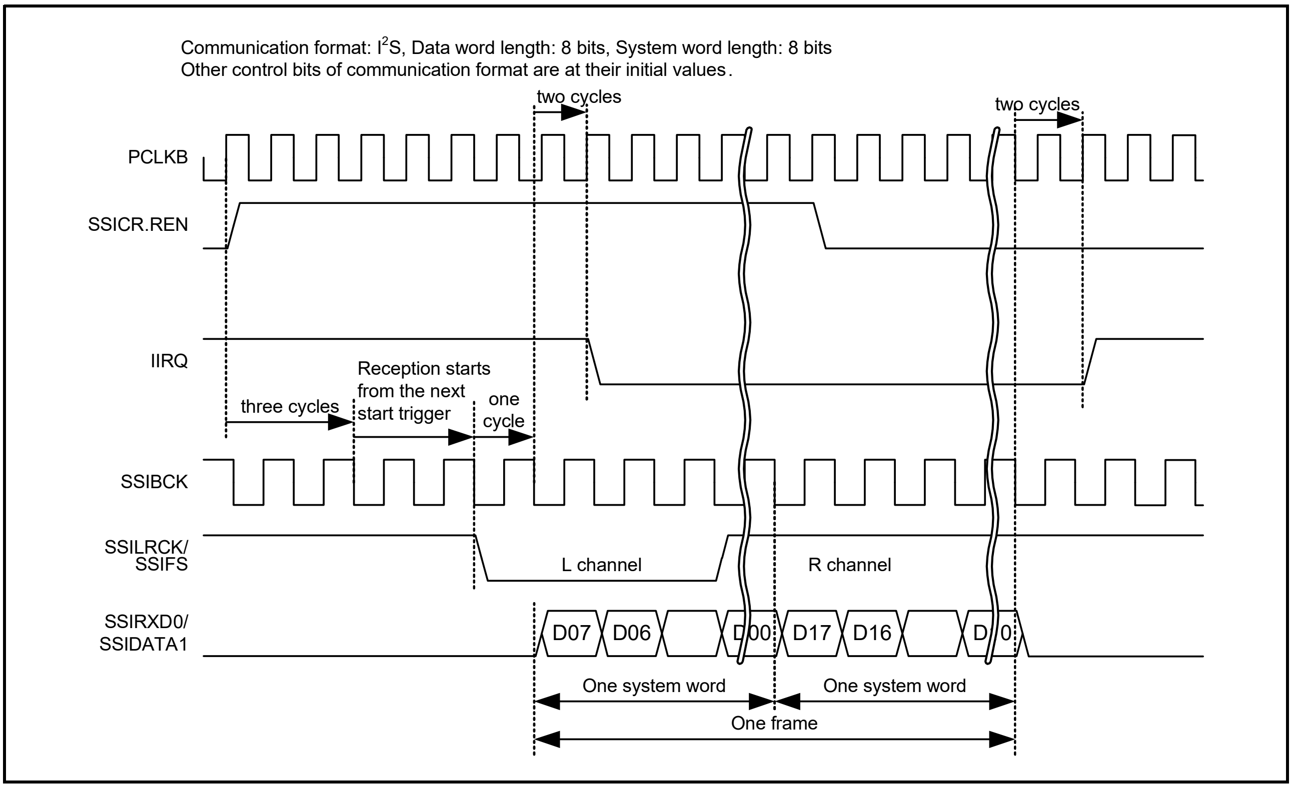

Figure 41.15 IIRQ setting timing (reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 01, a start trigger was generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

ROIRQ bit (Receive Overflow Error Status Flag)

This is a status flag that indicates a receive overflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see section 41.8.6, Error Handling. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 41.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

[Setting condition]

At completion of receiving new data while SSIFRDR is full.

[Setting timing]

3 cycles of PCLKB after reception is completed.

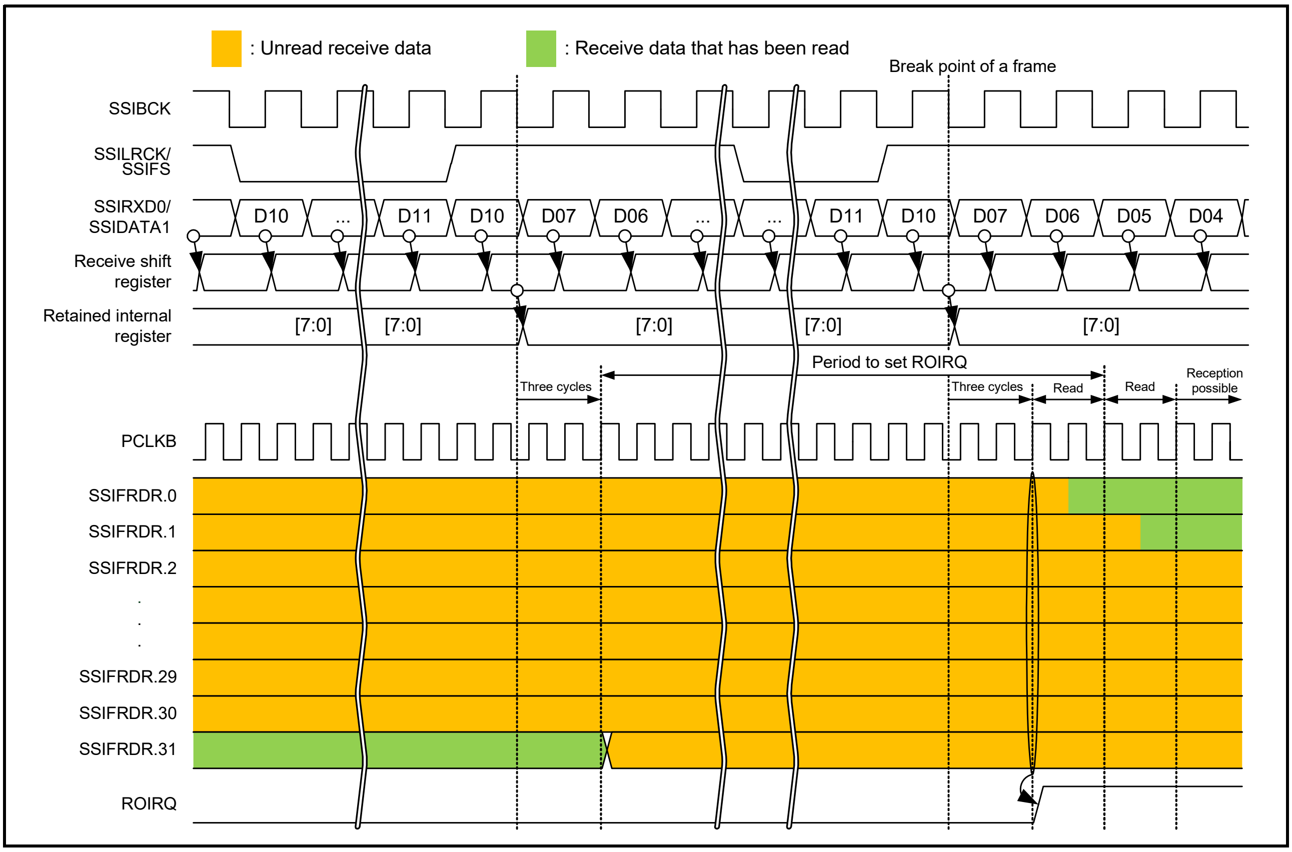

Figure 41.16 ROIRQ setting timing

RUIRQ bit (Receive Underflow Error Status Flag)

This is a status flag that indicates a receive underflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 41.8.6, Error Handling for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 41.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See Figure 41.17.

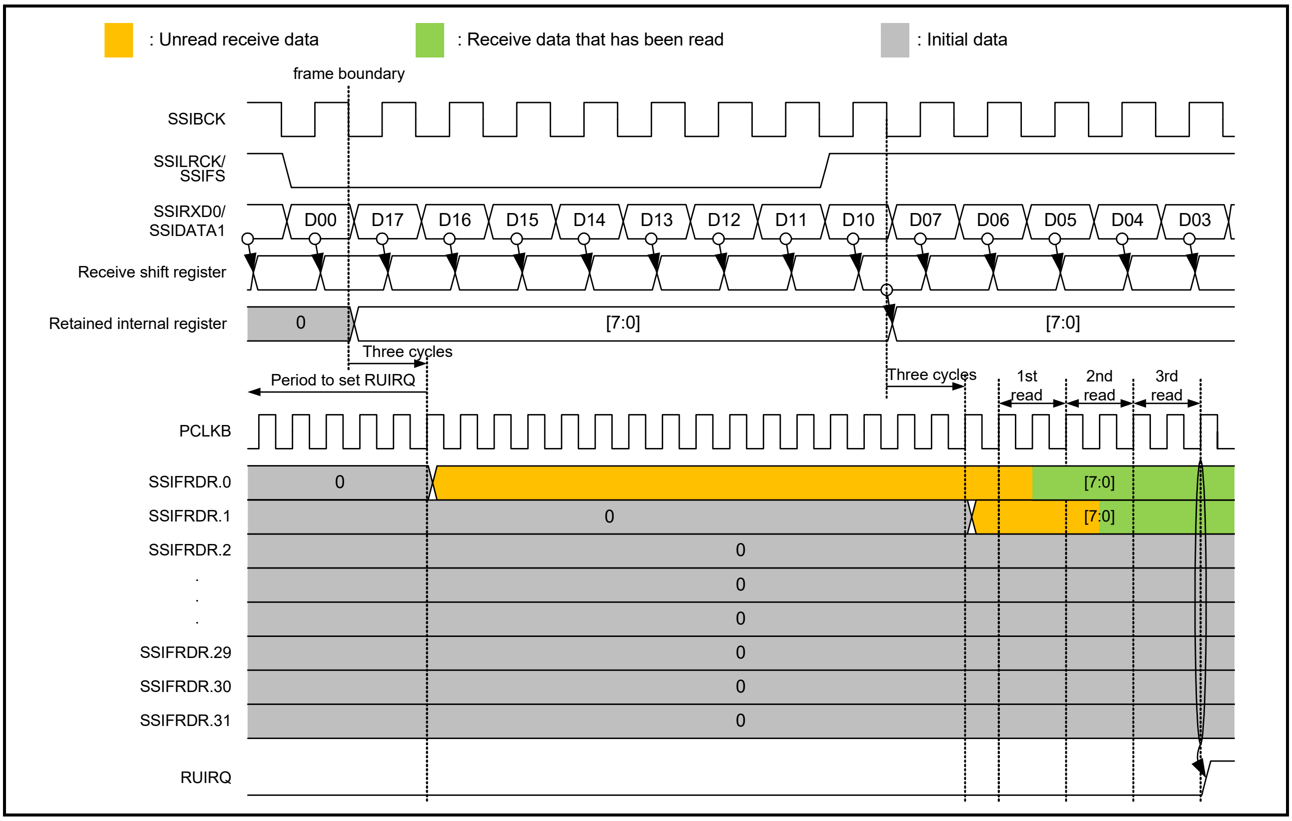

Figure 41.17 RUIRQ setting timing

TOIRQ bit (Transmit Overflow Error Status Flag)

This is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see section 41.8.6, Error Handling. This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

(1) Writing 0 to this bit after reading 1 from this bit*2

(2) Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

(1) When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 41.19)

(2) 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see Figure 41.18.

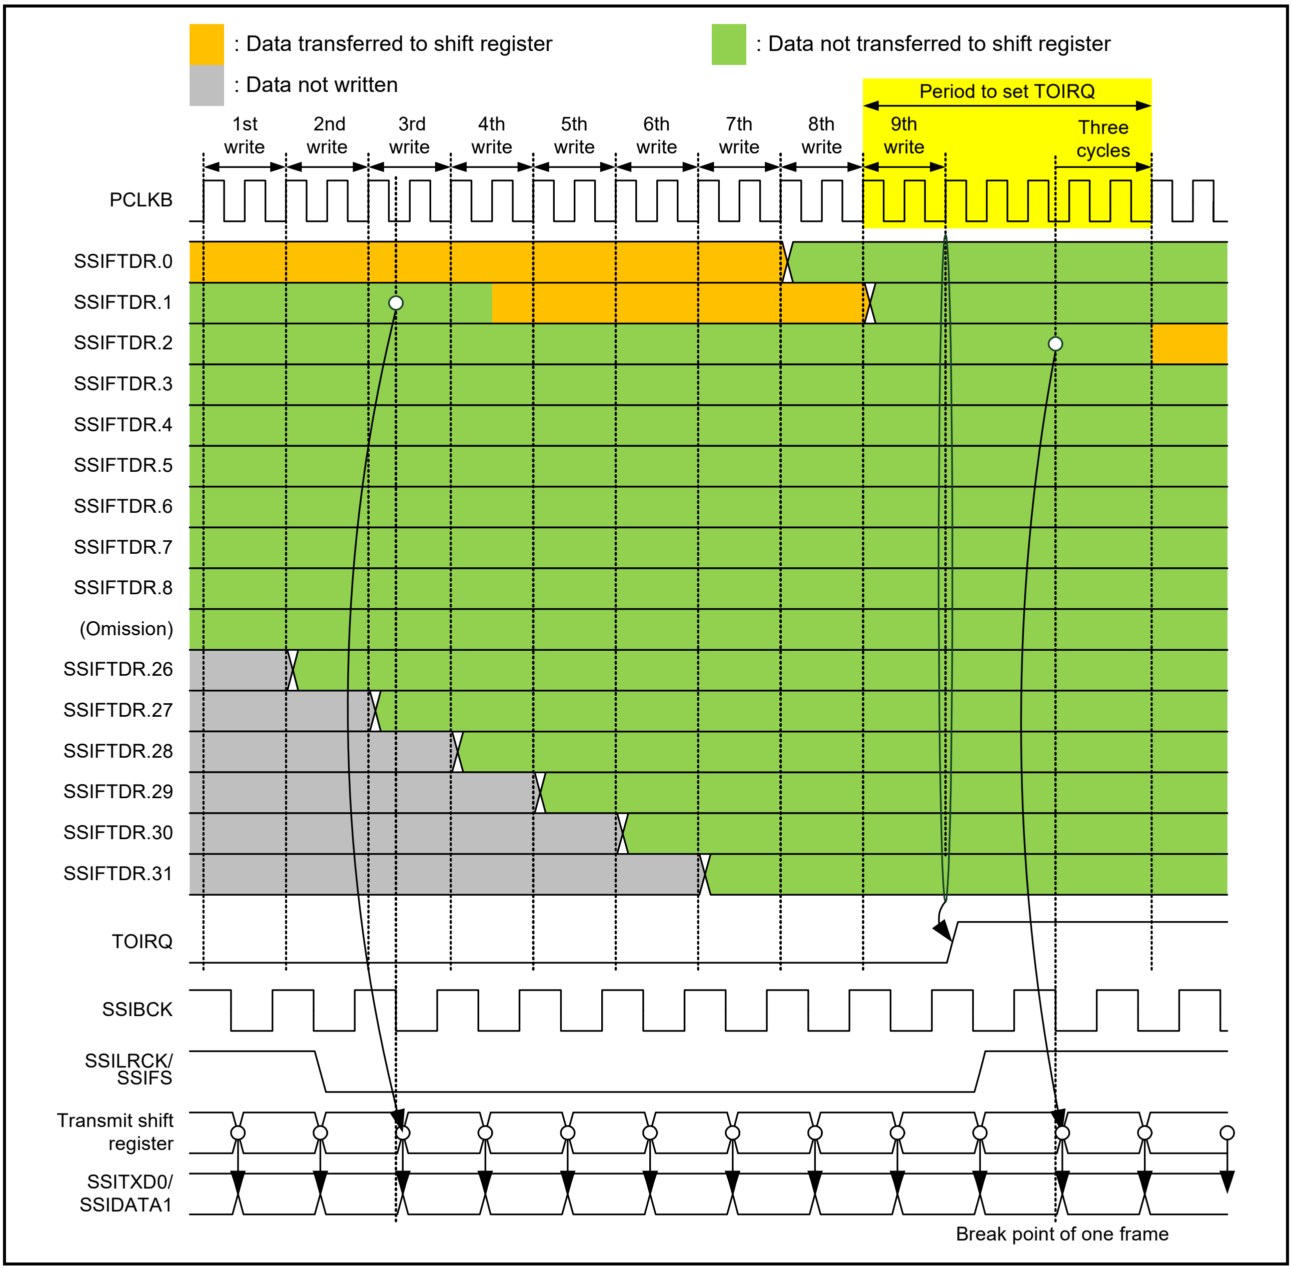

Figure 41.18 TOIRQ setting timing

TUIRQ bit (Transmit Underflow Error Status flag)

This is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0/SSIDATA1 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the communication stop procedure in Figure 41.56 and error-handling procedure in Figure 41.57. For the procedure to recover from an error, see section 41.8.6, Error Handling. This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

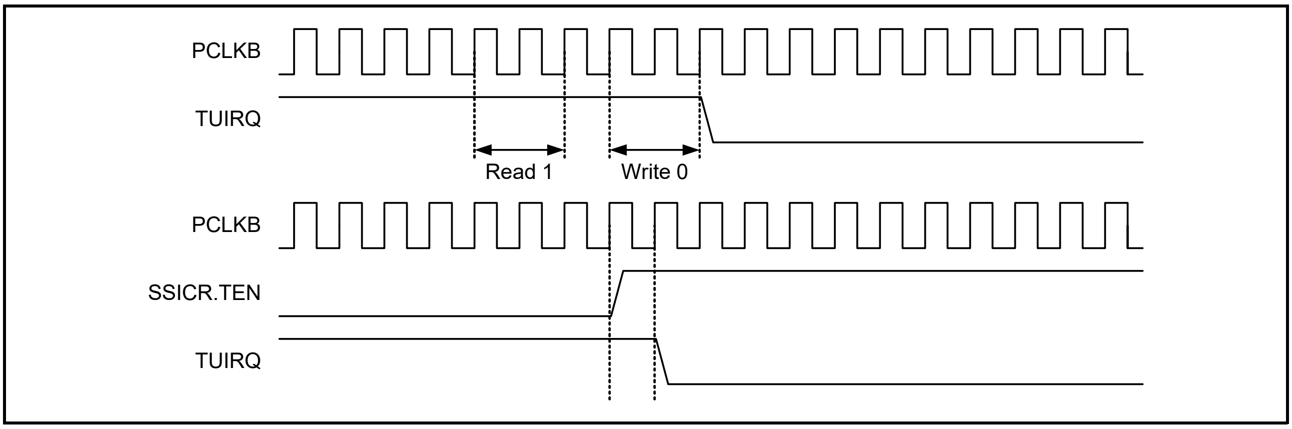

Figure 41.19 TUIRQ clearing timing

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see Figure 41.20 and Figure 41.21.

[Setting timing]

3 PCLKB cycles after the frame boundary. For details, see Figure 41.20.

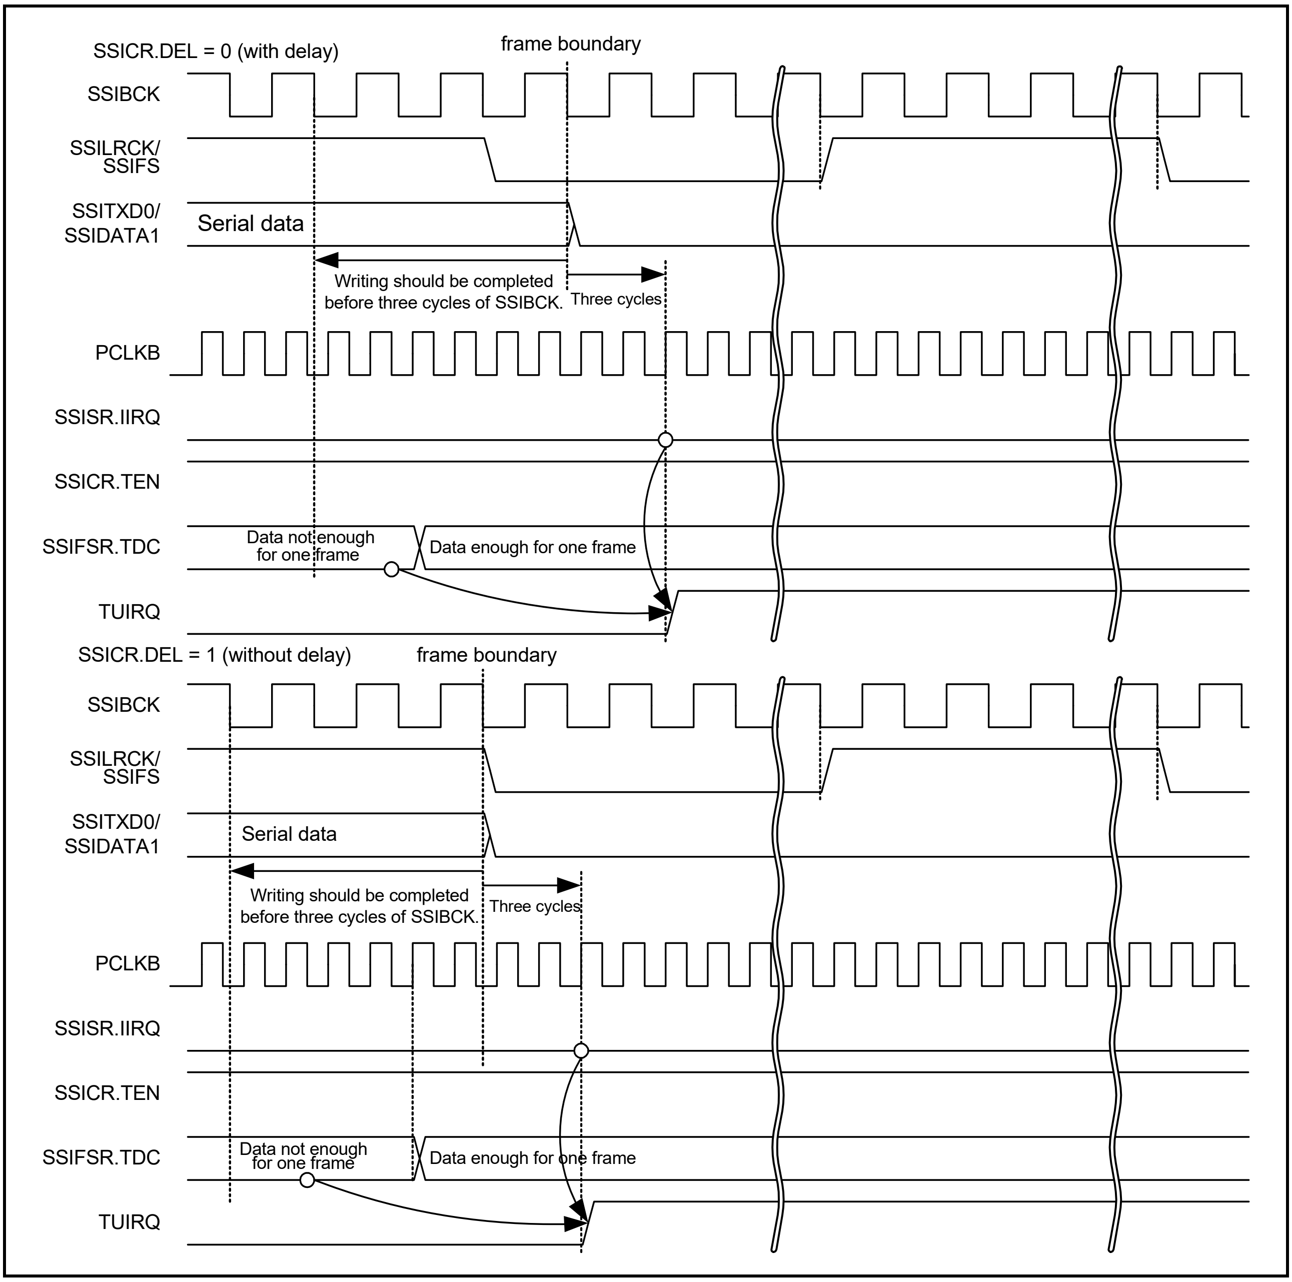

Figure 41.20 TUIRQ setting timing (when communication continues)

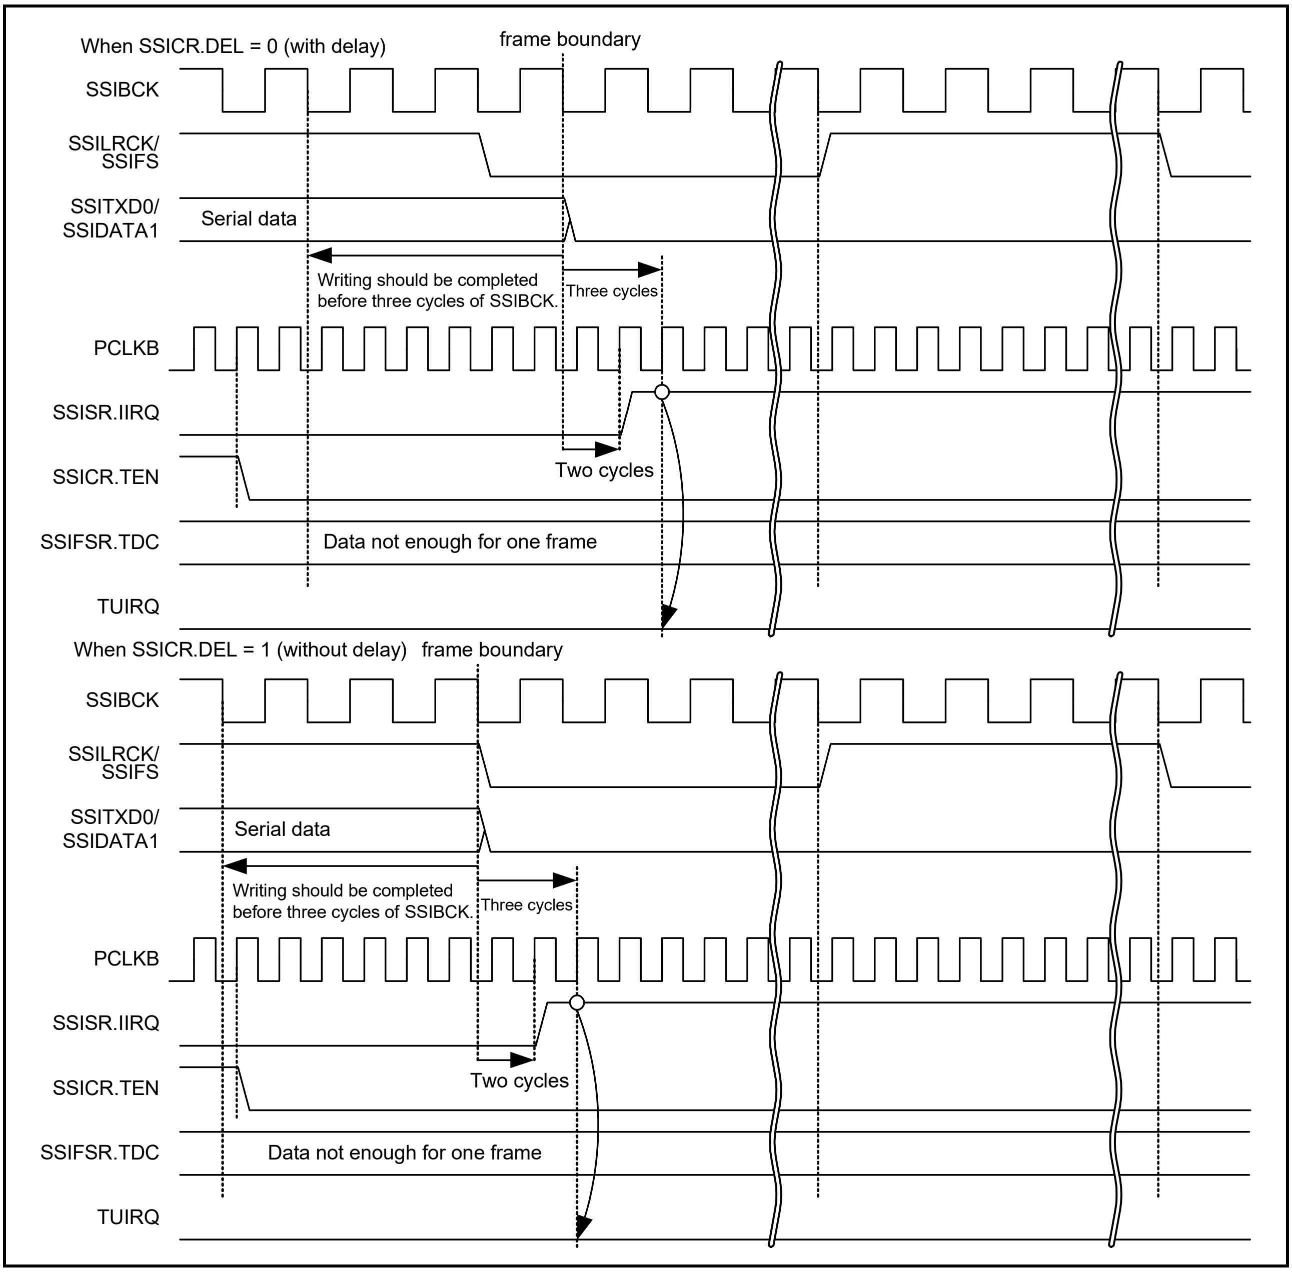

Figure 41.21 TUIRQ setting timing (when communication stops)

41.4.3 FIFO Control Register (SSIFCR)

Address(es): SSIE0.SSIFCR 4004 E010h, SSIE1.SSIFCR 4004 E110h

b31	AUCKE	AUDIO_MCK Enable in Master-mode Communication*1	0: Disables supply of AUDIO_MCK 1: Enables supply of AUDIO_MCK.	R/W

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

RFRST bit (Receive FIFO Data Register Reset)

This bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 41.5. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

TFRST bit (Transmit FIFO Data Register Reset)

This bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 41.6. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

Table 41.6 Bits subject to software reset by the TFRST bit

RIE bit (Receive Data Full Interrupt Output Enable)

This bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). Figure 41.22 shows the timing of generating the receive data full interrupt.

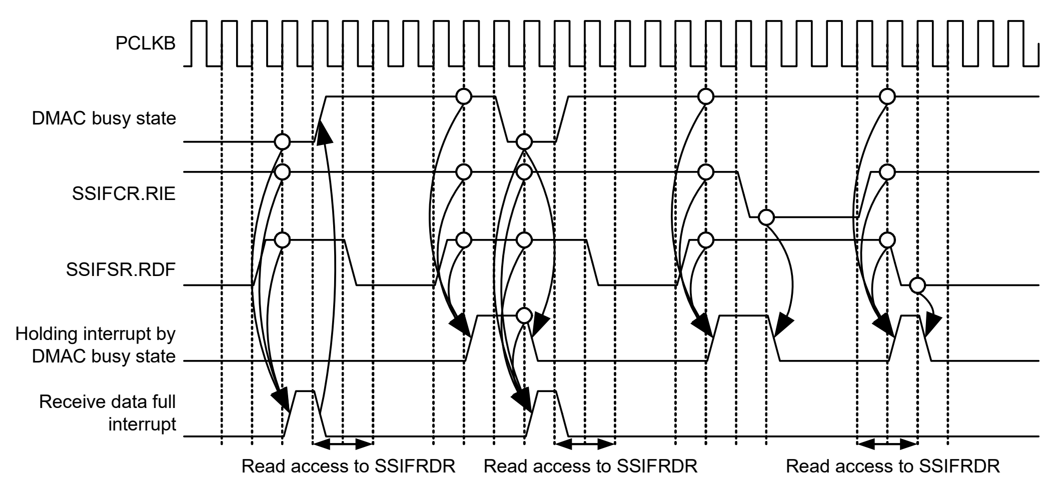

Figure 41.22 Timing of receive data full interrupt

TIE bit (Transmit Data Empty Interrupt Output Enable)

This bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES bit). Figure 41.23 shows the timing of generating the transmit data empty interrupt.

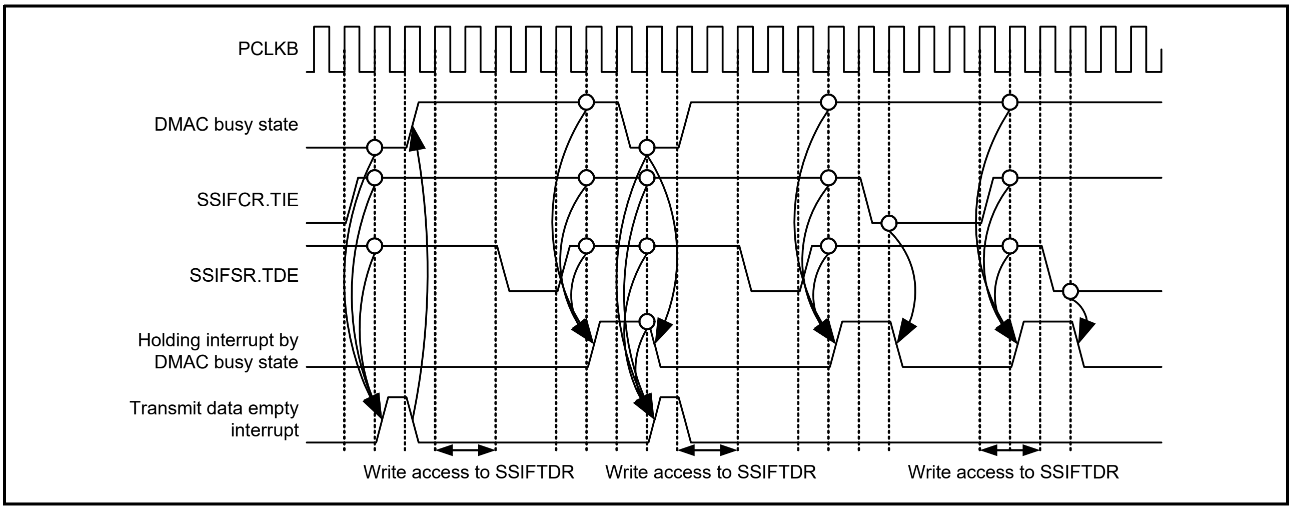

Figure 41.23 Timing of transmit data empty interrupt

BSW bit (Byte Swap Enable)

This bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see Figure 41.24.

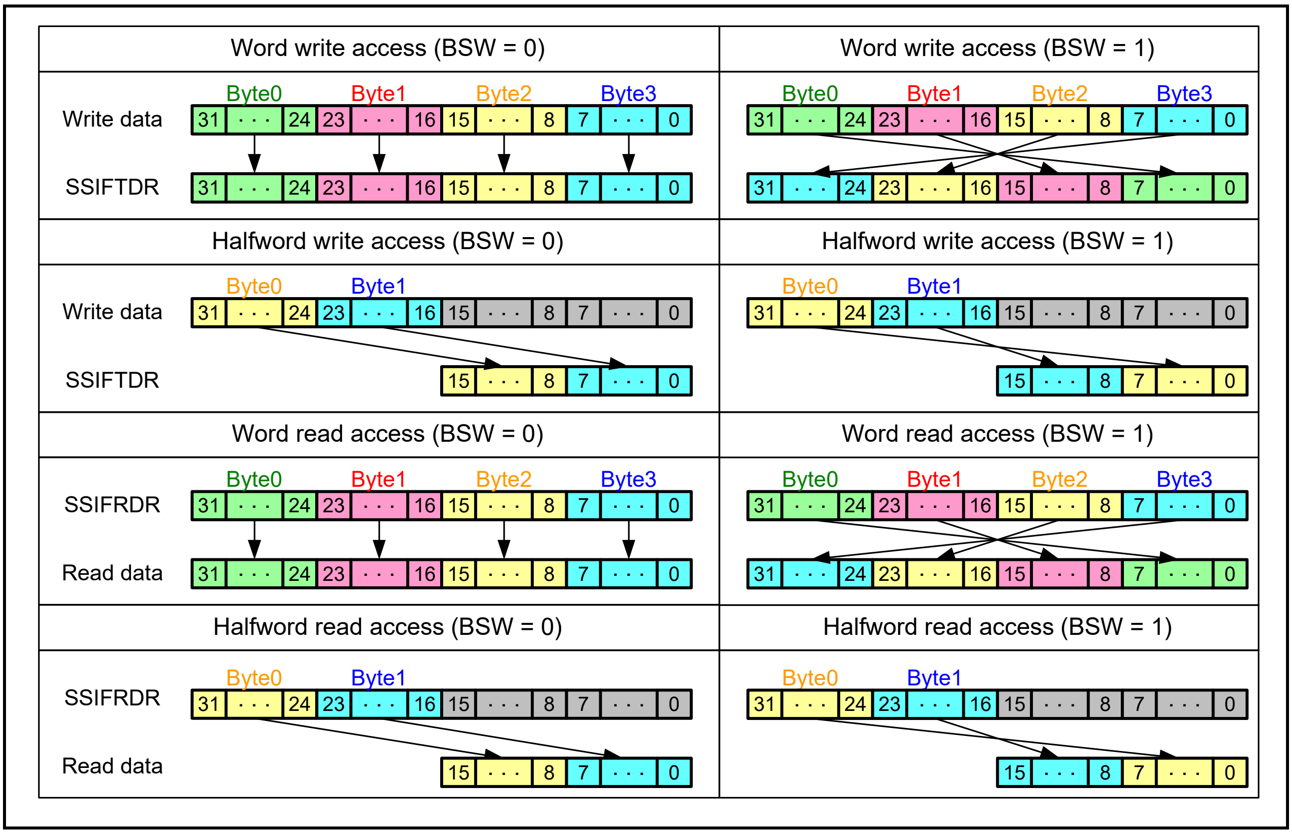

Figure 41.24 Operation example of byte swap

SSIRST bit (Software Reset)

This bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 41.7. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 41.7 Bits subject to software reset by the SSIRST bit

Symbol	Address (BASE+)		+0								+1

AUCKE bit (AUDIO_MCK Enable in Master-mode Communication)

This bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

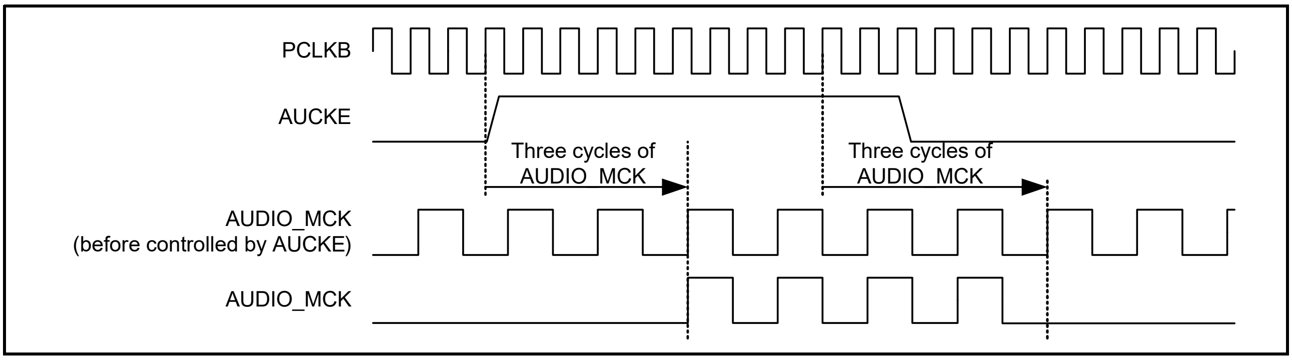

Figure 41.25 Stop/resume of AUDIO_MCK

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 41.52 or wait for an idle state by taking the procedure to resume communication in Figure 41.58.
In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE. If 0 is written to SSIFCR.ADCKE before SSIE becomes idle, take the procedure to start communication in Figure 41.52.

Figure 41.26 and Figure 41.27 show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCK pin.

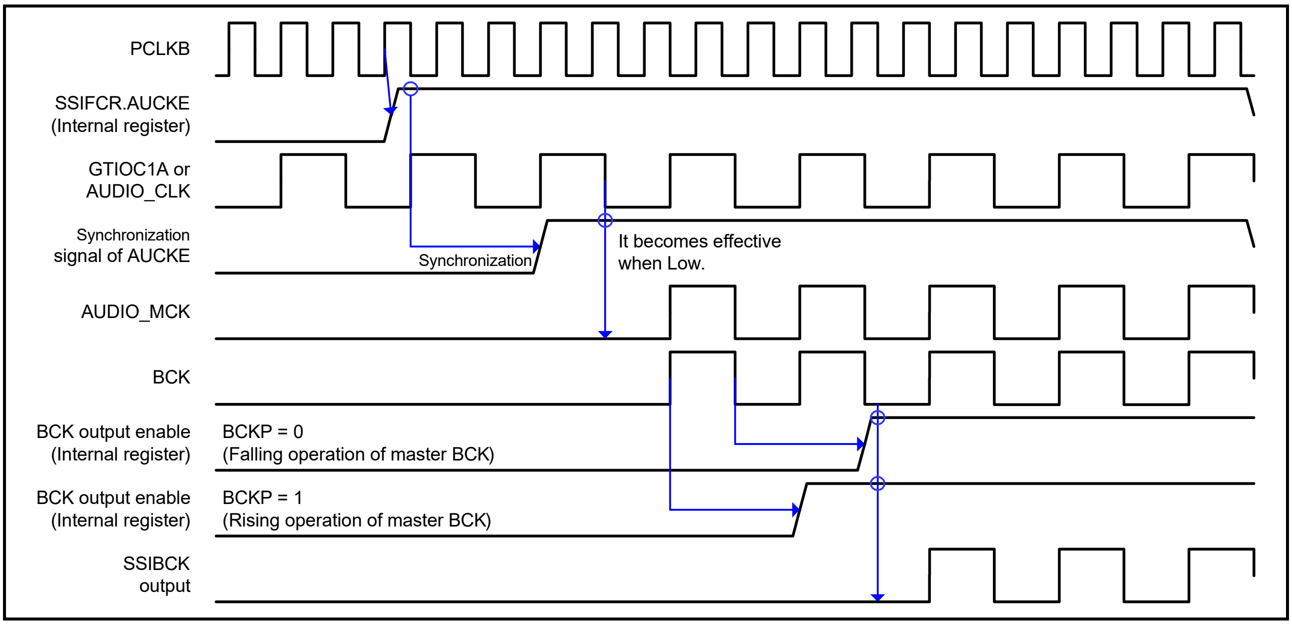

Figure 41.26 Timing diagram for the operation from system reset to start of master-mode communication

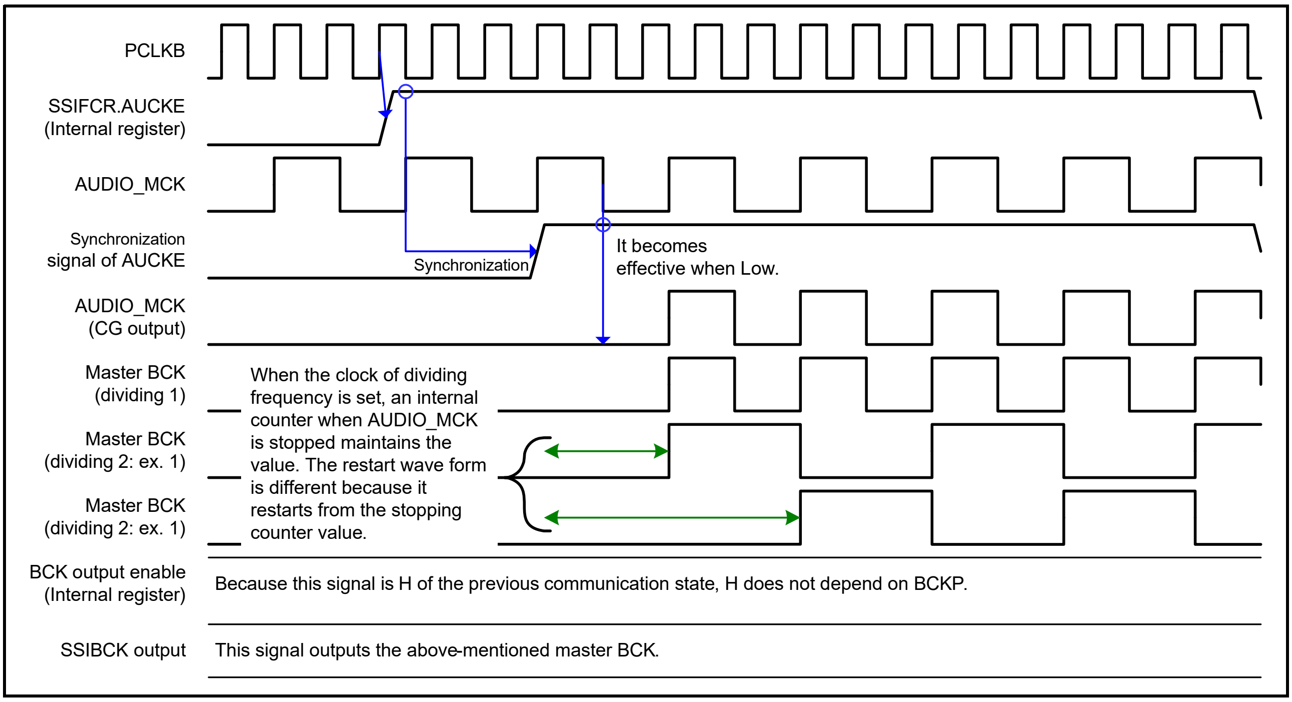

Figure 41.27 Timing diagram for the operation from stop of communication to start of master-mode communication

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCK pin is held. Therefore, the SSIBCK signal might stop in the H (high level) state.

41.4.4 FIFO Status Register (SSIFSR)

Address(es): SSIE0.SSIFSR 4004 E014h, SSIE1.SSIFSR 4004 E114h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TDC[5:0]						—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RDC[5:0]						—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	RDF	Receive Data Full Flag	0: The size of received data in SSIFRDR is not more than the value of SSISCR.RDFS 1: The size of received data in SSIFRDR is not less than the value of SSISCR.RDFS plus one.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	RDC[5:0]	Number of Receive FIFO Data Indication Flag	Number of receive FIFO data indication flag.	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TDE	Transmit Data Empty Flag	0: The free space of SSIFTDR is not more than the value of SSISCR.TDES 1: The free space of SSIFTDR is not less than the value of SSISCR.TDES plus one.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b29 to b24	TDC[5:0]	Number of Transmit FIFO Data Indication Flag	Number of transmit FIFO data indication flag.	R
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

RDF bit (Receive Data Full Flag)

This bit indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:*1

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 41.19)
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFRDR has data not less than the amount set with the SSISCR.RDFS bit plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bit plus one.

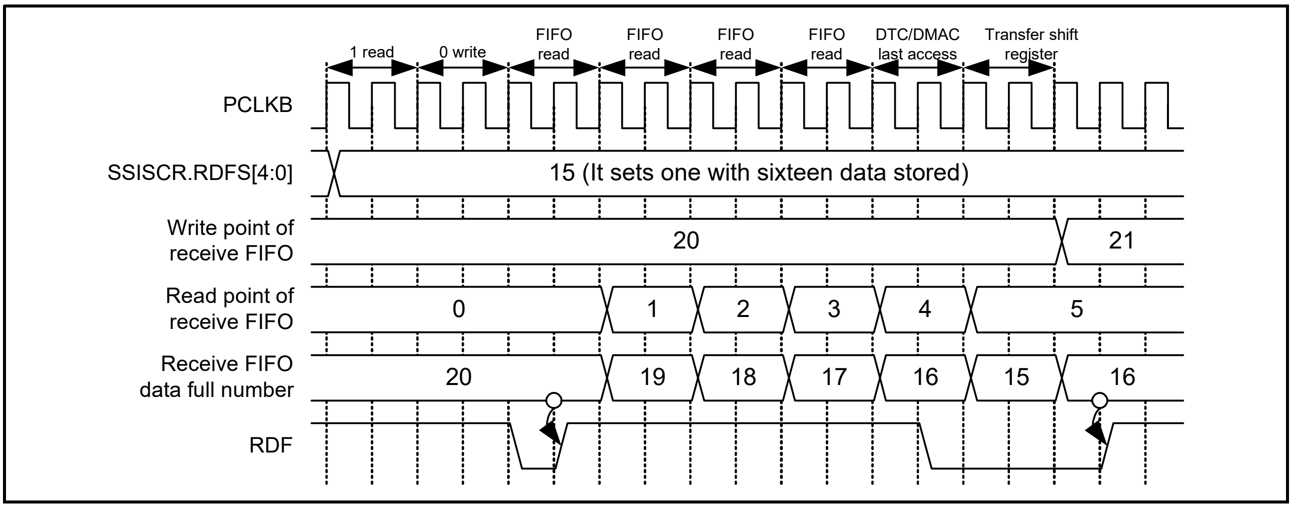

Figure 41.28 Timing diagram for setting and clearing RDF

RDC[5:0] bits (Number of Receive FIFO Data Indication Flag)

These bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With this flag as 0h, there is no received data. With 20h, the register is filled with received data and there is no free space.

TDE bit (Transmit Data Empty Flag)

This bit indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSIFCR.TTRG bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

(1) When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 41.19)

(2) Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than "size set in the SSISCR.TDES bits + 1."

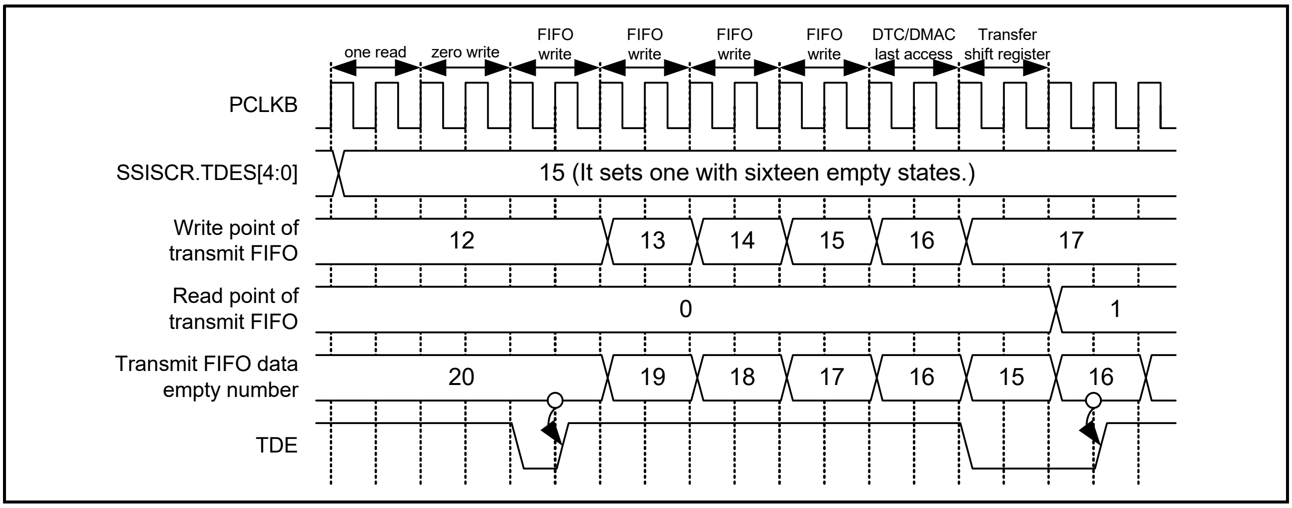

Figure 41.29 Timing diagram for setting and clearing TDE

TDC[5:0] bits (Number of Transmit FIFO Data Indication Flag)

These bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With this flag as 0h, there is no data to be transmitted. With 20h, there is no space to write data.

41.4.5 Transmit FIFO Data Register (SSIFTDR)

Address(es): SSIE0.SSIFTDR 4004 E018h, SSIE1.SSIFTDR 4004 E118h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit name	Description	R/W
b31 to b0	SSIFRDR[31:0]	Receive FIFO Data	Receive FIFO data.	R

When you use this register for reception, specify data reading from this register as the DTC/DMAC operation that is triggered by a receive data full interrupt. Determine the access size to this register according to the data word length to be communicated in Table 41.8.

Register access to the receive FIFO data register is same as for the transmit FIFO data register.

Figure 41.31 shows the configurations and operation examples of the receive FIFO data register and receive shift register.

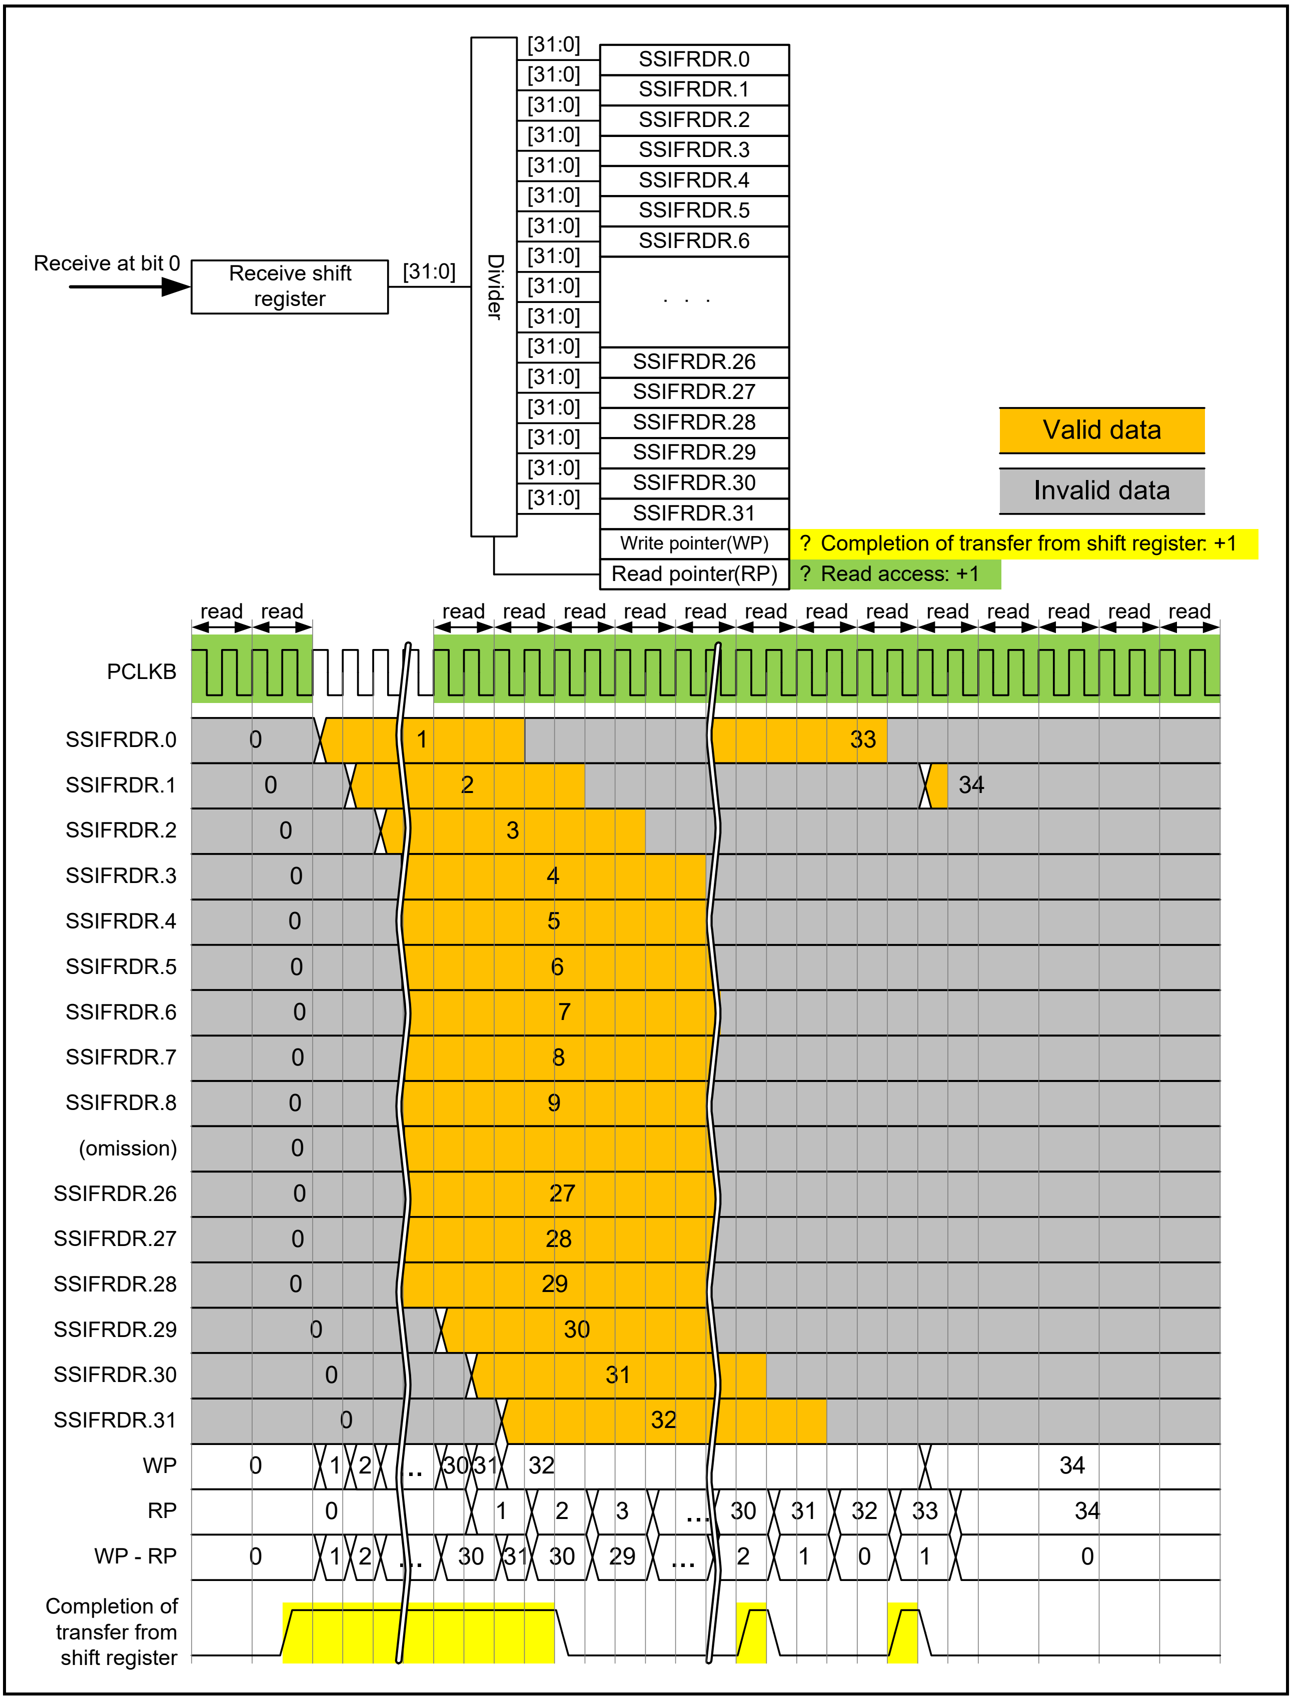

Figure 41.32 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example

41.4.7 Audio Format Register (SSIOFR)

Address(es): SSIE0.SSIOFR 4004 E020h, SSIE1.SSIOFR 4004 E120h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	BCKASTP	LRCONT	—	—	—	—	—	—	OMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	OMOD[1:0]	Audio Format Select*3, *4	00: I2S format 01: TDM format 10: Monaural format 11: Setting prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	LRCONT	Whether to Enable LRCK/FS Continuation*1, *2	0: Disables LRCK/FS continuation 1: Enables LRCK/FS continuation.	R/W
b9	BCKASTP	Whether to Enable Stopping BCK Output When SSIE is in Idle Status*1, *2	0: Always outputs BCK to the SSIBCK pin 1: Automatically controls output of BCK to the SSIBCK pin.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.

Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.

Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

OMOD[1:0] bits (Audio Format Select)

These bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in reference 41.4.7.

LRCONT bit (Whether to Enable LRCK/FS Continuation)

This bit enables or disables the output from SSILRCK/SSIFS pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCK/SSIFS pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

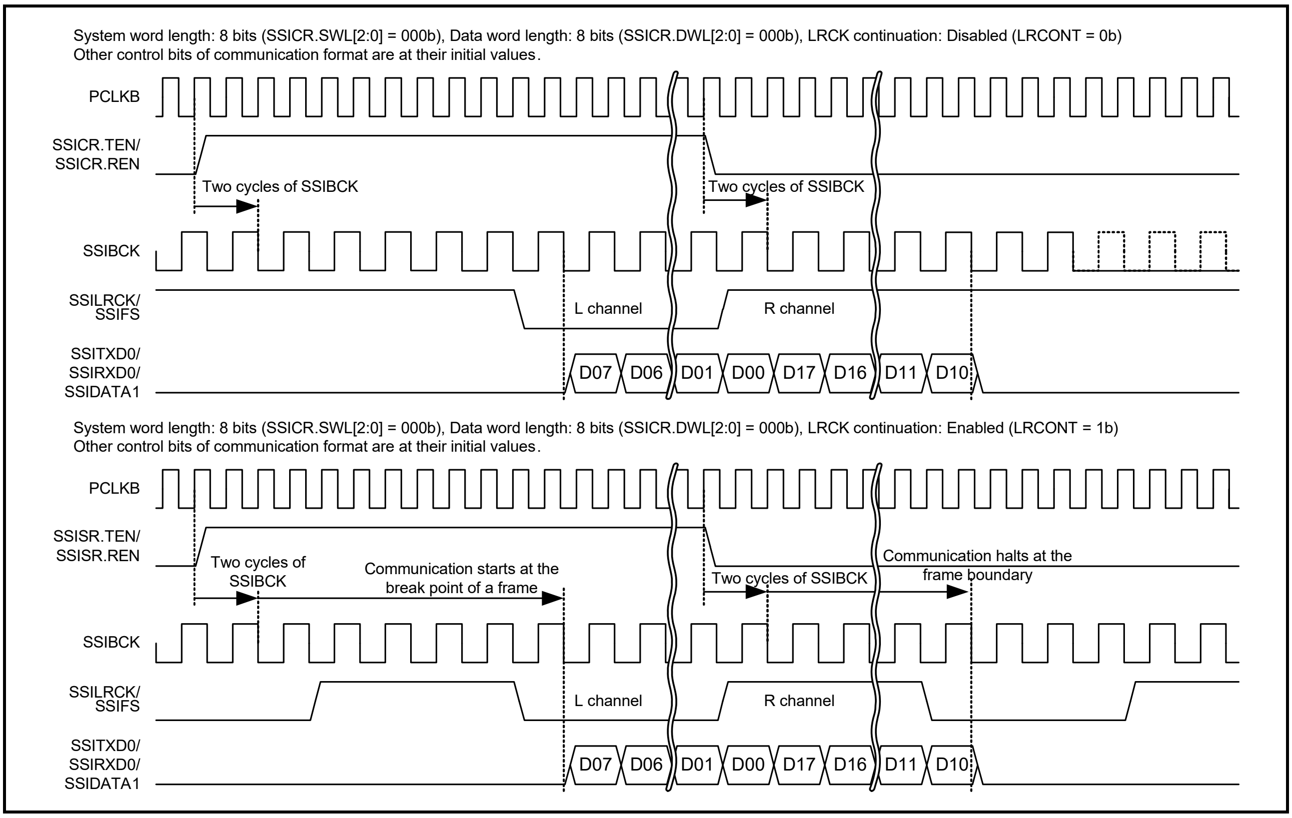

Figure 41.33 Example of LR clock/frame synchronization continuation operation

BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

This bit turns on or off the function to output BCK to the SSIBCK pin according to the communication shown in Figure 41.34 and Figure 41.35 in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCK pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

Table 41.9 BCKASTP bit status and SSIBCK pin output

BCKASTP Bit	SSIBCK Pin Output Status
0	Output
1	Stopped

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see Figure 41.34.

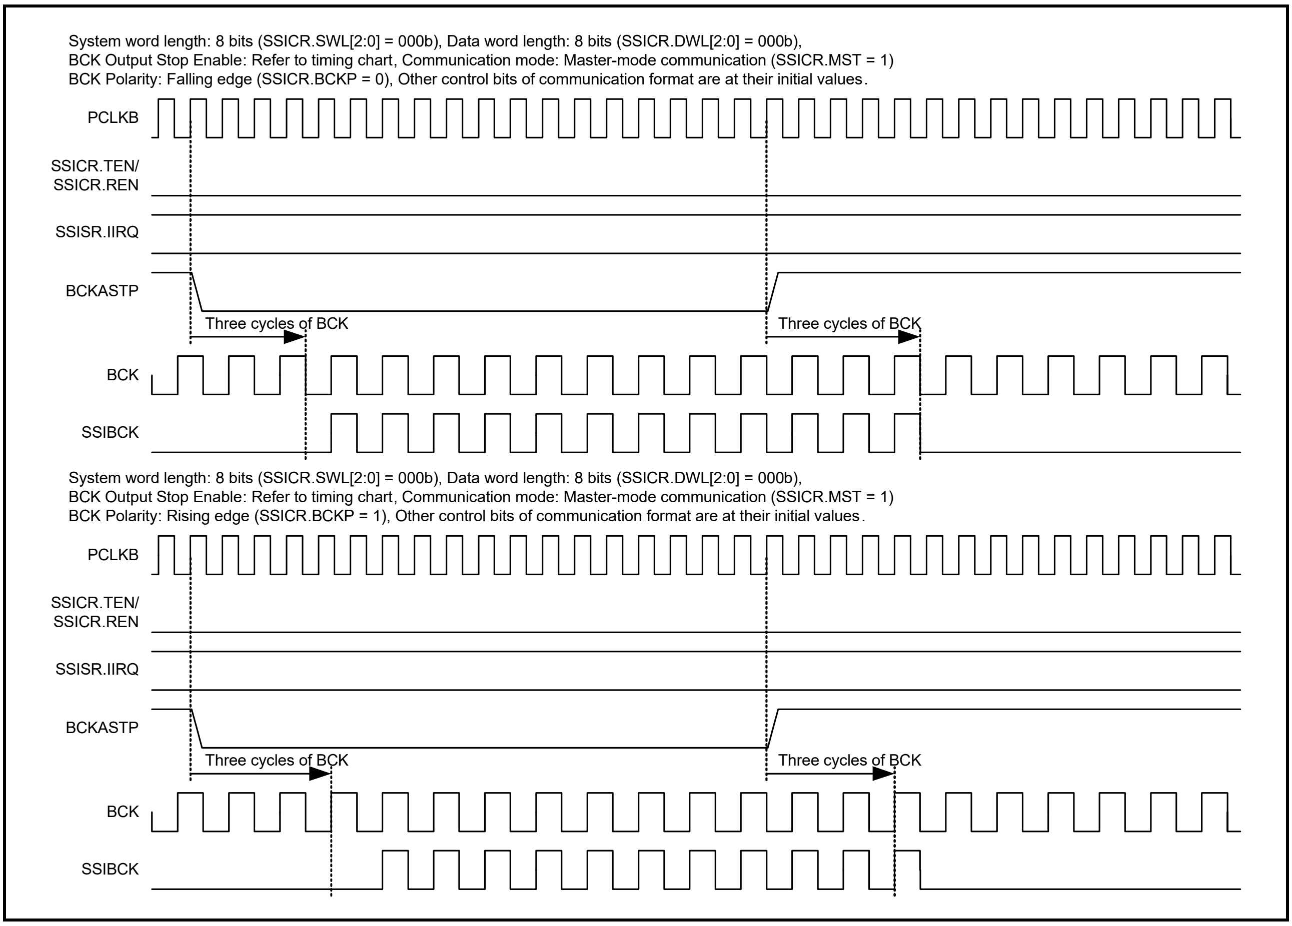

Figure 41.34 Example operation of the BCKASTP bit (idle state)

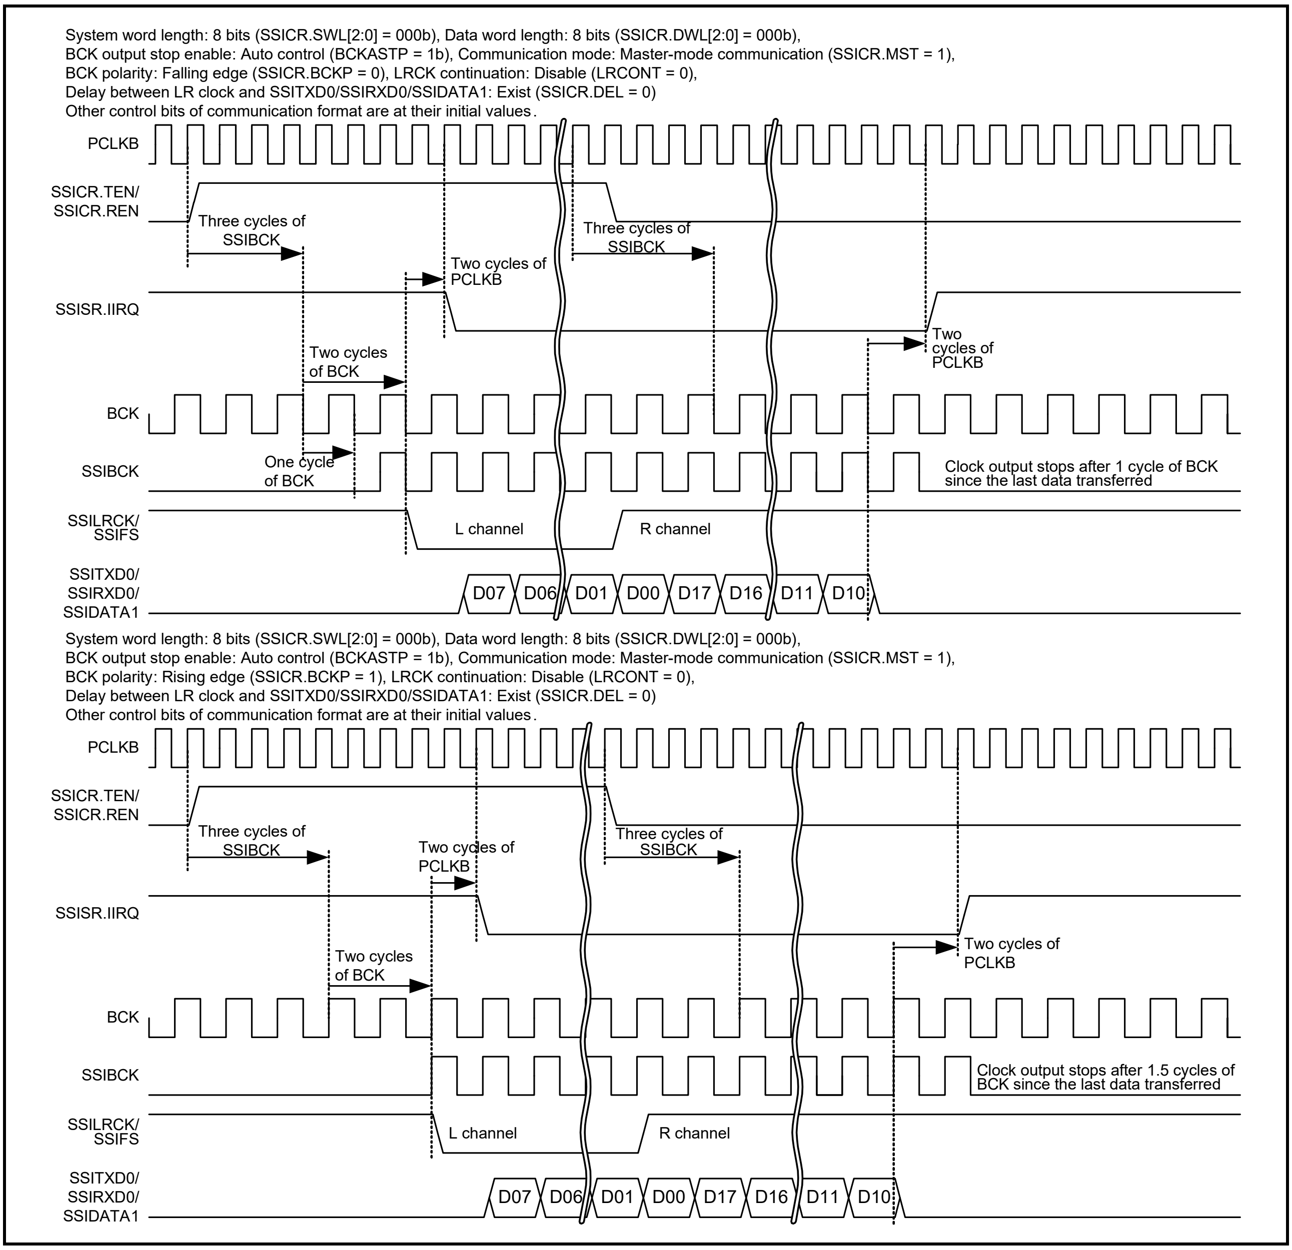
When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCK pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in Figure 41.35.



System word length: 8 bits (SSICR.SWL[2:0] = 000b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
BCK output stop enable: Auto control (BCKASTP = 1b), Communication mode: Master-mode communication (SSICR.MST = 1),
BCK polarity: Falling edge (SSICR.BCKP = 0), LRCK continuation: Disable (LRCONT = 0),
Delay between LR clock and SSITXD0/SSIRXD0/SSIDATA1: Exist (SSICR.DEL = 0)
Other control bits of communication format are at their initial values.

System word length: 8 bits (SSICR.SWL[2:0] = 000b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
BCK output stop enable: Auto control (BCKASTP = 1b), Communication mode: Master-mode communication (SSICR.MST = 1),
BCK polarity: Rising edge (SSICR.BCKP = 1), LRCK continuation: Disable (LRCONT = 0),
Delay between LR clock and SSITXD0/SSIRXD0/SSIDATA1: Exist (SSICR.DEL = 0)
Other control bits of communication format are at their initial values.

Figure 41.35 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)

41.4.8 Status Control Register (SSISCR)

Address(es): SSIE0.SSISCR 4004 E024h, SSIE1.SSISCR 4004 E124h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TDES[4:0]					—	—	—	RDFS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	RDFS[4:0]	RDF Setting Condition Select*1	b4 b0 0 0 0 0 0: SSIFRDR has one stage or more data size 0 0 0 0 1: SSIFRDR has two stages or more data size (snip) 1 1 1 1 0: SSIFRDR has thirty-one stages or more data size 1 1 1 1 1: SSIFRDR has thirty-two stages or more data size.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	TDES[4:0]	TDE Setting Condition Select*1	b12 b8 0 0 0 0 0: SSIFTDR has one stage or more free space 0 0 0 0 1: SSIFTDR has two stages or more free space (snip) 1 1 1 1 0: SSIFTDR has thirty-one stages or more free space 1 1 1 1 1: SSIFTDR has thirty-two stages or more free space.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

RDFS[4:0] bits (RDF Setting Condition Select)

These bits set the setting condition of the receive data full flag (RDF).

TDES[4:0] bits (TDE Setting Condition Select)

These bits set the setting condition of the transmit data empty flag (TDE).

41.5 Communication Formats

SSIE supports three communication formats. Table 41.10 shows supported communication formats.

Table 41.10 Supported communication formats

Communication Format	SSIOFR.OMOD[1:0]
I^{2}S format	00
TDM format	01
Monaural format	10

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 41.36.

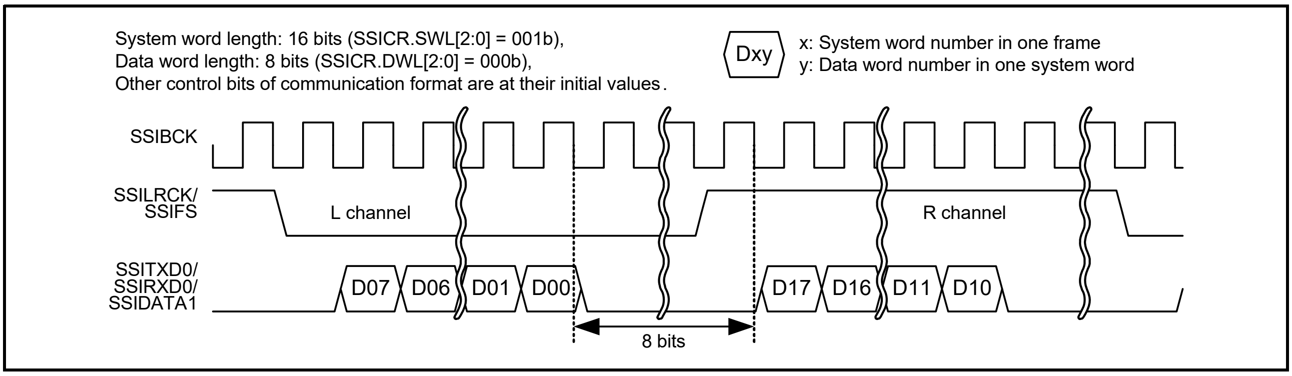


Figure 41.36 Example of padding bit transfer (I2S format: system word length > data word length)

Table 41.11 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). "-" indicates that the setting is prohibited.

Table 41.11 Number of padding bits

	SSICR.DWL[2:0]	**000b**	**001b**	**010b**	**011b**	**100b**	**101b**	**110b**	**111b**

111b	256	248	240	238	236	234	232	224	—

41.5.1 I2S Format

The I2S format is a communication format used for connection with I2S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCK/SSIFS signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 41.37 shows the I2S format without padding. See Figure 41.36 for the format with padding.

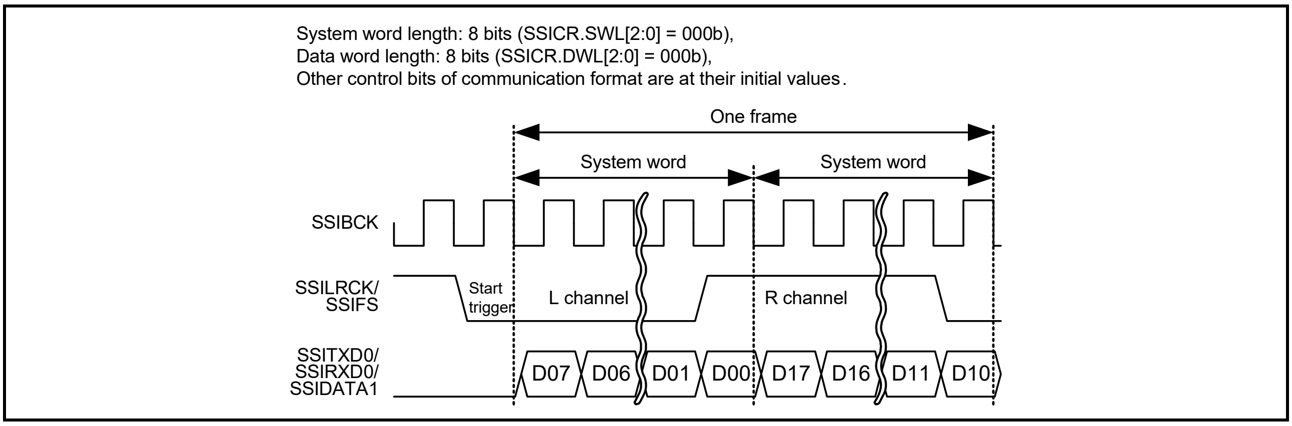

Figure 41.37 I2S format (without padding: system word length = data word length)

For the state of external pins when SSIE is in the idle state, see reference 41.7.1.

Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

41.5.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCK/SSIFS signal indicates a communication start trigger. Figure 41.38 and Figure 41.39 respectively show the monaural formats without and with padding.

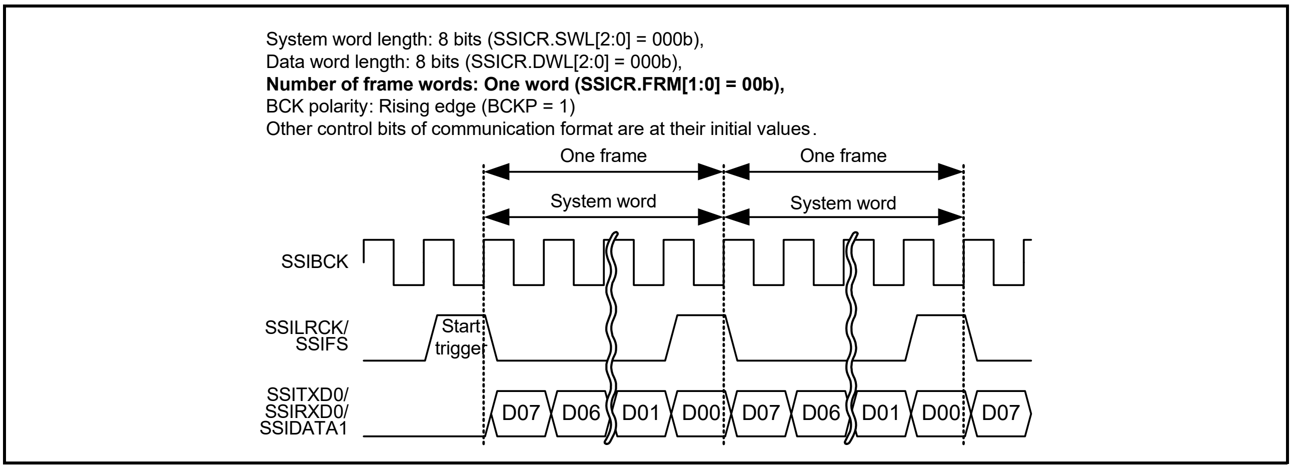

Figure 41.38 Short frame in monaural format (without padding: system word length = data word length)

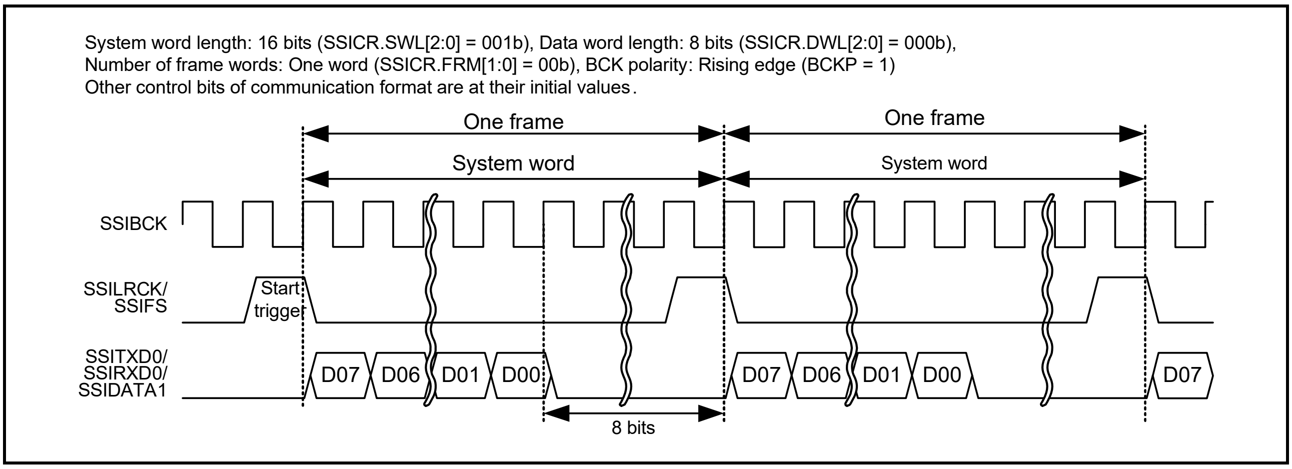

Figure 41.39 Short frame in monaural format (with padding: system word length > data word length)

The monaural formats supported by SSIE consist of short frames and long frames. See reference 41.5.2.1 and reference 41.5.2.2 for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see reference 41.7.1.

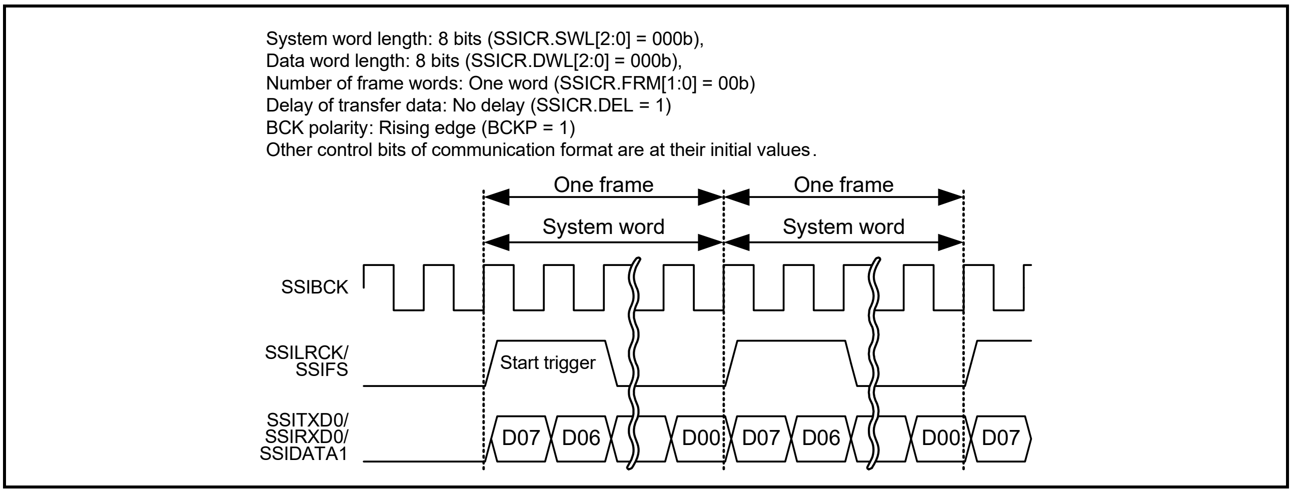
Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

41.5.2.1 Short frame

When a short frame is used (SSICR.DEL = 0), the SSILRCK/SSIFS signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCK. Data transfer starts at the falling edge of the signal.

41.5.2.2 Long frame

When a long frame is used (SSICR.DEL = 1), the SSILRCK/SSIFS signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCK. See Figure 41.40. Data transfer starts at the rising edge of the signal.

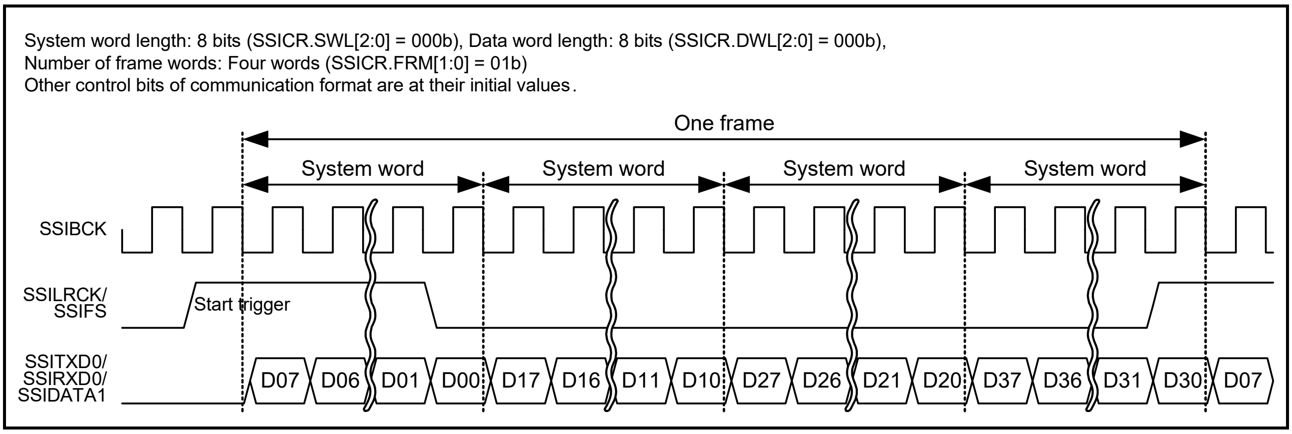


System word length: 8 bits (SSICR.SWL[2:0] = 000b),
Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Number of frame words: One word (SSICR.FRM[1:0] = 00b)
Delay of transfer data: No delay (SSICR.DEL = 1)
BCK polarity: Rising edge (BCKP = 1)
Other control bits of communication format are at their initial values.

Figure 41.40 Long frame in monaural format (without padding)

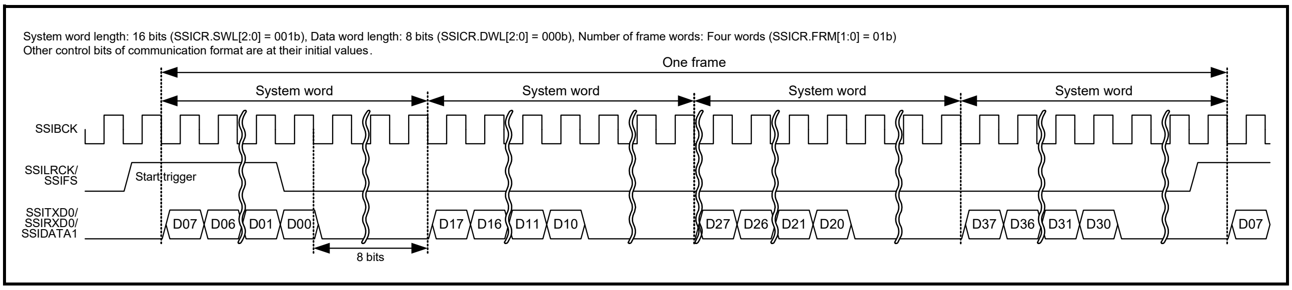
41.5.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK/SSIFS signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK/SSIFS signal is defined as the SYNC pulse and its rising edge means a start of one frame. Figure 41.41 and Figure 41.42 respectively show the TDM formats without and with padding.



System word length: 8 bits (SSICR.SWL[2:0] = 000b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b),
Number of frame words: Four words (SSICR.FRM[1:0] = 01b)
Other control bits of communication format are at their initial values.

Figure 41.41 TDM format (without padding: system word length = data word length)



System word length: 16 bits (SSICR.SWL[2:0] = 001b), Data word length: 8 bits (SSICR.DWL[2:0] = 000b), Number of frame words: Four words (SSICR.FRM[1:0] = 01b)
Other control bits of communication format are at their initial values.

Figure 41.42 TDM format (with padding: system word length > data word length)

For the state of external pins when SSIE is in the idle state, see reference 41.7.1.

Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

41.6 Communication Modes

SSIE supports the following communication modes. Table 41.13 lists the control bits that are not available with each communication mode. See reference 41.6.1 to reference 41.6.5 for details of these communication modes.

Table 41.12 Communication modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 41.13 Control bits that cannot be used in each communication mode

Communication Mode Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception
SSICR.CKS	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.CKDV	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.MUEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.TEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.REN	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.AUCKEN	Invalid	Invalid	Invalid	Available	Available	Available
SSIFCR.TIE	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RIE	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.TFRST	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RFRST	Available	Invalid	Available	Available	Invalid	Available
SSIOFR.BCKASTP	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.LRCONT	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.OMOD	Available	Available	Available	Available	Available	Available
SSISCR.TDES	Invalid	Available	Available	Invalid	Available	Available
SSISCR.RDFS	Available	Invalid	Available	Available	Invalid	Available

"Invalid" means it has no effect on operation. Writing is possible.

41.6.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCK and SSILRCK/SSIFS signals to be used for serial-data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

41.6.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCK and SSILRCK/SSIFS signals to be used for serial-data communication must be internally generated from the audio clock. These signals use the format according to the setting of SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

41.6.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

41.6.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

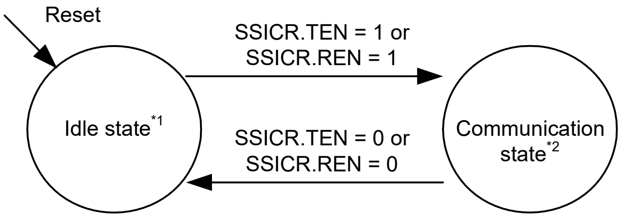
41.6.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

41.7 Operation

SSIE has the following two main operation states Figure 41.43 shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).



Note 1. See reference 41.8.1 for details of the idle state.
Note 2. See reference 41.8.2 for details of the communication state.

Figure 41.43 SSIE state transition

41.7.1 Idle State

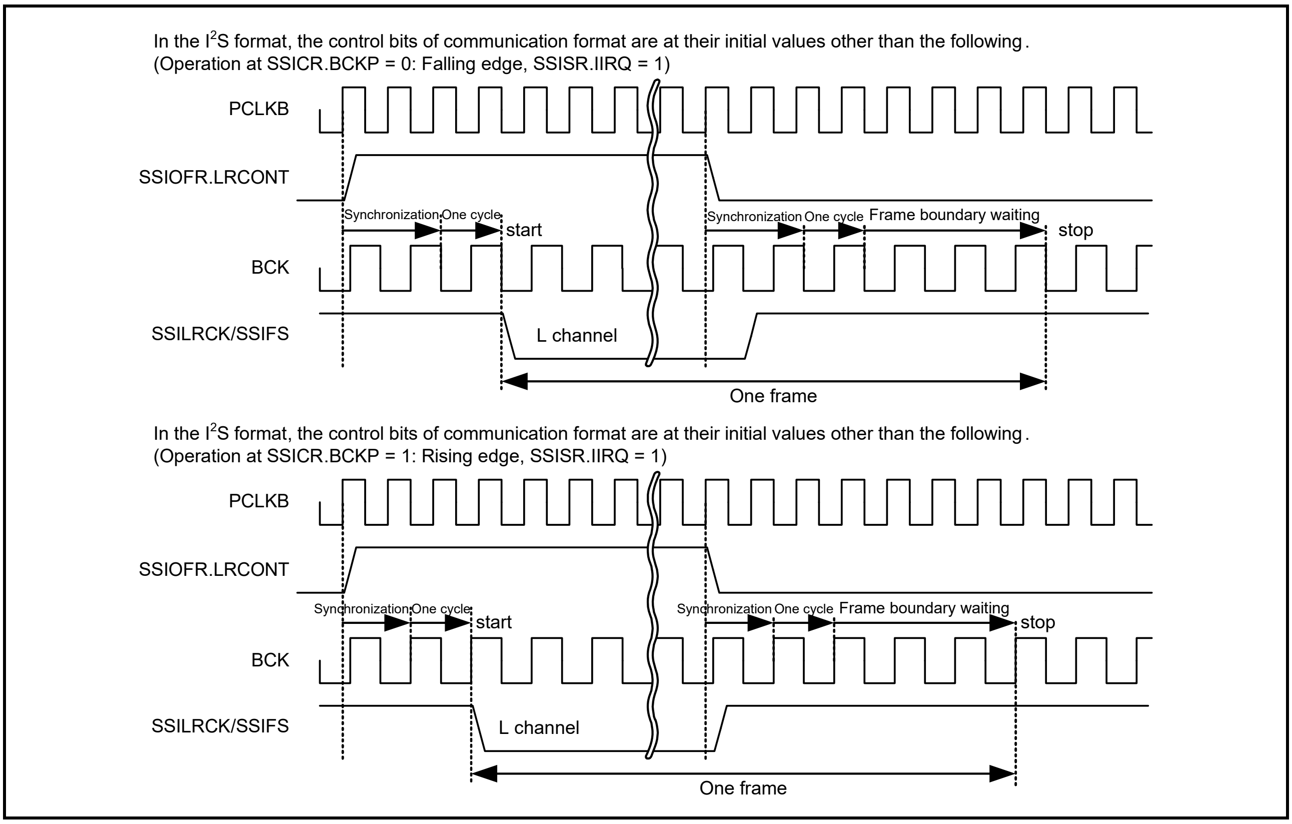
In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see Table 41.14.

Table 41.14 Output from external pins in the idle state

			Output from Pins		
SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	SSIBCK	SSILRCK/SSIFS	SSITXD0/SSIDATA1
0	—	—	Stop	Stop	Stop
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop

Table 41.14 Output from external pins in the idle state

			Output from Pins		
SSICR.MST	**SSIOFR.BCKASTP**	**SSIOFR.LRCONT**	**SSIBCK**	**SSILRCK/SSIFS**	**SSITXD0/SSIDATA1**
1	1	1	Stop	Supply	Stop



In the I²S format, the control bits of communication format are at their initial values other than the following.
(Operation at SSICR.BCKP = 0: Falling edge, SSISR.IIRQ = 1)

In the I²S format, the control bits of communication format are at their initial values other than the following.
(Operation at SSICR.BCKP = 1: Rising edge, SSISR.IIRQ = 1)

Figure 41.44 Example of disabling LR clock/frame synchronization continuation by SSIOFR.LRCONT

Note: To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.

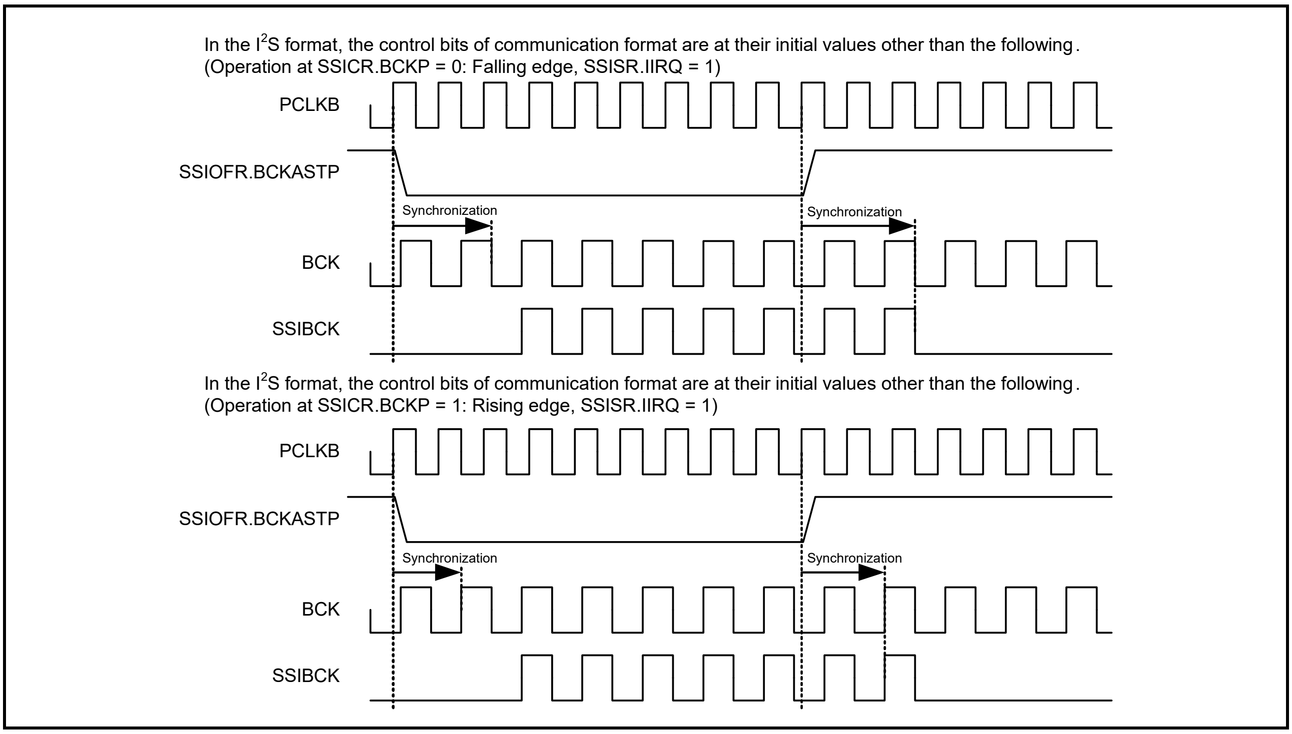


Figure 41.45 Example of stopping SSIBCK with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

41.7.2 Communication States

In this state, SSIE is during communication. Figure 41.46 shows transitions of communication states and Table 41.15 lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

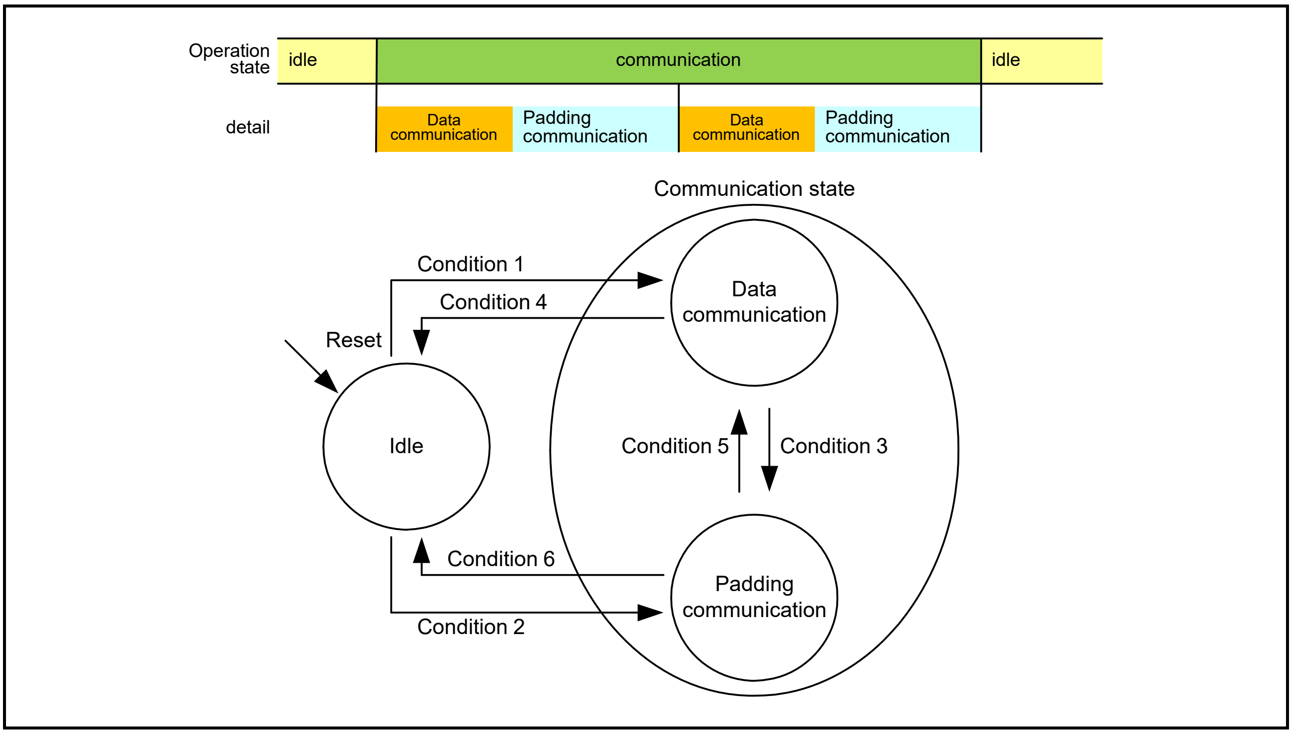

Figure 41.46 **Communication state transition**

Table 41.15 **Condition for communication state transition**

Condition Number	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following three conditions are all met: • SSICR.TEN = 1 or SSICR.REN = 1 • In the setting with padding bits • The last bit of the data words has been transferred.
4	Both the following two conditions are met: • SSICR.SDTA = 1 or without padding bits • While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred.
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	Both the following two conditions are met: • SSICR.SDTA = 0 and with padding bits • While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred.

See Table 41.11 for the setting with/without padding bits.

41.7.2.1 Data communication state

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see Figure 41.47 and Figure 41.48.

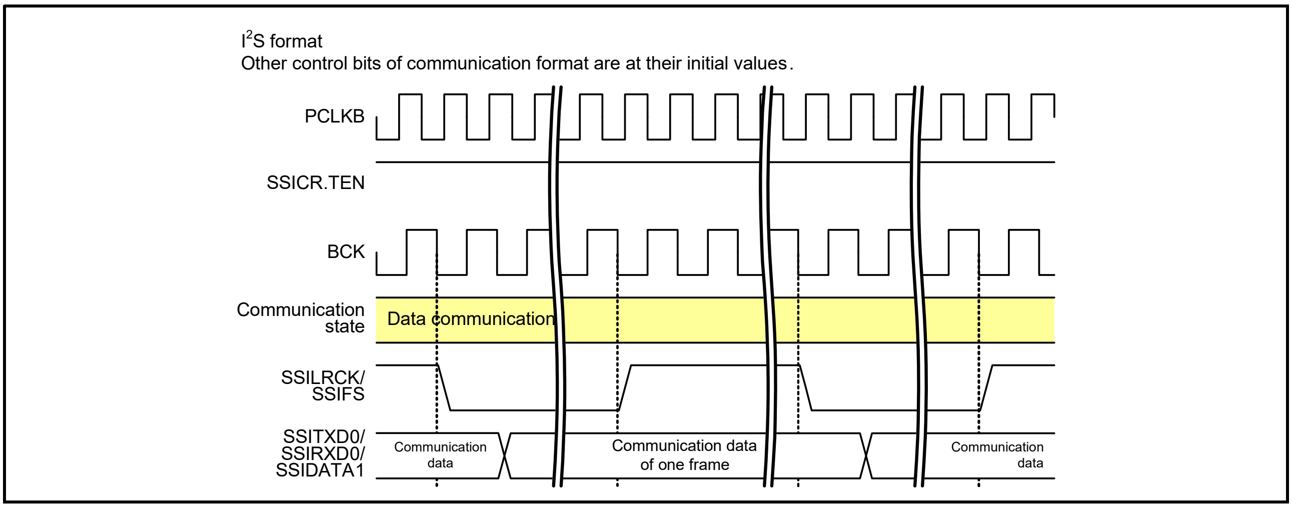

Figure 41.47 Continuation of the data communication

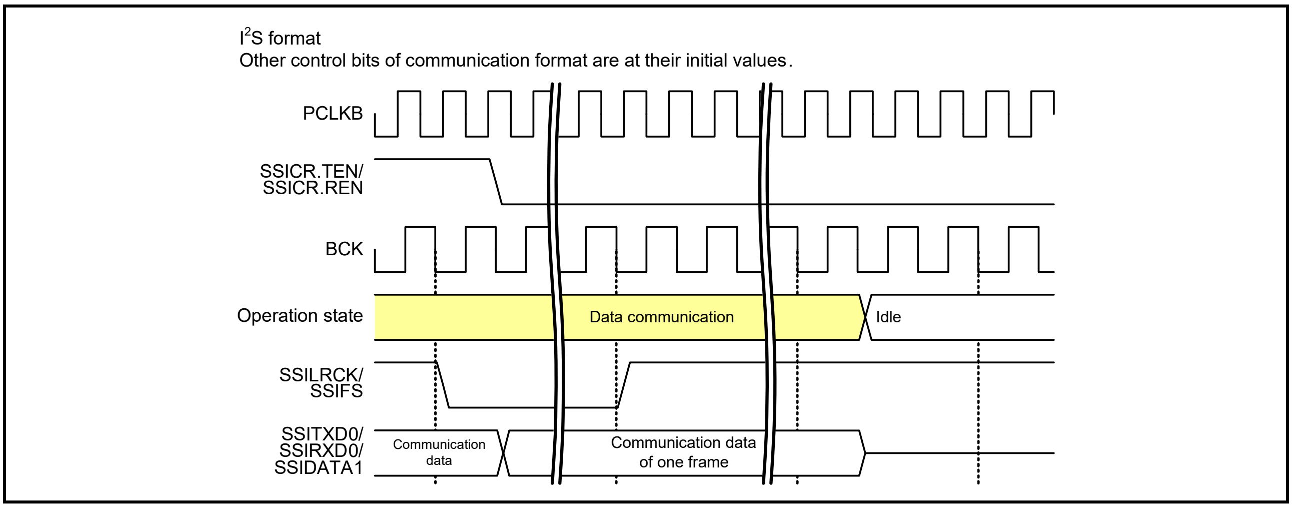

Figure 41.48 Halt from the data communication (without padding bits)

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in Figure 41.49. Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in Figure 41.51.

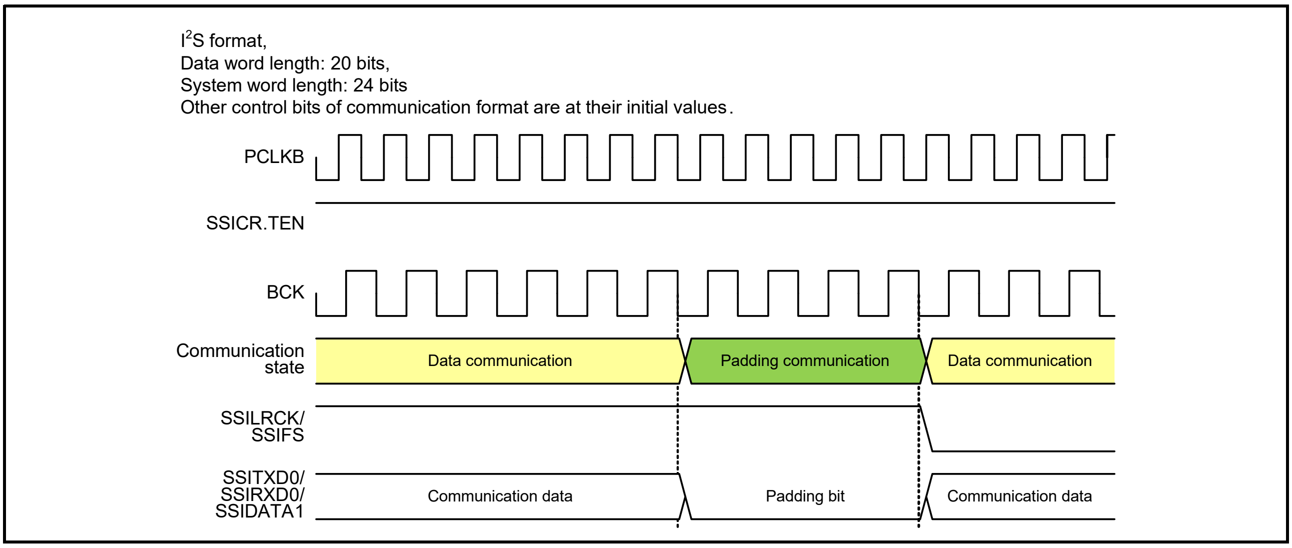

Figure 41.49 Transition from data communication to padding communication

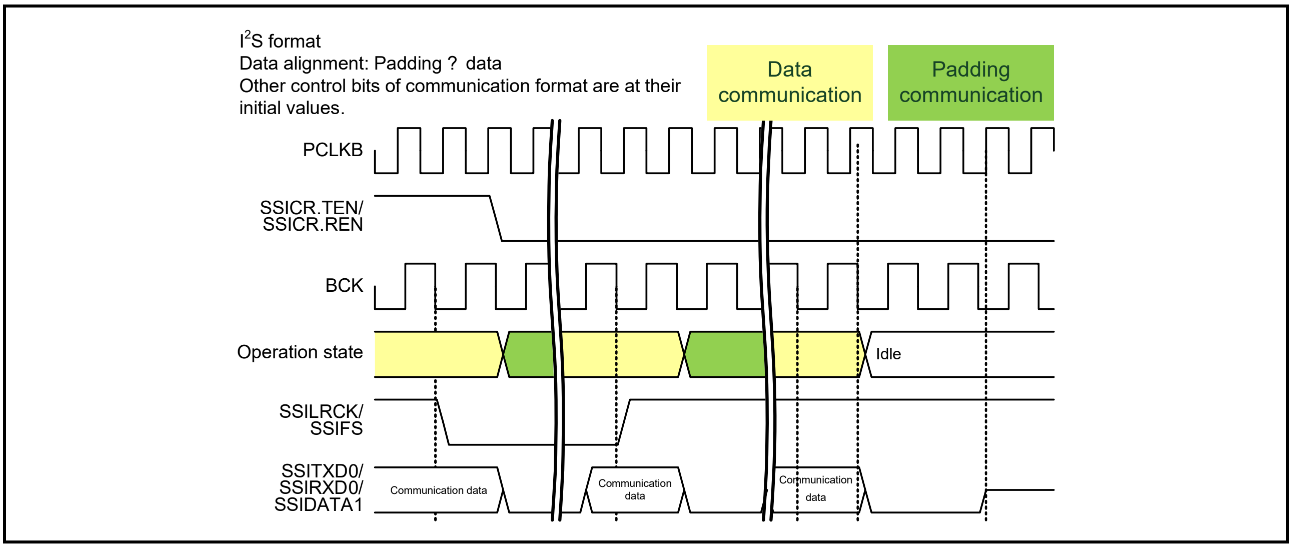

Figure 41.50 Halt from data communication (with padding bits)

41.7.2.2 Padding communication

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in Figure 41.49. If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in Figure 41.51.

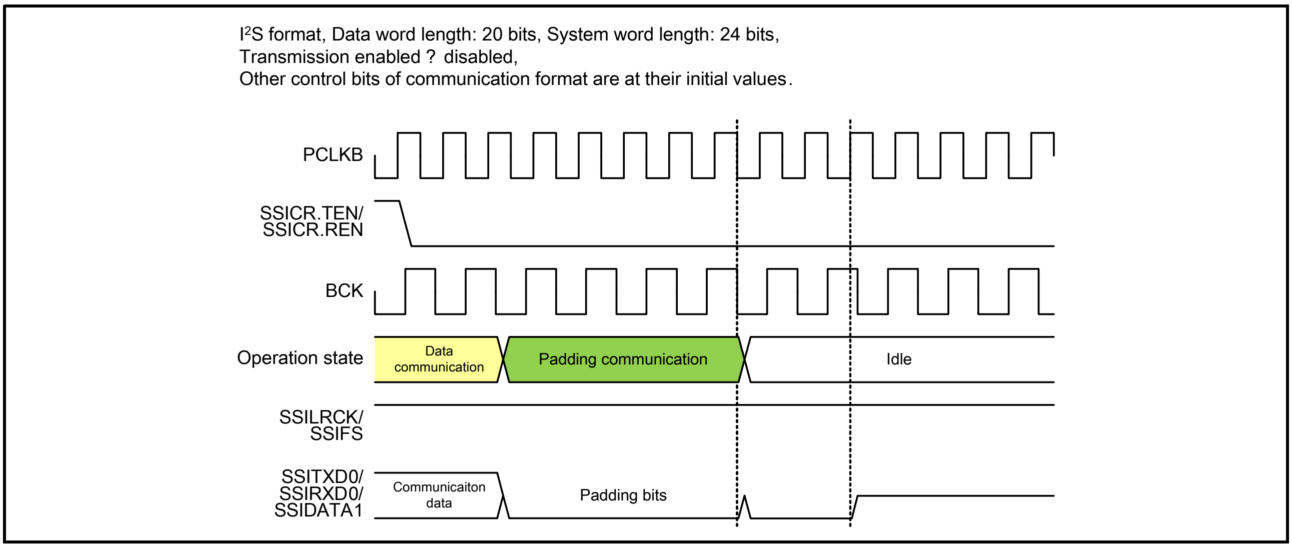

Figure 41.51 Halt from the padding communication

41.8 Communication Operation

Figure 41.52 shows the communication flow of SSIE.

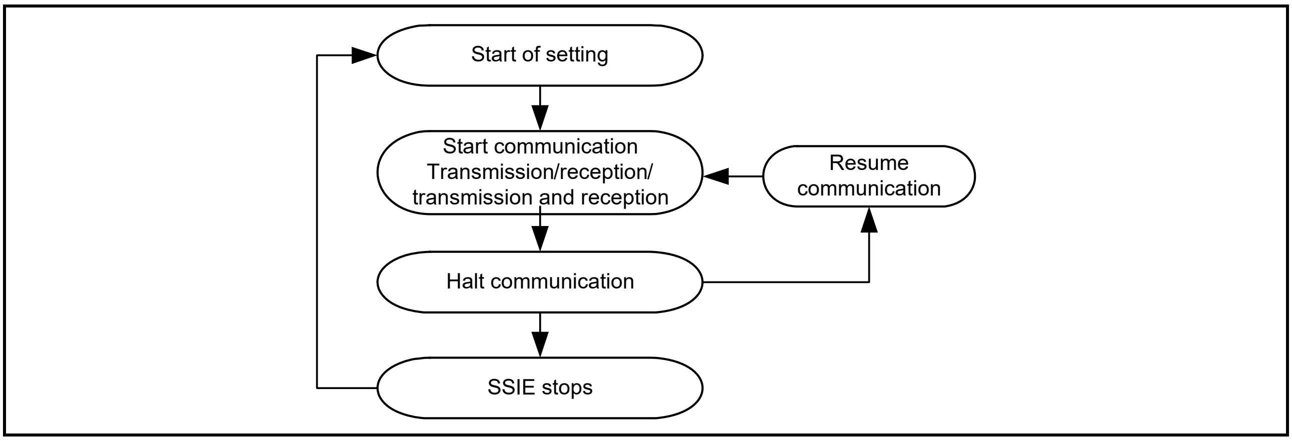

Figure 41.52 SSIE communication operation

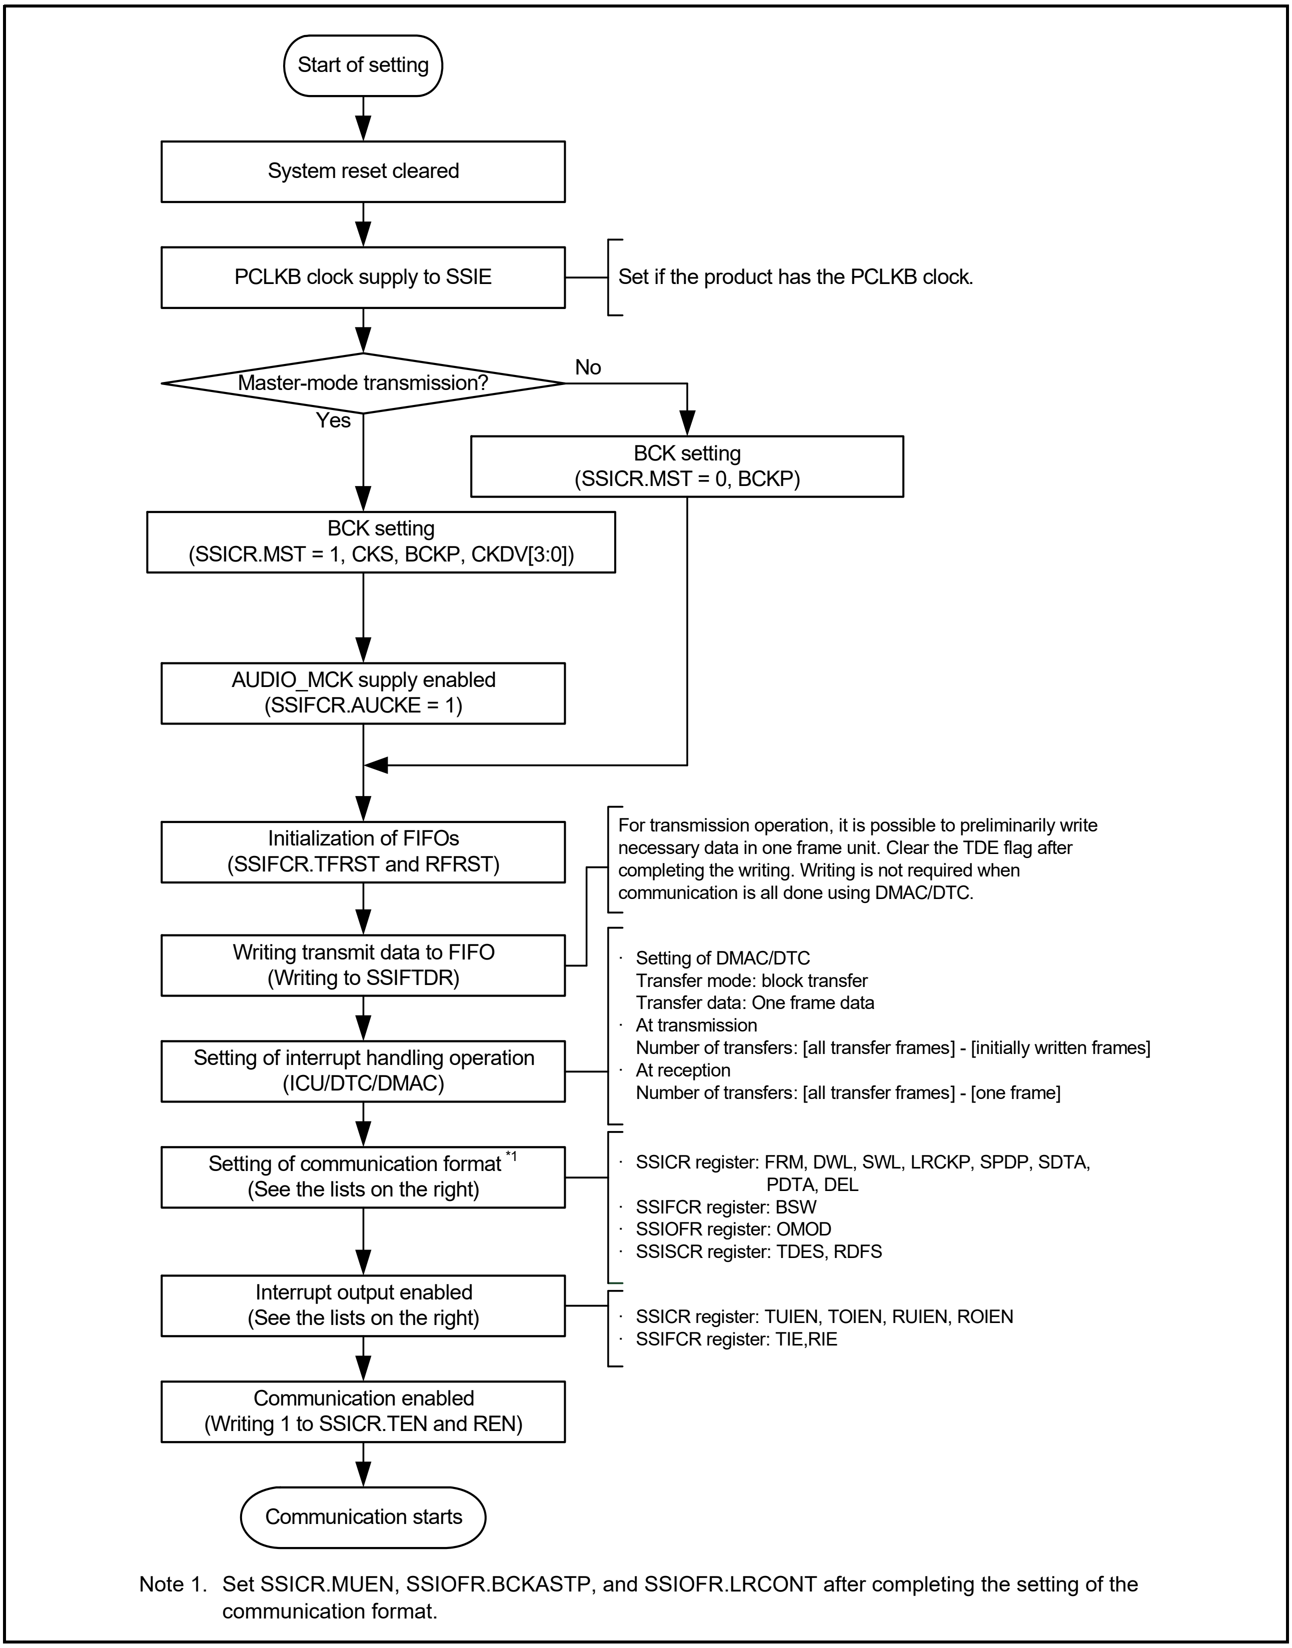
The procedure of each operation is described from reference 41.8.1 to reference 41.8.7.

41.8.1 Start Communication

This section describes how to start communication of SSIE. Figure 41.53 shows the procedure to start communication. Be sure to follow the procedure. See reference 41.8.2 for transmission operation and reference 41.8.3 for reception operation.



Note 1. Set SSICR.MUEN, SSIOFR.BCKASTP, and SSIOFR.LRCONT after completing the setting of the communication format.

Figure 41.53 Procedure to start communication (CPU operation procedure)

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

41.8.2 Transmission

The transmission procedure in Figure 41.54 must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCK/SSIFS with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

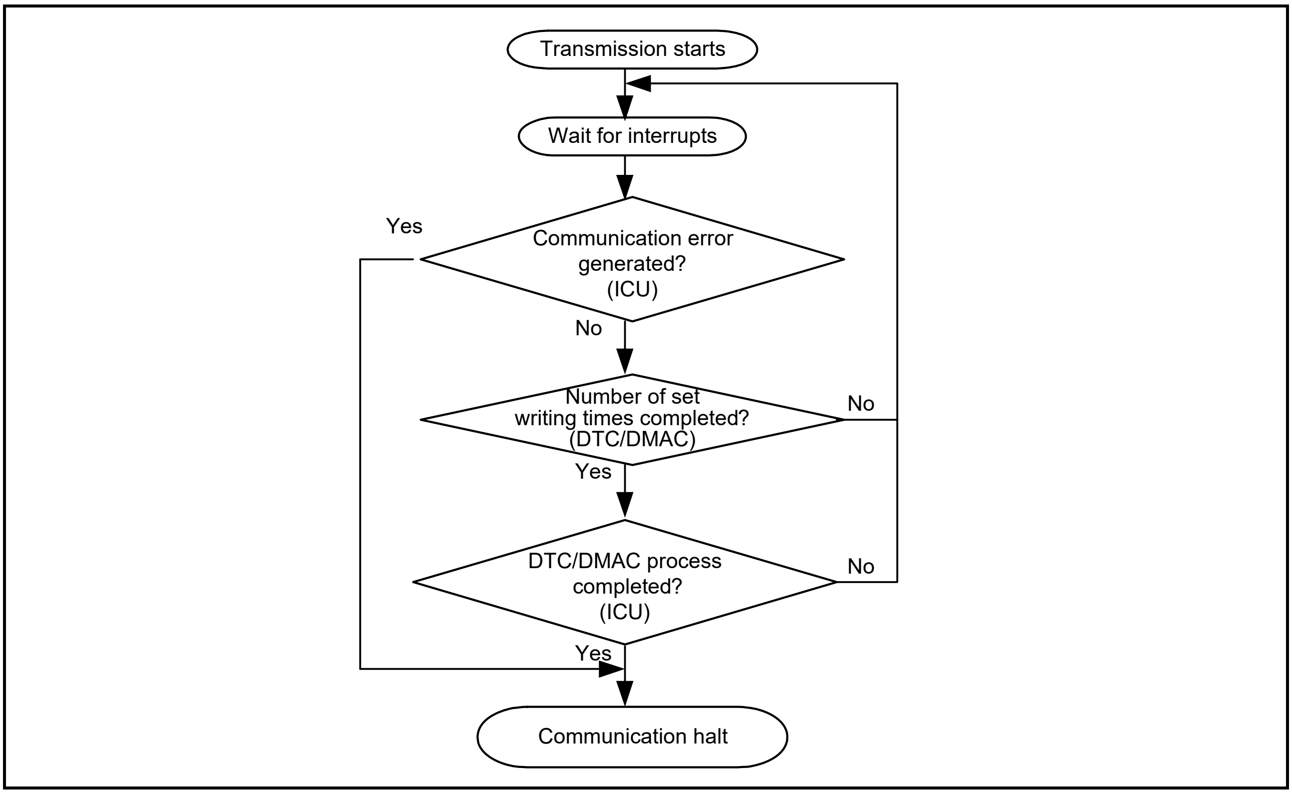


Figure 41.54 Transmission procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

41.8.3 Reception

The reception procedure in Figure 41.55 must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCK/SSIFS. SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times of reading must be specified in accordance with the data size of the receive FIFO data register indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

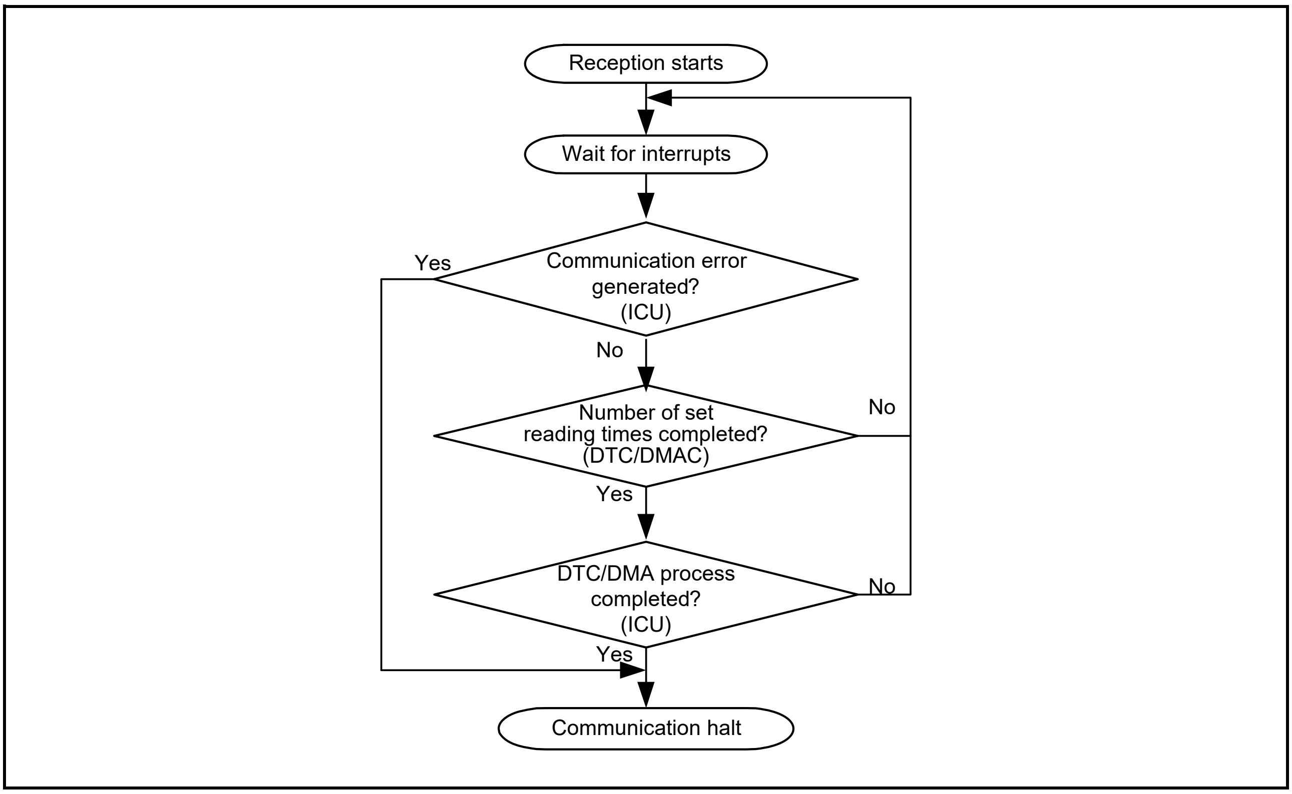

Figure 41.55 Reception procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

41.8.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCK/SSIFS with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in reference 41.8.2 and reference 41.8.3, respectively. For how to stop transmission and reception, see reference 41.8.5.

41.8.5 Halt Communication

This section describes how to halt communication of SSIE. Figure 41.56 shows the procedure to halt communication. Be sure to follow the procedure.

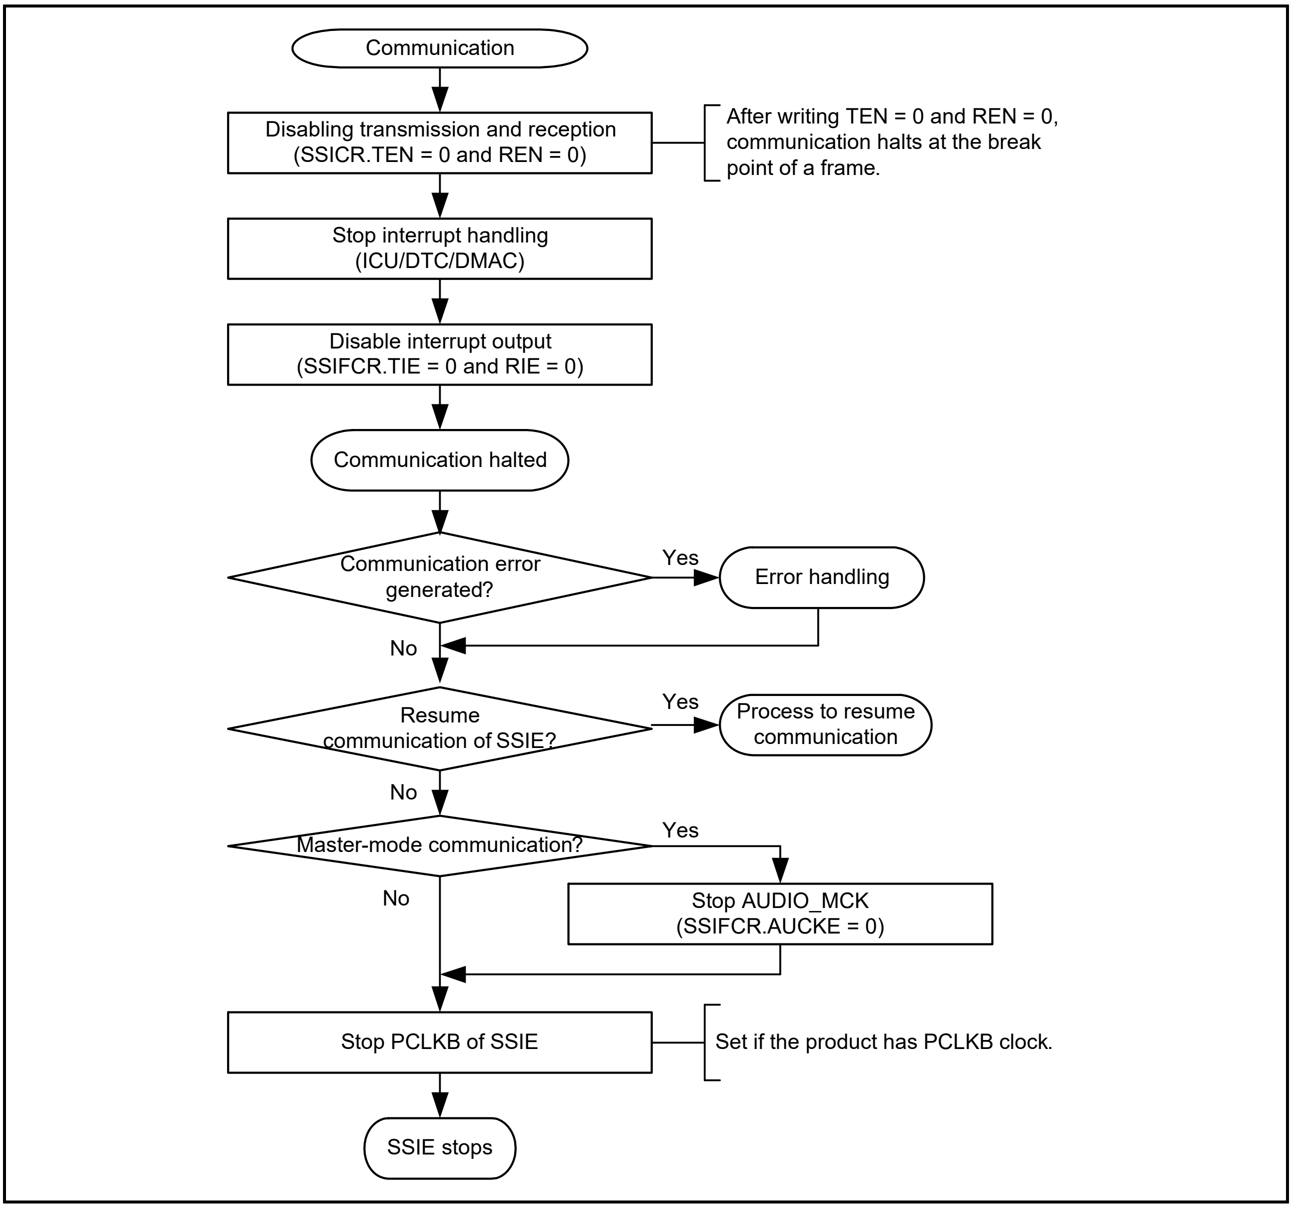

Figure 41.56 Procedure to halt communication (CPU operation procedure)

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1

To resume communication of SSIE in the previous setting, see reference 41.8.7.

Note: When communication of SSIE is halted according to the procedure to halt communication in Figure 41.56, resume communication according to the procedure to resume communication in Figure 41.58.

41.8.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

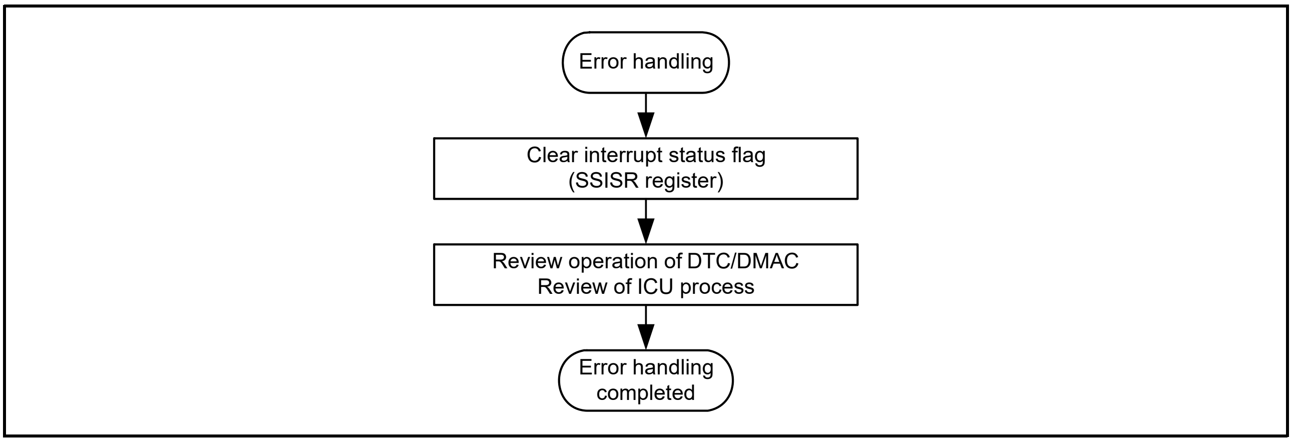

Figure 41.57 Error-handling procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See descriptions of flags in reference 41.4.2 for the setting conditions of error flags.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

41.8.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in Figure 41.58. The communication resume procedure is designed on the assumption that you resume the communication stopped by the communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in Figure 41.53. For details about the transmission operation and reception operation after starting communication, see reference 41.8.2 and reference 41.8.3, respectively.

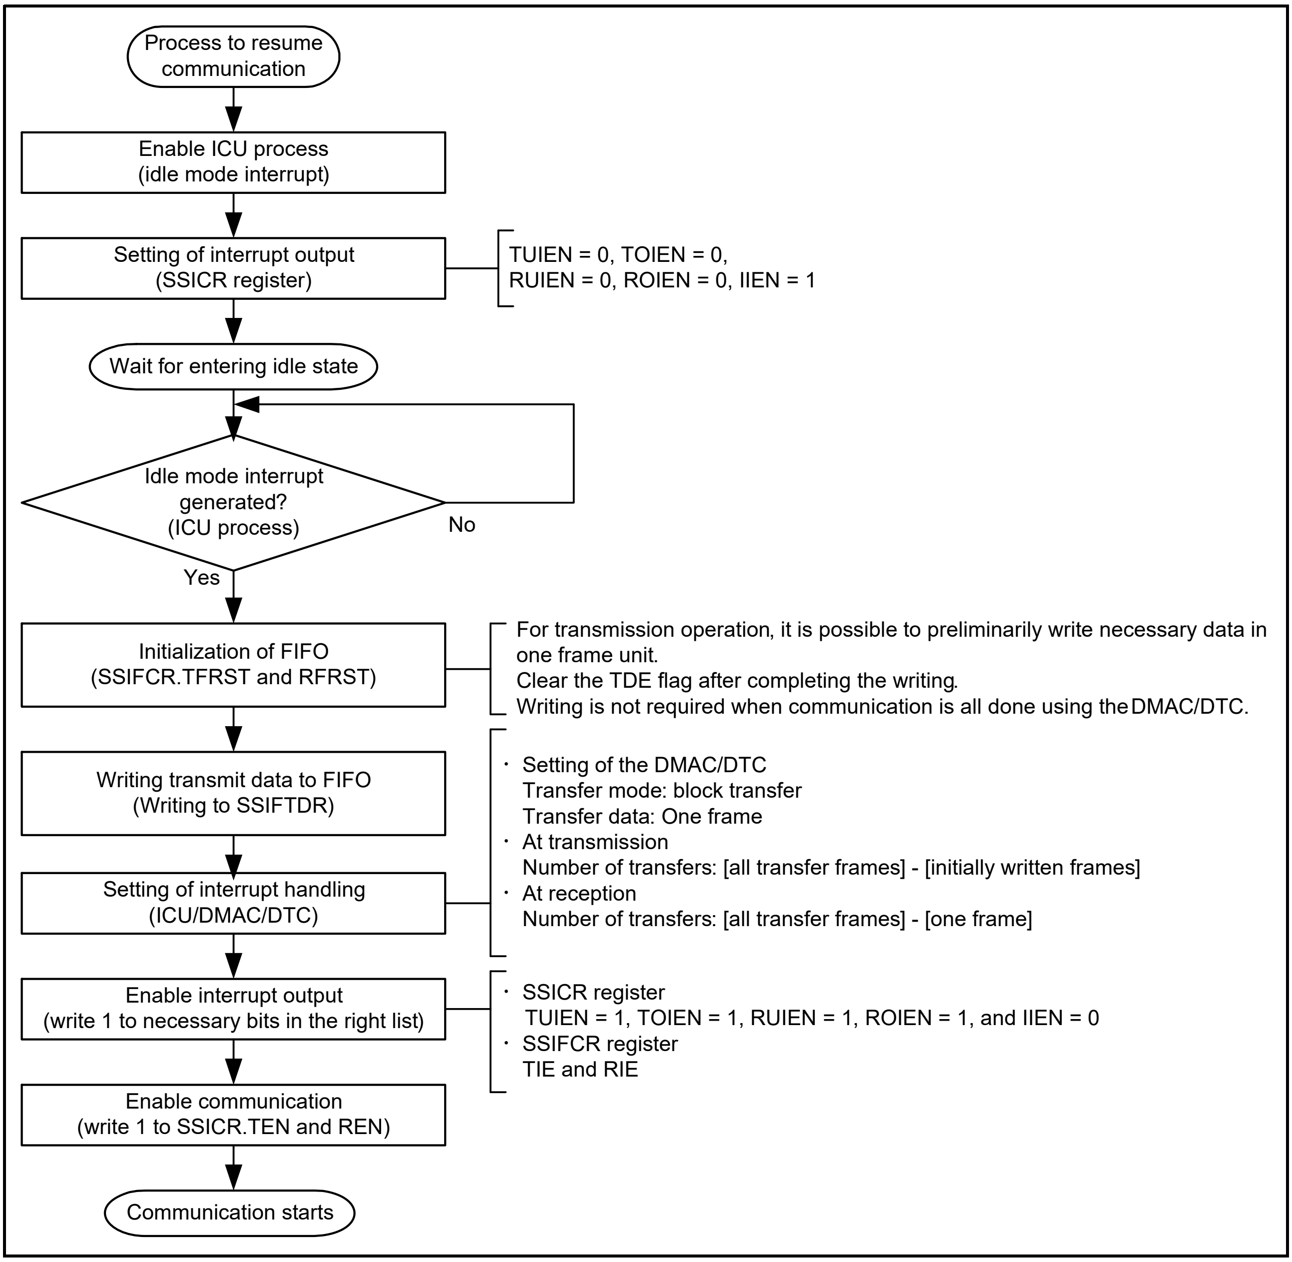

Figure 41.58 Procedure to resume communication (CPU operation procedure)

41.9 Interrupts

Table 41.16 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 41.16 SSIE interrupt sources

Channel	Interrupt source	Description	Interrupt flag	DMAC/DTC activation
SSIE0	SSIE0_SSIF	• Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE0_SSIRXI	Receive data full interrupt	SSIFSR.RDF	Possible
	SSIE0_SSITXI	Transmit data empty interrupt	SSIFSR.TDE	Possible
SSIE1	SSIE1_SSIF	• Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE1_SSIRT	• Receive data full interrupt • Transmit data empty interrupt	SSIFSR.RDF/ SSIFSR.TDE	Possible

41.9.1 SSIEn_SSIF Interrupt

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

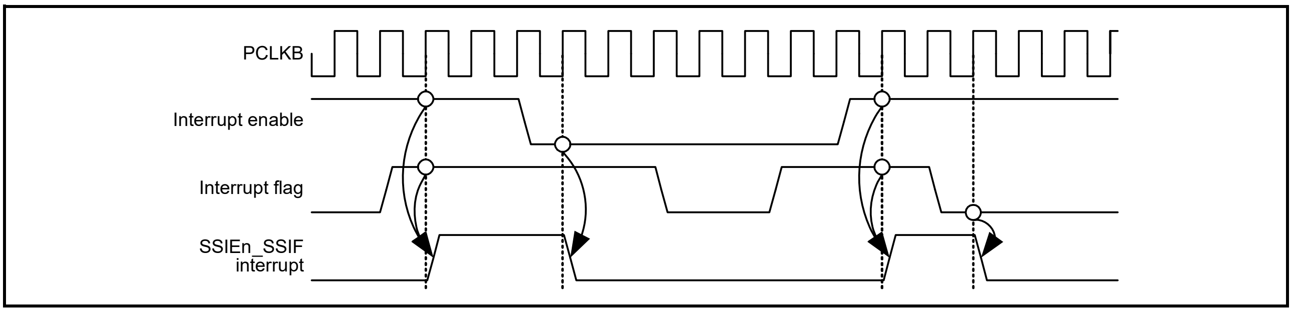

Figure 41.59 Timing Diagram of the common interrupt source, SSIEn_SSIF

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIRQ = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

41.9.2 SSIE0_SSITXI Interrupt [Full-duplex communication]

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1

  SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1

  CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 41.60.

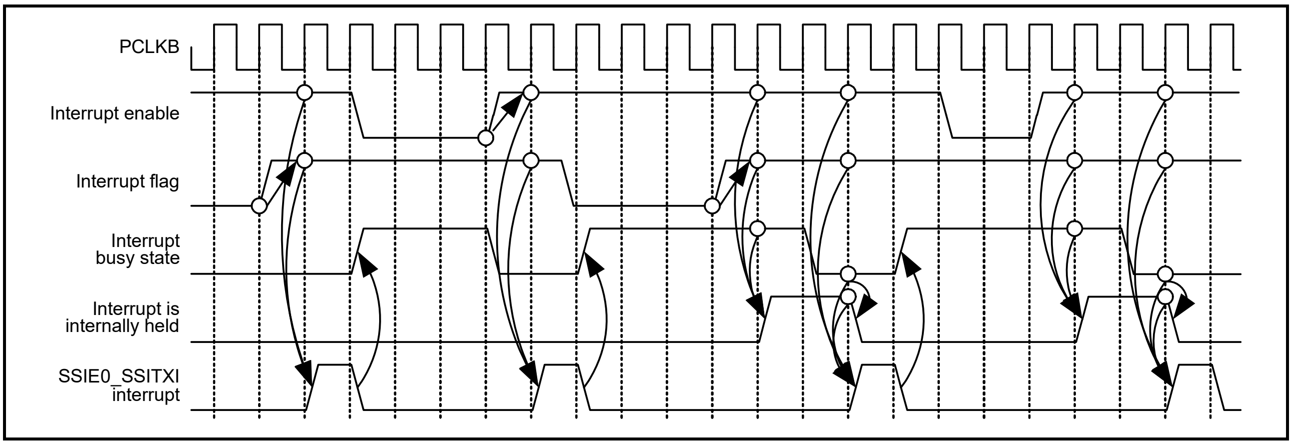

Figure 41.60 SSIE0_SSITXI interrupt timing diagram

41.9.3 SSIE0_SSIRXI Interrupt [Full-duplex communication]

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.

  SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1

  CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in Figure 41.60.

41.9.4 SSIE1_SSIRT Interrupt [Half-duplex communication]

This interrupt is output by two sources, transmit data empty interrupt and receive data full interrupt. When this interrupt is generated, read the interrupt flag and specify the interrupt source.

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 41.61.

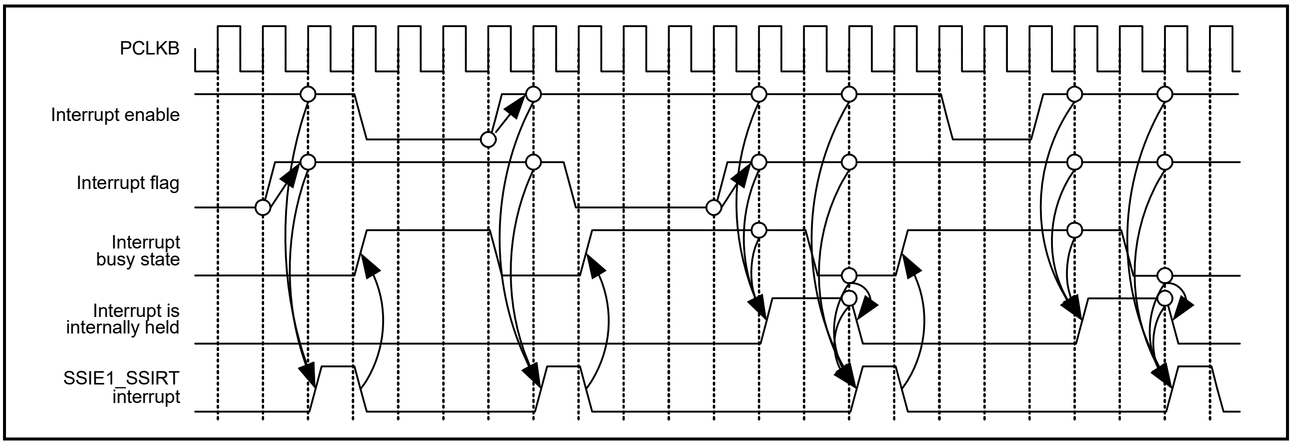

Figure 41.61 SSIE1_SSIRT interrupt timing diagram

41.10 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

41.10.1 Software Reset Procedure

(1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in Figure 41.62. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication in Figure 41.53. See reference 41.8.2 and reference 41.8.3 respectively for transmission and reception after communication is resumed.

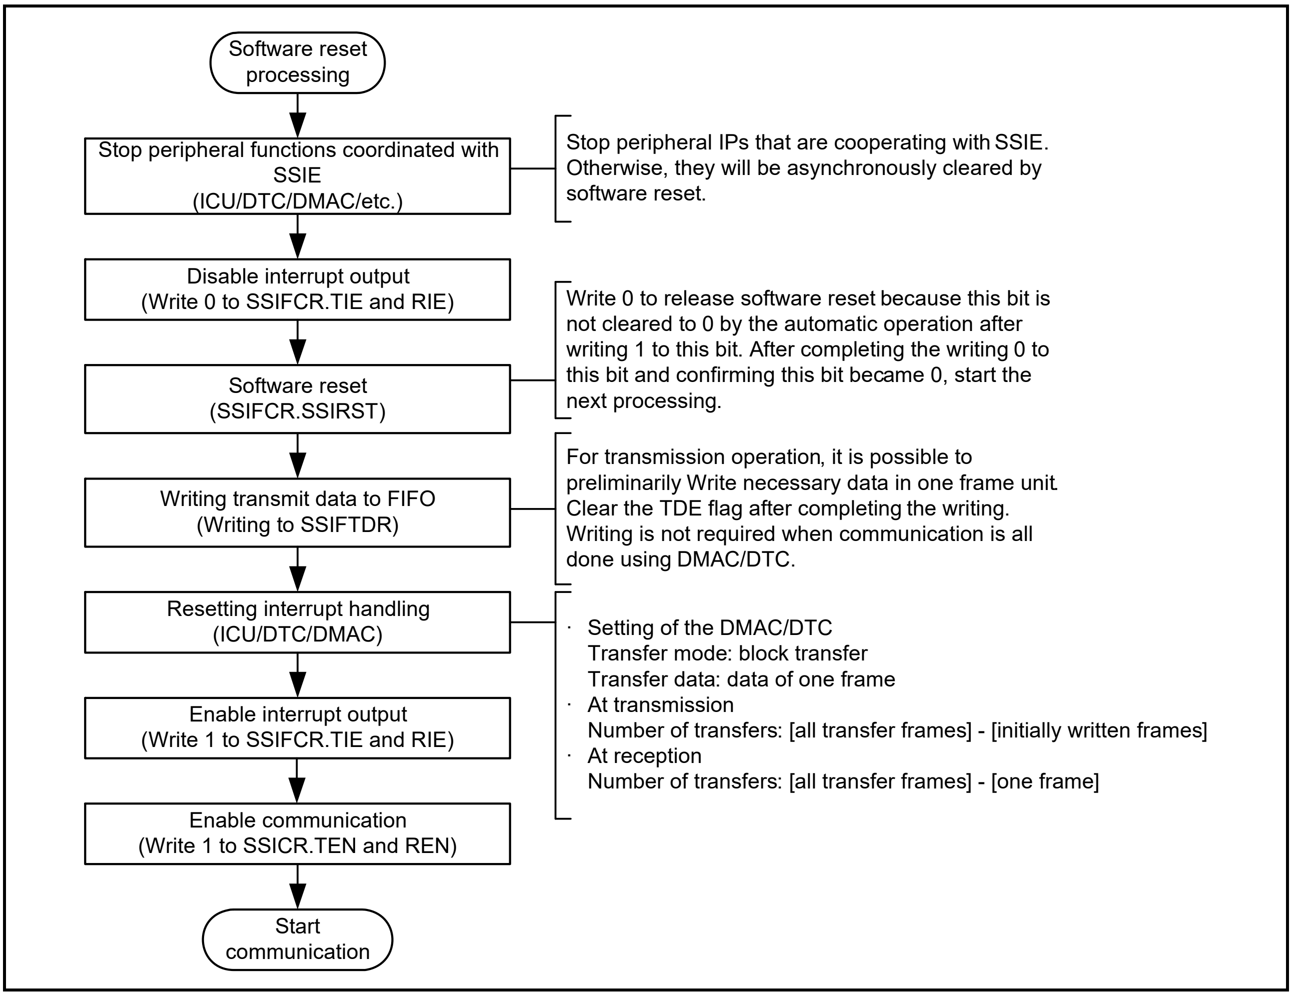

Figure 41.62 Software reset procedure (CPU operation procedure)

(2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in Figure 41.53 and procedure to resume communication in Figure 41.58.

(3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in Figure 41.53 and procedure to resume communication in Figure 41.58.

41.11 Notes

41.11.1 Notes for Slave-mode Communication

41.11.1.1 ADCKE control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 41.53 or wait for an idle state by taking the procedure to resume communication in Figure 41.58.

41.11.1.2 SSILRCK/SSIFS pin

SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

41.11.2 Notes for Master-mode Communication

41.11.2.1 ADCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE.

41.11.2.2 LRCONT control

To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see Figure 41.44.

41.11.2.3 BCKASTP control

To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see Figure 41.45.

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK pin before and during communication.

41.11.3 Notes for Communication Flow

41.11.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 41.56 and error-handling procedure in Figure 41.57.

41.11.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

41.11.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

41.11.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit and the SSICR.REN bit again and resume transfer.

41.11.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in Figure 41.56, resume communication according to the procedure to resume communication in Figure 41.58.

41.11.4 Write Access Restriction

41.11.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

(1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK/SSIFS signal. For details, see reference 41.8.2, reference 41.8.3, and reference 41.8.4. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

41.11.4.2 SSISR register

(1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

(2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

41.11.4.3 Communication state

Writing to the bits with orange-shaded area in Table 41.17 is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 41.17 Bits protected from writing during communication

Symbol	Address (BASE+)		+0								+1

42. Sampling Rate Converter (SRC)

42.1 Overview

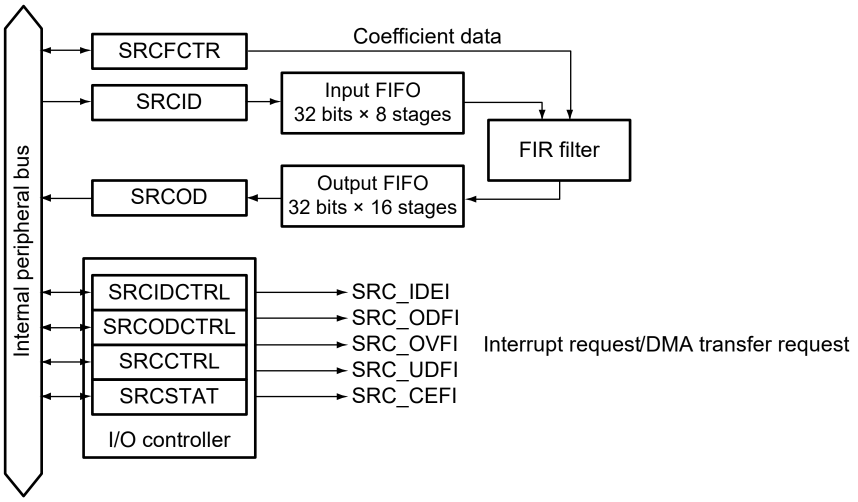
The Sampling Rate Converter (SRC) is used to convert the sampling rate of data produced by various audio decoders, including WMA, MP3, and AAC. Both 16-bit stereo and monaural data are supported. The sampling rate of the input signal can be one of the following (in kHz): 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, or 48 kHz. The sampling rate of the output signal can be one of the following (in kHz): 8, 16, 32, 44.1, or 48 kHz. Independent FIFOs are provided for input and output. In a typical application, a DMA controller can be used to transfer PCM audio data from the SRAM (for example) to the SRC. Sample-converted audio data from the SRC can then be transferred using the DMA Controller to the SSIE interface, from where it can be transmitted to an external audio codec.

Table 42.1 shows the SRC specifications and Figure 42.1 shows a block diagram.

Table 42.1 SRC specifications

Parameter		Specifications
Data size		16 bits (stereo/monaural)
Sampling rates	Input	Selectable to 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, or 48 kHz
	Output	Selectable to 8*1, 16*1, 32, 44.1, or 48 kHz
Processing capacity		Maximum of 7.7 μs for one sample output interval (PCLKB = 60 MHz, 462 clocks)
SNR		80 db or higher
Interrupt sources		Five Input FIFO empty, output FIFO full, output FIFO overflow, output FIFO underflow, and conversion end
DMA transfer sources		Two Input FIFO empty and output FIFO full
Module-stop function		Module-stop state can be set to reduce power consumption

Note 1. Only when input of 44.1 kHz is selected.



SRCFCTR: Filter Coefficient Table
SRCID: Input Data Register
SRCOD: Output Data Register
SRCIDCTRL: Input Data Control Register
SRCODCTRL: Output Data Control Register
SRCCTRL: Control Register
SRCSTAT: Status Register

Figure 42.1 SRC block diagram

42.2 Register Descriptions

42.2.1 Input Data Register (SRCID)

Address(es): SRC.SRCID 4004 DFF0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SRCID register is a 32-bit write-only register used to input the data before sampling rate conversion. All the bits are read as 0. The data input to SRCID is stored in the 8-stage input FIFO. When the number of data units in the input FIFO is 8, writing to SRCID has no effect.

For stereo data, bits [31:16] are for Lch data, and bits [15:0] are for Rch data. For monaural data, data in bits [31:16] is valid, and data in bits 15 to 0 is invalid.

The data subject to sampling rate conversion is aligned differently depending on the IED setting in SRCIDCTRL. Table 42.2 shows the correspondence between the IED setting and data alignment.

Table 42.2 Data alignment before sampling rate conversion

IED	Lch[15:8]	Lch[7:0]	Rch[15:8]	Rch[7:0]
0	SRCID[31:24]	SRCID[23:16]	SRCID[15:8]	SRCID[7:0]
1	SRCID[23:16]	SRCID[31:24]	SRCID[7:0]	SRCID[15:8]

42.2.2 Output Data Register (SRCOD)

Address(es): SRC.SRCOD 4004 DFF4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SRCOD register is a 32-bit read-only register used to output the data after sampling rate conversion. The data in the 16-stage output FIFO is read through SRCOD. When the output FIFO is empty after the start of conversion, the value previously read is read again.

The data in SRCOD is aligned differently depending on the OCH and OED settings in SRCODCTRL. Table 42.3 shows the correspondence between the OCH and OED settings and data alignment in SRCOD.

Table 42.3 Data alignment in SRCOD (1 of 2)

OCH	OED	SRCOD[31:24]	SRCOD[23:16]	SRCOD[15:8]	SRCOD[7:0]
0	0	Lch[15:8]	Lch[7:0]	Rch[15:8]*1	Rch[7:0]*1
	1	Lch[7:0]	Lch[15:8]	Rch[7:0]*1	Rch[15:8]*1

Table 42.3 Data alignment in SRCOD (2 of 2)

OCH	OED	SRCOD[31:24]	SRCOD[23:16]	SRCOD[15:8]	SRCOD[7:0]
1*2	0	Rch[15:8]	Rch[7:0]	Lch[15:8]	Lch[7:0]
	1	Rch[7:0]	Rch[15:8]	Lch[7:0]	Lch[15:8]

Note 1. When processing monaural data, the data in these bits is invalid. Discard the invalid data after reading from SRCOD in 32-bit units.

Note 2. When processing monaural data, the data in these bits is invalid.

42.2.3 Input Data Control Register (SRCIDCTRL)

Address(es): SRC.SRCIDCTRL 4004 DFF8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IED	IEN	—	—	—	—	—	—	IFTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	IFTRG[1:0]	Input FIFO Data Triggering Number	b1 b0 0 0: 0 0 1: 2 1 0: 4 1 1: 6.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	IEN	Input FIFO Empty Interrupt Enable	0: Disable input FIFO empty interrupts 1: Enable input FIFO empty interrupts.	R/W
b9	IED	Input Data Endian*1	0: Little endian 1: Big endian.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only rewrite this bit while the SRCCTRL.SRCEN bit is 0.

The SRCIDCTRL register is a 16-bit read/write register that specifies the endian format of input data, enables or disables the interrupt requests, and specifies the triggering number of data units.

IFTRG[1:0] bits (Input FIFO Data Triggering Number)

The IFTRG[1:0] bits specify the data unit count at which the IINT flag in the Status Register (SRCSTAT) sets to 1. When the number of data units stored in the input FIFO becomes equal to or less than the specified triggering number, the IINT flag sets to 1.

IEN bit (Input FIFO Empty Interrupt Enable)

The IEN bit enables or disables issuing of the input FIFO empty interrupt request when the number of data units in the input FIFO becomes equal to or less than the triggering number specified in the IFTRG[1:0] bits, resulting in the IINT flag in the Status Register (SRCSTAT) setting to 1.

IED bit (Input Data Endian)

The IED bit specifies the endian format of the input data.

42.2.4 Output Data Control Register (SRCODCTRL)

Address(es): SRC.SRCODCTRL 4004 DFFAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OCH	OED	OEN	—	—	—	—	—	—	OFTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	OFTRG[1:0]	Output FIFO Data Trigger Number	b1 b0 0 0: 1 0 1: 4 1 0: 8 1 1: 12.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	OEN	Output FIFO Full Interrupt Enable	0: Disable output FIFO full interrupts 1: Enable output FIFO full interrupts.	R/W
b9	OED	Output Data Endian	0: Little endian 1: Big endian.	R/W
b10	OCH	Output Data Channel Exchange *1	0: Do not exchange channels (use same order as data input) 1: Exchange channels (use opposite order from data input).	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only rewrite this bit while the SRCCTRL.SRCEN bit is 0.

The SRCODCTRL register is a 16-bit read/write register that specifies whether to exchange the channels for the output data, specifies the endian format of output data, enables or disables the interrupt requests, and specifies the triggering number of data units.

OFTRG[1:0] bits (Output FIFO Data Trigger Number)

The OFTRG[1:0] bits specify the data unit count at which the OINT flag in the Status Register (SRCSTAT) sets to 1. When the number of data units in the output FIFO becomes equal to or greater than the specified triggering number, the OINT flag sets to 1.

OEN bit (Output FIFO Full Interrupt Enable)

The OEN bit enables or disables issuing of the output FIFO full interrupt request when the number of data units in the output FIFO becomes equal to or greater than the number specified in the OFTRG[1:0] bits, resulting in the OINT flag in the Status Register (SRCSTAT) setting to 1.

OED bit (Output Data Endian)

The OED bit specifies the endian format of the output data.

OCH bit (Output Data Channel Exchange)

The OCH bit specifies whether to exchange the channels for the Output Data Register (SRCOD). Do not set this bit to 1 when processing monaural data.

42.2.5 Control Register (SRCCTRL)

Address(es): SRC.SRCCTRL 4004 DFFCh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b15	FICRAE	Filter Coefficient Table Access Enable	0: Disable reads to and writes from filter coefficient table RAM 1: Enable reads to and writes from filter coefficient table RAM.	R/W

Note 1. Only valid when the IFS[3:0] bits are 1001b.
Note 2. When SRCEN = 1, do not change the settings of the following bits:
IED bit in SRCIDCTRL, OED and OCH bits in SRCODCTRL, OFS[2:0], IFS[3:0], and FICRAE bits in SRCCTRL.

The SRCCTRL register is a 16-bit read/write register that enables or disables access to the Filter Coefficient Table, module operations, and interrupt requests, and specifies flush processing, clear processing of the internal work memory, and the input and output sampling rates.

OFS[2:0] bits (Output Sampling Rate)

The OFS[2:0] bits specify the output sampling rate.

IFS[3:0] bits (Input Sampling Rate)

The IFS[3:0] bits specify the input sampling rate.

CL bit (Internal Work Memory Clear)

Writing 1 to the CL bit clears the input FIFO, output FIFO, input buffer memory, intermediate buffer memory, and accumulator, and then the CL bit clears to 0. This bit is read as 0. Even if SRCEN = 0, writing 1 to this bit clears the processing.

FL bit (Internal Work Memory Flush)

Writing 1 to the FL bit initiates flush processing by starting conversion of the sampling rate of all the data in the input FIFO, input buffer memory, and intermediate memory. This bit is read as 0. When SRCEN = 0, writing 1 to this bit does not trigger flush processing.

In addition, when 1 is written to the FL bit while the number of data units in the input buffer memory is less than the values shown in Table 42.6, valid output data cannot be received. The internal work memory is cleared without triggering the flush processing.

OVEN bit (Output FIFO Overflow Interrupt Enable)

The OVEN bit enables or disables issuing of the output FIFO overflow interrupt request when the OVF flag in the Status Register (SRCSTAT) is set to 1.

When OVEN = 1: Conversion processing stops until the OVF flag is cleared by the CPU accessing SRCSTAT when the output FIFO overflow interrupt is generated. Writing of conversion results to the output FIFO also stops.

When OVEN = 0: The OVF flag automatically clears when the output FIFO has space, and conversion processing can be continued.

UDEN bit (Output FIFO Underflow Interrupt Enable)

The UDEN bit enables or disables issuing of the output FIFO underflow interrupt request when the output FIFO is read and the UDF flag in the Status Register (SRCSTAT) sets to 1 while the number of data units in the output FIFO is zero.

SRCEN bit (Module Enable)

The SRCEN bit enables or disables SRC operation. Writing 1 to these bits while SRCEN = 0 clears the internal work memory.

CEEN bit (Conversion End Interrupt Enable)

The CEEN bit enables or disables issuing of a conversion end interrupt request when the CEF flag in the Status Register (SRCSTAT) sets to 1 after flush processing is complete and all the output data is read.

FICRAE bit (Filter Coefficient Table Access Enable)

The FICRAE bit enables or disables access to the filter coefficient table RAM. After flush processing is complete, the number of output data units obtained as a result of conversion can be calculated using the following formulas:

$$\frac{\text{Number of output data units} - 1}{\text{Output sampling rate}} = \frac{\text{Number of input data units} \times n - 1}{\text{Input sampling rate} \times n}$$

$$\text{Number of output data units} = \left[(\text{Number of input data units} \times n - 1) \times \frac{\text{Output sampling rate}}{\text{Input sampling rate} \times n} \right] + 1$$

The value of n can be obtained from Table 42.4. The number of input data units must be equal to or greater than the values in Table 42.5.

Table 42.4 Sampling rate settings and value of n

OFS[2:0] setting (output sampling rate [kHz])	IFS[3:0] setting (input sampling rate [kHz])								
	0000b (8.0)	0001b (11.025)	0010b (12.0)	0100b (16.0)	0101b (22.05)	0110b (24.0)	1000b (32.0)	1001b (44.1)	1010b (48.0)
000b (44.1)	6	4	4	3	2	2	3	—	1
001b (48.0)	6	4	4	3	2	2	3	1	—
010b (32.0)	4	8	4	2	4	2	—	2	1
100b (8.0)	—	—	—	—	—	—	—	1	—
101b (16.0)	—	—	—	—	—	—	—	1	—

Conversion processing does not start, and so output data is not obtained, until the specified number of data units are input. The minimum number of input data units necessary for obtaining the first output data depends on the IFS and OFS bit settings. Table 42.5 shows the relation between the settings in the IFS and OFS bits and the number of initial input data required. Table 42.6 shows the relation between the settings in the IFS and OFS bits and the number of initial input data required for processing.

Table 42.5 Relation between sampling rate settings and number of initial input data units required

OFS[2:0] setting (output sampling rate [kHz])	IFS[3:0] setting (input sampling rate [kHz])								
	0000b (8.0)	0001b (11.025)	0010b (12.0)	0100b (16.0)	0101b (22.05)	0110b (24.0)	1000b (32.0)	1001b (44.1)	1010b (48.0)

42.2.6 Status Register (SRCSTAT)

Address(es): SRC.SRCSTAT 4004 DFFEh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OFDN[4:0]					IFDN[3:0]				—	CEF	FLF	UDF	OVF	IINT	OINT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit name	Description	R/W
b0	OINT	Output FIFO Full Interrupt Request Flag	0: Number of data units in output FIFO has not become equal to or greater than specified triggering number 1: Number of data units in output FIFO has become equal to or greater than specified triggering number.	R/(W) *1
b1	IINT	Input FIFO Empty Interrupt Request Flag	0: Number of data units in input FIFO has not become equal to or smaller than specified triggering number 1: Number of data units in input FIFO has become equal to or smaller than specified triggering number.	R/(W) *1
b2	OVF	Output FIFO Overflow Interrupt Request Flag	0: No output FIFO overflow occurred 1: Output FIFO overflow occurred.	R/(W) *1
b3	UDF	Output FIFO Underflow Interrupt Request Flag	0: No output FIFO underflow occurred 1: Output FIFO underflow occurred.	R/(W) *1
b4	FLF	Flush Processing Status Flag	0: Flush processing complete 1: Flush processing in progress.	R
b5	CEF	Conversion End Flag	0: Not all output data read 1: All output data read.	R/(W) *1
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10 to b7	IFDN[3:0]	Input FIFO Data Count	Indicates the number of data units in the input FIFO.	R
b15 to b11	OFDN[4:0]	Output FIFO Data Count	Indicates the number of data units in the output FIFO.	R

Note 1. Only 0 can be written after having read as 1.

The SRCSTAT register is a 16-bit read/write register that indicates the number of data units in the input and output FIFOs, whether the various interrupt sources were generated, and the flush processing status.

OINT flag (Output FIFO Full Interrupt Request Flag)

The OINT flag indicates that the number of data units in the output FIFO has become equal to or greater than the triggering number specified in the OFTRG[1:0] bits in the Output Data Control Register (SRCODCTRL).

[Setting condition]

- When the number of data units in the output FIFO becomes equal to or greater than the specified triggering number.

[Clearing conditions]

- Writing 0 to the OINT flag after reading it as 1
- When the last DMA transfer is executed
- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

IINT flag (Input FIFO Empty Interrupt Request Flag)

The IINT flag indicates that the number of data units in the input FIFO has become equal to or smaller than the triggering number specified in the IFTRG[1:0] bits in the Input Data Control Register (SRCIDCTRL).

[Setting conditions]

- When the number of data units in the input FIFO becomes equal to or smaller than the specified triggering number

- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

[Clearing conditions]

- Writing 0 to the IINT flag after reading is as 1
- When the last DMA transfer is executed.

OVF flag (Output FIFO Overflow Interrupt Request Flag)

The OVF flag indicates that the sampling rate conversion for the next data completes when the output FIFO is full. The conversion stops until the OVF flag is cleared.

[Setting condition]

- When the sampling rate conversion for the next data completes when the output FIFO is full.

[Clearing conditions]

- Writing 0 to the OVF flag after reading it as 1 while the SRCCTRL.OVEN bit is 1
- When the number of data units in the output FIFO decreases after reading SRCOD while the SRCCTRL.OVEN bit is 0
- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

UDF flag (Output FIFO Underflow Interrupt Request Flag)

The UDF flag indicates that the output FIFO is read when the number of data units in the output FIFO is zero.

[Setting condition]

- When the output FIFO is read while the number of data units in the output FIFO is zero.

[Clearing conditions]

- Writing 0 to the UDF flag after reading it as 1
- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

FLF flag (Flush Processing Status Flag)

The FLF flag indicates whether flush processing is in progress or not.

[Setting condition]

- Writing 1 to the SRCCTRL.FL bit
  (When flush processing is not in progress, however, FLF does not set to 1.)

[Clearing conditions]

- When flush processing completes
- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

CEF flag (Conversion End Flag)

The CEF flag indicates that all the output data is read after flush processing completes.

[Setting condition]

- When the number of data units in the output FIFO is zero on completion of flush processing.

[Clearing conditions]

- Writing 0 to the CEF flag after reading it as 1.

- Writing 1 to the SRCCTRL.CL bit
- Writing 1 to the SRCCTRL.SRCEN bit while it is 0.

IFDN[3:0] bits (Input FIFO Data Count)

The IFDN[3:0] bits indicate the number of data units in the input FIFO.

OFDN[4:0] bits (Output FIFO Data Count)

The OFDN[4:0] bits indicate the number of data units in the output FIFO.

42.2.7 Filter Coefficient Table n (SRCFCTRn) (n = 0 to 5551)

Address(es): SRCRAM.SRCFCTR0 to 5551 4004 8000h to 4004 D6BFh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	SRCFCOE[21:16]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRCFCOE[15:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

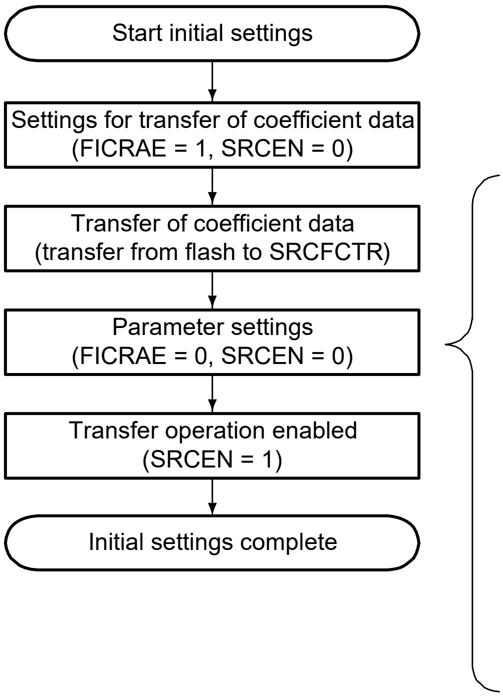
Bit	Symbol	Bit name	Description	R/W
b21 to b0	SRCFCOE[21:0]	Filter Coefficient Table	Stores the filter coefficient value.	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SRCFCTR0 to SRCFCTR5551 are 32-bit read/write SRAM modules that store the filter coefficients to be used for sampling rate conversion. This SRAM can be read from and written to through the peripheral bus only when the FICRAE bit is 1 and the SRCEN bit is 0 in SRCCTRL. Bits 31 to 22 are reserved and are read as 0, and their write values should be 0. Bits 21 to 0 are used for storage of the filter coefficient values, whose initial values are undefined.

42.3 Operation

42.3.1 Initial Settings

Figure 42.2 shows an example flow for the initial settings. After the module-stop state is released, the filter coefficient data stored in the flash and other areas must be transferred to the Filter Coefficient Table (SRCFCTR) before SRC conversion starts. When a filter coefficient value is already stored in the Filter Coefficient Table, skip this transfer and set the required parameters to start the conversion.



Register	Bit	Parameters to be set
SRCCTRL	FICRAE	Filter Coefficient Table access enable
	SRCEN	Module enable

Register	Bit	Parameters to be set
SRCCTRL	CEEN	Enabling/disabling of the SRC_CEFI interrupt
	UDEN	Enabling/disabling of the SRC_UDFI interrupt
	OVEN	Enabling/disabling of the SRC_OVFI interrupt
	IFS[3:0]	Input sampling rate
	OFS[2:0]	Output sampling rate
SRCIDCTRL	IED	Input data endianness
	IEN	Enabling/disabling of the SRC_IDEI interrupt
	IFTRG[1:0]	Input FIFO triggering number
SRCODCTRL	OCH	Exchanging of output data channels
	OED	Output data endianness
	OEN	Enabling/disabling of the SRC_ODFI interrupt
	OFTRG[1:0]	Output FIFO triggering number

Figure 42.2 Example flow for initial settings

42.3.2 Data Input

Figure 42.3 shows an example flow for data input.

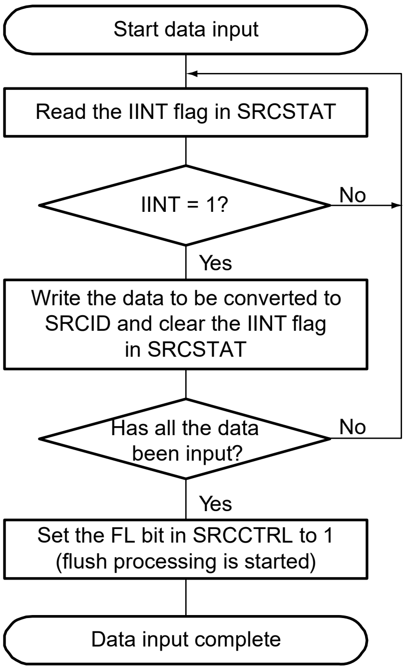


Figure 42.3 Data input flow

(1) When issuing interrupts to the CPU

1. Set the IEN bit in SRCIDCTRL to 1.
2. When the IINT flag in SRCSTAT sets to 1, the IDEI interrupt request is issued. In the interrupt processing routine, read the IINT flag and confirm that it is 1, write data to SRCID, and write 0 to the IINT flag. Then return from the interrupt processing routine.
3. Repeat step 2 until all the data is input, and write 1 to the FL bit in SRCCTRL.

(2) When using interrupts to activate the DMAC

1. Assign the SRC_IDEI interrupt of the SRC to one channel of the DMAC.
2. Set the IEN bit in SRCIDCTRL to 1.
3. When the IINT flag in SRCSTAT sets to 1, the SRC_IDEI interrupt request is issued, activating the DMAC. When data is written to the SRCID register using DMA transfer, and when the number of data units in the input FIFO exceeds the triggering number specified in the IFTRG[1:0] bits in SRCIDCTRL, the IINT flag in SRCSTAT clears to 0.
4. Repeat step 3 until all the data is input, and write 1 to the FL bit in SRCCTRL.

(3) When using SSIE interface interrupts to activate the DMAC to transfer input data from the SSIE interface

1. Assign the SSIE interface to one channel of the DMAC as a DMA transfer request source. Set SSIFRDR of the SSIE interface as a transfer source and SRCID of the SRC as a transfer destination, and set the SSIE interface to enable reception operation.
2. When the RDF bit in SSIFSR sets to 1, the SSIE interface issues an interrupt request, activating the DMAC. The DMAC then reads data from SSIFRDR and writes the data to SRCID.
3. Repeat step 2 until all the data is input, and write 1 to the FL bit in SRCCTRL.

Note: The input FIFO has eight stages. The number of data units that can be transferred (the empty space in the FIFO) when an SRC_IDEI interrupt request is issued depends on the settings in the IFTRG[1:0] bits in SRCIDCTRL. Because the input FIFO is not equipped with a function to prevent or detect overflow, the transferred data is destroyed when overflow occurs. To prevent this, take the settings in the IFTRG[1:0] bits in SRCCTRL into consideration when setting the number of data units to be continuously transferred by the DMA.

42.3.3 Data Output

Figure 42.4 shows an example flow for data output.

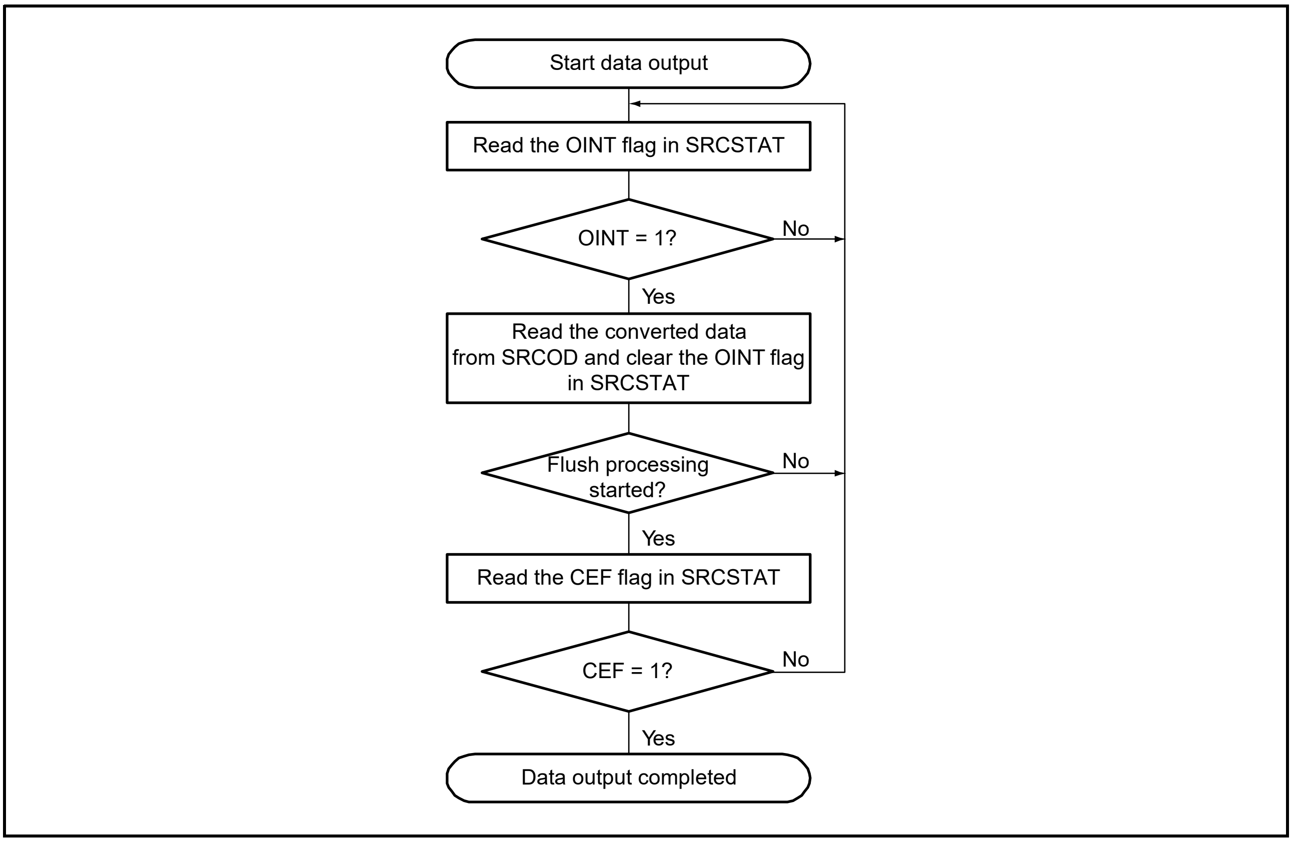

Figure 42.4 Data output flow

(1) When issuing interrupts to the CPU

1. Set the OEN bit in SRCODCTRL to 1.
2. When the OINT flag in SRCSTAT sets to 1, the SRC_ODFI interrupt request is issued. In the interrupt processing routine, read the OINT flag and confirm that it is 1, read data from SRCOD, and write 0 to the OINT flag. Then return from the interrupt processing routine.
3. After flush processing starts, repeat step 2 until the CEF flag in SRCSTAT is read as 1.

(2) When using interrupts to activate the DMAC

1. Assign the SRC_ODFI interrupt of the SRC to one channel of the DMAC.
2. Set the OEN bit in SRCODCTRL to 1.
3. When the OINT flag in SRCSTAT sets to 1, the SRC_ODFI interrupt request is issued, activating the DMAC. When data is read from SRCOD using DMA transfer, and when the number of data units in the output data FIFO becomes equal to or less than the triggering number specified in the OFTRG[1:0] bits, the OINT flag in SRCSTAT clears to 0.
4. After flush processing starts, repeat step 3 until the FLF flag in SRCSTAT is read as 0.

(3) When using SSIE interface interrupts to activate the DMAC to transfer output data to the SSIE interface

1. Set the OVEN bit in SRCCTRL to 0 to disable SRC_OVFI interrupt request generation.
2. Assign the SSIE interface to one channel of the DMAC as a DMA transfer request source. Set SRCID of the SRC as a transfer source and SSIFTDR of the SSIE interface as a transfer destination, and set the SSIE interface to enable transmission operation.
3. When the TDE bit in SSIFSR sets to 1, the SSIE interface issues an interrupt request, activating the DMAC. The DMAC then reads data from SRCOD and writes the data to SSIFTDR.

4. After flush processing starts, repeat step 3 until the CEF flag in SRCSTAT is read as 1.

Note 1. The output FIFO has 16 stages. The conversion stops when no data is read and an overflow occurs in the output FIFO. Even in an overflow state, data can be read from the output FIFO, but the procedure to restart conversion might be required depending on the settings. (For details, see the OVEN bit in SRCCTRL.)

Note 2. When the number of data units in the output FIFO is zero, incorrect data is read. To prevent this, take the settings of the OFTRG[1:0] bits into consideration when setting the number of data units to be continuously transferred by the DMAC.

42.4 Interrupts

The SRC interrupt sources include:

- Input FIFO empty (SRC_IDEI)
- Output FIFO full (SRC_ODFI)
- Output FIFO overflow (SRC_OVFI)
- Output FIFO underflow (SRC_UDFI)
- Conversion end (SRC_CEFI).

Table 42.7 lists the interrupt request types and generation conditions.

Table 42.7 Interrupt requests and generation conditions

Interrupt request	Abbreviation	Interrupt condition	DMAC activation
Input FIFO empty	SRC_IDEI	IINT = 1, IEN = 1, and SRCEN = 1	Possible
Output FIFO full	SRC_ODFI	OINT = 1, OEN = 1, and SRCEN = 1	Possible
Output FIFO overflow	SRC_OVFI	OVF = 1, OVEN = 1, and SRCEN = 1	Not possible
Output FIFO underflow	SRC_UDFI	UDF = 1, UDEN = 1, and SRCEN = 1	Not possible
Conversion end	SRC_CEFI	CEF = 1, CEEN = 1, and SRCEN = 1	Not possible

When an interrupt condition is satisfied, the CPU executes the interrupt exception handling routine. Clear the interrupt source flags during this routine.

The SRC_IDEI and SRC_ODFI interrupts can activate the DMAC. If the DMAC is activated, the interrupts from the SRC are not sent to the CPU.

Do not clear the IINT and OINT flags through a write by the CPU (writing 0 after reading 1) during the DMA transfer.

42.5 Usage Notes

42.5.1 Notes on Accessing Registers

The following writes to SRCCTRL require 3 cycles of the peripheral clock (PCLKB) for the values to be updated in SRCSTAT:

- Writes of 1 to the FL bit in SRCCTRL, for the FLF flag in SRCSTAT to set
- Writes of 1 to the CL bit in SRCCTRL, for each bit in SRCSTAT to initialize
- Writes of 1 to the SRCEN bit in SRCCTRL while the SRCEN bit is 0, for each bit in SRCSTAT to initialized.

However, because the CPU executes any subsequent instruction without waiting for the completion of writes to a register, the updated state of SRCSTAT cannot be correctly read by an instruction immediately after the write instruction to SRCCTRL. To check the updated state of SRCSTAT, perform a dummy read of SRCCTRL or SRCSTAT after the instruction used to write to SRCCTRL.

42.5.2 Notes on Flush Processing

When 1 is written to the FL bit in the SRC Control Register (SRCCTRL), the SRC continues conversion processing by adding 0-data to the input data endpoint. Because of this, only execute flush processing when the audio data endpoint is input and there is no subsequent data.

To perform conversion again after flush processing, clear the internal work memory in either of the following ways.

- Write 1 to the CL bit in SRCCTRL
- Write 0 and then 1 to the SRCEN bit in SRCCTRL.

42.5.3 Notes on DMAC or DTC Transfer

When the DMAC or DTC is used for data transfer to the I/O data registers (SRCID and SRCOD), do not clear the IINT and OINT flags in the Status Register (SRCSTAT) by the CPU (writing 0 after reading 1) during transfer by the DMAC or DTC.

42.5.4 Notes on SRC Operation

Do not access the Filter Coefficient Table while the SRC is operating (SRCCTRL.SRCEN = 1).

42.5.5 Settings for the Module-Stop Function

SRC operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SRC module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

43. SD/MMC Host Interface (SDHI)

43.1 Overview

The Secure Digital Host Interface (SDHI) and MultiMediaCard (MMC) Interface provide the functionality required to connect a variety of external memory cards with the MCU. The SDHI supports both 1-bit and 4-bit buses for connecting different memory cards that support SD, SDHC, and SDXC formats. When developing host devices that are compliant with the SD Specifications, you must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

The MMC interface supports 1-bit, 4-bit, and 8-bit MMC buses that provide eMMC 4.51 (JEDEC Standard JESD 84-B451) device access. This interface also provides backward compatibility and supports for high-speed SDR transfer modes.

Table 43.1 lists the SD/MMC Host Interface specifications and Figure 43.1 shows a block diagram.

Table 43.1 SD/MMC Host Interface specifications

Interface	Parameter	Specifications
SD	SD bus interface	• Compatible with SD memory card and SDIO card • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
SD and MMC shared	SDHI clock frequency	The SDHI clock is generated by dividing PCLKA by 2^n (n = 1 to 9).
	Error check functions	CRC7 (command/response), CRC16 (transfer data)
	Interrupt sources	Card access interrupt (SDHI_MMCn_ACCS), SDIO access interrupt (SDHI_MMCn_SDIO), Card detection interrupt (SDHI_MMCn_CARD) (n = 0 to 1)
	DMA transfer sources	DMAC and DTC triggerable by the SBFAI interrupt SD buffer is read and write accessible using the DMAC
	Other functions	• Card detect function • Write protect support
MMC	MMC bus interface	Transfer bus mode selectable from 1-bit, 4-bit, or 8-bit
	Transfer modes	Backward compatible mode or high-speed SDR mode selectable
	Other functions	e.MMC device access supported

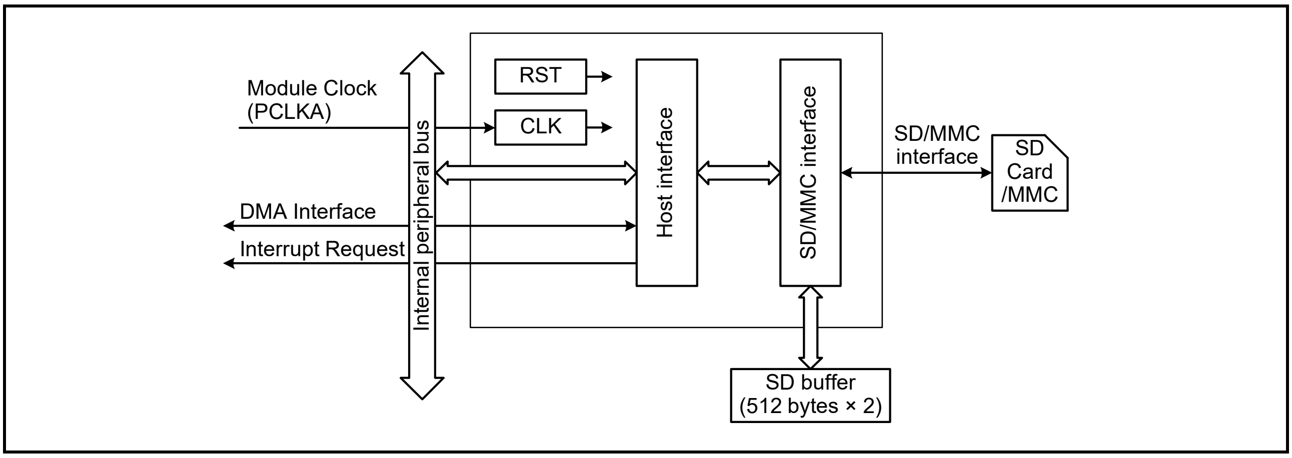

Figure 43.1 SD/MMC Host Interface block diagram

Table 43.2 SDHI I/O pins

Channel	Pin name	I/O	Description
Ch 0	SD0CLK	Output	SDHI clock
	SD0CMD	I/O	Command output, response input

43.2 Register Descriptions

43.2.1 Command Type Register (SD_CMD)

Address(es): SDHI0.SD_CMD 4006 2000h, SDHI1.SD_CMD 4006 2400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	CMDIDX[5:0]	Command Index Field Value Select	These bits configure the command index field value. The examples shown include the bit values for the ACMD[1:0] bits. b7 b0 0 0 0 0 0 1 1 0: CMD6 0 0 0 1 0 0 1 0: CMD18 0 1 0 0 1 1 0 1: ACMD13	R/W

Bit	Symbol	Bit name	Description	R/W
b7, b6	ACMD[1:0]	Command Type Select	b7 b6 0 0: CMD 0 1: ACMD. Other settings are prohibited.	R/W
b10 to b8	RSPTP[2:0]	Response Type Select*1	b10 b8 0 0 0: Normal mode Depending on the command, the response type and transfer method are selected in the ACMD[1:0] and CMDIDX[5:0] bits. At this time, the values for b15 to b11 in this register are invalid. 0 1 1: Extended mode and no response 1 0 0: Extended mode and R1, R5, R6, or R7 response 1 0 1: Extended mode and R1b response 1 1 0: Extended mode and R2 response 1 1 1: Extended mode and R3 or R4 response. Other settings are prohibited.	R/W
b11	CMDTP	Data Transfer Select*2	0: Do not include data transfer (bc, bcr, or ac) in command 1: Include data transfer (adtc) in command.	R/W
b12	CMDRW	Data Transfer Direction Select*3	0: Write (SD/MMC Host Interface → SD card/MMC) 1: Read (SD/MMC Host Interface ← SD card/MMC).	R/W
b13	TRSTP	Block Transfer Select*3	0: Single block transfer 1: Multiple blocks transfer.	R/W
b15, b14	CMD12AT[1:0]	CMD12 Automatic Issue Select*4	b15 b14 0 0: Automatically issue CMD12 during multiblock transfer 0 1: Do not automatically issue CMD12 during multiblock transfer. Other settings are prohibited.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Some commands cannot be used in normal mode.
Note 2. The CMDTP bit is only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SD_CMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. See Table 43.8 and Table 43.9 for setting examples. Do not write to the SD_CMD register when the SD_INFO2.CBSY flag is 1.

43.2.2 SD Command Argument Register (SD_ARG)

Address(es): SDHI0.SD_ARG 4006 2008h, SDHI1.SD_ARG 4006 2408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	—	—	These bits specify command format[39:8] (argument).	R/W

The SD_ARG register is used for setting the argument field value. Set the SD_ARG register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0000_0000h regardless of the SD_ARG register value.

43.2.3 SD Command Argument Register 1 (SD_ARG1)

Address(es): SDHI0.SD_ARG1 4006 200Ch, SDHI1.SD_ARG1 4006 240Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	—	—	These bits specify command format[39:24] (argument).	R/W
b31 to b16	—	Reserved	These bits are read as 0.	R

The SD_ARG1 register is used for setting the argument field value. Set the SD_ARG1 register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0000_0000h regardless of the SD_ARG1 register value.

43.2.4 Data Stop Register (SD_STOP)

Address(es): SDHI0.SD_STOP 4006 2010h, SDHI1.SD_STOP 4006 2410h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	STP	Transfer Stop	Data transfer stops when this bit is set to 1.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SEC	Block Count Register Value Select *1	0: Disable SD_SECCNT register value 1: Enable SD_SECCNT register value.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SD_STOP register stops data transfer. During a multiblock transfer sequence, the SD_SECCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SD_STOP register.

STP bit (Transfer Stop)

When the STP bit is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SDHI. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly.

When STP is set to 1 during transfer for single block write, the access end flag sets when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 during transfer for single block read, the access end flag sets immediately after the STP bit is set, and CMD12 is not issued.

When STP is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 after a command sequence is completed, CMD12 is not issued and the access end flag does not set.

Set STP to 1 after the response end flag sets.

Set STP to 0 after the access end flag sets.

SEC bit (Block Count Register Value Select)

When SD_CMD is set in the following section to start the command sequence while the SEC bit is set to 1, CMD12 is automatically issued to stop multiblock transfer with the number of blocks set in SD_SECCNT.

CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000)

SD_CMD[15:13] = 001 in extended mode (CMD12 is automatically issued, multiple block transfer)

When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued.

43.2.5 Block Count Register (SD_SECCNT)

Address(es): SDHI0.SD_SECCNT 4006 2014h, SDHI1.SD_SECCNT 4006 2414h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When performing a multiblock transfer, SD_SECCNT is a read/write register used to set the number of blocks to be transferred. For example, when the register value is 0000_0001h, 1 block is transferred. When the register value is 0000_FFFFh, 65,535 blocks are transferred and when the register value is FFFF_FFFFh, 4,294,967,295 blocks are transferred. Do not set this register to 0000_0000h. Do not rewrite the SD_SECCNT register when the SD_INFO2.CBSY flag is 1.

43.2.6 SD Card Response Register 10 (SD_RSP10), SD Card Response Register 32 (SD_RSP32), SD Card Response Register 54 (SD_RSP54)

Address(es): SDHI0.SD_RSP10 4006 2018h, SDHI1.SD_RSP10 4006 2418h, SDHI0.SD_RSP32 4006 2020h, SDHI1.SD_RSP32 4006 2420h SDHI0.SD_RSP54 4006 2028h, SDHI1.SD_RSP54 4006 2428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

43.2.7 SD Card Response Register 1 (SD_RSP1), SD Card Response Register 3 (SD_RSP3), SD Card Response Register 5 (SD_RSP5)

Address(es): SDHI0.SD_RSP1 4006 201Ch, SDHI1.SD_RSP1 4006 241Ch, SDHI0.SD_RSP3 4006 2024h, SDHI1.SD_RSP3 4006 2424h, SDHI0.SD_RSP5 4006 202Ch, SDHI1.SD_RSP5 4006 242Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	—	—	These bits store the response from the SD card/MMC.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

43.2.8 SD Card Response Register 76 (SD_RSP76)

Address(es): SDHI0.SD_RSP76 4006 2030h, SDHI1.SD_RSP76 4006 2430h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b23 to b0	—	—	These bits store the response from the SD card/MMC.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

43.2.9 SD Card Response Register 7 (SD_RSP7)

Address(es): SDHI0.SD_RSP7 4006 2034h, SDHI1.SD_RSP7 4006 2434h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	—	—	These bits store the response from the SD card/MMC.	R

Bit	Symbol	Bit name	Description	R/W
b31 to b8	—	Reserved	These bits are read as 0.	R

SD_RSP10, SD_RSP32, SD_RSP54, SD_RSP1, SD_RSP3, SD_RSP5, SD_RSP76, and SD_RSP7 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SD/MMC Host Interface divides and stores the response among the four registers.

Table 43.3 lists the correspondence between the response type and its storage destination.

Table 43.3 Correspondence between response type and storage destination

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R1	[39:8]	—	[39:8]*1	—	—	—	—	—
R1b	[39:8]	—	[39:8]*1	—	—	—	—	—
R2	[39:8]	[71:40]	[103:72]	—	—	—	[127:104]	—
R3	[39:8]	—	—	—	—	—	—	—
R4	[39:8]	—	—	—	—	—	—	—
R5	[39:8]	—	—	—	—	—	—	—
R6	[39:8]	—	—	—	—	—	—	—
R7	[39:8]	—	—	—	—	—	—	—

Note 1. The responses for CMD18 and CMD25 are stored in registers SD_RSP10 and SD_RSP54. Therefore, even if the SD_RSP10 register is overwritten with the response for the automatically issued CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SD_RSP54 register.

43.2.10 SD Card Interrupt Flag Register 1 (SD_INFO1)

Address(es): SDHI0.SD_INFO1 4006 2038h, SDHI1.SD_INFO1 4006 2438h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0*1	0	0*1

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	RSPEND	Response End Detection Flag	0: Response end not detected 1: Response end detected.	R(/W)*2
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	ACEND	Access End Detection Flag	0: Access end not detected 1: Access end detected.	R(/W)*2
b3	SDCDRM	SDnCD Removal Flag	0: SD card/MMC removal not detected by the SDnCD pin 1: SD card/MMC removal detected by the SDnCD pin.	R(/W)*2
b4	SDCDIN	SDnCD Insertion Flag	0: SD card/MMC insertion not detected by the SDnCD pin 1: SD card/MMC insertion detected by the SDnCD pin.	R(/W)*2
b5	SDCDMON	SDnCD Pin Monitor Flag	0: SDnCD pin level is high*3 1: SDnCD pin level is low.*3	R
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	SDWPMON	SDnWP Pin Monitor Flag	0: SDnWP pin level is high 1: SDnWP pin level is low.	R

Bit	Symbol	Bit name	Description	R/W
b8	SDD3RM	SDnDAT3 Removal Flag	0: SD card/MMC removal not detected by the SDnDAT3 pin 1: SD card/MMC removal detected by the SDnDAT3 pin.	R(/W)*2
b9	SDD3IN	SDnDAT3 Insertion Flag	0: SD card/MMC insertion not detected by the SDnDAT3 pin 1: SD card/MMC insertion detected by the SDnDAT3 pin.	R(/W)*2
b10	SDD3MON	SDnDAT3 Pin Monitor Flag	0: SDnDAT3 pin level is low 1: SDnDAT3 pin level is high.	R
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 3. The flag changes when the pin level continues for the period set in the SD_OPTION.CTOP[3:0] bits or longer.

The SD_INFO1 register indicates the detection of a response end or access end for a command sequence. The SD_INFO1 register also indicates the detection SD card/MMC insertion/removal and the write protection status.

During a multiblock transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag sets to 1, but the RSPEND flag remains set to 0.

If the command sequence is stopped because of a communication error or timeout, the ACEND flag or RSPEND flag sets to 1.

After a reset is canceled, the SDD3MON bit, SDD3IN flag, and SDD3RM flag values are changed in accordance with the status of the SDnDAT3 (n = 0, 1) pin, and their values are changed when data is being transferred in wide bus mode. These 3 bits are used only for SD card. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

RSPEND flag (Response End Detection Flag)

The RSPEND flag indicates that a response end was detected.

[Setting conditions]

- When reception of the response is completed
- When transmission of a command without response is completed
- When reception of the busy state after R1b response is completed
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to RSPEND
- When a command without data is issued.

Note: When a command is issued in absence of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND flag (Access End Detection Flag)

The ACEND flag indicates that an access end was detected.

[Setting conditions]

- When read access to the buffer is completed for transfer of single block read
- When read access to the buffer for the last block of data is completed for transfer of multiple block read
- When read access to the buffer and reception of the response to CMD12 are completed for transfer of multiple block read with automatic issuing of CMD12
- When reception of the busy state after reception of the CRC status is completed for transfer of single block write

- When reception of the busy state after reception of the CRC status of the last block of data is completed for transfer of multiple block write
- When reception of the response busy state for CMD12 is completed for transfer of multiple block write with automatic issuing of CMD12
- When reception of the response to CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block read
- When reception of the response busy state for CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block write
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to ACEND
- When the access end bit is set to 1.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM flag (SDnCD Removal Flag)

The SDCDRM flag indicates that SDnCD was removed.

[Setting condition]

- After a change in SDnCD from 0 to 1, Mcycle elapsed with SDnCD held at 1.

[Clearing conditions]

- When 0 is written to SDCDRM.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDCDIN flag (SDnCD Insertion Flag)

The SDCDIN flag indicates that SDnCD was inserted.

[Setting condition]

- After a change in SDnCD from 1 to 0, Mcycle elapsed with SDnCD held at 0.

[Clearing conditions]

- When 0 is written to SDCDIN.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDD3RM flag (SDnDAT3 Removal Flag)

The SDD3RM flag indicates that SDnDAT3 was removed.

[Setting condition]

- After a change in SDnDAT3 from 1 to 0, two cycles of PCLKA elapsed with SDnDAT3 held at 0.

[Clearing condition]

- When 0 is written to SDD3RM.

SDD3IN flag (SDnDAT3 Insertion Flag)

The SDD3IN flag indicates that SDnDAT3 was inserted.

[Setting condition]

- After a change in SDnDAT3 from 0 to 1, two cycles of PCLKA elapsed with SDnDAT3 held at 1.

[Clearing condition]

- When 0 is written to SDD3IN.

43.2.11 SD Card Interrupt Flag Register 2 (SD_INFO2)

Address(es): SDHI0.SD_INFO2 4006 203Ch, SDHI1.SD_INFO2 4006 243Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	CMDE	Command Error Detection Flag	0: Command error not detected 1: Command error detected.	R/W*1
b1	CRCE	CRC Error Detection Flag	0: CRC error not detected 1: CRC error detected.	R/W*1
b2	ENDE	End Bit Error Detection Flag	0: End bit error not detected 1: End bit error detected.	R/W*1
b3	DTO	Data Timeout Detection Flag	0: Data timeout not detected 1: Data timeout detected.	R/W*1
b4	ILW	SD_BUF0 Illegal Write Access Detection Flag	0: Illegal write access to the SD_BUF0 register not detected 1: Illegal write access to the SD_BUF0 register detected.	R/W*1
b5	ILR	SD_BUF0 Illegal Read Access Detection Flag	0: Illegal read access to the SD_BUF0 register not detected 1: Illegal read access to the SD_BUF0 register detected.	R/W*1
b6	RSPTO	Response Timeout Detection Flag	0: Response timeout not detected 1: Response timeout detected.	R/W*1
b7	SDD0MON	SDHI_D0 Pin Status Flag	0: SDnDAT0 pin is low 1: SDnDAT0 pin is high.	R
b8	BRE	SD_BUF0 Read Enable Flag	0: Disable read access to the SD_BUF0 register 1: Enable read access to the SD_BUF0 register.	R/W*1
b9	BWE	SD_BUF0 Write Enable Flag	0: Disable write access to the SD_BUF0 register 1: Enable write access to the SD_BUF0 register.	R/W*1
b12 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13	SD_CLK_CTRLEN	SD_CLK_CTRL Write Enable Flag	0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is disabled 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is enabled.	R
b14	CBSY	Command Sequence Status Flag	0: Command sequence complete 1: Command sequence in progress (busy).	R
b15	ILA	Illegal Access Error Detection Flag	0: Illegal access error not detected 1: Illegal access error detected.	R/W*1
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SD_INFO2 register indicates the status of the SD buffer and the status of the SD card/MMC. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

CMDE flag (Command Error Detection Flag)

The CMDE flag indicates that a command error was detected. The command sequence stops when a command error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section section 43.3.12, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 43.3.13, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- The command index of the transmitted command differs from the command index of the received response.
- The command index of a command issued within a command sequence differs from the command index of the received response.

[Clearing condition]

- When 0 is written to CMDE.

CRCE flag (CRC Error Detection Flag)

The CRCE flag indicates that a CRC error was detected. The command sequence stops when a CRC error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 43.3.12, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 43.3.13, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the CRC status.
- When a CRC error occurs in the read data.
- When a CRC error occurs in the response.
- A CRC error in the response to a command issued within a command sequence.

[Clearing condition]

- When 0 is written to CRCE.

ENDE flag (End Bit Error Detection Flag)

The ENDE flag indicates that an end bit error was detected. The command sequence is stopped when an end bit error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 43.3.12, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 43.3.13, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the response length (and the end bit is not detected).
- When an error occurs in the read data length (and the end bit is not detected among the valid bits).
- When an error occurs in the CRC status length (and the end bit is not detected).
- An error in the length of a response to a command issued within a command sequence, for example when the end bit is not detected.

[Clearing condition]

- When 0 is written to ENDE.

DTO flag (Data Timeout Detection Flag)

The DTO flag indicates that a data timeout was detected. The command sequence stops when a data timeout occurs.

[Setting conditions]

- After R1b response, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After CRC status, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After write data, the CRC status is not received though Ncycle has elapsed.
- After read command, read data is not received though a time longer than Ncycle has elapsed.
- After CMD12 is issued within a command sequence, the busy state (SDnDAT0 = 0) for longer than Ncycle continues.
- After the reception of read data, read data for the next block are not received though a time longer than Ncycle has elapsed.
- After release of the read wait state, read data for the next block are not received though a time longer than Ncycle has elapsed.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to DTO.

ILW flag (SD_BUF0 Illegal Write Access Detection Flag)

The ILW flag indicates that an SD_BUF0 illegal write access was detected.

[Setting conditions]

- When data is written to SD_BUF0 while it is not in the data read/write command state.
- When data is written to SD_BUF0 while SD_BUF is full.
- When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length.
- When data is written to SD_BUF0 while a busy state after the CRC status continues for longer than Ncycle.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to ILW.

ILR flag (SD_BUF0 Illegal Read Access Detection Flag)

The ILR flag indicates that an SD_BUF0 illegal read access was detected.

[Setting conditions]

- When SD_BUF is empty while SD_BUF0 is read.
- When data with a CRC error or END error is read from SD_BUF0.

[Clearing condition]

- When 0 is written to ILR.

RSPTO flag (Response Timeout Detection Flag)

The RSPTO flag indicates that a response timeout was detected. The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 43.3.12, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 43.3.13, IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting condition]

- When a response is not received though a time longer than 640 cycles of SD/MMC clock has elapsed (including a response to a command issued within a command sequence).

[Clearing condition]

- When 0 is written to RSPTO.

SDD0MON flag (SDHI_D0 Pin Status Flag)

The SDD0MON flag indicates the status of the SDHI_D0 pin. If the data timeout (DTO) is set but the response timeout (RSPTO) is not set after the Erase command is issued, the end of the Erase sequence (SDD0MON = 1) is confirmed by polling DAT0.

If a communication error or timeout occurs during a write sequence, the DAT0 bit might retain the value 0.

While the SD/MMC clock is stopped, the DAT0 bit retains the value before the clock is stopped.

BRE flag (SD_BUF0 Read Enable Flag)

The BRE flag indicates that SD_BUF0 is enabled for reading.

[Setting conditions]

- When data set in SD_SIZE is stored in SD_BUF0 at single block transfer.
- When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF0 at multiple block transfer.

[Clearing conditions]

- When 0 is written to BRE
- Reading of a block of data from SD_BUF0 by DMA transfer

When data is read from SD_BUF0 by the CPU, clear BRE then read the amount of data specified in SD_SIZE.

Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF0 and BRE is set.

BWE flag (SD_BUF0 Write Enable Flag)

The BWE flag indicates that SD_BUF0 is enabled for writing.

[Setting conditions]

- When SD_BUF0 is empty at single block transfer.
- When either bank 1 or bank 2 of SD_BUF0 is empty at multiple block transfer.

[Clearing conditions]

- When 0 is written to BWE.
- Writing of a block of data to SD_BUF0 by DMA transfer.

When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified in SD_SIZE.

SD_CLK_CTRLEN flag (SD_CLK_CTRL Write Enable Flag)

When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SD_CLK_CTRLEN bit is set to 0. The SD_CLK_CTRLEN bit is set to 1 after 8 cycles of SDCLK have elapsed after the CBSY bit clears to 0 on completion of the command sequence.

ILA flag (Illegal Access Error Detection Flag)

The ILA flag indicates that an illegal access error was detected.

[Setting conditions]

- Writing of data to SD_CMD within a command sequence (CBSY = 1).
- When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0000 1100b (CMD12) are set in SD_CMD.

[Clearing condition]

- When 0 is written to ILA.

43.2.12 SD INFO1 Interrupt Mask Register (SD_INFO1_MASK)

Address(es): SDHI0.SD_INFO1_MASK 4006 2040h, SDHI1.SD_INFO1_MASK 4006 2440h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SDD3INM	SDD3RMM	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Bit name	Description	R/W
b0	RSPENDM	Response End Interrupt Request Mask	0: Do not mask response end interrupt request 1: Mask response end interrupt request.	R/W
b1	—	Reserved	This bit is read as 0 and cannot be modified.	R
b2	ACENDM	Access End Interrupt Request Mask	0: Do not mask access end interrupt request 1: Mask access end interrupt request.	R/W
b3	SDCDRMM	SDnCD Removal Interrupt Request Mask	0: Do not mask SD card/MMC removal interrupt request by the SDnCD pin 1: Mask SD card/MMC removal interrupt request by the SDnCD pin.	R/W
b4	SDCDINM	SDnCD Insertion Interrupt Request Mask	0: Do not mask SD card/MMC insertion interrupt request by the SDnCD pin 1: Mask SD card/MMC insertion interrupt request by the SDnCD pin.	R/W
b7 to b5	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b8	SDD3RMM	SDnDAT3 Removal Interrupt Request Mask	0: Do not mask SD card/MMC removal interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC removal interrupt request by the SDnDAT3 pin.	R/W
b9	SDD3INM	SDnDAT3 Insertion Interrupt Request Mask	0: Do not mask SD card/MMC insertion interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC insertion interrupt request by the SDnDAT3 pin.	R/W
b31 to b10	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

The SD_INFO1_MASK register enables or disables interrupt requests from the status flags in the SD_INFO1 register. See Table 43.5, Interrupt sources, for details on the relationship between the status flags and the requested interrupt source.

43.2.13 SD INFO2 Interrupt Mask Register (SD_INFO2_MASK)

Address(es): SDHI0.SD_INFO2_MASK 4006 2044h, SDHI1.SD_INFO2_MASK 4006 2444h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ILAM	—	—	—	—	—	BWEM	BREM	—	RSPTOM	ILRM	ILWM	DTOM	ENDEM	CRCEM	CMDEM
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b0	CMDEM	Command Error Interrupt Request Mask	0: Do not mask command error interrupt request 1: Mask command error interrupt request.	R/W
b1	CRCEM	CRC Error Interrupt Request Mask	0: Do not mask CRC error interrupt request 1: Mask CRC error interrupt request.	R/W
b2	ENDEM	End Bit Error Interrupt Request Mask	0: Do not mask end bit detection error interrupt request 1: Mask end bit detection error interrupt request.	R/W
b3	DTOM	Data Timeout Interrupt Request Mask	0: Do not mask data timeout interrupt request 1: Mask data timeout interrupt request.	R/W
b4	ILWM	SD_BUF0 Register Illegal Write Interrupt Request Mask	0: Do not mask illegal write detection interrupt request for the SD_BUF0 register 1: Mask illegal write detection interrupt request for the SD_BUF0 register.	R/W
b5	ILRM	SD_BUF0 Register Illegal Read Interrupt Request Mask	0: Do not mask illegal read detection interrupt request for the SD_BUF0 register 1: Mask illegal read detection interrupt request for the SD_BUF0 register.	R/W
b6	RSPTOM	Response Timeout Interrupt Request Mask	0: Do not mask response timeout interrupt request 1: Mask response timeout interrupt request.	R/W
b7	—	Reserved	This bit is 0 when read and cannot be modified.	R
b8	BREM	BRE Interrupt Request Mask	0: Do not mask read enable interrupt request for the SD buffer 1: Mask read enable interrupt request for the SD buffer.	R/W
b9	BWEM	BWE Interrupt Request Mask	0: Do not mask write enable interrupt request for the SD_BUF0 register 1: Mask write enable interrupt request for the SD_BUF0 register.	R/W
b10	—	Reserved	This bit is read as 0.	R
b11	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b14 to b12	—	Reserved	These bits are read as 0.	R
b15	ILAM	Illegal Access Error Interrupt Request Mask	0: Do not mask illegal access error interrupt request 1: Mask illegal access error interrupt request.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0.
When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_INFO2_MASK register enables or disables interrupt requests from the status flags in the SD_INFO2 register. See Table 43.5 for details on the relationship between the status flags and the requested interrupt source.

43.2.14 SD Clock Control Register (SD_CLK_CTRL)

Address(es): SDHI0.SD_CLK_CTRL 4006 2048h, SDHI1.SD_CLK_CTRL 4006 2448h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CLKCTRLEN	CLKEN	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CLKSEL[7:0]	SDHI Clock Frequency Select*1	b7 b0 0 0 0 0 0 0 0 0: PCLKA/2 0 0 0 0 0 0 0 1: PCLKA/4 0 0 0 0 0 0 1 0: PCLKA/8 0 0 0 0 0 1 0 0: PCLKA/16 0 0 0 0 1 0 0 0: PCLKA/32 0 0 0 1 0 0 0 0: PCLKA/64 0 0 1 0 0 0 0 0: PCLKA/128 0 1 0 0 0 0 0 0: PCLKA/256 1 0 0 0 0 0 0 0: PCLKA/512. Other settings are prohibited.	R/W
b8	CLKEN	SD/MMC Clock Output Control*1	0: Disable SD/MMC clock output (fix SDnCLK signal low) 1: Enable SD/MMC clock output.	R/W
b9	CLKCTRLEN	SD/MMC Clock Output Automatic Control Select	0: Disable automatic control of SD/MMC clock output 1: Enable automatic control of SD/MMC clock output.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

The SDCLKCTRL register controls the SD/MMC clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SD_CMD register to start a command sequence. Do not write to the SDCLKCTRL register when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

CLKCTRLEN bit (SD/MMC Clock Output Automatic Control Select)

The CLKCTRLEN bit enables or disables the automatic control function for SD/MMC clock output, which causes the SD/MMC clock to output only within a command sequence.

The timing with which SD/MMC clock output starts and stops is as follows:

- SD/MMC clock output starts after writing to SD_CMD
- SD/MMC clock output stops when 8 cycles of SD/MMC clock have elapsed after the end of the command sequence.

In addition, SD/MMC clock is fixed to 0 while CLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit.

43.2.15 Transfer Data Length Register (SD_SIZE)

Address(es): SDHI0.SD_SIZE 4006 204Ch, SDHI1.SD_SIZE 4006 244Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	LEN[9:0]	Transfer Data Size Setting	These bits specify the transfer data size.*1	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD_SIZE register sets the transfer data size.

LEN[9:0] bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set in the LEN[9:0] bits from 1 byte to 512 bytes. When CMD12 is automatically issued during a multiblock transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multiblock transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32-, 64-, 128-, or 256-byte multiblock read transfer can only be performed during an SDIO multiblock transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

43.2.16 SD Card Access Control Option Register (SD_OPTION)

Address(es): SDHI0.SD_OPTION 4006 2050h, SDHI1.SD_OPTION 4006 2450h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WIDTH	—	WIDTH8	—	—	—	—	TOUTMASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0*2	1	0*2	0	0	0	0	0*2	1*2	1*2	1*2	0*2	1*2	1*2	1*2	0*2

Bit	Symbol	Bit name	Description		R/W
b3 to b0	CTOP[3:0]	Card Detection Time Counter *1	b3 b0 0 0 0 0: PCLKA × 2^{10} 0 0 0 1: PCLKA × 2^{11} 0 0 1 0: PCLKA × 2^{12} 0 0 1 1: PCLKA × 2^{13} 0 1 0 0: PCLKA × 2^{14} 0 1 0 1: PCLKA × 2^{15} 0 1 1 0: PCLKA × 2^{16} 0 1 1 1: PCLKA × 2^{17}.	b3 b0 1 0 0 0: PCLKA × 2^{18} 1 0 0 1: PCLKA × 2^{19} 1 0 1 0: PCLKA × 2^{20} 1 0 1 1: PCLKA × 2^{21} 1 1 0 0: PCLKA × 2^{22} 1 1 0 1: PCLKA × 2^{23} 1 1 1 0: PCLKA × 2^{24} 1 1 1 1: Setting prohibited.	R/W

Bit	Symbol	Bit name	Description	R/W
b7 to b4	TOP[3:0]	Timeout Counter*1	b7 b4 0 0 0 0: SDHI clock × 2^{13} 0 0 0 1: SDHI clock × 2^{14} 0 0 1 0: SDHI clock × 2^{15} 0 0 1 1: SDHI clock × 2^{16} 0 1 0 0: SDHI clock × 2^{17} 0 1 0 1: SDHI clock × 2^{18} 0 1 1 0: SDHI clock × 2^{19} 0 1 1 1: SDHI clock × 2^{20}. b7 b4 1 0 0 0: SDHI clock × 2^{21} 1 0 0 1: SDHI clock × 2^{22} 1 0 1 0: SDHI clock × 2^{23} 1 0 1 1: SDHI clock × 2^{24} 1 1 0 0: SDHI clock × 2^{25} 1 1 0 1: SDHI clock × 2^{26} 1 1 1 0: SDHI clock × 2^{27} 1 1 1 1: Setting prohibited.	R/W
b8	TOUTMASK	Timeout Mask	0: Activate timeout 1: Inactivate timeout (do not set RSPTO and DTO bits of SD_INFO2 or E6 to E0 bits of SDERRSTS2). When timeout occurs because of an inactivated timeout, execute a software reset to terminate the command sequence.	R/W
b12 to b9	—	Reserved	These bits are read as 0.	R
b13	WIDTH8*2	Bus Width	See bit 15 WIDTH bit.	R/W
b14	—	Reserved	This bit is read as 1.	R
b15	WIDTH	Bus Width*2	b15 b13 0 1: 8-bit width 0 0: 4-bit width 1 0: 1-bit width 1 1: 1-bit width. For 1-byte write transfers, set 4-bit or 1-bit width. Do not set 8-bit width.	R/W
b31 to b16	—	Reserved	These bits are read as 0.	R

Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.
Note 2. The initial value is applied at a reset and when the SOFT_RST.SDRST flag is 0.

The SD bus width and timeout counter are set in the SD_OPTION register.

43.2.17 SD Error Status Register 1 (SD_ERR_STS1)

Address(es): SDHI0.SD_ERR_STS1 4006 2058h, SDHI1.SD_ERR_STS1 4006 2458h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0*3	1*3	0*3	0*3	0*3	0*3	0*3	0	0	0*3	0*3	0*3	0*3	0*3	0*3

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	CMDE0	Command Error Flag 0	0: No error exists in command index field value of a command*1 response 1: Error exists in command index field value of a command*1 response.	R
b1	CMDE1	Command Error Flag 1	0: No error exists in command index field value of a command*2 response 1: Error exists in command index field value of a command*2 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the CMDE0 flag).	R
b2	RSPLENE0	Response Length Error Flag 0	0: No error exists in command*1 response length 1: Error exists in command*1 response length.	R

Bit	Symbol	Bit name	Description	R/W
b3	RSPLENE1	Response Length Error Flag 1	0: No error exists in command*2 response length 1: Error exists in command*2 response length (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPLENE0 flag).	R
b4	RDLENE	Read Data Length Error Flag	0: No read data length error occurred 1: Read data length error occurred.	R
b5	CRCLENE	CRC Status Token Length Error Flag	0: No CRC status token length error occurred 1: CRC status token length error occurred.	R
b7, b6	—	Reserved	These bits are read as 0.	R
b8	RSPCRCE0	Response CRC Error Flag 0	0: No CRC error detected in command*1 response 1: CRC error detected in command*1 response.	R
b9	RSPCRCE1	Response CRC Error Flag 1	0: No CRC error detected in command*2 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPCRCE0 flag) 1: CRC error detected in command*2 response.	R
b10	RDCRCE	Read Data CRC Error Flag	0: No CRC error detected in read data 1: CRC error detected in read data.	R
b11	CRCTKE	CRC Status Token Error Flag	0: No error detected in CRC status token 1: Error detected in CRC status token.	R
b14 to b12	CRCTK[2:0]	CRC Status Token	These bits store the CRC status token value (normal value is 010b).	R
b15	—	Reserved	This bit is read as 0	R
b31 to b16	—	Reserved	These bits are read as undefined	R

Note 1. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 2. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 3. The initial value is applied at a reset and when the SOFT_RST.SDRST flag is 0.

The SD_ERR_STS1 register indicates the CRC status token, CRC error, end bit error, and command error.

43.2.18 SD Error Status Register 2 (SD_ERR_STS2)

Address(es): SDHI0.SD_ERR_STS2 4006 205Ch, SDHI1.SD_ERR_STS2 4006 245Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CRCBSYTO	CRCTO	RDTO	BSYTO1	BSYTO0	RSPTO1	RSPTO0
Value after reset:	0	0	0	0	0	0	0	0	0	0*4	0*4	0*4	0*4	0*4	0*4	0*4

Bit	Symbol	Bit name	Description	R/W
b0	RSPTO0	Response Timeout Flag 0	0: After command*1 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*1 was issued, response was not received in 640 or more cycles of the SD/MMC clock.	R
b1	RSPTO1	Response Timeout Flag 1	0: After command*2 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*2 was issued, response was not received after 640 or more cycles of the SD/MMC clock (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPTO0 flag).	R

Bit	Symbol	Bit name	Description	R/W
b2	BSYTO0	Busy Timeout Flag 0	0: After R1b response was received, SD/MMC was released from the busy state during the specified period*3 1: After R1b response was received, SD/MMC was in the busy state after the specified period*3 elapsed.	R
b3	BSYTO1	Busy Timeout Flag 1	0: After CMD12 was automatically issued, SD/MMC was released from the busy state during the specified period*3 1: After CMD12 was automatically issued, SD/MMC was in the busy state after the specified period*3 elapsed (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the BSYTO0 flag).	R
b4	RDTO	Read Data Timeout Flag	When a read command is issued, this flag sets to 1 when read data is not received after the specified period*3 elapses. When read data is received, this flag sets to 1 when the next block of read data is not received after the specified period*3 elapses. When the SD/MMC exits the read wait state, this flag sets to 1 when the next block of read data is not received after the specified period*3 elapses.	R
b5	CRCTO	CRC Status Token Timeout Flag	0: After CRC data was written to the SD card/MMC, a CRC status token was received during the specified period*3 1: After CRC data was written to the SD card/MMC, a CRC status token was not received after the specified period*3 elapsed.	R
b6	CRCBSYTO	CRC Status Token Busy Timeout Flag	0: After a CRC status token was received, the SD/MMC was released from the busy state during the specified period*3 1: After a CRC status token was received, the SD/MMC was in the busy state after the specified period*3 elapsed.	R
b31 to b7	—	Reserved	These bits are read as 0.	R

Note 1. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. Set the SD_OPTION.TOP[3:0] bits to select the number of *n* cycles.
Note 4. The initial value is applied at a reset and when the SOFT_RST.SDRST flag is 0.

The SD_ERR_STS2 register indicates the timeout status.

43.2.19 SD Buffer Register (SD_BUF0)

Address(es): SDHI0.SD_BUF0 4006 2060h, SDHI1.SD_BUF0 4006 2460h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register. This register is internally connected to two 512-byte buffers.

If both buffers are not empty when executing multiple block read, the SD card/MMC clock is stopped to suspend receiving data. When one of the buffers is empty, the SD card/MMC clock is supplied to resume receiving data.

43.2.20 SDIO Mode Control Register (SDIO_MODE)

Address(es): SDHI0.SDIO_MODE 4006 2068h, SDHI1.SDIO_MODE 4006 2468h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	INTEN	SDIO Interrupt Acceptance Enable*1	0: Disable SDIO interrupt acceptance 1: Enable SDIO interrupt acceptance.	R/W
b1	—	Reserved	This bit is read as 0.	R
b2	RWREQ	Read Wait Request	0: Allow SD/MMC to exit read wait state 1: Request for SD/MMC to enter read wait state.	R/W
b7 to b3	—	Reserved	These bits are read as 0.	R
b8	IOABT	SDIO Abort	If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
b9	C52PUB	SDIO None Abort	If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is issued after the transfer process is complete, and the command sequence is completed.	R/W
b31 to b10	—	Reserved	These bits are read as 0.	R

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SDIO_MODE register controls reception of the SDIO interrupt, CMD52 issuance during multiblock transfer, and read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ bit (Read Wait Request)

When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks.

[Read wait state releasing]

- The read wait state is released, when RWREQ is cleared to 0 in the read wait state.
- When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 is issued, and then the read wait state is released.
- When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. You must set RWREQ and C52PUB simultaneously.

When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag sets.

IOABT bit (SDIO Abort)

When the IOABT bit is set to 1 in a CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communication error or timeout, CMD52 is not issued. Although continued buffer access is possible even after IOABT is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly. Set SD_ARG before setting IOABT to 1.

When IOABT is set to 1 during transfer for a single block write, the access end flag sets when SD_BUF0 becomes empty, and CMD52 is not issued. If SD_BUF0 contains data, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 during transfer for single block read, the access end flag sets immediately after IOABT is set, and CMD52 is not issued.

When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 after a command sequence is completed, CMD52 is not issued and the access end flag does not set.

Set IOABT to 1 after the response end flag sets.

Set IOABT to 0 after the access end flag sets.

C52PUB bit (SDIO None Abort)

When the C52PUB bit is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF0 becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, you must set RWREQ to 1 in addition to C52PUB.

Set SD_ARG before setting C52PUB to 1.

Set C52PUB to 1 after the response end flag sets.

43.2.21 SDIO Interrupt Flag Register (SDIO_INFO1)

Address(es): SDHI0.SDIO_INFO1 4006 206Ch, SDHI1.SDIO_INFO1 4006 246Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	IOIRQ	SDIO Interrupt Status Flag	0: No SDIO interrupt detected 1: SDIO interrupt detected.	R(/W)*1
b2, b1	—	Reserved	The read value is undefined. The write value should be 1.	R/W
b13 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	EXPUB52	EXPUB52 Status Flag	Indicates the status of the EXPUB52.	R(/W)*1
b15	EXWT	EXWT Status Flag	Indicates the status of the EXWT.	R(/W)*1
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the bit.

The SDIO_INFO1 register indicates the status of the SDIO card access. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

IOIRQ flag (SDIO Interrupt Status Flag)

The IOIRQ flag indicates that an SDIO interrupt occurred.

[Setting condition]

- When SDIO interrupt from an SDIO card is received while INTEN in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to IOIRQ.*1

Note 1. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit can be set again.

EXPUB52 flag (EXPUB52 Status Flag)

The EXPUB52 flag indicates the EXPUB52 status.

[Setting conditions]

- While the last block in the CMD53 (multiple block) sequence is transferred, C52PUB in SDIO_MODE is set to 1.
- While C52PUB is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred.

[Clearing condition]

- When 0 is written to EXPUB52.

EXWT flag (EXWT Status Flag)

The EXWT flag indicates the EXWT status.

[Setting condition]

- While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to EXWT.

43.2.22 SDIO INFO1 Interrupt Mask Register (SDIO_INFO1_MASK)

Address(es): SDHI0.SDIO_INFO1_MASK 4006 2070h, SDHI1.SDIO_INFO1_MASK 4006 2470h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EXWTM	EXPUB52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQM
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit name	Description	R/W
b0	IOIRQM	IOIRQ Interrupt Mask Control	0: Do not mask IOIRQ interrupts 1: Mask IOIRQ interrupts.	R/W
b2, b1	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b13 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	EXPUB52M	EXPUB52 Interrupt Request Mask Control	0: Do not mask EXPUB52 interrupt requests 1: Mask EXPUB52 interrupt requests.	R/W

Bit	Symbol	Bit name	Description	R/W
b15	EXWTM	EXWT Interrupt Request Mask Control	0: Do not mask EXWT interrupt requests 1: Mask EXWT interrupt requests.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SDIO_INFO1_MASK register enables or disables interrupt requests from the status flags in the SDIO_INFO1 register. See Table 43.5, Interrupt sources for details on the relationship between the status flags and the requested interrupt source.

43.2.23 DMA Mode Enable Register (SD_DMAEN)

Address(es): SDHI0.SD_DMAEN 4006 21B0h, SDHI1.SD_DMAEN 4006 25B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0.	R
b1	DMAEN	DMA Transfer Enable[*1, *2]	0: Disable use of DMA transfer to access SD_BUF0 register 1: Enable use of DMA transfer to access SD_BUF0 register.	R/W
b3, b2	—	Reserved	These bits are read as 0.	R
b4	—	Reserved	This bit is read as 1.	R
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7, b6	—	Reserved	These bits are read as 0.	R
b9, b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11, b10	—	Reserved	These bits are read as 0.	R
b12	—	Reserved	This bit is read as 1.	R
b31 to b13	—	Reserved	These bits are read as 0.	R

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY bit is 1.

Note 2. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_DMAEN register enables or disables DMA transfers.

DMAEN bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SD_CMD register.

43.2.24 Software Reset Register (SOFT_RST)

Address(es): SDHI0.SOFT_RST 4006 21C0h, SDHI1.SOFT_RST 4006 25C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit name	Description	R/W
b0	SDRST	Software Reset Control	0: Reset SD/MMC Host Interface software 1: Cancel reset of SD/MMC Host Interface software.	R/W
b2, b1	—	Reserved	These bits are read as 1.	R
b31 to b3	—	Reserved	These bits are read as 0.	R

Table 43.4 lists the bits and flags initialized by SD/MMC Host Interface software reset.

Table 43.4 Bits and flags initialized by SD/MMC Host Interface software reset

Register	Bit/flag
SD_STOP	SEC
SD_INFO1	RSPEND, ACEND
SD_INFO2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, SDD0MON, BRE, BWE, SD_CLK_CTRLEN, ILA
SD_CLK_CTRL	CLKEN
SD_OPTION	CTOP[3:0], TOP[3:0], WIDTH Bits b8 and b13 in the SD_OPTION register are also initialized by the SDHI software reset.
SD_ERR_STS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SD_ERR_STS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIO_INFO1	IOIRQ, EXPUB52, EXWT

43.2.25 SD Interface Mode Setting Register (SDIF_MODE)

Address(es): SDHI0.SDIF_MODE 4006 21CCh, SDHI1.SDIF_MODE 4006 25CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b8	NOCHKCR	CRC Check Mask	CRC check mask bit for MMC test commands. Set when CRC16 or CRC status value check is not executed. 0: Enable CRC check 1: Disable CRC Check (ignore CRC16 valued when reading and ignore CRC status value when writing).	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

NOCHKCR bit (CRC Check Mask)

The NOCHKCR bit is used for MMC test commands. This bit is set when CRC16 or CRC status value check is not executed.

43.2.26 Swap Control Register (EXT_SWAP)

Address(es): SDHI0.EXT_SWAP 4006 21E0h, SDHI1.EXT_SWAP 4006 25E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0 and cannot be modified.	R
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	—	Reserved	This bit is read as 0 and cannot be modified.	R
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	—	Reserved	This bit is read as 0 and cannot be modified.	R
b6	BWSWP	SD_BUF0 Swap Write*1	0: Normal write operation 1: Swap the byte endian order before writing to SD_BUF0 register.	R/W
b7	BRSWP	SD_BUF0 Swap Read*1	0: Normal read operation 1: Swap the byte endian order before reading SD_BUF0 register.	R/W
b10 to b8	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b12, b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14, b13	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b31 to b16	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The EXT_SWAP register selects whether or not the byte endian order is swapped when accessing the SD_BUF0 register. See section 43.3.1 for details on the differences in accessing the SD_BUF0 register based on the EXT_SWAP register value.

43.3 Operation

43.3.1 SD/MMC Interface

When data is read from the SD card/MMC, the process is as follows:

1. The SD/MMC Host Interface receives data from the SD card/MMC through the SDnDAT signal (see Figure 43.2 and Figure 43.3).

2. The received data is stored in SD_BUF of the MMC Host Interface (see Figure 43.4).
3. The data stored in SD_BUF is read from SD_BUF0 (see Figure 43.5).

When data is written to the SD card/MMC, the specified procedure is reversed.

When accessing SD_BUF0, pay attention to the transfer order in SDnDAT and the store order in SD_BUF. If required, you can change the byte endian of the data read from or written to SD_BUF0 using the SDSWAP register. See Figure 43.6.

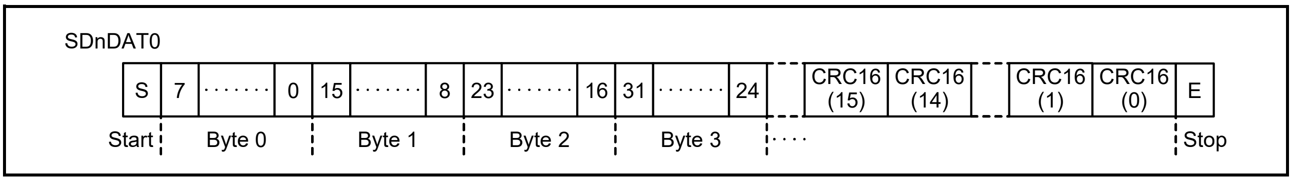

Figure 43.2 SDnDAT in 1-bit width mode

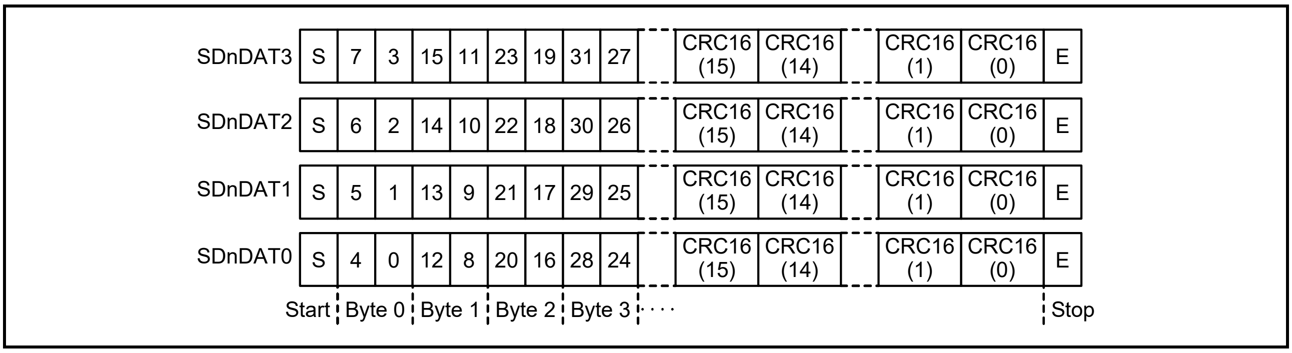

Figure 43.3 SDnDAT in 4-bit width mode

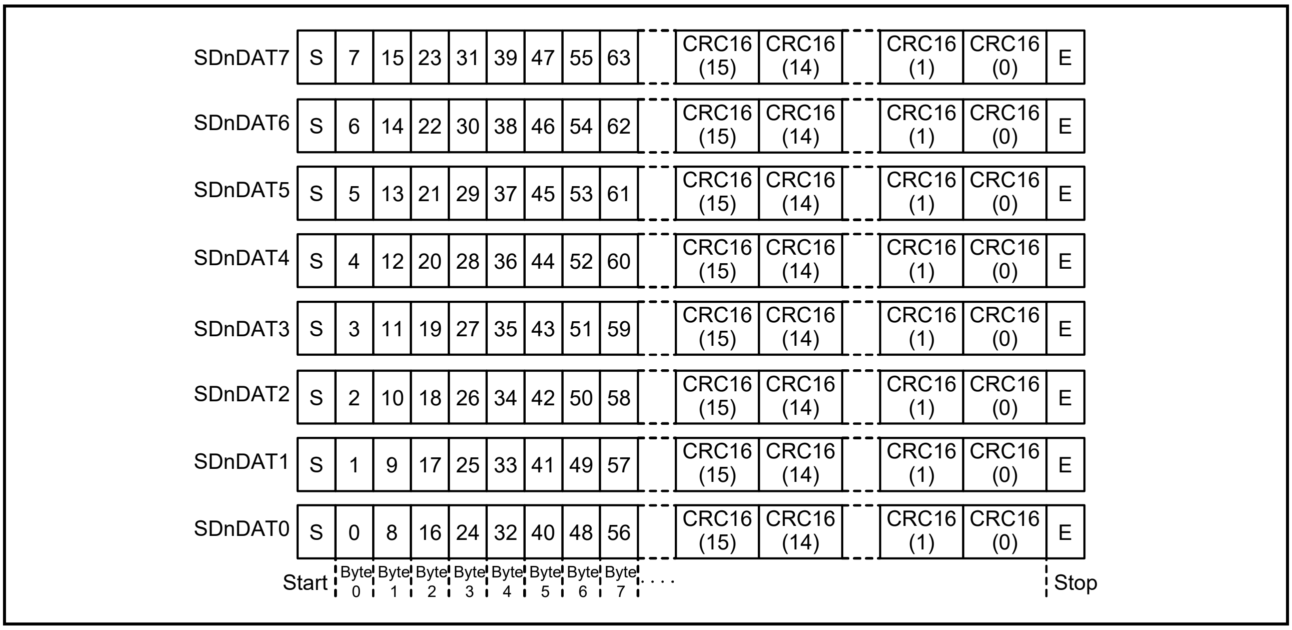

Figure 43.4 SDnDAT in 8-bit width mode

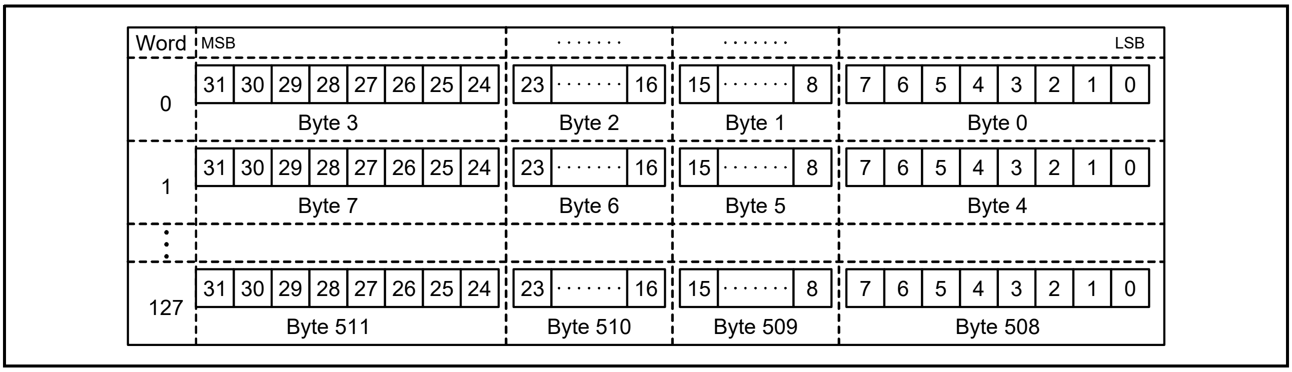

Figure 43.5 SD_BUF store data

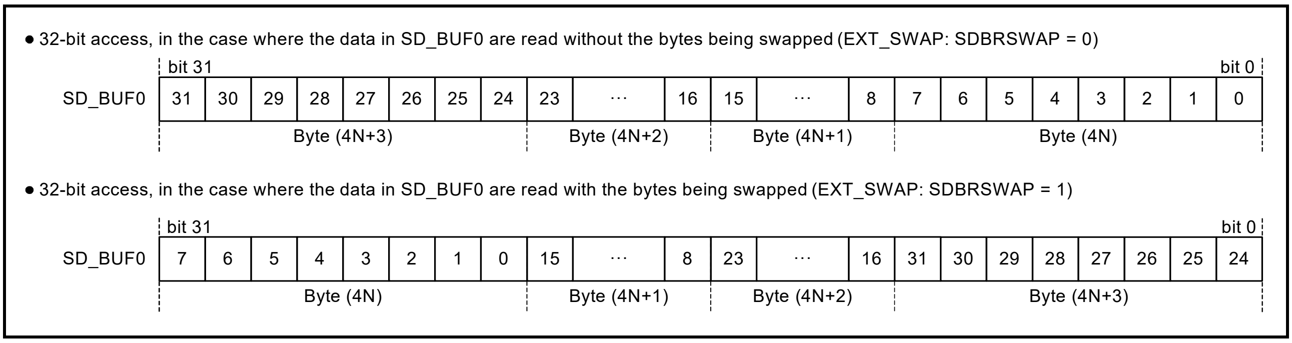

Figure 43.6 Read from SD_BUF0

43.3.2 Card Detect/Write Protect

43.3.2.1 Card detect

The SD/MMC Host Interface has two types of card detect functions.

(1) Card detect with SDnCD (n = 0, 1)

Figure 43.7 shows the timing for card detect using SDnCD. SDnCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is determined by the specification of the SD/MMC host device.

(2) Card insertion

SDnCD is pulled down when a card is inserted. At this point, if SDnCD is pulled down for the Mcycle period (set in SD_OPTION), SDCDIN in SD_INFO1 is set to 1. It is cleared by writing 0.

(3) Card removal

SDnCD is pulled up when a card is removed. At this point, if SDnCD is pulled up for the Mcycle period (set in SD_OPTION), SDCDRM in SD_INFO1 is set to 1. It is cleared by writing 0.

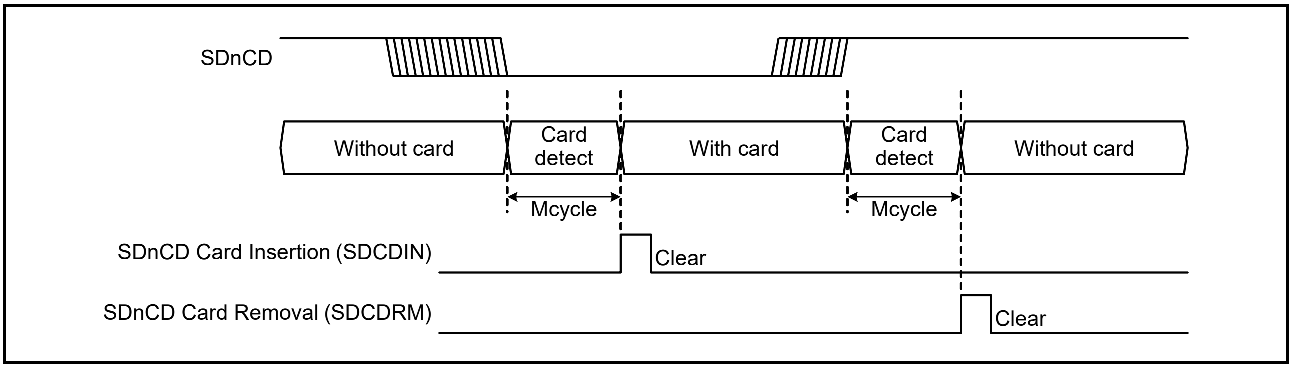

Figure 43.7 Example of card detect with SDnCD

(4) SD card detect with SDnDAT3 (n = 0, 1)

Figure 43.8 shows the timing when the SD card is detected with SDnDAT3. In addition, SDnDAT3 is pulled down by the host device, and the resistance value for pulling down is determined by the specification of the SD host device.

(5) Card insertion

When an SD card is inserted, SDnDAT3 is pulled up and SDD3IN in SD_INFO1 is set to 1. It is cleared by writing 0.

(6) Card removal

When an SD card is removed, SDnDAT3 is pulled down and SDD3RM in SD_INFO1 is set to 1. It is cleared by writing 0.

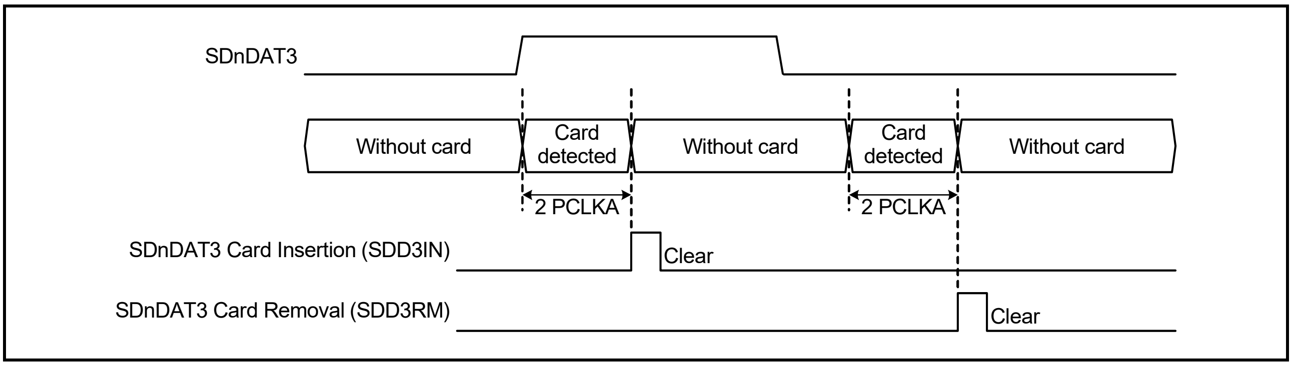

Figure 43.8 SD card detect with SDnDAT3

43.3.2.2 Write protect

The SD/MMC Host Interface has two types of write protect functions.

(1) Write protect with SDnWP (n = 0, 1)

SDnWP is connected to the card socket and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is determined by the specification of the SD host device. When the SDnWP state is reflected to SDWPMON in SD_INFO1, the write protect state is set after the SD card is inserted.

(2) Write protect with command

The internal write protection of the card and the lock/unlock operation of the card are realized by the command.

43.3.3 Interrupt Request and DMA Transfer Request

43.3.3.1 Interrupts

Table 43.5 lists the SDHI interrupt sources. The SDHI requests an interrupt when:

- The status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1 set to 1

- The associated bits in the SD_INFO1_MASK, SD_INFO2_MASK, and SDIO_INFO1_MASK registers are 0.

When clearing the status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1, write 0 to the status flags to be cleared and write 1 to the status flags that are not being cleared.

Table 43.5 Interrupt sources

	Status flag register		Interrupt mask register		Interrupt name	
Interrupt sources	Register symbol	Bit symbol	Register symbol	Bit symbol	Ch 0	Ch 1
Card Access Interrupt (CACI)	SD_INFO1	ACEND	SD_INFO1_MASK	ACENDM	SDHI_MMC0_ACCS	SDHI_MMC1_ACCS

43.3.3.2 DMA transfer requests (SDHI_MMCn_ODMSDBREQ, n = 0 to 1)

The SD/MMC Host Interface has two types of DMA transfer requests.

(1) SD_BUF write DMA transfer request

- When the BWE bit in SD_INFO2 is set to 1 while the DMAEN bit in SD_DMAEN is set to 1, the SD_BUF write DMA transfer request is asserted.
- The SD_BUF write DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
- The BWE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request for writing to SD_BUF by DMA transfer.
- The number of DMA transfers must be n x one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BWE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit, or to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BWE bit is set.

(2) SD_BUF read DMA transfer request

- When the BRE bit in SD_INFO2 is set to 1 while the DMAEN bit in the SD_DMAEN register is set to 1, the SD_BUF read DMA transfer request is asserted.
- The SD_BUF read DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
- The BRE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request to write to SD_BUF by DMA transfer.
- The number of DMA transfers must be n x one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BRE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit or in response to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BRE bit is set.

43.3.4 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the associated status flag in the SD_INFO2 register sets to 1. Also, depending on the source of the error, the associated flag in the SD_ERR_STS1 or SD_ERR_STS2 register sets to 1.

The status flags in registers SD_ERR_STS1 and SD_ERR_STS2 clear to 0 by writing to the SD_CMD register, or by setting the SOFT_RST.SDRST bit to 0.

Table 43.6 Communication errors

Communication error	Interrupt flag register		Error status register		This occurs when...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SD_INFO2	ENDE	SD_ERR_STS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error*1
				RSPLENE0	The response length is in error*2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response*1
				RSPCRCE0	There is a CRC error in the response*2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match*1
				CMDE0	The command index field value for the transmitted command and received response do not match*2

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Table 43.7 Timeouts

Timeout	Interrupt flag register		Error status register		This occurs when...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SD_INFO2	RSPTO	SD_ERR_STS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse*1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse*2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set*3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set*3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set*3 elapses
					After the read data is received, the next block read data is not received even after at least the period set*3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set*3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set*3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set*3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Note 3. The period is set in the SD_OPTION.TOP[3:0] bits.

43.3.5 Command without Data Transfer (SD/MMC)

Figure 43.9 and Figure 43.10 show example flows.

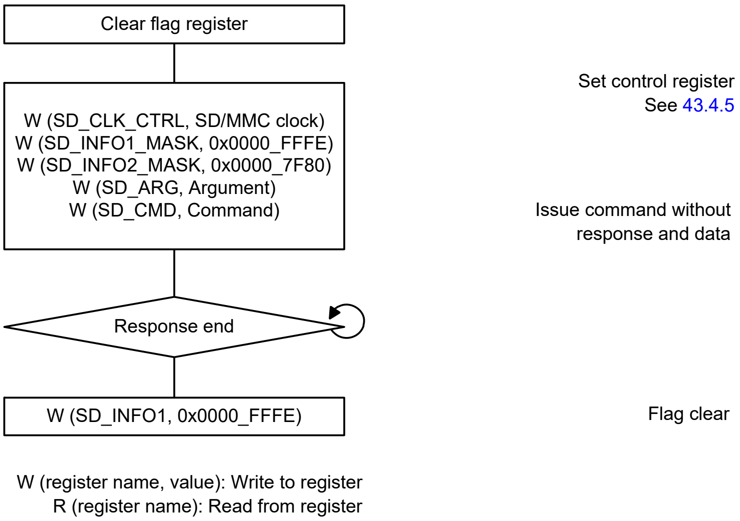

Figure 43.9 Example flow of command without response and data

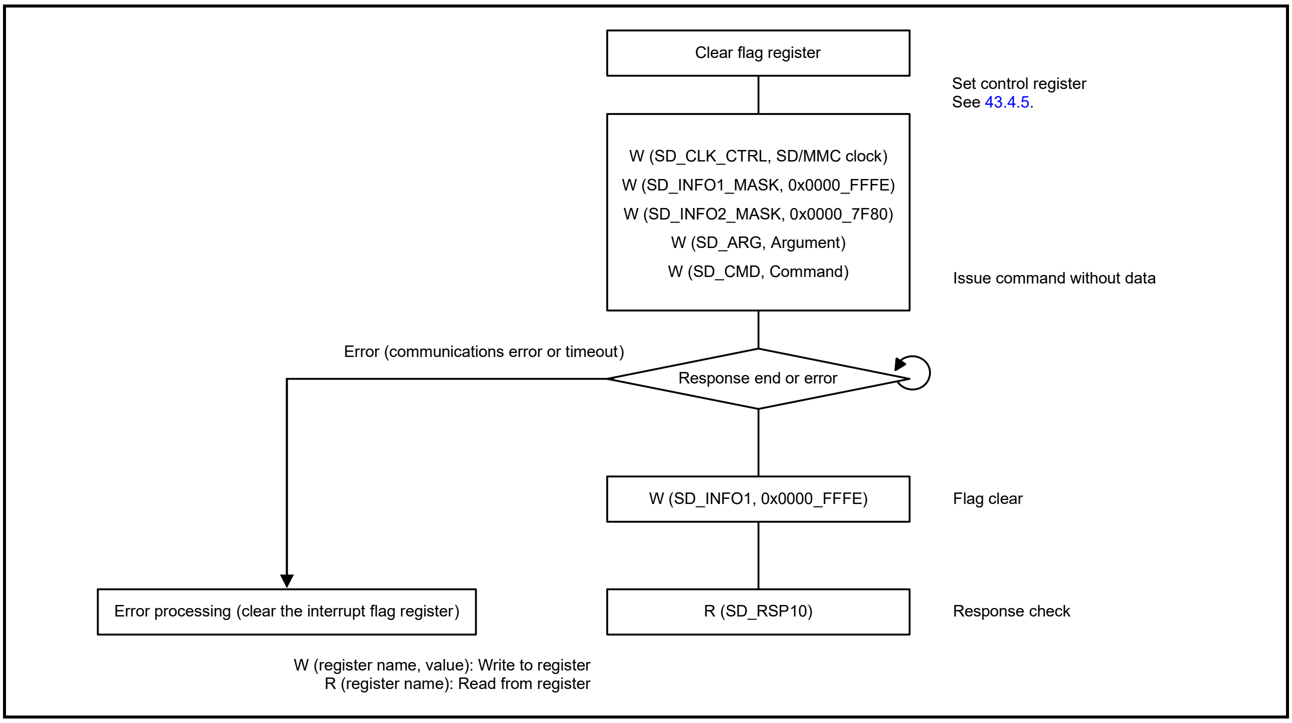

Figure 43.10 Example flow of command without data

43.3.5.1 Operation for command without data transfer

The following legend is used for description of register read/write.

W (register name, value): Write to register

R (register name): Read from register

The operation is described in the following section.

(1) Command without response and data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When transmission of a command is completed, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

(2) Command without data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to the SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When a response is received, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

e. Read a response from SD_RSP10. Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

43.3.6 Single Block Read (SD/MMC)

Figure 43.11 shows an example flow of a single block read operation.

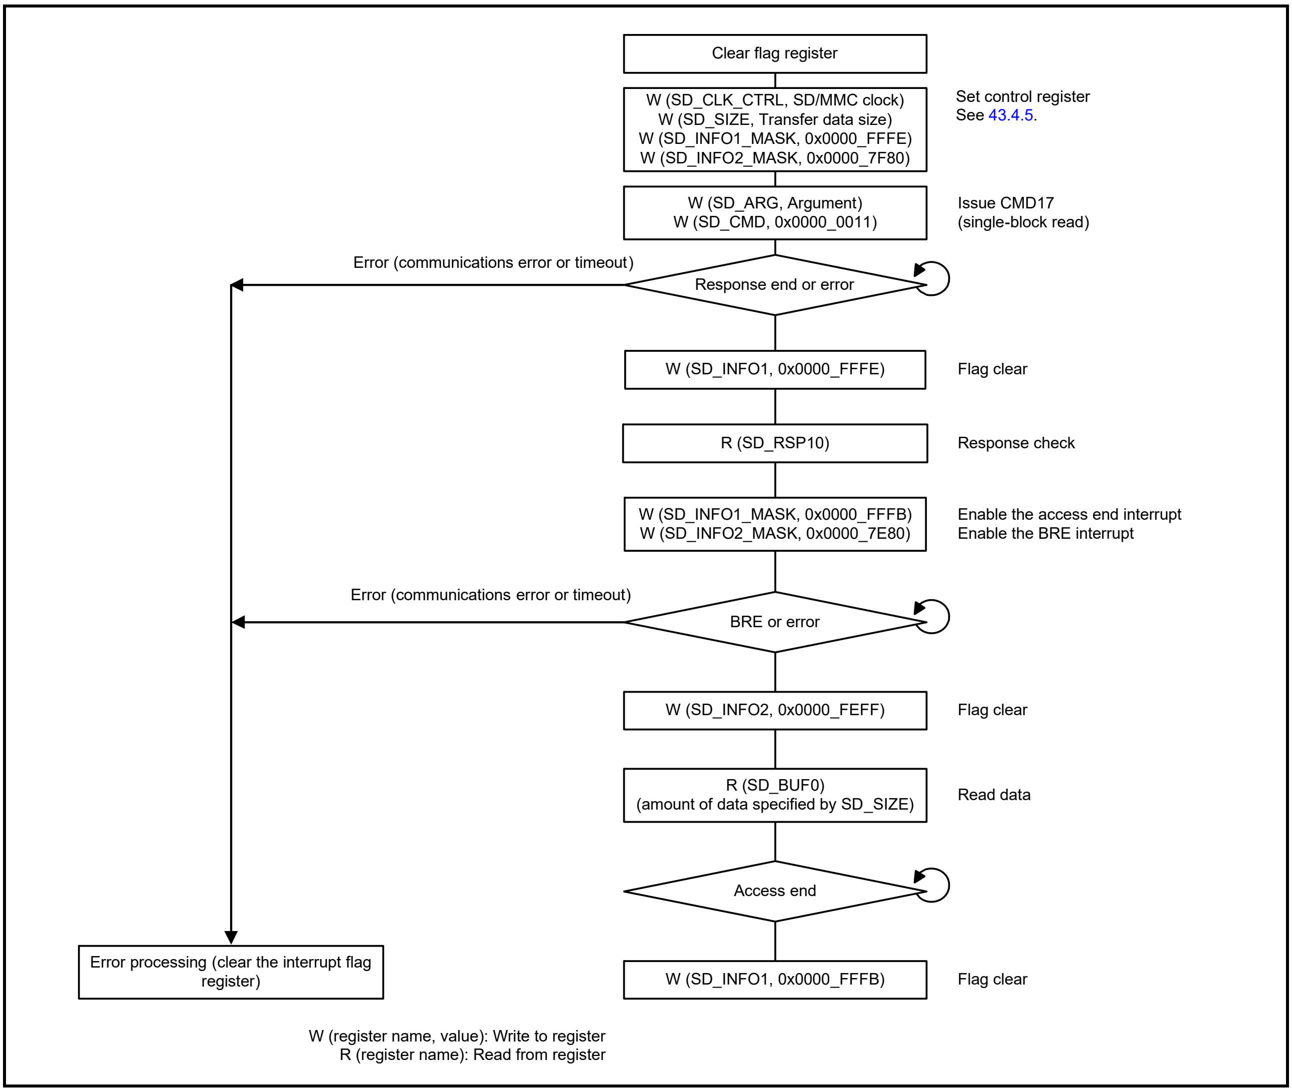

Figure 43.11 Example flow of single block read operation

43.3.6.1 Single block read operation

The operation of the single block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD17)
Set CMD17 argument in SD_ARG and write 0x0000_0011 to SD_CMD. CMD17 is issued and the single block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO1 is set, halting the command sequence also leads to the generation of an interrupt.

e. Data receive from SD card/MMC and data read
Write 0x0000_FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_7E80

to SD_INFO2_MASK to enable the BRE interrupt. When the data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0.
A communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress.

f. Operation complete
When the data read from SD_BUF0 is completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to end the single block read operation.
Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

43.3.7 Single Block Write (SD/MMC)

Figure 43.12 shows an example flow of a single block write operation.

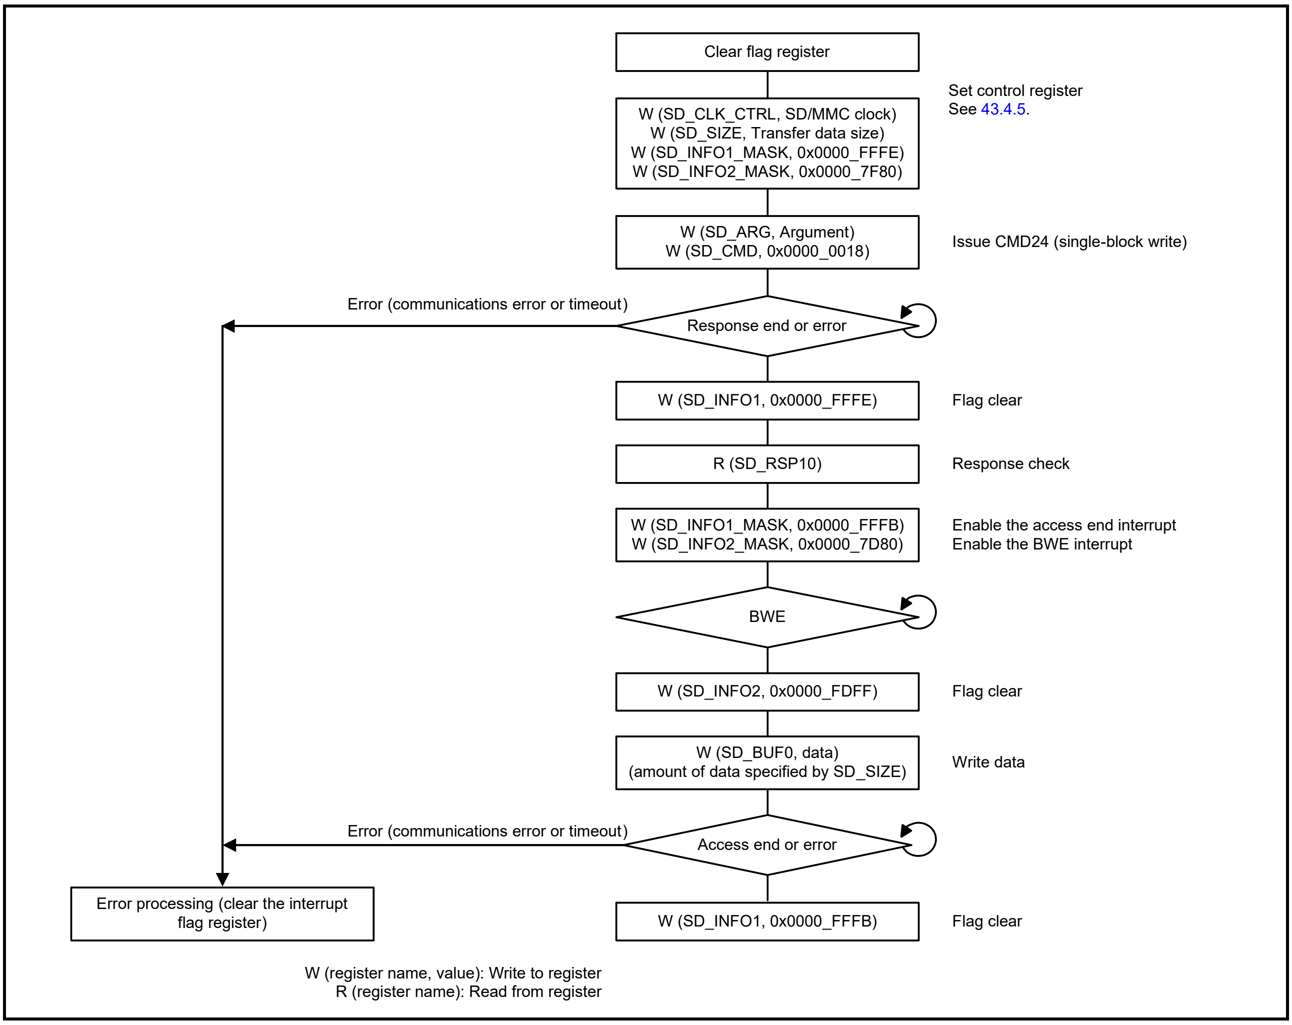

Figure 43.12 Example of single block write operation

43.3.7.1 Single block write operation

The operation of the single block write is described as follows:

a. Flag register clear
   First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
   Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD24)
   Set CMD24 argument in SD_ARG and write 0x0000_0018 to SD_CMD. CMD24 is issued and the single block write operation is started.

d. Response check
   On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO is set, halting the command sequence also leads to the generation of an interrupt.

e. Data write and data transmit to SD card/MMC
   Write 0x0000_FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card/MMC.
   However, a communications error or timeout might be generated if data is being transmitted after writing to SD_BUF0.

f. Operation complete
   When the CRC status and busy state are received from the SD card/MMC, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to end the single block write operation.
   In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

43.3.8 Multiple Block Read (SD/MMC)

Figure 43.13 shows an example flow of a multiple block read operation.

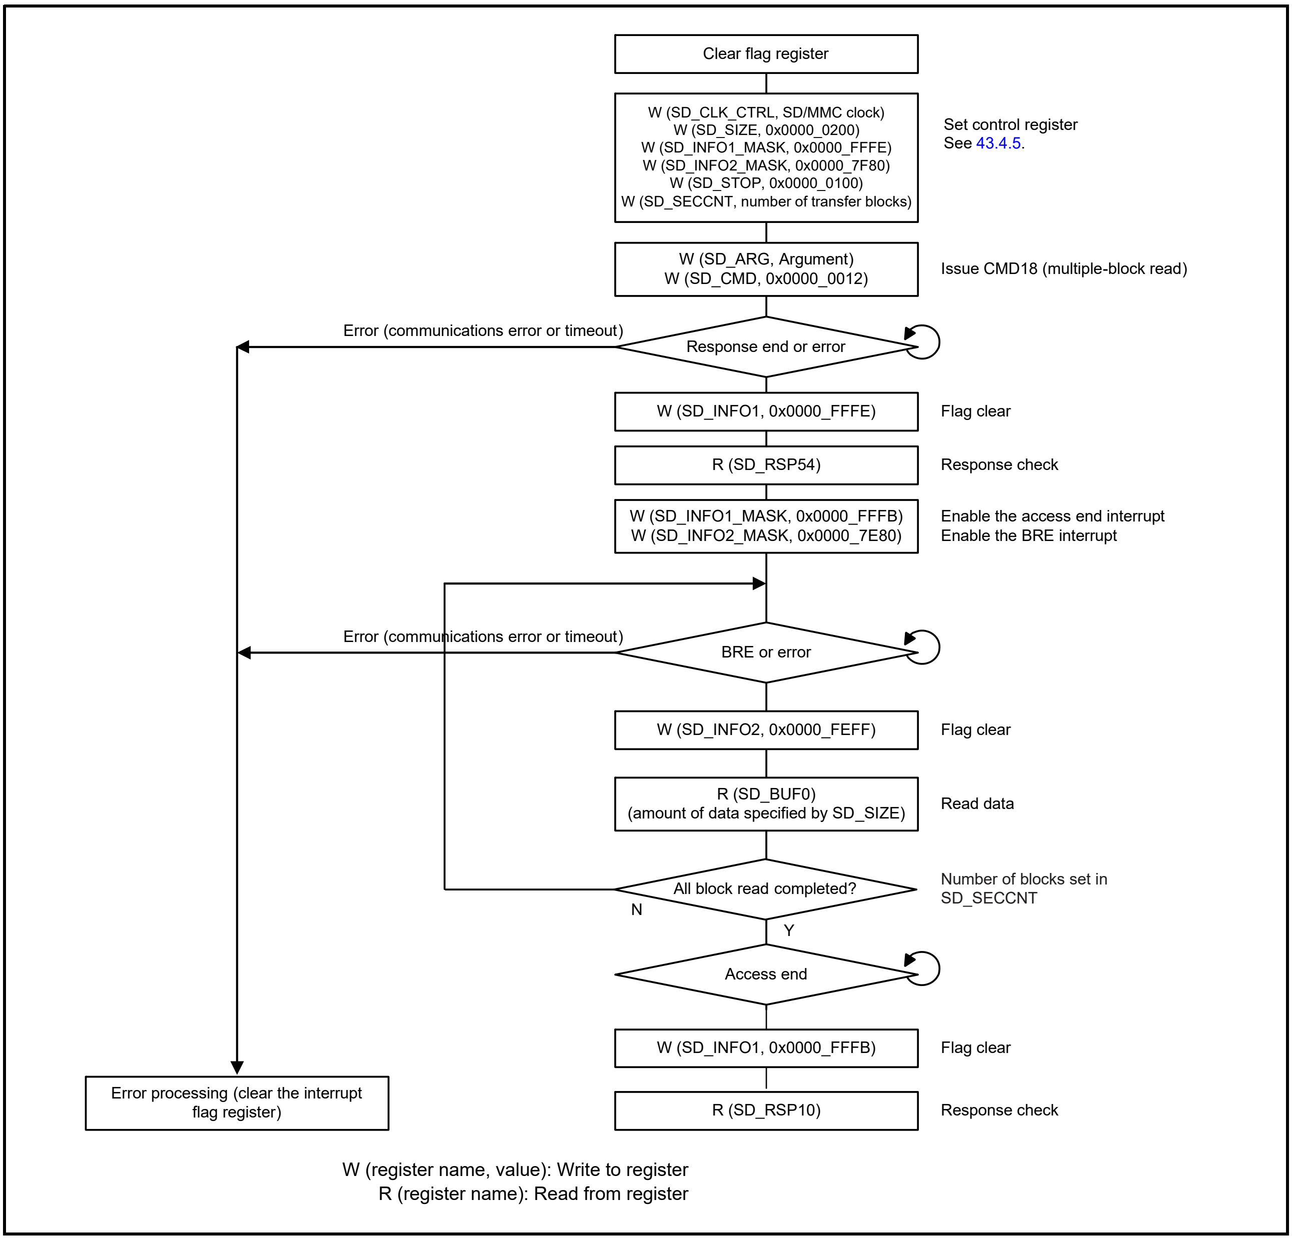

Figure 43.13 Example of multiple block read operation

43.3.8.1 Multiple block read operation

The operation of the multiple block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD18)
Set CMD18 argument in SD_ARG and write 0x0000_0012 to SD_CMD. CMD18 is issued and the multiple block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear

RSPEND to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data receive from SD card/MMC and data read
Write 0x0000_FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_7E80 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks that is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data read and the CMD12 response received are completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to read the response. This is the end of multiple block read operation. In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

43.3.9 Multiple Block Write (SD/MMC Using Internal Timer)

Figure 43.14 shows an example flow of a multiple block write using internal timer.

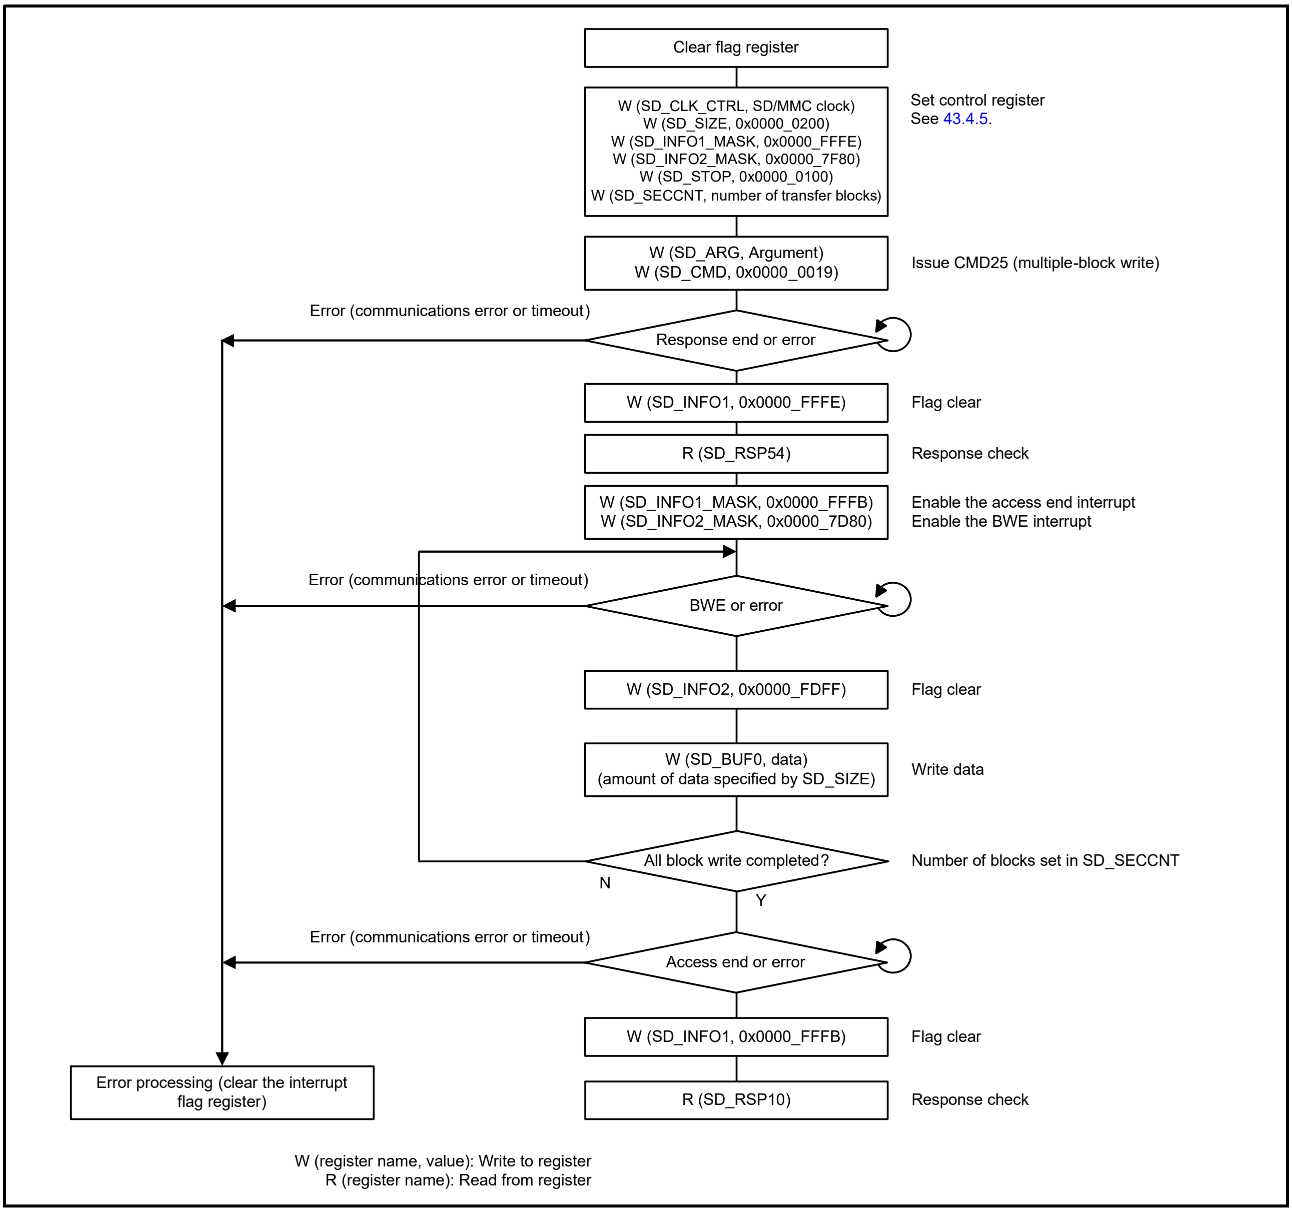

Figure 43.14 Example of multiple block write operation using internal timer

43.3.9.1 Multiple block write operation using internal timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD25)
Set CMD25 argument in SD_ARG and write 0x0000_0019 to SD_CMD. CMD25 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error,

the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to SD card/MMC
Write 0x0000_FFFB to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_7D80 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card/MMC. The CRC status and busy state are received from the SD card/MMC. This repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs.

43.3.10 Multiple Block Write (MMC using external timer)

Figure 43.15 shows an example flow of a multiple block write using an external timer.

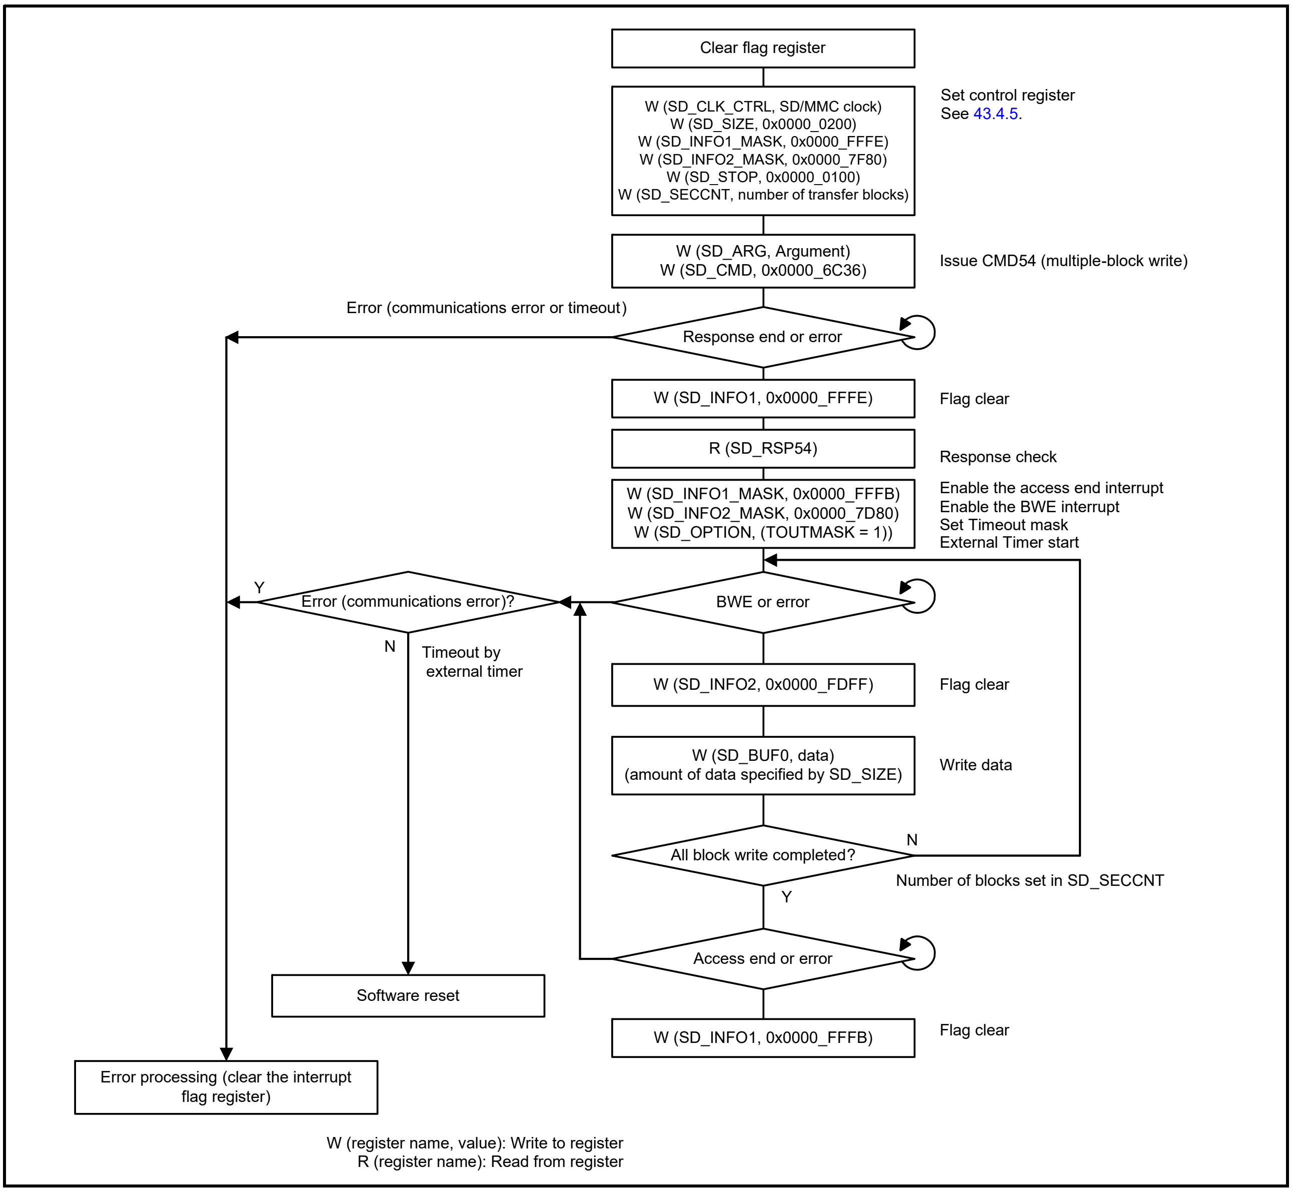

Figure 43.15 **Example of multiple block write operation using external timer**

43.3.10.1 Multiple block write operation using external timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD54)
Set CMD54 Argument in SD_ARG and write 0x0000_6C36 to SD_CMD. CMD54 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes

CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to MMC
Write 0x0000_FFFB to SD_INFO1_MASK to enable the access end interrupt, write 0x0000_7D80 to SD_INFO2_MASK to enable the BWE interrupt and set 1 to TOUTMASK of SD_OPTION to inactivate timeout. In addition, start external timer. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the MMC. The CRC status and busy state are received from the MMC. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs when receiving response. Execute software reset if a timeout by external timer occurs when transmitting data.

43.3.11 IO_RW_DIRECT Command (SD: CMD52)

Figure 43.16 shows an example flow of an IO_DIRECT command (CMD52) operation.

43.4 Usage Notes

43.4.1 SD_BUF Illegal Write Access (SD/MMC)

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified in SD_SIZE must be written.

If the data exceeds the size specified in SD_SIZE is written, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 might not be transmitted and the SD_CLK_CTRLEN bit in SD_INFO2 is held at the value of 0. If this occurs, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SD_CLK_CTRLEN bit to 1.

However, this does not apply to the single byte or three bytes when the SD_SIZE setting is odd, or to the fraction of bytes when the SD_SIZE setting is even (the 2 bytes that are not in a 4-byte unit), because the portion of dummy data writing is regarded as excess data and ignored.

43.4.2 Block Number Constraint for Multiple Block Read (SD)]

When performing a multiple block read of one or two blocks, depending on the timing with which the SD card response register is read, the response value might not be read properly. To prevent this, do one of the following:

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

43.4.2.1 Mechanism of incorrect reading

Figure 43.25 shows the processing flows of the SDHI (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation in Figure 43.25, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response might be read. This problem does not occur for multiple block reads of three or more blocks, because CMD12 is not issued until the block of data is read. The problem also does not occur for multiple block writes, because the CMD25 response is read before the block of data is sent.

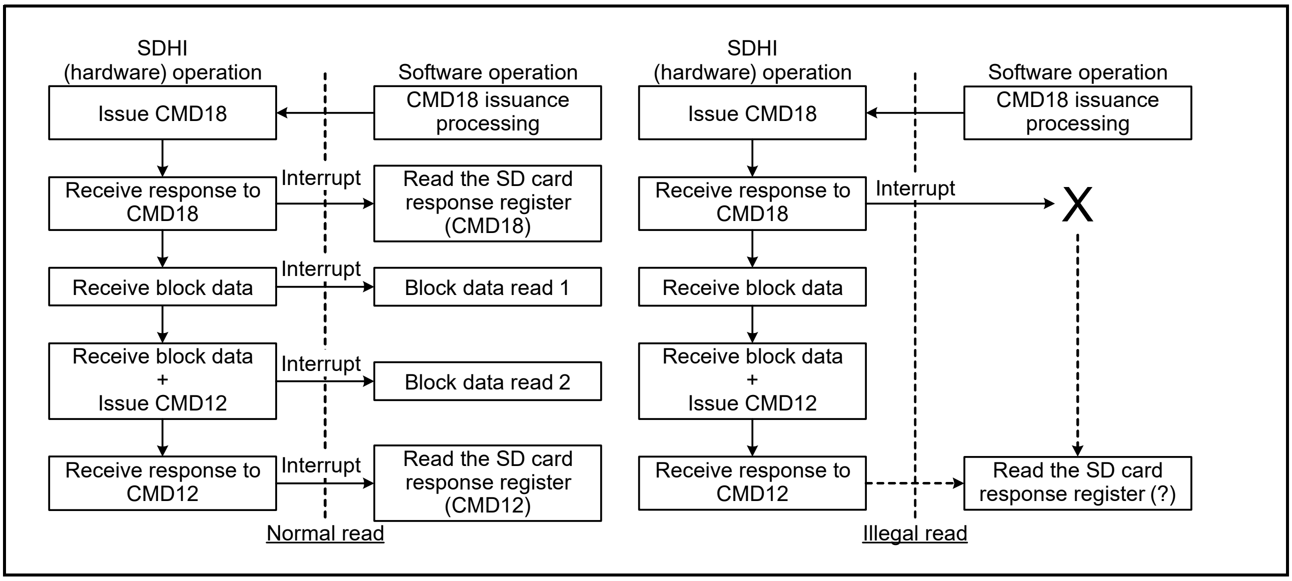

Figure 43.25 Multiple block read operation flow chart (two blocks)

43.4.3 Automatic Control of SD/MMC Clock Output (SD/MMC)

In the SD Card/MMC standard, 74 cycles of SD/MMC clock must be output before initialization of the card. For this reason, use automatic control of SD/MMC clock output after 74 cycles of SD/MMC clock are output. In addition, if automatic control of SD/MMC clock output was in use, SD/MMC clock output is stopped on completion of the sequence for a communications error or timeout. When state transitions within the SD card/MMC are necessary after completion of the sequence, release automatic control of SD/MMC clock output and restart supply of the SD/MMC clock to the SD card/MMC.

43.4.4 Control of the C52PUB Setting for Multiple Block Write (SD)

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write because of CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by using one of the following procedures, as appropriate:

(a) When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

(b) When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2,....) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by DMA transfer.

43.4.5 Notes on SD_CLK_CTRL Register Settings (SD/MMC)

When the SD_CLK_CTRLEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, you must check that the SD_CLK_CTRLEN bit in SD_INFO2 is 1.

43.4.6 Specification Limitations

1. The Suspend/Resume operation of the SDIO is not supported.
2. The SPI bus is not supported. (SD/MMC)
3. The shared bus and 8-bit SD bus of the embedded SDIO are not supported.
4. Stream transfer of MMC is not supported.
5. High Priority Interrupt (HPI) of MMC is not supported.
6. Boot Operation/Alternative Boot Operation of MMC is not supported.
7. Open-ended multiple block transfer of MMC is not supported.

43.4.7 STP Bit Setting during Multiple Block Read (SD/MMC)

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence might not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SD_CLK_CTRLEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence does not stop because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, you must leave the SEC bit in SD_STOP as 1.

43.4.8 Register Setting Notes

1. All registers in section 43.2, Register Descriptions are accessed in 32-bit access-only.
2. When setting registers, set them after the I/O Port Register setting.

44. Parallel Data Capture Unit (PDC)

44.1 Overview

The MCU provides one Parallel Data Capture Unit (PDC). The PDC communicates with external I/O devices, including image sensors, and transfers parallel data such as an image output from the external I/O device through the DTC or DMAC to the on-chip SRAM and external address spaces (the CS and SDRAM areas). Table 44.1 lists the PDC specifications, Figure 44.1 shows a block diagram, and Table 44.2 lists the I/O pins.

Table 44.1 PDC specifications

Parameter	Specifications
Capture range	Any amount of parallel data within the following ranges in the vertical and horizontal directions: • Vertical direction: 1 to 4095 lines • Horizontal direction: 4 to 4095 bytes
Parallel transfer clock (PIXCLK)	Operating frequency: 1 to 27 MHz*1
Interrupt sources	• Receive data ready • Frame end • Overrun • Underrun • Error in the setting for the number of lines • Error in setting for the number of bytes per line
Startup of DTC or DMAC	Frame end and receive data ready interrupts can start DTC or DMAC
Parallel transfer clock output (PCKO)	• Operating frequency: 1 to 30 MHz*2 • Clock source: Peripheral module clock B (PCLKB) • Frequency division ratio: Selectable from 2, 4, 6, 8, 10, 12, 14, and 16.
Other functions	• PDC reset function • Selectable active polarity for VSYNC and HSYNC signals • Monitoring of VSYNC and HSYNC signals • Endian order selectable
Module-stop function	Module-stop state can be set to reduce power consumption
Internal bus interface	Internal peripheral bus 5

Note 1. Set the frequency of the parallel data transfer clock (PIXCLK) to a value less than that of 0.6 × PCLKB (peripheral module clock).

Note 2. The operating frequency is 30 MHz when peripheral module clock B (PCLKB) is 60 MHz and the frequency division ratio is 2.

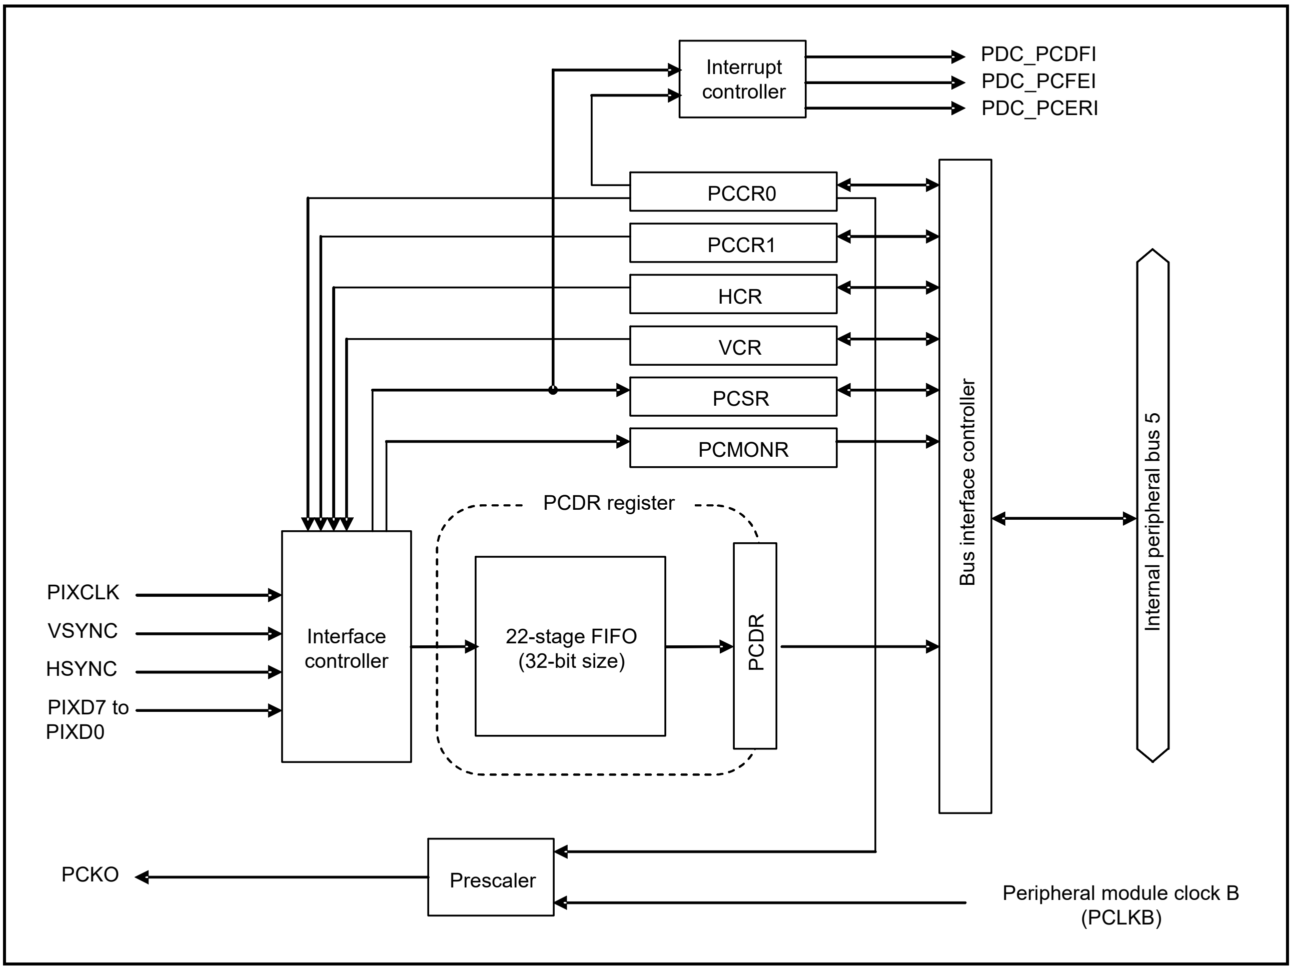

Figure 44.1 PDC block diagram

Table 44.2 PDC I/O pins

Pin name	I/O	Description
PIXCLK	Input	Parallel transfer clock
VSYNC	Input	Vertical synchronization signal
HSYNC	Input	Horizontal synchronization signal
PIXD7 to PIXD0	Input	8-bit data
PCKO	Output	Output for the parallel transfer clock

44.2 Register Descriptions

44.2.1 PDC Control Register 0 (PCCR0)

Address(es): PDC.PCCR0 4009 4000h

b14	EDS	Endian Select	0: Little endian 1: Big endian.	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 1 can be written to this bit.

Only set the PCCR0 register while the PCE bit in the PCCR1 register is 0.

PCKE bit (PIXCLK Input Enable)

The PCKE bit enables or disables input through the PIXCLK pin. Set this bit to 1 before enabling reception. After enabling input through the PIXCLK pin, use the PRST bit to initialize the PDC.

Disable reception operations before setting this bit to 0.

VPS bit (VSYNC Signal Polarity Select)

The VPS bit selects the active polarity of the VSYNC signal.

HPS bit (HSYNC Signal Polarity Select)

The HPS bit selects the active polarity of the HSYNC signal.

PRST bit (PDC Reset)

The PRST bit initializes the internal status of the PDC and the PDC registers targeted by reset. See section 44.3.11, Reset State, for the target registers. Set the PCKE bit to 1 before resetting the PDC.

When 1 is written to the PRST bit, initialization starts in synchronization with the PIXCLK. After initialization completes, the PRST bit clears to 0. After a PDC reset, ensure that the PIXCLK pin has an input signal. Also, after 1 is written to the PRST bit, do not proceed to the next step until verifying that the bit has returned to 0.

For consecutive PDC resets, wait for at least 1 PIXCLK cycle after verifying that the PRST bit has returned to 0.

DFIE bit (Receive Data Ready Interrupt Enable)

The DFIE bit enables or disables the generation of receive data ready interrupt requests.

FEIE bit (Frame End Interrupt Enable)

The FEIE bit enables or disables the generation of frame end interrupt requests.

OVIE bit (Overrun Interrupt Enable)

The OVIE bit enables or disables the generation of overrun interrupt requests.

UDRIE bit (Underrun Interrupt Enable)

The UDRIE bit enables or disables the generation of underrun interrupt requests.

VERIE bit (Vertical Line Number Setting Error Interrupt Enable)

The VERIE bit enables or disables the generation of vertical line number setting error interrupt requests.

HERIE bit (Horizontal Byte Number Setting Error Interrupt Enable)

The HERIE bit enables or disables the generation of horizontal byte number setting error interrupt requests.

PCKOE bit (PCKO Output Enable)

The PCKOE bit enables or disables an output from PCKO. When the PCKOE bit is cleared to 0 during low output of PCKO, it might cause high output on clearing, resulting in corruption of the duty cycle.

PCKDIV[2:0] bits (PCKO Frequency Division Ratio Select)

The PCKDIV[2:0] bits select the frequency division ratio of PCKO. The PCKO output is a clock signal derived by dividing the PCLKB clock signal by a value from 2 to 16, based on the setting in the PCKDIV[2:0] bits. The PCKO operating frequency, the resulting PCLKB division, must fall within the range from 1 to 30 MHz.

EDS bit (Endian Select)

The EDS bit selects the endian order for the captured data.

44.2.2 PDC Control Register 1 (PCCR1)

Address(es): PDC.PCCR1 4009 4004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	PCE	PDC Operation Enable	0: Disable reception operations 1: Enable reception operations.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PCE bit (PDC Operation Enable)

The PCE bit enables or disables reception operations. When the PCE bit is set to 1 during assertion of the VSYNC signal, the PDC starts reception operations from the next valid edge of the VSYNC signal.

Only clear the PCE bit to 0 while reception or continued reception operations are stopped, including for the frame end interrupt. For more on continued reception, see section 44.3.6, Continued Reception Operations at Frame End.

44.2.3 PDC Status Register (PCSR)

Address(es): PDC.PCSR 4009 4008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	HERF	VERF	UDRF	OVRF	FEF	FEMPF	FBSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit name	Description	R/W
b0	FBSY	Frame Busy Flag	0: Reception operations are stopped 1: Reception operations are ongoing.	R
b1	FEMPF	FIFO Empty Flag	0: FIFO is not empty 1: FIFO is empty.	R
b2	FEF	Frame End Flag	0: No frame end occurred 1: Frame end occurred.	R/(W) *1
b3	OVRF	Overrun Flag	0: No FIFO overrun occurred 1: FIFO overrun occurred.	R/(W) *1
b4	UDRF	Underrun Flag	0: No underrun occurred 1: Underrun occurred.	R/(W) *1
b5	VERF	Vertical Line Number Setting Error Flag	0: No vertical line number setting error occurred 1: Vertical line number setting error occurred.	R/(W) *1
b6	HERF	Horizontal Byte Number Setting Error Flag	0: No horizontal byte number setting error occurred 1: Horizontal byte number setting error occurred.	R/(W) *1

Bit	Symbol	Bit name	Description	R/W
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to these flags, to clear them after they are read as 1.

FBSY flag (Frame Busy Flag)

The FBSY flag indicates the state of PDC operations.

[Setting condition]

- On detection of the valid edge of the VSYNC signal after the enabling of reception operations.

[Clearing conditions]

- On reception of one frame of data in accordance with the settings in the VCR and HCR registers*1
- When an overrun, underrun, vertical line number setting error, or horizontal byte number setting error occurs
- When the PCCR1.PCE bit is 0.

Note 1. This flag is 0 during continued reception operations.

FEMPF flag (FIFO Empty Flag)

The FEMPF flag indicates the state of the FIFO when a vertical line number setting error or a horizontal byte number setting error occurs. It clears to 0 following an overrun and undefined following an underrun.

[Setting conditions]

- On reading of the PCDR register while the FIFO is empty
- On detection of a valid edge of the VSYNC signal
- On PDC reset.

[Clearing condition]

- On storage of the data captured in the FIFO.

FEF flag (Frame End Flag)

The FEF flag indicates the end of a frame.

[Setting condition]

- Reception of one frame of data in accordance with the settings in the VCR and HCR registers.*1

[Clearing conditions]

- On PDC reset
- When 0 is written to the flag after it is read as 1.

Note 1. For continued reception operations, this flag sets to 1 on their completion.

OVRF flag (Overrun Flag)

The OVRF flag indicates the occurrence of an overrun.

[Setting condition]

- When receive data arrives while the FIFO is full.

[Clearing conditions]

- On PDC reset
- When 0 is written to the flag after it is read as 1.

UDRF flag (Underrun Flag)

The UDRF flag indicates the occurrence of an underrun.

[Setting condition]

- On reading of the PCDR register while the FIFO is empty.

[Clearing conditions]

- On PDC reset
- When 0 is written to the flag after it is read as 1.

VERF flag (Vertical Line Number Setting Error Flag)

The VERF flag indicates an error in the setting for the number of lines.

[Setting condition]

- When the VSYNC signal is negated because fewer lines were captured than the value in the VCR register.

[Clearing conditions]

- On PDC reset
- When 0 is written to the flag after it is read as 1.

HERF flag (Horizontal Byte Number Setting Error Flag)

The HERF flag indicates an error in the number of bytes in a line.

[Setting condition]

- When the HSYNC signal is negated because fewer bytes in a line were captured than the value in the HCR register.

[Clearing conditions]

- On PDC reset
- When 0 is written to the flag after it is read as 1.

44.2.4 PDC Pin Monitor Register (PCMONR)

Address(es): PDC.PCMONR 4009 400Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HSYNC	VSYNC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	VSYNC	VSYNC Signal Status Flag	0: VSYNC signal level is low 1: VSYNC signal level is high.	R
b1	HSYNC	HSYNC Signal Status Flag	0: HSYNC signal level is low 1: HSYNC signal level is high.	R
b31 to b2	—	Reserved	These bits are read as 0.	R

VSYNC flag (VSYNC Signal Status Flag)

The VSYNC flag indicates the state of the VSYNC signal.

HSYNC flag (HSYNC Signal Status Flag)

The HSYNC flag indicates the state of the HSYNC signal.

44.2.5 PDC Receive Data Register (PCDR)

Address(es): PDC.PCDR 4009 4010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PDC includes a 32-bit-wide, 22-stage FIFO for the storage of captured data. The FIFO is mapped to the 4-byte PCDR register and four bytes of data are read from the PCDR register at a time. The receive data ready flag sets for every 32 bytes of received data, and this also results in a receive data ready interrupt if the DFIE bit in the PCCR0 register is set to 1. When a receive data ready interrupt is generated, read the PCDR register eight times. Figure 44.2 shows a schematic view of the PCDR register.

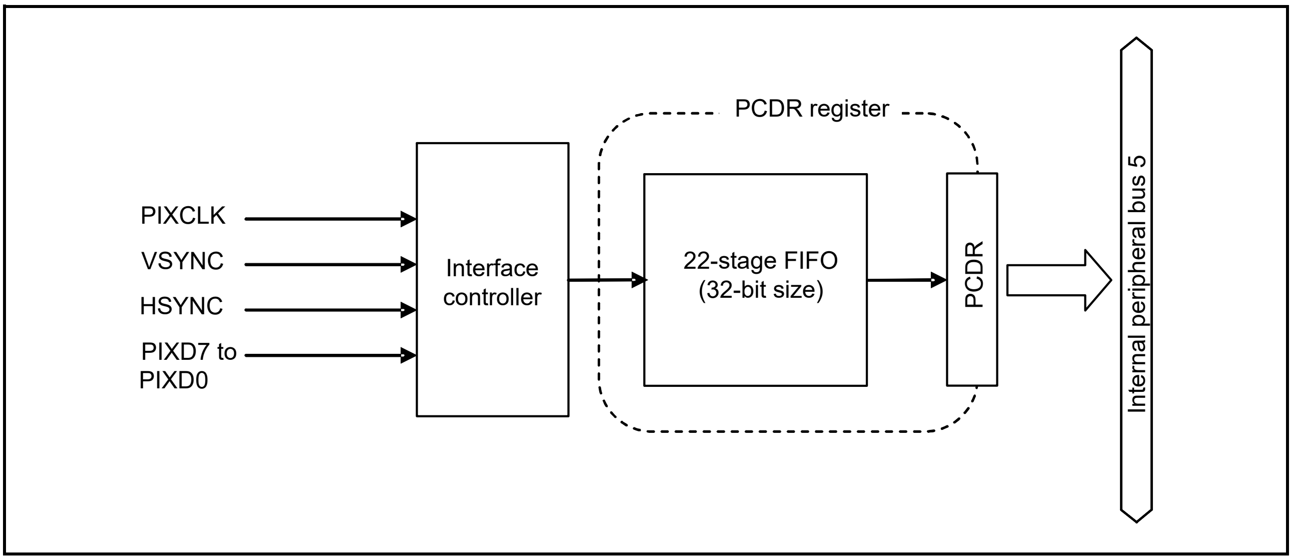

Figure 44.2 Schematic view of PCDR register

For the format of the captured data, either big or little endian can be selected in the EDS bit of the PCCR0 register. Figure 44.3 shows the data arrangements for the endian formats.

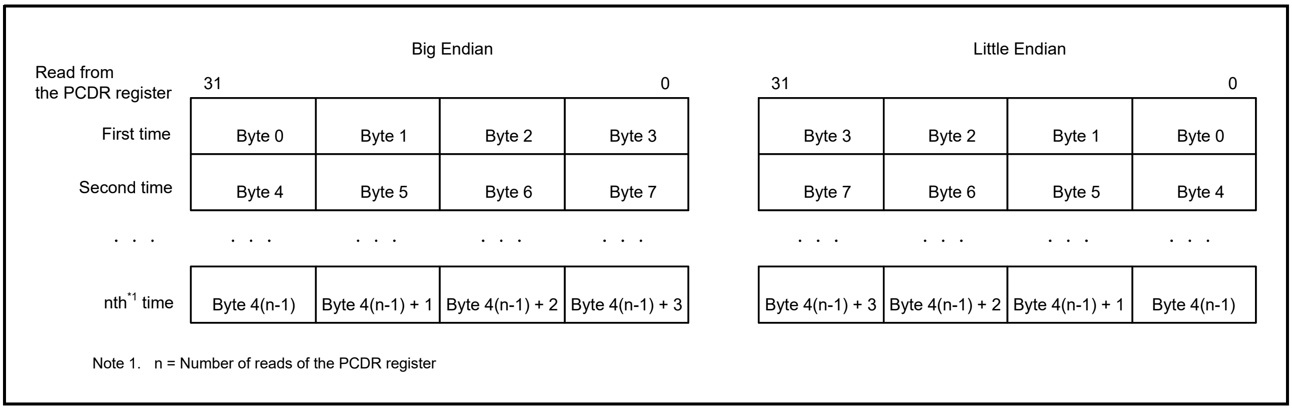

Figure 44.3 Endian formats

44.2.6 Vertical Capture Register (VCR)

Address(es): PDC.VCR 4009 4014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	VSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	VST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b11 to b0	VST[11:0]	Vertical Capture Start Line Position	These bits specify the number of the line where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	VSZ[11:0]	Vertical Capture Size	These bits specify the number of lines to be captured.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the VCR register setting and the capture range, see section 44.3.3, VCR and HCR Register Settings and the Capture Range. Only set the VCR register while the PCE bit in the PCCR1 register is 0.

VST[11:0] bits (Vertical Capture Start Line Position)

The VST[11:0] bits specify the number of the line where capture is to start. To set the first line, set these bits to 000h; to set the 4095th line, set them to FFEh. The VST[11:0] setting must be within the range from 000h to FFEh and, in combination with the VSZ[11:0] setting, satisfy the following relationship:

Setting range of the VST[11:0] bits: $1 \leq \text{VST[11:0]} + \text{VSZ[11:0]} \leq \text{FFFh}$.

VSZ[11:0] bits (Vertical Capture Size)

The VSZ[11:0] bits specify the number of lines to be captured. To set one line, set these bits to 001h; to set 4095 lines, set them to FFFh. The VSZ[11:0] setting must be within the range from 001h to FFFh and, in combination with the VST[11:0] setting, satisfy the following relationship:

Setting range of the VSZ[11:0] bits: $1 \leq \text{VST[11:0]} + \text{VSZ[11:0]} \leq \text{FFFh}$.

44.2.7 Horizontal Capture Register (HCR)

Address(es): PDC.HCR 4009 4018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	HSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	HST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b11 to b0	HST[11:0]	Horizontal Capture Start Byte Position	These bits specify the horizontal position in bytes where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	HSZ[11:0]	Horizontal Capture Size	These bits specify the number of bytes to be captured horizontally.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the HCR register setting and the capture range, see section 44.3.3, VCR and HCR Register Settings and the Capture Range. Only set the HCR register while the PCE bit in the PCCR1 register is 0.

HST[11:0] bits (Horizontal Capture Start Byte Position)

The HST[11:0] bits specify the horizontal position in bytes where capture is to start. To set the first byte, set these bits to 000h; to set the 4092th byte, set them to FFBh. The HST[11:0] setting must be within the range from 000h to FFBh and, in combination with the HSZ[11:0] setting, satisfy the following relationship:

Setting range of the HST[11:0] bits: $1 \leq \text{HST}[11:0] + \text{HSZ}[11:0] \leq \text{FFFh}$.

HSZ[11:0] bits (Horizontal Capture Size)

The HSZ[11:0] bits specify the number of bytes to be captured per line. To set four bytes, set these bits to 004h; to set 4095 bytes, set them to FFFh. The HSZ[11:0] setting must be within the range from 004h to FFFh and, in combination with the HST[11:0] setting, satisfy the following relationship:

Setting range of the HSZ[11:0] bits: $1 \leq \text{HST}[11:0] + \text{HSZ}[11:0] \leq \text{FFFh}$.

44.3 Operation

44.3.1 Transfer Formats

The PDC supports the four transfer formats shown in Figure 44.4 to Figure 44.7. The format is determined by the settings in the VPS and HPS bits in the PCCR0 register.

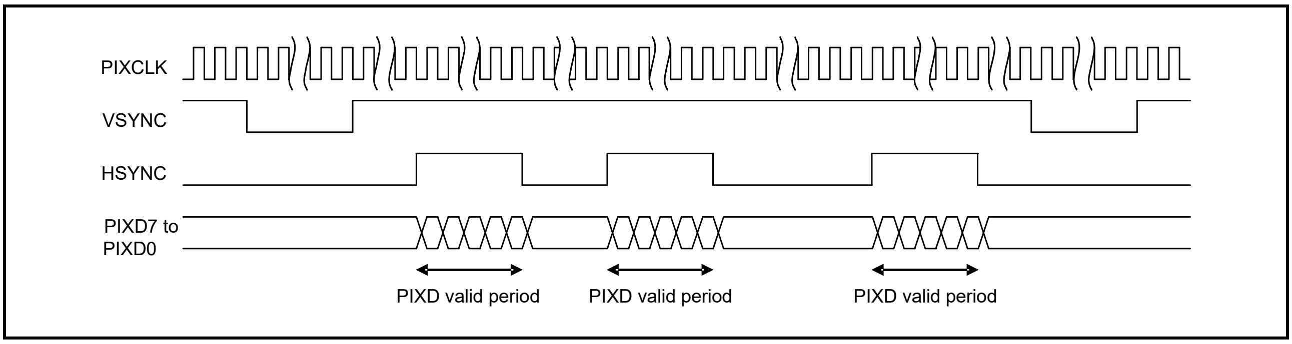

Figure 44.4 PDC transfer format when VPS = 0 and HPS = 0

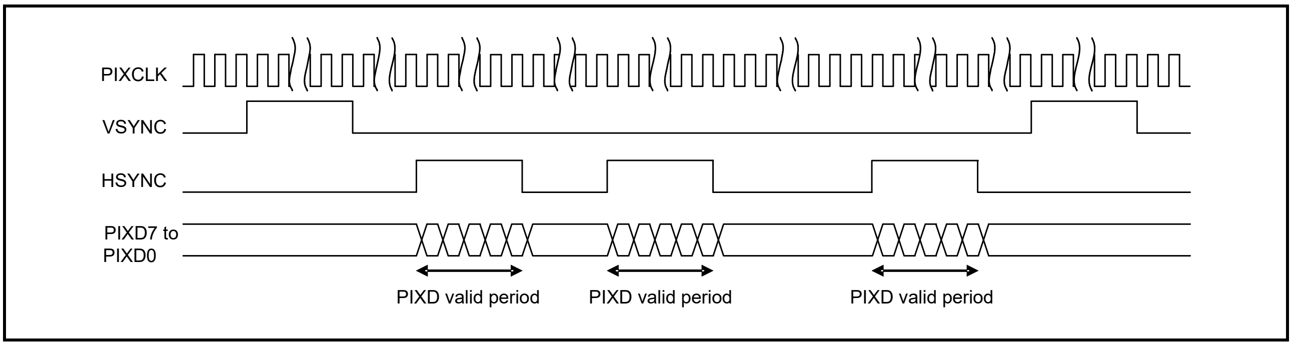

Figure 44.5 PDC transfer format when VPS = 1 and HPS = 0

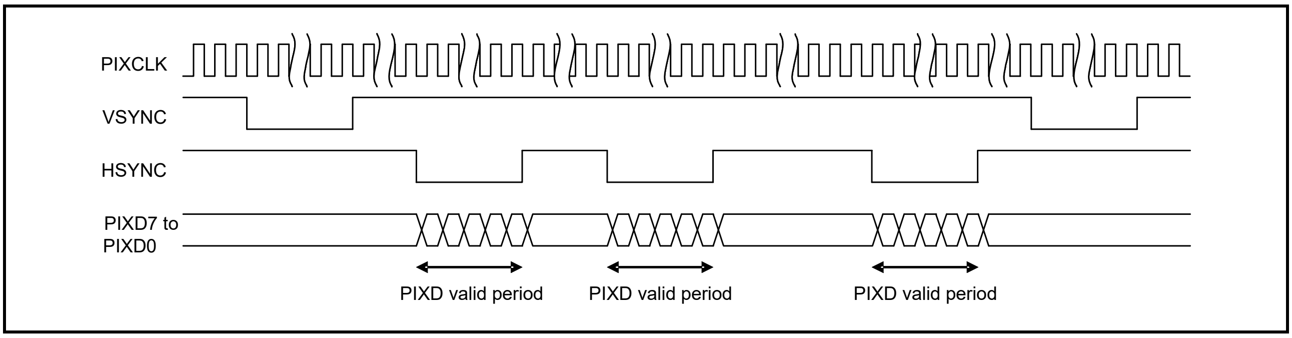

Figure 44.6 PDC transfer format when VPS = 0 and HPS = 1

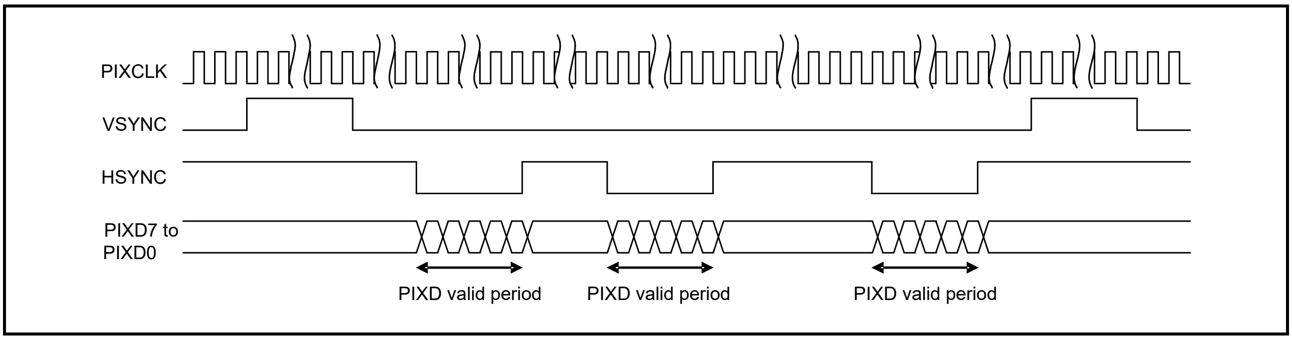

Figure 44.7 PDC transfer format when VPS = 1 and HPS = 1

44.3.2 Transfer Timing

Figure 44.8 and Table 44.3 show the timing of transfers by the PDC.

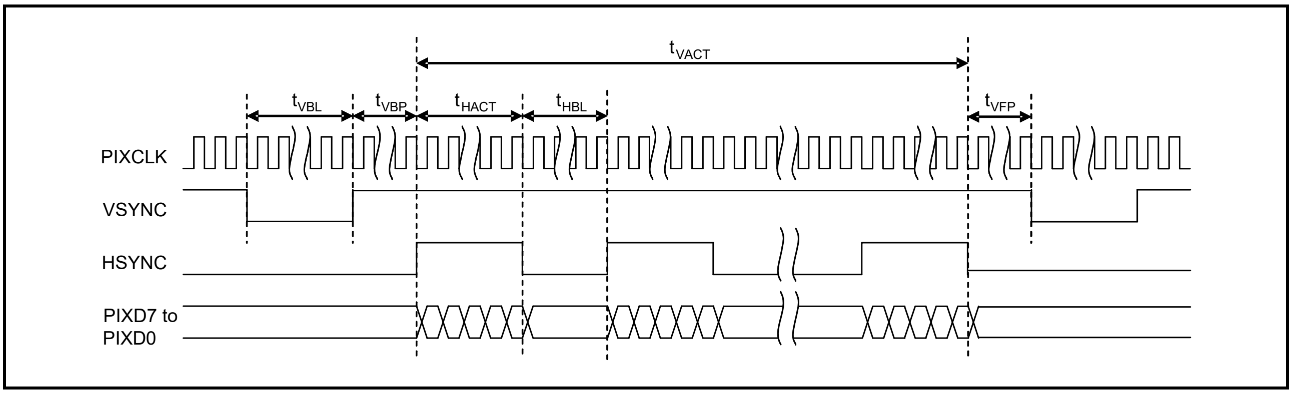

Figure 44.8 PDC transfer timing when VPS = 0 and HPS = 0

Table 44.3 PDC transfer timing when VPS = 0 and HPS = 0

Parameter	Symbol	Min[*1]	Max	Unit
Vertical blanking period	t_{VBL}	128	-	PIXCLK
Vertical backporch	t_{VBP}	10	-	PIXCLK
Horizontal valid period	t_{HACT}	4	4095	PIXCLK
Horizontal blanking period	t_{HBL}	128	-	PIXCLK
Vertical frontporch	t_{VFP}	10	-	PIXCLK
Vertical valid period	t_{VACT}	1	4095	Line

Note 1. The minimum values are the lowest the PDC is capable of achieving. Operation at these values cannot guarantee the avoidance of overruns, vertical line number setting errors, or horizontal byte number setting errors.

44.3.3 VCR and HCR Register Settings and the Capture Range

Figure 44.9 and Figure 44.10 show the relationship between the settings in the VCR and HCR registers and the capture range.

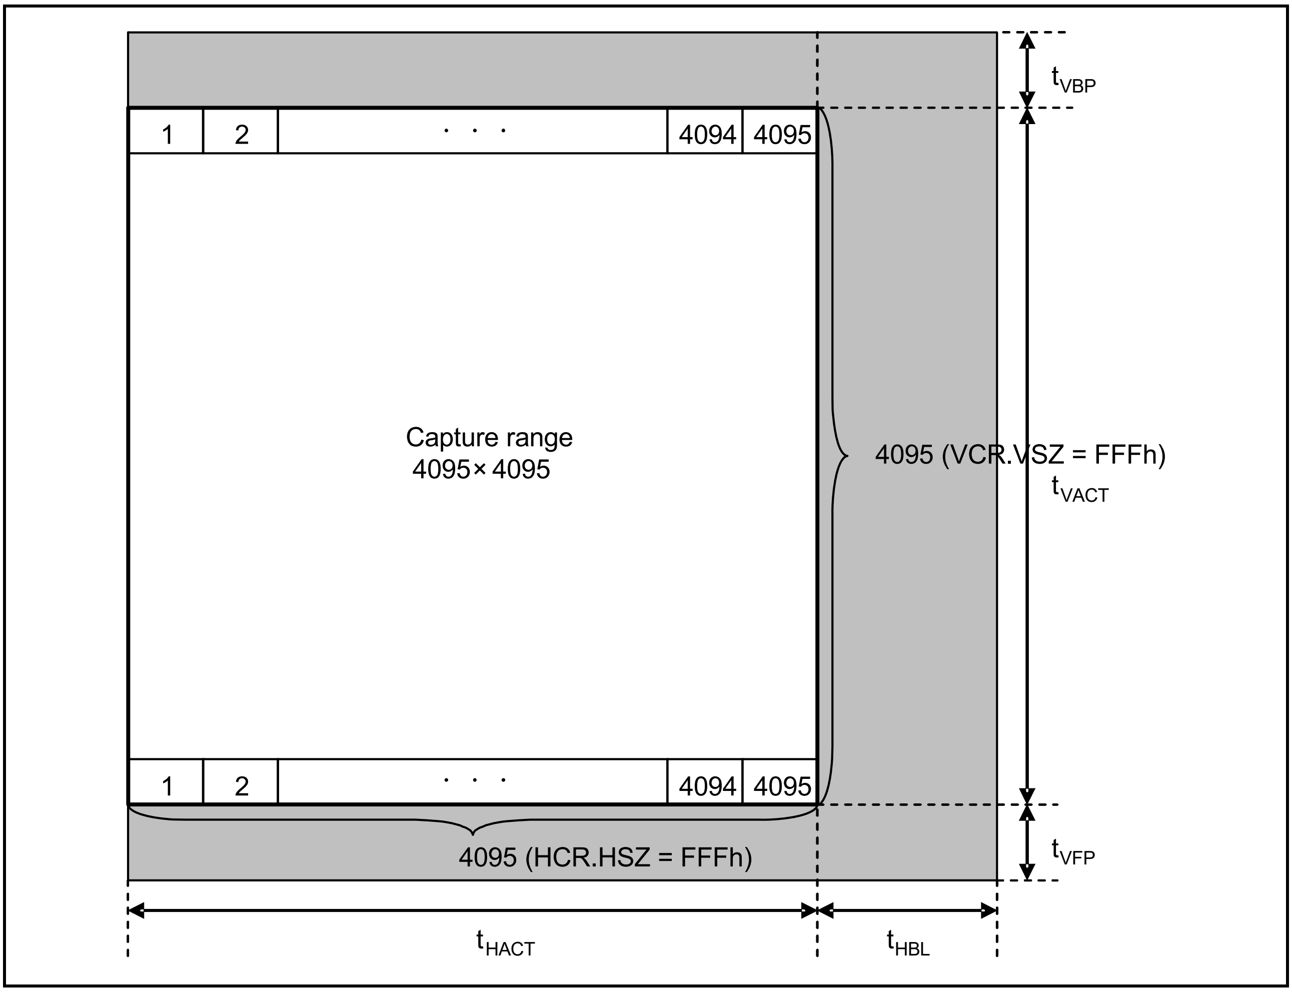

Figure 44.9 Settings in the VCR and HCR registers and the capture range when VCR = 0FFF 0000h and HCR = 0FFF 0000h

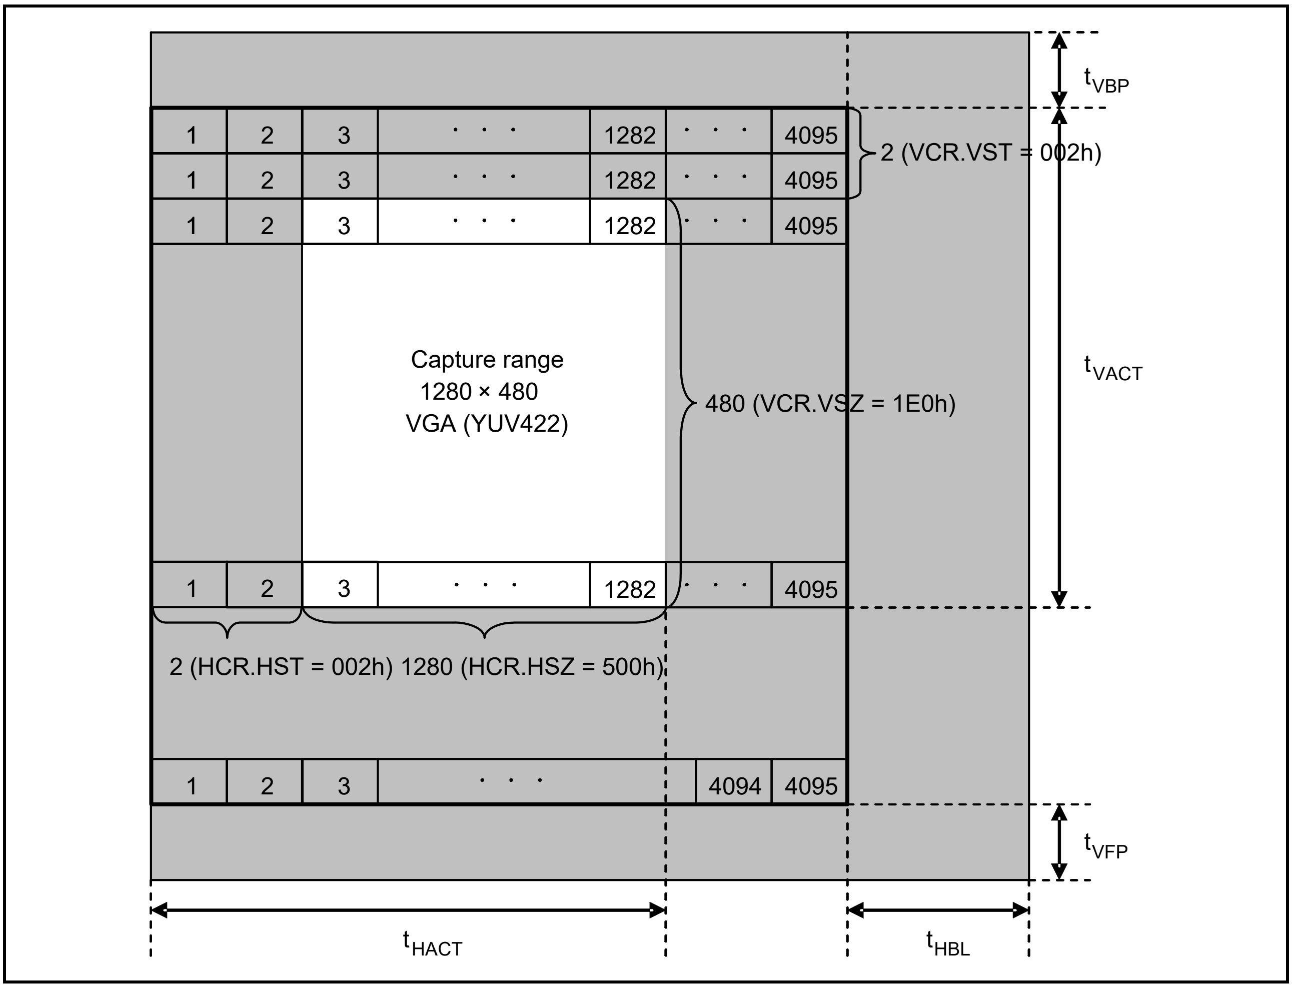

Figure 44.10 Settings in the VCR and HCR registers and the capture range when VCR = 01E0 0002h and HCR = 0500 0002h

44.3.4 Reception Operation

Figure 44.11 shows an example of reception operations when receive data ready interrupts (to start the DTC or DMAC) and frame end interrupts are in use.

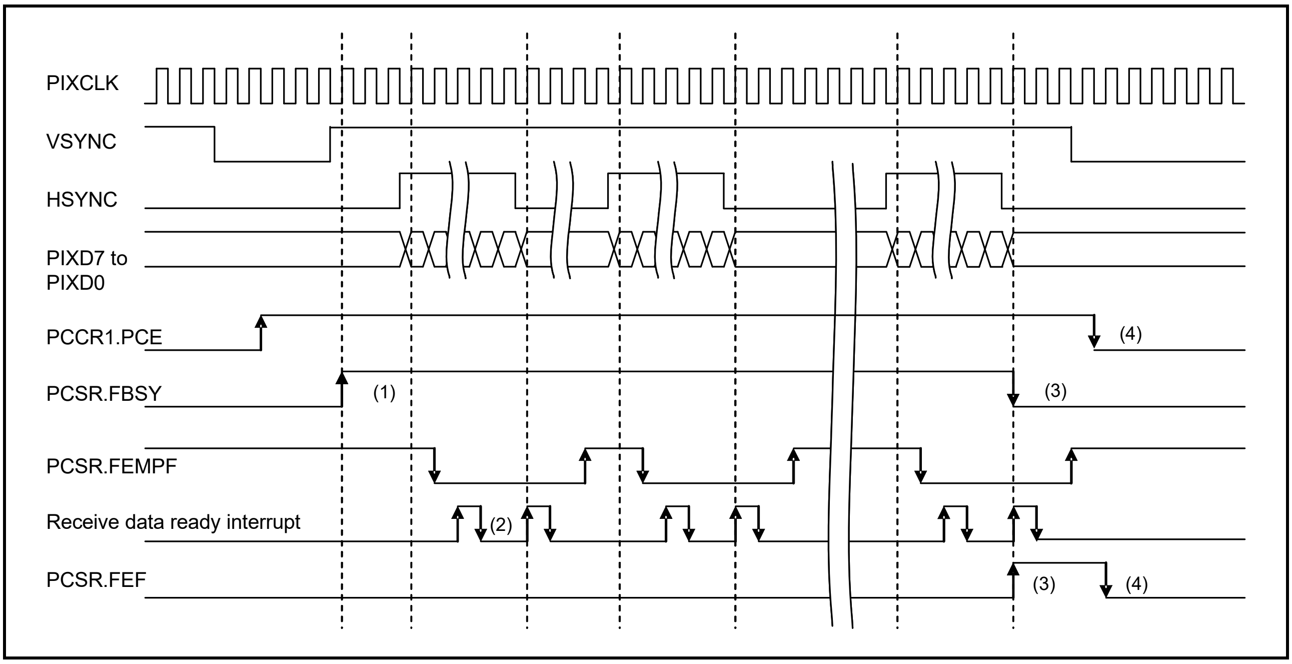

Figure 44.11 Example of reception operations

This section describes the actual operations at the times indicated by (1), (2), (3), and (4) in Figure 44.11.

When a valid edge of the VSYNC signal is detected after the PCE bit in the PCCR1 register is set to 1, the FEMPF flag in the PCSR register sets to 1 and the FIFO is initialized. Concurrently, the FBSY flag in the PCSR register sets to 1 and reception operations start.

When data within the capture range set in the VCR and HCR registers is received, the data is stored in the FIFO. The PDC generates a receive data ready interrupt every time it receives 32 bytes of data, and the interrupt starts transfer of the captured data by the DTC or DMAC to the on-chip SRAM or an external address space. The FIFO is likely to overrun if reading the PCDR register takes more time than reception of the data. Check the OVRF flag in the PCSR register to verify an overrun.

After reception of the last byte of data is complete, the FBSY flag in the PCSR register clears to 0 and the FEF flag in the PCSR register sets to 1 so that a receive data ready interrupt and frame end interrupt are generated.

The FEMPF flag in the PCSR register is polled by the frame end interrupt, after which the program must verify the completion of data transfer by the DTC or DMAC. After the PCE bit in the PCCR1 register is cleared to 0, the FEF flag in the PCSR register also clears to 0, and the reception of one frame of data is complete.

If the FEF flag in the PCSR register sets to 1 before the PCE bit in the PCCR1 register is set to 1, valid edges of the VSYNC signal are not detected and reception operations are not started. Clear the FEF flag in the PCSR register to 0 to start data reception operations.

44.3.5 Operation during Horizontal Blanking Period

If the horizontal blanking period begins but the number of received data bytes has not reached 32 bytes since the previous receive data ready, the count of the received data bytes is retained and carried over to the next valid period. Figure 44.12 shows an example of operation during the horizontal blanking period.

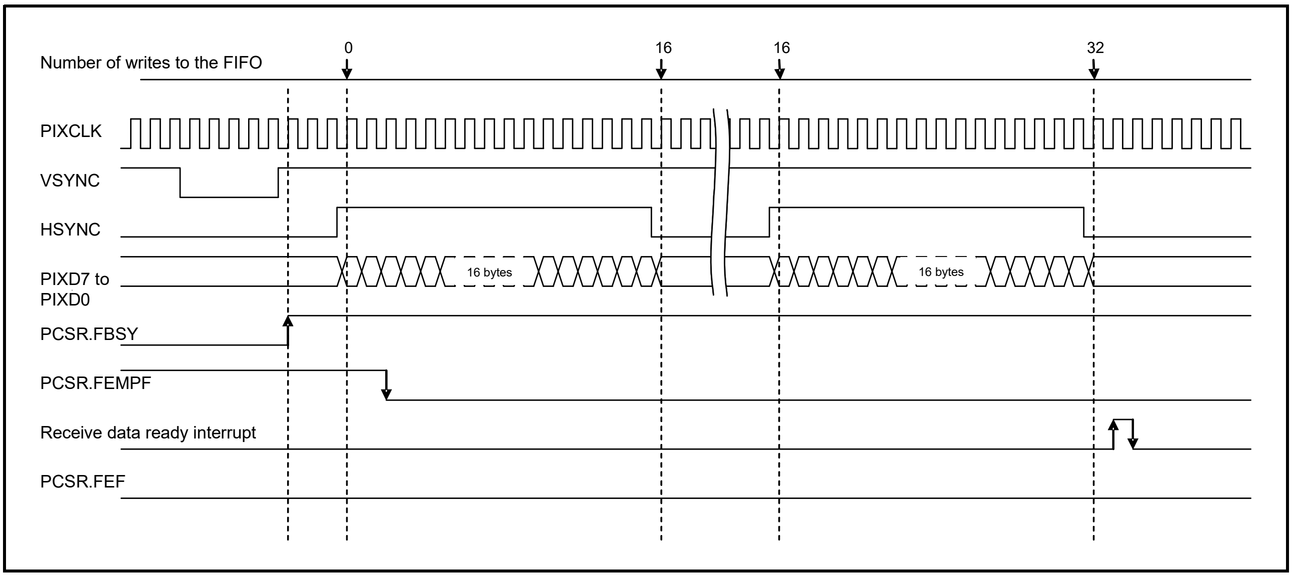

Figure 44.12 Example operation during horizontal blanking period

44.3.6 Continued Reception Operations at Frame End

When the last of the data is received but fewer than 32 bytes of data have been received since the previous receive data ready, the PDC continues to receive data until the number reaches 32, an operation called *continued reception*. When continued reception ends, the PDC generates a receive data ready interrupt and a frame end interrupt. Always input PIXCLK during continued reception. If the data stored in the FIFO is read during this operation, the values are undefined. Figure 44.13 shows an example operation at frame end.

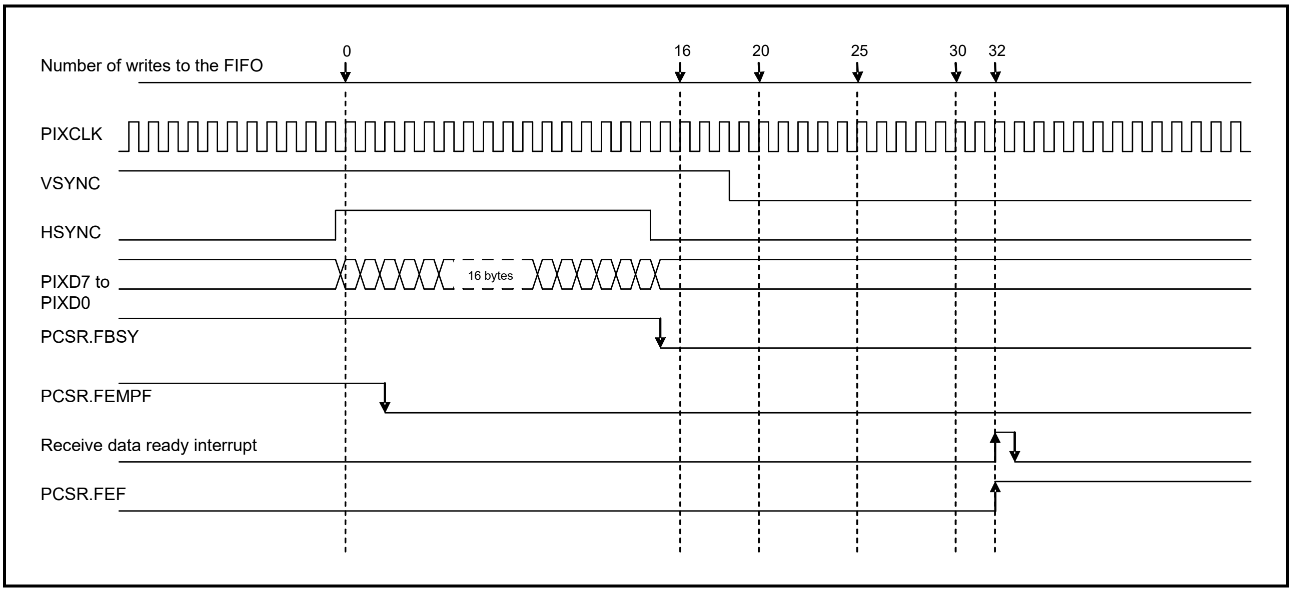

Figure 44.13 Example of continued reception operations at frame end

44.3.7 Error Detection

The PDC provides error detection capabilities, enabling the software to respond to errors during reception operations. Table 44.4 summarizes the conditions for each type of error and the interrupt flags set in response.

Table 44.4 Error detection

Error factor	Conditions for error detection	Interrupt flag	Operation example
Overrun	Receive data arrives while the FIFO is full.*1	PCSR.OVRF	Figure 44.14
Underrun	PCDR register is read while the FIFO is empty.	PCSR.UDRF	Figure 44.15
Vertical line number error	VSYNC signal is negated when the number of captured lines is less than the value set in the VCR register.	PCSR.VERF	Figure 44.16
Horizontal byte number error	HSYNC signal is negated when the number of bytes captured in a line is less than the value set in the HCR register.	PCSR.HERF	Figure 44.17

Note 1. This includes data reception during continued reception operations.

When an error is detected, the PDC sets the associated interrupt flag to 1 to stop reception operations. While the interrupt flag is 1, the PDC does not detect valid edges of the VSYNC signal and does not start reception operations. Clear all error source interrupt flags to 0 to start reception operations.

When an error occurs, data stored in the FIFO is disabled.

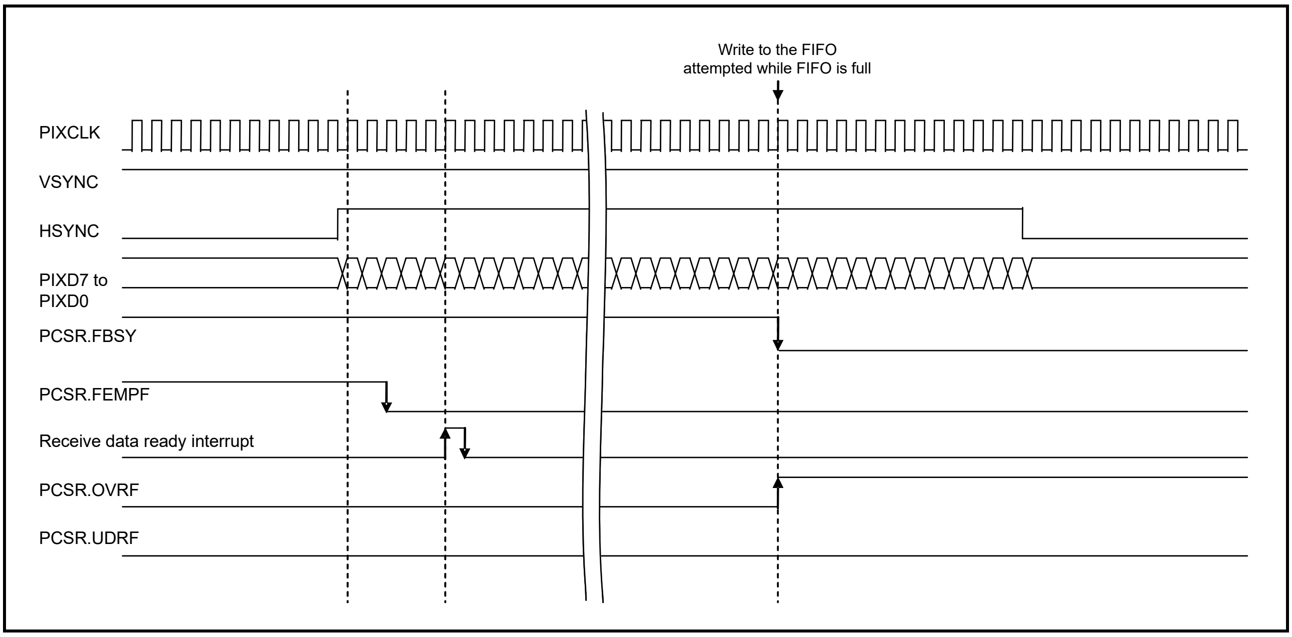

Figure 44.14 Operation when an overrun is detected

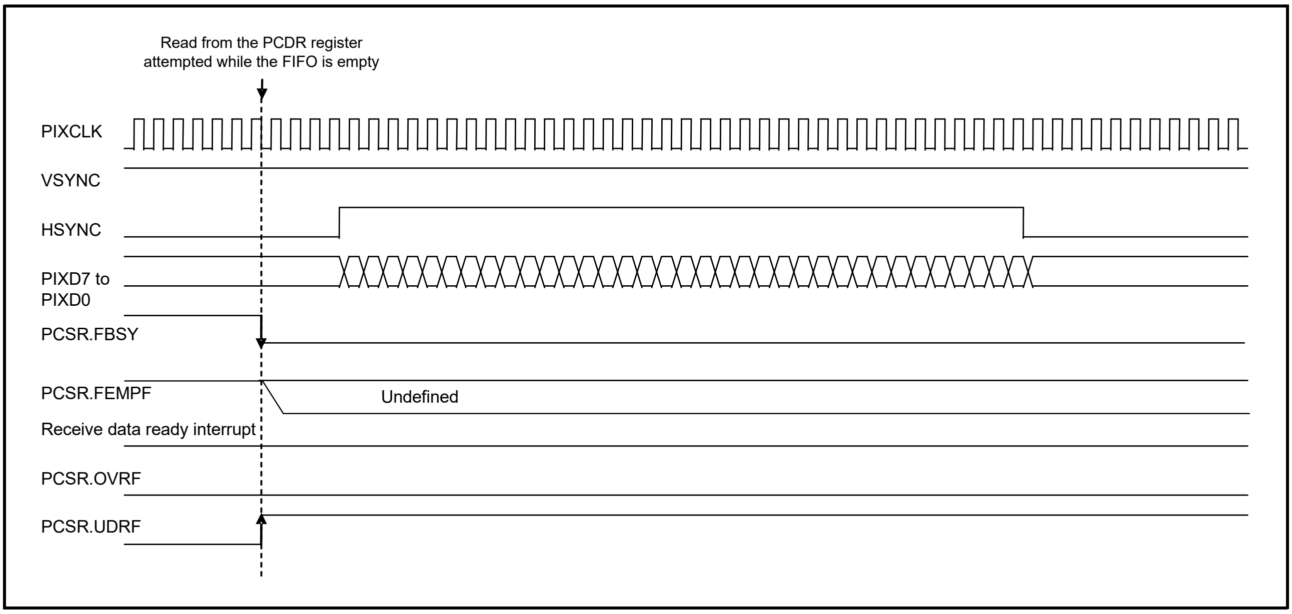

Figure 44.15 Operation when an underrun is detected

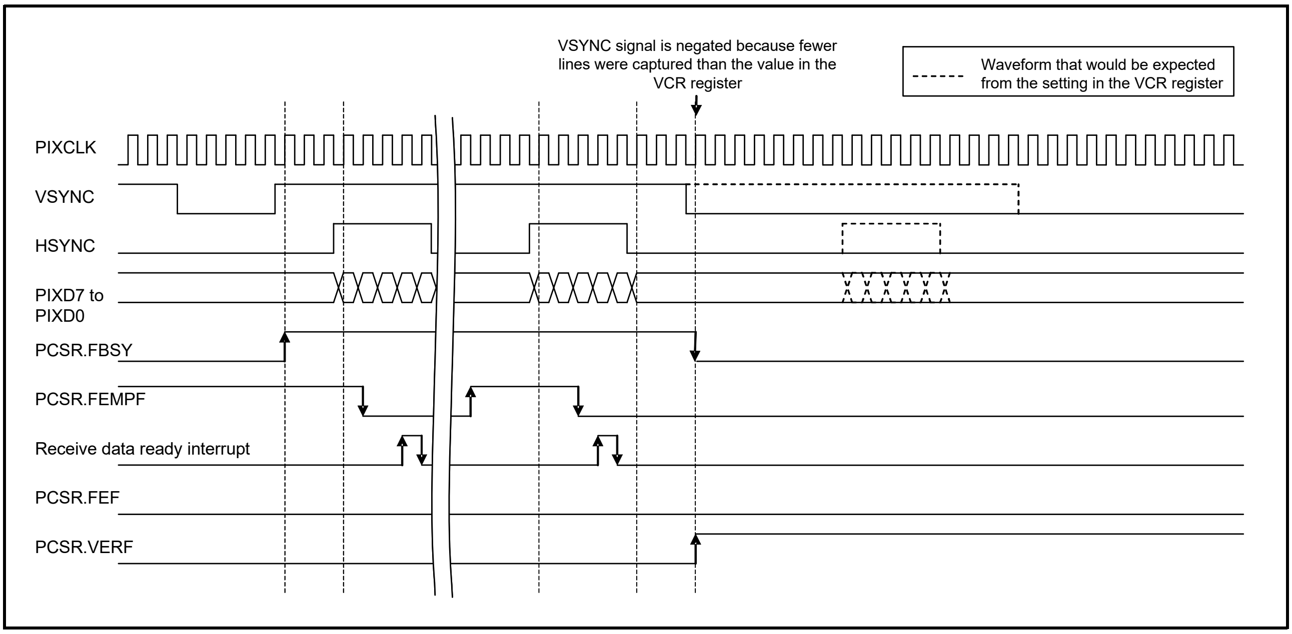

Figure 44.16 Operation when a vertical line number setting error is detected

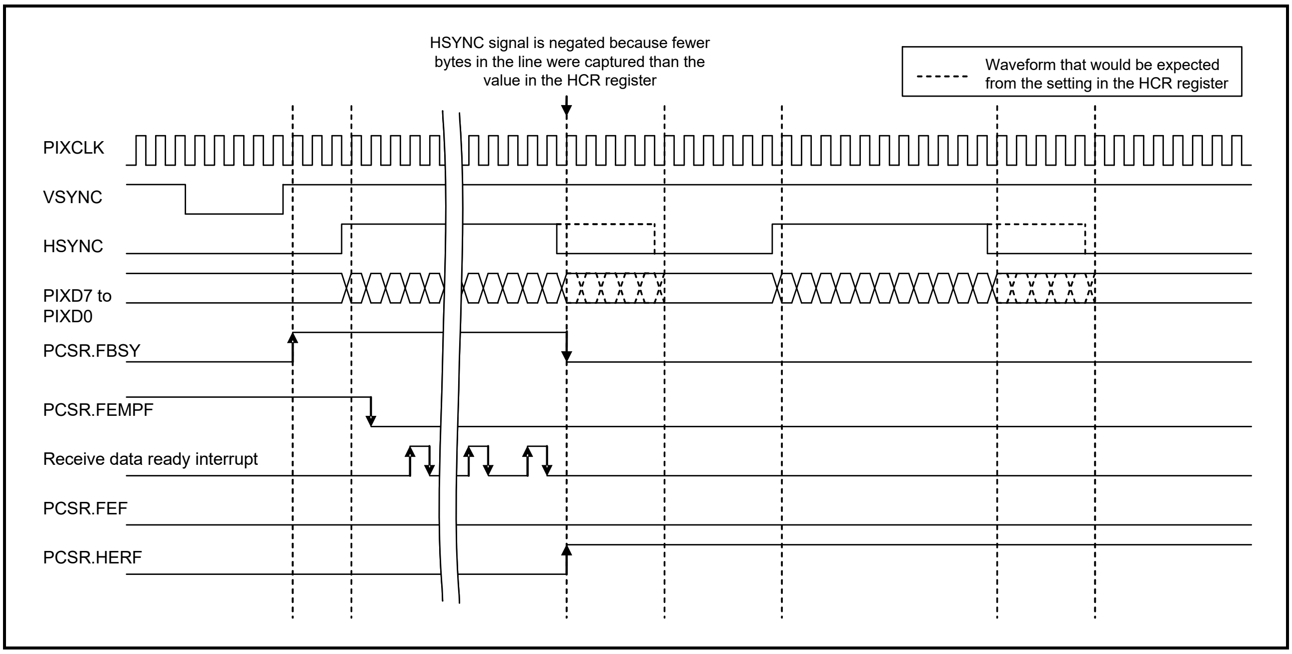

Figure 44.17 Operation when a horizontal byte number setting error is detected

44.3.8 Initial Settings

Figure 44.18 shows an example flow for initial settings. For a description of how to set up the input and output ports and the Interrupt Controller Unit (ICU), see the descriptions given in the sections on the relevant blocks.

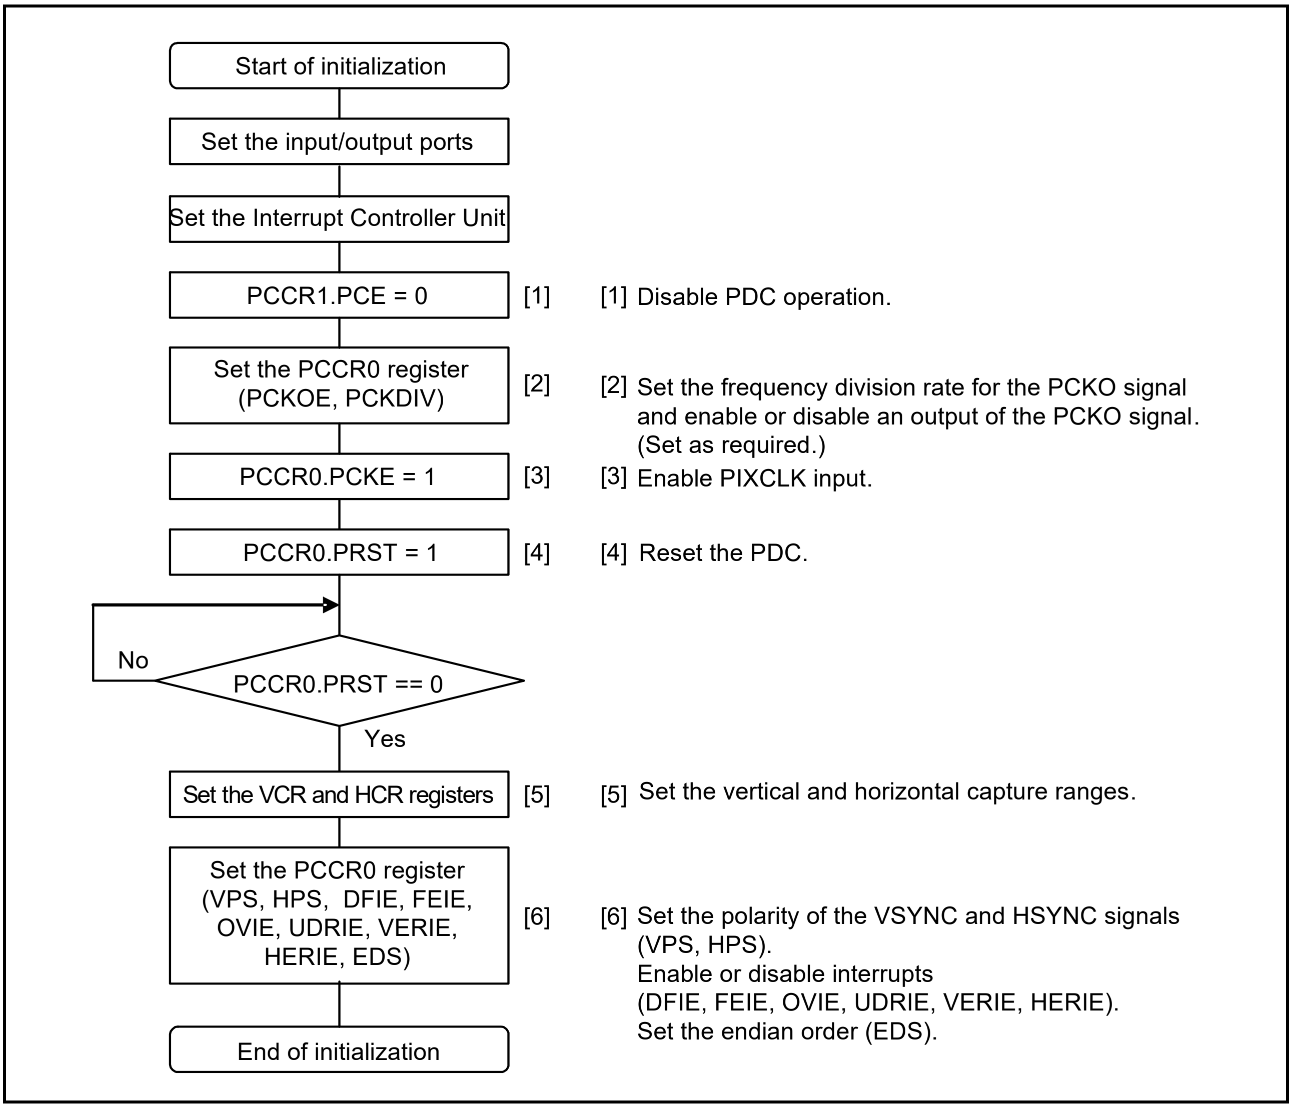

Figure 44.18 Example flow for initial PDC settings

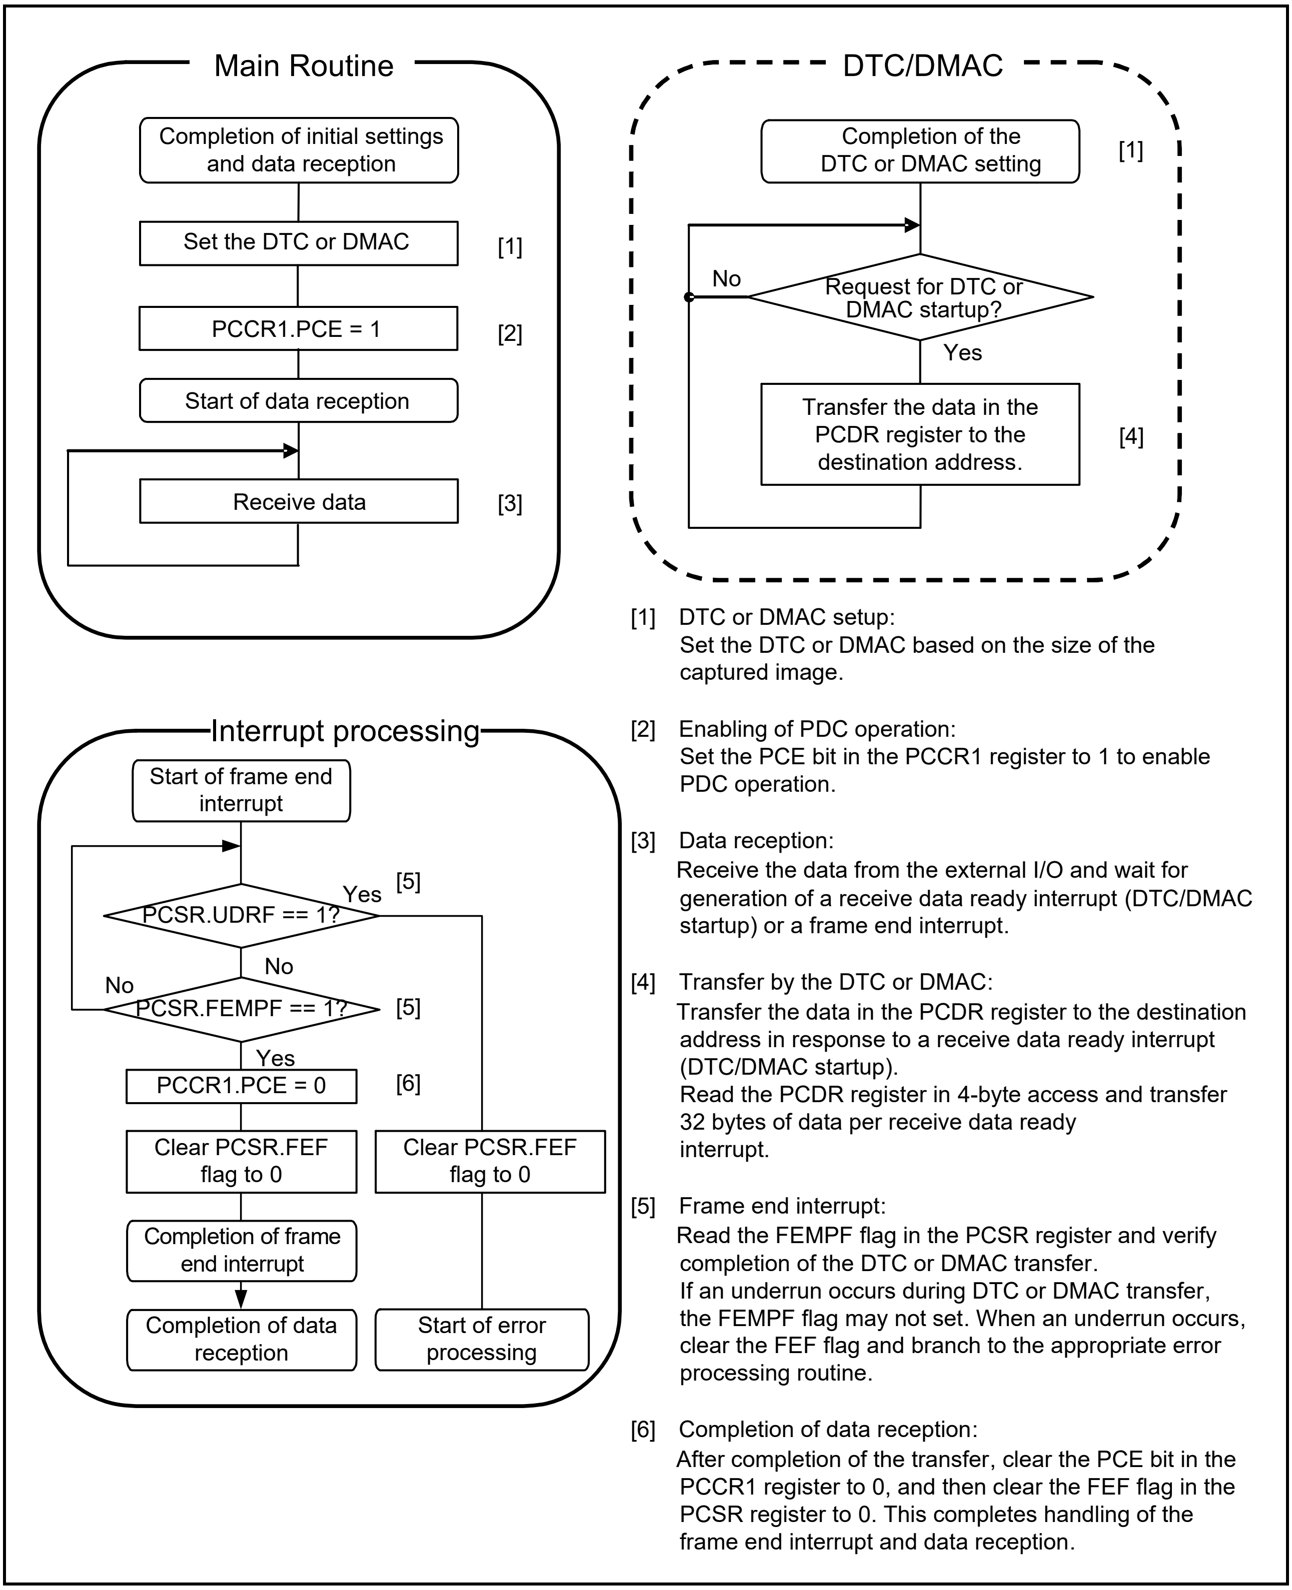
44.3.9 Operation Flows

Figure 44.19 shows an example operation flow when the receive data ready interrupt (to start the DTC or DMAC) and frame end interrupt are in use. For a description of how to set up the DTC or DMAC, see section 17, DMA Controller (DMAC), and section 18, Data Transfer Controller (DTC).



[1] DTC or DMAC setup:
Set the DTC or DMAC based on the size of the captured image.

[2] Enabling of PDC operation:
Set the PCE bit in the PCCR1 register to 1 to enable PDC operation.

[3] Data reception:
Receive the data from the external I/O and wait for generation of a receive data ready interrupt (DTC/DMAC startup) or a frame end interrupt.

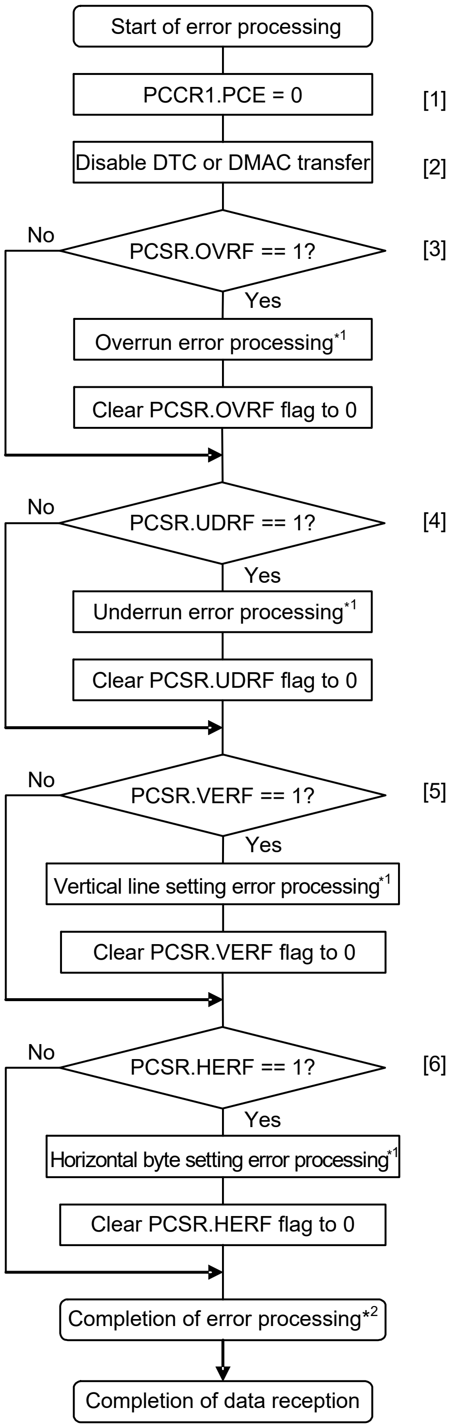
[4] Transfer by the DTC or DMAC:
Transfer the data in the PCDR register to the destination address in response to a receive data ready interrupt (DTC/DMAC startup).
Read the PCDR register in 4-byte access and transfer 32 bytes of data per receive data ready interrupt.

[5] Frame end interrupt:
Read the FEMPF flag in the PCSR register and verify completion of the DTC or DMAC transfer.
If an underrun occurs during DTC or DMAC transfer, the FEMPF flag may not set. When an underrun occurs, clear the FEF flag and branch to the appropriate error processing routine.

[6] Completion of data reception:
After completion of the transfer, clear the PCE bit in the PCCR1 register to 0, and then clear the FEF flag in the PCSR register to 0. This completes handling of the frame end interrupt and data reception.

Figure 44.19 Example operation flow

Figure 44.20 shows an example of the operation flow when responding to an error interrupt.



[1] Disabling of PDC operation:
Clear the PCE bit in the PCCR1 register to 0 to disable PDC operation.

[2] Disabling of the DTC or DMAC transfer:
Disable the transfer of the DTC or DMAC.

[3] Overrun flag check:
Read the PCSR register to check the state of the OVRF flag. If the flag is set, overrun error handling proceeds, and the flag is then cleared.

[4] Underrun flag check:
Read the PCSR register to check the state of The UDRF flag. If the flag is set, underrun error handling proceeds, and the flag is then cleared.

[5] Check of the vertical line setting error flag:
Read the PCSR register to check the state of the VERF flag. If the flag is set, vertical line setting error handling proceeds, and the flag is then cleared.

[6] Check of the horizontal byte setting error flag:
Read the PCSR register to check the status of the HERF flag. If the flag is set, horizontal byte setting error handling proceeds, and the flag is then cleared.

Note 1. Processing for each type of error is defined by the user, so the user needs to prepare error processing for each.

Note 2. If the CPU, DTC, or DMAC reads the PCDR register after an error interrupt occurrs in response to an interrupt source other than an underrun, an underrun may occur.
If an underrun occurs on completion of error processing, run the error processing again and clear the UDRF flag.
Since underruns still require detection after error processing, do not disable the underrun interrupt before the error processing.

Figure 44.20 Example error processing flow

44.3.10 Interrupt Sources

The PDC interrupt sources include:

- Receive data ready
- Frame end
- Overrun

- Underrun
- Vertical line number setting error
- Horizontal byte number setting error.

The PDC can start the DTC or DMAC in response to a receive data ready interrupt request for the transfer of data.

Table 44.5 summarizes the PDC interrupt sources. When an interrupt condition listed in Table 44.5 is satisfied, the associated interrupt is generated. For receive data ready interrupts, the program can clear the interrupt source flag by reading the PCDR register. For the frame end interrupts, clear the FEF flag in the PCSR register. For an overrun, underrun, vertical line number setting error, or a horizontal byte number setting error, the program must check the flags to identify the error source flag, because their interrupt vectors are allocated to the same address by PDC_PCERI. After identifying the source, the program must clear the associated error interrupt source flag (OVRF, UDRF, VERF, or HERF) in the PCSR register.

When the DTC or DMAC module is to handle data transfer, first select the module. After enabling the module for transfers, set up the PDC. For information on setting up the DTC and DMAC, see section 17, DMA Controller (DMAC), and section 18, Data Transfer Controller (DTC).

On completion of output, the request flag clears automatically. An interrupt request signal retained internally can also be cleared by setting the associated interrupt enable bit (the DFIE bit in the PCCR0 register) to 0.

Table 44.5 PDC interrupt sources

Interrupt source	Abbreviation	Interrupt conditions	DTC/DMAC activation
Receive Data Ready	PDC_PCDFI	Receive data ready occurs while the DFIE bit in the PCCR0 register is 1.	Possible
Frame End	PDC_PCFEI	Frame end occurs while the FEIE bit in the PCCR0 register is 1.	Impossible
Errors	PDC_PCERI	• An overrun occurs while the OVIE bit in the PCCR0 register is 1 • An underrun occurs while the UDRIE bit in the PCCR0 register is 1 • A vertical line number setting error occurs while the VERIE bit in the PCCR0 register is 1 • A horizontal byte number setting error occurs while the HERIE bit in the PCCR0 register is 1.	Impossible

44.3.11 Reset State

The PDC has two types of resets: a PDC reset (writing 1 to PCCR0.PRST bit) and other resets.

Other resets include:

- RES pin reset
- Power-on reset
- Voltage monitor reset 0
- Voltage monitor reset 1
- Voltage monitor reset 2
- Deep Software Standby reset
- Independent watchdog timer reset
- Watchdog timer reset
- Software reset
- SRAM parity error reset
- SRAM ECC error reset
- Illegal instruction reset
- Oscillation stop detection reset
- Bus master MPU error reset

- Bus slave MPU error reset
- Stack pointer error reset
- Watchdog timer reset in reset sequence.

Table 44.6 shows the register states following the two types of resets.

Table 44.6 Register states on reset

PDC register	PDC reset	Other resets
PCCR0	Retained	Reset
PCCR1	Retained	Reset
PCSR	Reset	Reset
PCMONR	Retained	Reset
PCDR	Retained	Reset
VCR	Retained	Reset
HCR	Retained	Reset

44.4 Usage Notes

44.4.1 Settings for the Module-Stop Function

PDC operation can be disabled or enabled using the MSTPC2 bit in Module Stop Control Register C (MSTPCRC). The PDC is initially stopped (MSTPC2 =1) after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

44.4.2 Constraints on the Low-Power Function

When reducing PDC power consumption by using the low-power function, set the PCE bit in the PCCR1 register to 0 to disable reception operations, and set the PCKE bit in the PCCR0 register to 0 to disable input through the PIXCLK pin. Use the low-power function after these settings are complete.

If the PCKOE bit in the PCCR0 register is set to 1, set it to 0 to stop output of the PCKO signal, in addition to disabling input through the PIXCLK pin in PCKE. Use the low-power function after these settings are complete.

44.4.3 Constraints on Error Interrupts

When an error interrupt occurs, the DTC or DMAC might still be transmitting parallel data, depending on their operation state. Because of this, the error interrupt processing routine must prohibit data transmission by the DTC or DMAC immediately after prohibiting PDC operation (PCCR1.PCE = 0).

44.4.4 Constraints on Using the DTC

When the DTC is used with the receive data ready interrupt, set the DISEL bit in the MRB register to 0 and the SZ bit in the MRA register to 10b.

The maximum number of blocks the DTC can transfer in block transfer mode is 65,536. If 32 bytes are transferred per block transfer, this represents a total of up to 2,097,152 bytes. If more data is to be transferred, set up the DTC again during the horizontal blanking period. For details, see section 18, Data Transfer Controller (DTC).

44.4.5 Constraints on Using the DMAC

When the DMAC is used with the receive data ready interrupt, set the SZ bit in the DMTMD register to 10b, and configure the DESL[8:0] bits in the DELSRn register (n = 0 to 7) appropriately.

The maximum number of blocks the DMAC can transfer in block transfer mode is 65,536. If 32 bytes are transferred per block transfer, this represents a total of up to 2,097,152 bytes. If more data is to be transferred, set up the DMAC again during the horizontal blanking period. For details, see section 14, Interrupt Controller Unit (ICU) and section 17, DMA Controller (DMAC).

45. Boundary Scan

45.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std. 1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. Table 45.1 lists the boundary scan specifications, Figure 45.1 shows a block diagram, and Table 45.2 lists the I/O pins.

Table 45.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

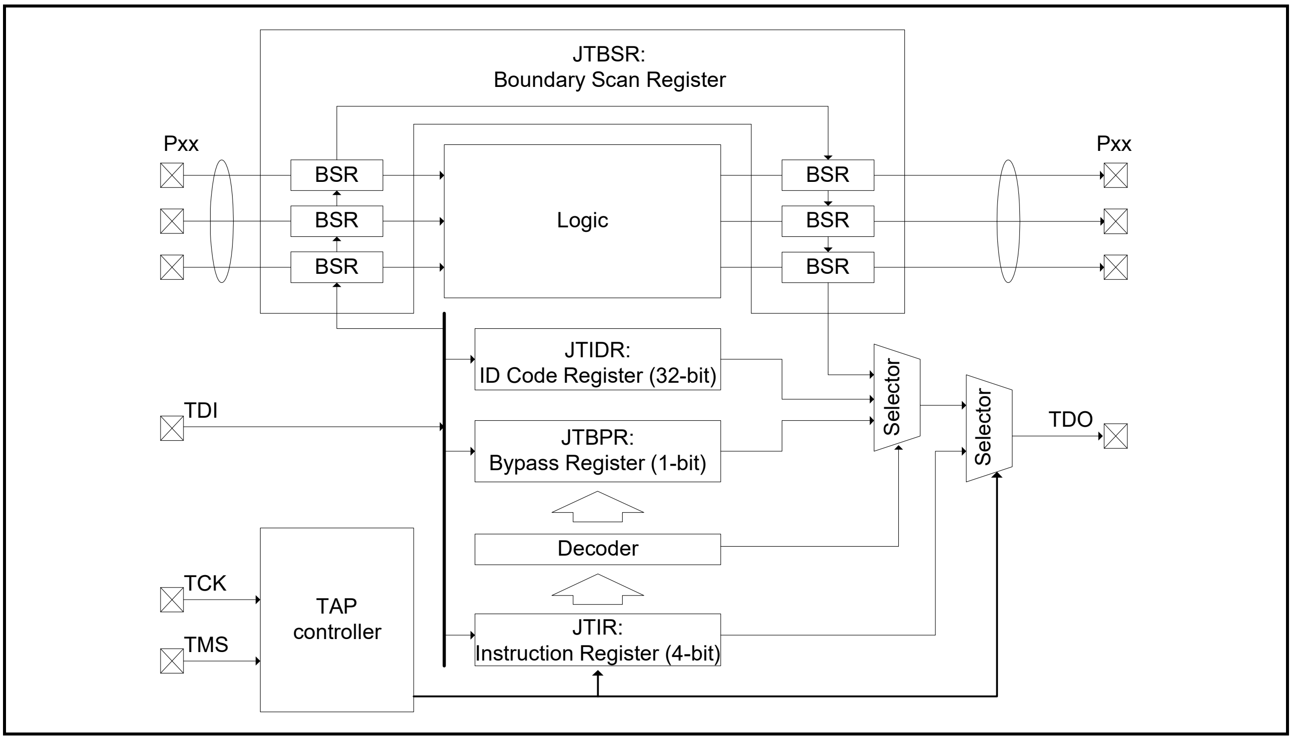


Figure 45.1 Boundary scan function block diagram

Table 45.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: The MCU does not support the TRST pin for the JTAG interface.

45.2 Register Descriptions

Table 45.3 lists the boundary scan registers.

Table 45.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	Eh
ID Code Register	JTIDR	0832 9447h
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

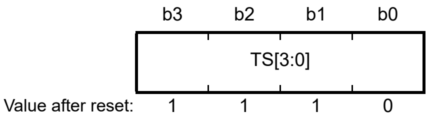
- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 45.4 shows the availability of serial transfer for the registers.

Table 45.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

45.2.1 Instruction Register (JTIR)



Bit	Symbol	Bit name	Description	R/W
b3 to b0	TS[3:0]	Test Bit Set	The command configuration for these bits is shown in Table 45.5.	—

Table 45.5 Command configuration

TS3	TS2	TS1	TS0	Instruction
0	0	0	0	EXTEST
0	0	0	1	SAMPLE/PRELOAD
0	0	1	1	IDCODE (Renesas code)
0	1	0	1	CLAMP
0	1	1	0	HIGHZ
1	1	1	1	BYPASS
Other settings				Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

45.2.2 ID Code Register (JTIDR)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DID[31:0]															
Value after reset:	0	0	0	0	1	0	0	0	0	0	1	1	0	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DID[31:0]															
Value after reset:	1	0	0	1	0	1	0	0	0	1	0	0	0	1	1	1

Bit	Symbol	Bit name	Description	R/W
b31 to b0	DID[31:0]	Device ID	These bits store the fixed value that indicates the device IDCODE.	—

JTIDR data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the IDCODE of JTIDR changes into the Arm® debug code. See the *ARM® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

45.2.3 Bypass Register (JTBPR)

JTBPR is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

45.2.4 Boundary Scan Register (JTBSR)

JTBSR is a shift register for controlling the external input and output pins of the MCU, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions. The BSDL file describes the associations between the JTBSR bits and the pins of the MCU. The value after reset is undefined.

45.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI, and TDO, are assigned as default pin functions. The TCK, TMS, and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

45.3.1 TAP Controller

Figure 45.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

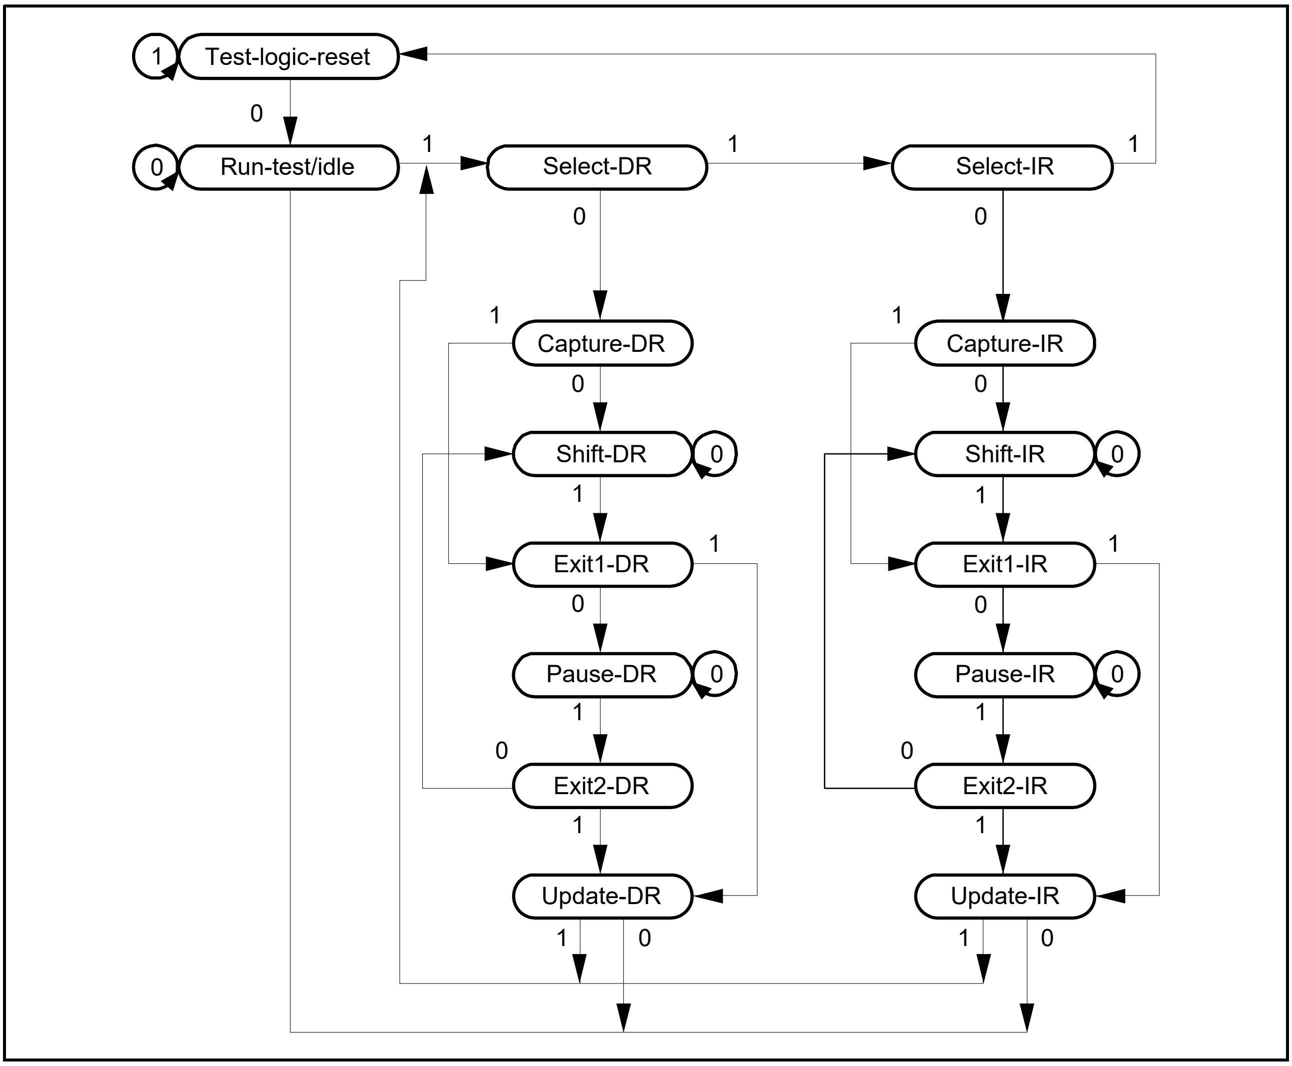


Figure 45.2 State transition diagram of TAP controller

45.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The Bypass Register (JTBPR) is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when the MCU is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the print circuit board, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of the MCU to the Boundary Scan Register (JTBSR), output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to the MCU and output signals are also directly output to the external circuits. The MCU system circuit is not affected by this instruction.

In SAMPLE operation, the Boundary Scan Register (JTBSR) latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the Boundary Scan Register (JTBSR) prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the Boundary Scan Register (JTBSR) value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The Bypass Register (JTBPR) is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of Boundary Scan Register (JTBSR) is maintained regardless of the state of the TAP controller.

The Bypass Register (JTBPR) is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

45.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 45.3.

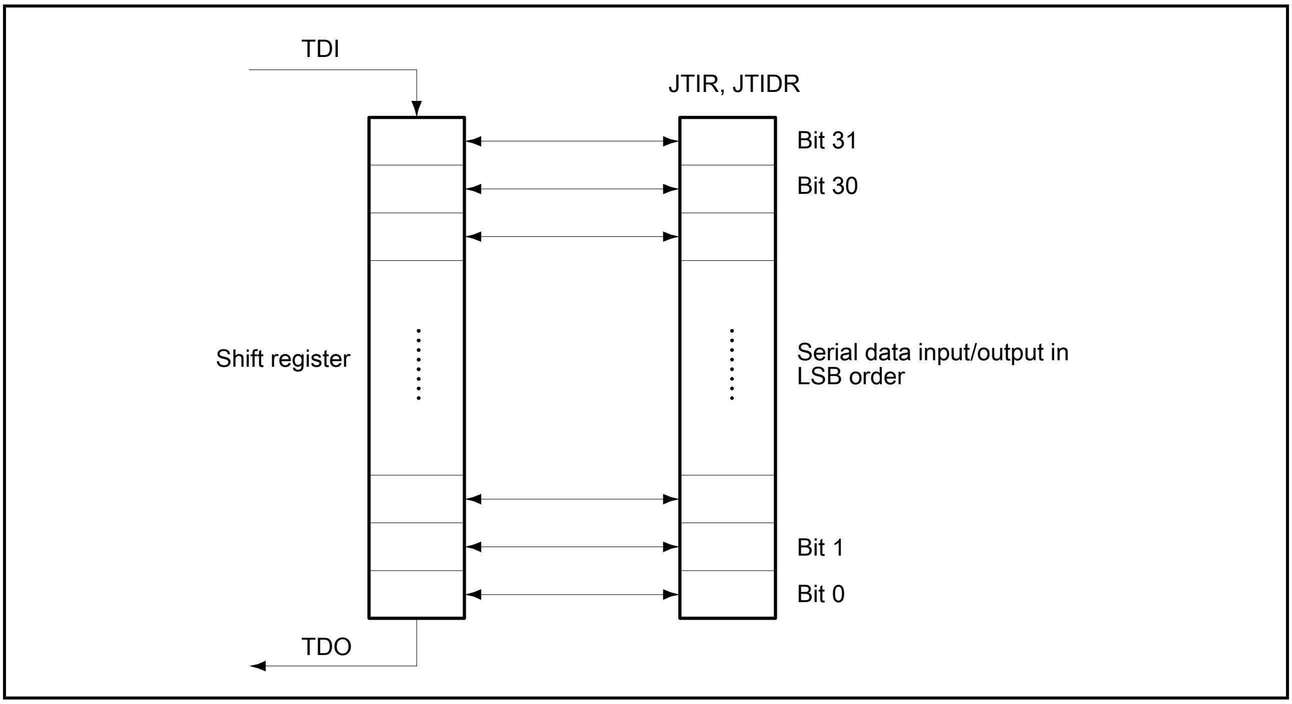

Figure 45.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCL, VCL0, VSS, VBATT, AVCC0, AVSS0, VCC_USB, VSS_USB, AVCC_USBHS, AVSS_USBHS, PVSS_USBHS, VCC_USBHS VSS1_USBHS, and VSS2_USBHS) cannot be boundary-scanned
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL, USBHS_RREF) cannot be boundary-scanned
- Clock pins (EXTAL, XTAL, XCIN, and XCOUT) cannot be boundary-scanned
- Reset signal (RES) cannot be boundary-scanned
- USB-dedicated pins (USB_DP, USB_DM, USBHS_DP, USBHS_DM) cannot be boundary-scanned
- The boundary-scan pins (TCK, TMS, TDI, and TDO) cannot be boundary-scanned.

46. Secure Cryptographic Engine (SCE7)

The MCU incorporates a Secure Cryptographic Engine (SCE7) module to provide security functions. The module consists of an access management circuit, encryption engine, and random number generator. In combination with the Renesas Synergy Software Package (SSP) Crypto library, the SCE7 can prevent eavesdropping (confidentiality), falsification of information (integrity), and impersonation (authenticity).

The SCE7 module can only be used with the SSP Crypto library. For details, see the Crypto Framework and the SCE Crypto Driver sections in the *Renesas Synergy™ Software Package (SSP) User's Manual*.

46.1 Overview

Table 46.1 shows the SCE7 specifications and Figure 46.1 shows the SCE7 block diagram.

Table 46.1 SCE7 specifications (1 of 2)

Parameter	Description
Access control	Access management circuit • In case of irregular access to the SCE7 due to a falsified program or runaway execution of a program, this circuit blocks all subsequent access and stops the output of data from the SCE7.
Encryption engine	Advanced Encryption Standard (AES): Compliant with NIST FIPS PUB 197 algorithm • Key sizes: 128, 192, or 256 bits • Block size: 128 bits • Chaining modes - ECB, CBC, CTR: Compliant with NIST SP 800-38A - GCM: Compliant with NIST SP 800-38D - XTS: Compliant with NIST SP 800-38E - GCTR. • Throughput for 128-bit data - 11 PCLKB cycles for 128-bit key - 15 PCLKB cycles for 256-bit key*1. AES-GCM • AES-GCM is realized by combining AES-GCTR and GHASH. Triple Data Encryption Standard (3DES): • 192-bit key length • Operates on a fixed 8-byte block of data • Used in legacy Secure Socket Layer (SSL) and Transport Layer Security (TLS) protocols • Throughput for 64-bit data - 16 PCLKB cycles for 56-bit key. Alleged RC4 (ARC4) • 2048-bit key length • Throughput for 128-bit data - 16 PCLKB cycles for 2048-bit key. Key management • Wrapped keys are only valid within the SCE7.
Generation of random numbers	128-bit true random number generator

Table 46.1 SCE7 specifications (2 of 2)

Parameter	Description

Signature generation and verification	RSA
	• Support for 1024-bit and 2048-bit key sizes
	• Signature generation, signature verification, public-key encryption, private-key decryption.
	
	DSA
	• Support for DSA key sizes:
	  • (1024-bit, 160-bit)
	  • (2048-bit, 224-bit)
	  • (2048-bit, 256-bit).
	• Signature generation, signature verification.
	
	ECC
	• Support for curve P-192, P-224, P-256, and P-384
	• Signature generation, signature verification
	• Scalar multiplication.

Message digest computation	HASH • SHA1, SHA224, SHA256, and MD5.
Unique ID	• A unique ID to the MCU, is accessible from the access management circuit through the dedicated bus • Combining the unique ID with the key generation information prevents the illicit copying of data to another MCU.
Privileged mode	• The privileged mode signal is connected to the access management circuit and is used to limit control of the SCE7 module to privileged mode only.
Low power consumption	Setting of the module stop state is possible.

Note 1. This does not include the overhead for calling functions of the SSP Crypto library.

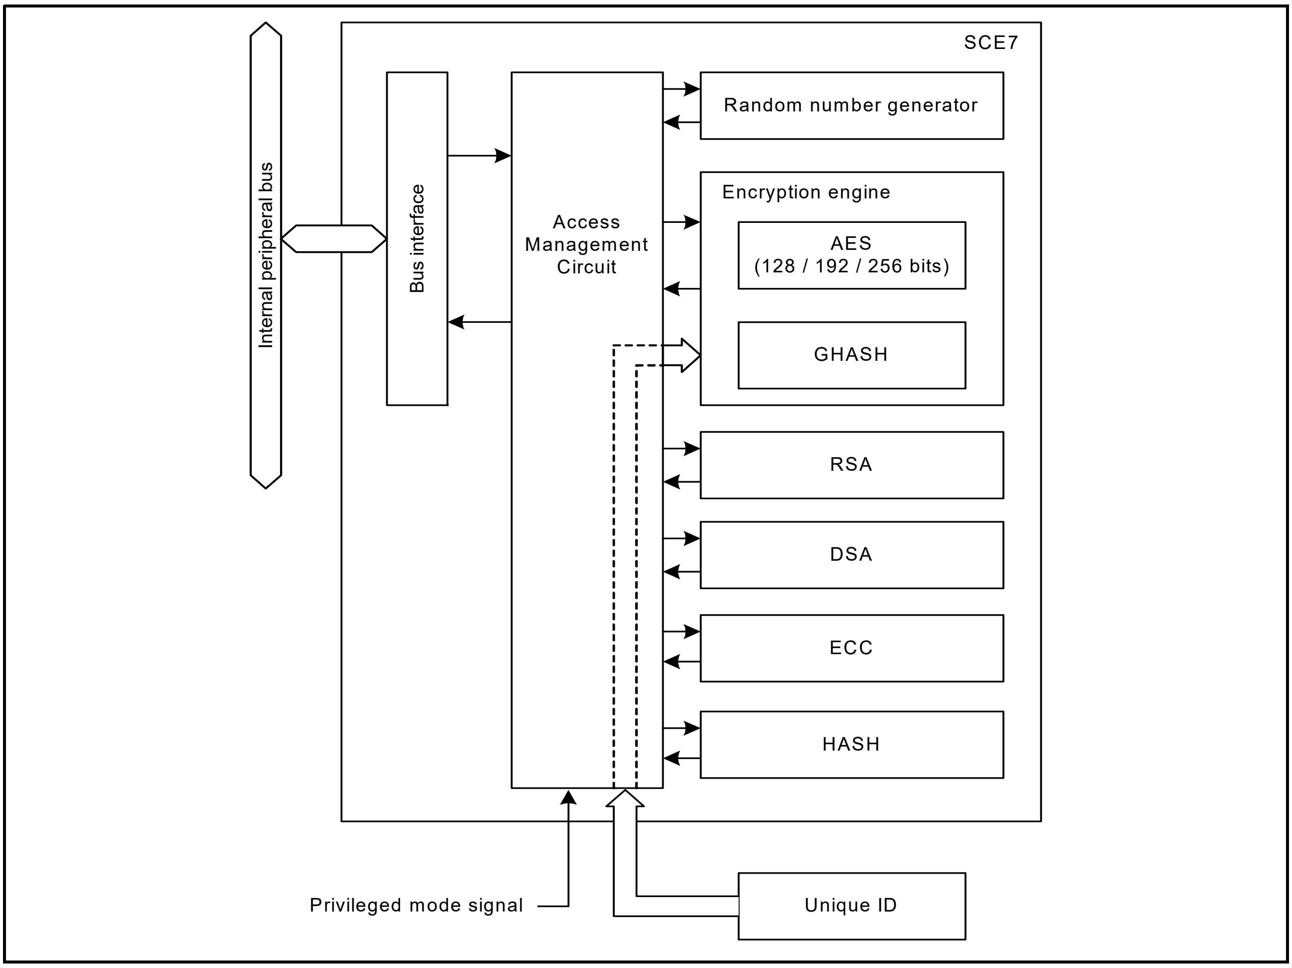

Figure 46.1 SCE7 block diagram

46.2 Operation

46.2.1 Encryption Engine

The encryption engine performs the following operation in hardware, see Figure 46.2:

- Plaintext to ciphertext encryption
- Ciphertext to plaintext decryption.

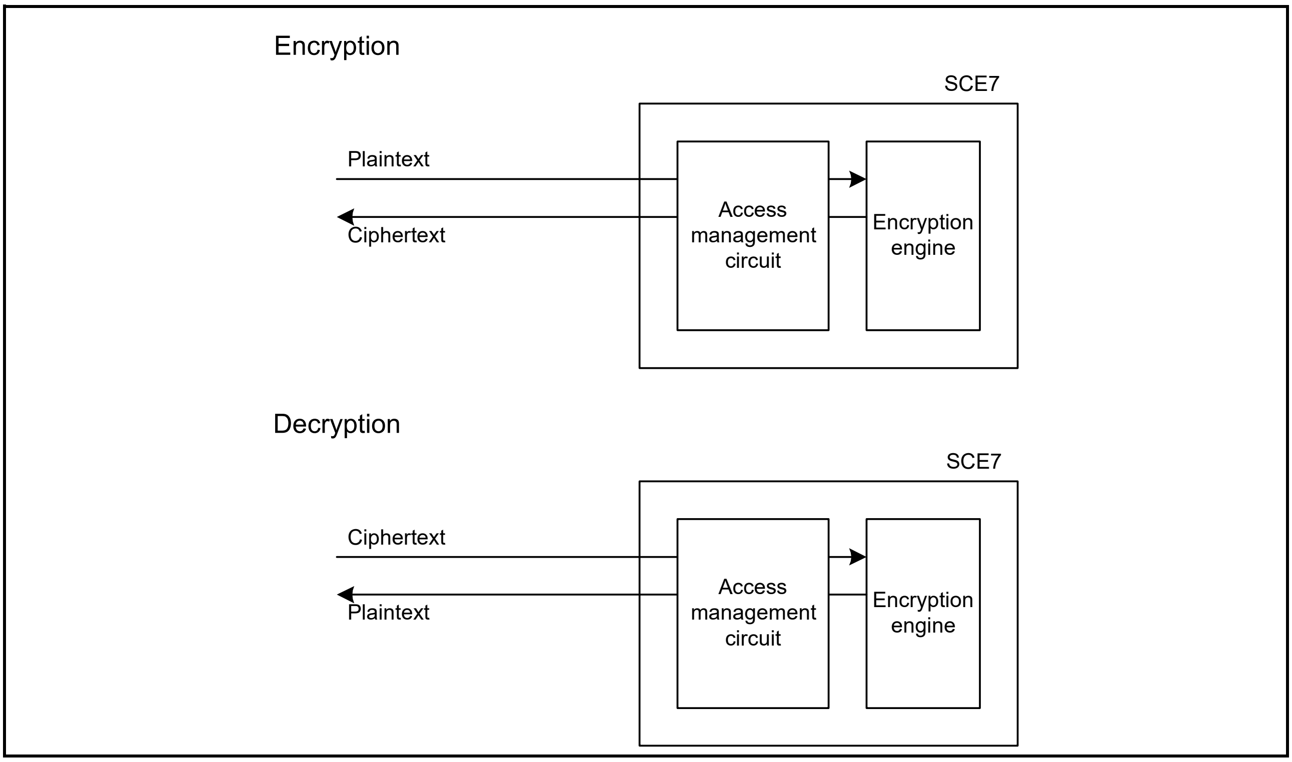

Figure 46.2 Encryption and decryption processes by encryption engine

46.2.2 Encryption and Decryption

To encrypt or decrypt data:

1. Input the data to encrypt or decrypt in the SCE7. The SCE7 converts the plaintext data to ciphertext or ciphertext data to plaintext.
2. Read the converted data.

The encryption engine has an input buffer and an output buffer, enabling encryption/decryption to proceed in parallel with data input/output. Figure 46.3 shows the encryption engine timing.

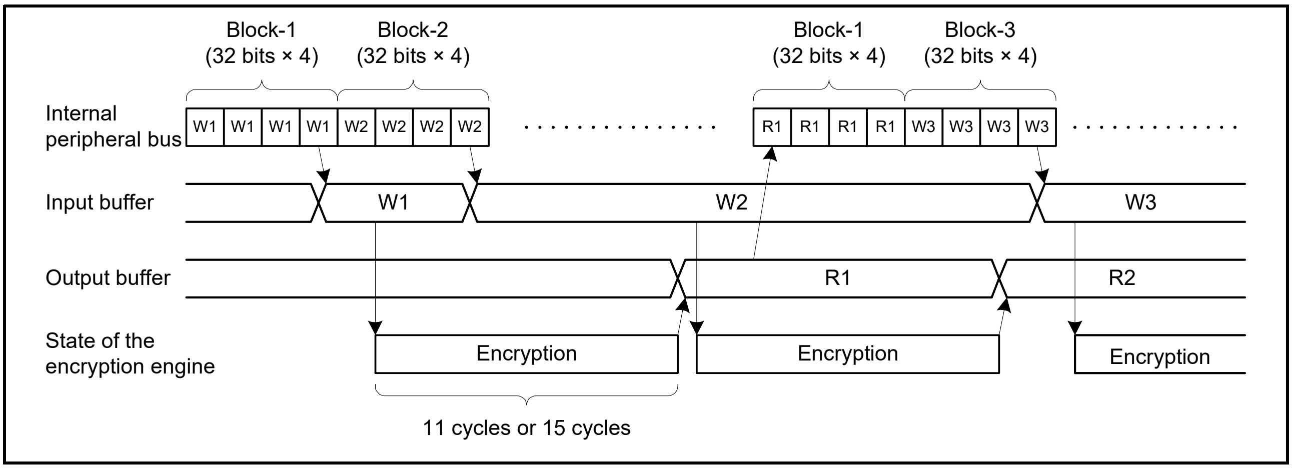

Figure 46.3 Encryption and decryption timing (AES)

46.3 Usage Notes

46.3.1 Software Standby Mode

When Software Standby mode is entered while the encryption engine is in processing, proper processing cannot be resumed after exiting Software Standby mode. Software Standby mode should therefore be entered while the encryption engine is not running.

46.3.2 Settings for the Module-Stop Function

The Module Stop Control Register C (MSTPCRC) can enable or disable SCE7 operation. The SCE7 module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

47. 12-Bit A/D Converter (ADC12)

47.1 Overview

The MCU provides two 12-bit successive approximation A/D converter (ADC12) units. In unit 0, up to 13 analog input channels are selectable. In unit 1, up to 11 analog input channels, temperature sensor output, and internal reference voltage are selectable for conversion. The A/D conversion accuracy is selectable from 12-, 10-, and 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

ADC12 features include:

- 13 channels (unit 0), 11 channels (unit 1)
- PCLKB = 60 MHz (maximum)
- PCLKC = 60 MHz (maximum)
- Analog channels: AN000 to AN007, AN016 to AN020 (unit 0), AN100 to AN103, AN105 to AN107, AN116 to AN119 (unit 1)
- Resolution: 12-bit, 10-bit, 8-bit
- Dedicated sample-and-hold circuit embedded
- Programmable Gain Amplifier embedded.

The ADC12 supports the following operating modes:

- Single scan mode for converting the analog inputs of arbitrarily selected channels in ascending order of channel number
- Continuous scan mode for sequentially converting analog inputs of arbitrarily selected channels continuously in ascending order of channel number
- Group scan mode for arbitrarily dividing analog inputs of channels into two groups (A and B) and converting the analog input of the selected channel for each group in ascending order of channel number.

In group scan mode, you can start Group A and Group B A/D conversion at different times by individually selecting their scan start conditions. In addition, when a priority control operation for Group A is set, the ADC12 accepts Group A scan starting during Group B A/D conversion, suspending Group B conversion. This allows you to assign higher priority to A/D conversion start for Group A.

In double-trigger mode, the analog input of an arbitrarily selected channel is converted in single scan mode or group scan mode (Group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D-converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three voltage values generated in the ADC12 is A/D-converted.

The temperature sensor output and the internal reference voltage are selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output, and then the internal reference voltage.

The ADC12 provides a compare function (Window A and Window B). This compare function specifies the upper reference value for Window A and lower reference value for Window B, and outputs an interrupt request when the A/D-converted value of the selected channel meets the comparison conditions.

Table 47.1 lists the ADC12 specifications and Table 47.2 list the functions. Figure 47.1 shows a block diagram of ADC12 unit 0 and Figure 47.2 shows a block diagram of ADC12 unit 1. Table 47.3 lists the I/O pins.

Table 47.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	Two units, 0 and 1
Input channels	• Unit 0: Up to 13 channels • Unit 1: Up to 11 channels

Table 47.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Extended analog function	Temperature sensor output, internal reference voltage
A/D conversion method	Successive approximation method
Resolution	12 bits, selectable to 12-bit, 10-bit, or 8-bit conversion
Conversion time	0.4 µs/channel, when A/D conversion clock PCLKC (ADCLK) is operating at 60 MHz (See Table 60.40 and Table 60.41 about the condition)
A/D conversion clock	Peripheral module clock PCLKB*1 and A/D conversion clock PCLKC (ADCLK)*1 can be set with the following division ratios: PCLKB to PCLKC (ADCLK) frequency ratios = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4
Data registers	• 24 registers for analog input (13 for unit 0, 11 for unit 1), one for A/D-converted data duplication in double-trigger mode in each unit, and 2 for A/D-converted data duplication in extended operation in double-trigger mode in each unit • One register for temperature sensor output • One register for internal reference voltage • One register for self-diagnosis • Storing of A/D conversion results in A/D data registers • 8-, 10-, and 12-bit accuracy output for A/D conversion results • A/D-converted value addition mode, in which the sum of all A/D conversion results are stored in the in the A/D data registers as the conversion accuracy bit count + 2 bits.*4 • Double-trigger mode (selectable in single scan and group scan modes): The first unit of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplexing register. • Extended operation in double-trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplexing register provided for the associated trigger
Operating modes	• Single scan mode: - A/D conversion is performed only once on the analog inputs of arbitrarily selected channels, on the temperature sensor output, and on the internal reference voltage. • Continuous scan mode: - A/D conversion is performed repeatedly on the analog inputs of arbitrarily selected channels, on the temperature sensor output, and on the internal reference voltage. • Group scan mode: - Analog inputs of arbitrarily selected channels, the temperature sensor output, and the internal reference voltage are divided into Group A and Group B, and A/D conversion of the analog input selected on a group basis is performed only once. - The scan start conditions can be independently selected for Group A and Group B, allowing A/D conversion of Group A and Group B to be started independently. • Group scan mode (when Group A is given priority): - If a Group A trigger is input during A/D conversion on Group B, the A/D conversion on Group B stops and A/D conversion is processed on Group A. - Restart (rescan) of Group B conversion after completion of Group A conversion can be set.
Conditions for A/D conversion start	• Software trigger • Synchronous triggers from the Event Link Controller (ELC). • Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	• Dedicated sample-and-hold function with optional constant sampling and 3 channels in units 0 and 1 • Variable sampling state count • Self-diagnosis of ADC12 • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (discharge and precharge functions) • Double-trigger mode (duplication of A/D conversion data) • Switching function for 8-, 10-, and 12-bit conversion*2 • Automatic clear function for A/D data registers • Digital comparison of values in the comparison and data registers, and between values in the data registers
Programmable gain amplifier	• Amplification of analog input signals to enable A/D conversion, with 3 channels in units 0 and 1 • Compatible with single-ended input and differential input

Table 47.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources and ELC events	• ADC12i_ADI: A/D scan end interrupt • ADC12i_GBADI: A/D scan end interrupt for Group B • ADC12i_CMPAI: Window A compare match • ADC12i_CMPBI: Window B compare match • ADC12i_WCMPM: compare match • ADC12i_WCMPUM: compare mismatch
ELC interface	Scan can be started by a trigger from the ELC
Bus interface	Bus clock synchronized with peripheral clock (PCLKB), maximum frequency = 60 MHz
Reference voltage	• Unit 0: VREFH0 is the high potential reference voltage. VREFL0 is the low potential reference voltage. • Unit 1: VREFH is the high potential reference voltage. VREFL is the low potential reference voltage.
Module-stop function	Module-stop state can be set to reduce power consumption*3

i = 0 for unit 0, and i = 1 for unit 1.

Note 1. Peripheral module clock PCLKB is specified in the SCKDIVCR.PCKB[2:0] bits, and A/D conversion clock ADCLK in the SCKDIVCR.PCKC[2:0] bits in units 0 and 1.

Note 2. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see section 47.3.6, Analog Input Sampling and Scan Conversion Time.

Note 3. For details, see section 11, Low Power Modes.

Note 4. The number of extended bits for addition varies with the A/D conversion accuracy and the number of addition times. A 2-bit extension is up to 4 times conversion (3 times addition) when the A/D conversion accuracy is 8, 10, or 12 bits. A 4-bit extension is 16 times conversion (15 times addition) when the A/D conversion accuracy is 12 bits.

Table 47.2 ADC12 functions

Parameter			Unit 0 (ADC120)	Unit 1 (ADC121)
Analog input channel			AN000 to AN007, AN016 to AN020 Internal reference voltage Temperature sensor output	AN100 to AN103, AN105 to AN107, AN116 to AN119 Internal reference voltage Temperature sensor output
Conditions for A/D conversion start	Software	Software trigger	Enabled	Enabled
	External trigger	Trigger input pin	ADTRG0	ADTRG1
	Synchronous trigger (trigger from ELC)	ELC trigger	ELC_AD00, ELC_AD01	ELC_AD10, ELC_AD11
Channel-dedicated sample-and-hold function	Target channel		AN000 to AN002	AN100 to AN102
Programmable gain amplifier	Target channel		AN000 to AN002	AN100 to AN102
	Differential input pin		PGAVSS000	PGAVSS100
Interrupt			ADC120_ADI ADC120_GBADI ADC120_CMPAI ADC120_CMPBI	ADC121_ADI ADC121_GBADI ADC121_CMPAI ADC121_CMPBI
Output to ELC			ADC120_ADI ADC120_WCMPM ADC120_WCMPUM	ADC121_ADI ADC121_WCMPM ADC121_WCMPUM
Module-stop function settings*1, *2			MSTPCRD.MSTPD16 bit	MSTPCRD.MSTPD15 bit

Note 1. For details, see section 11, Low Power Modes.

Note 2. Wait for 1 µs or longer to start A/D conversion after release from the module-stop state.

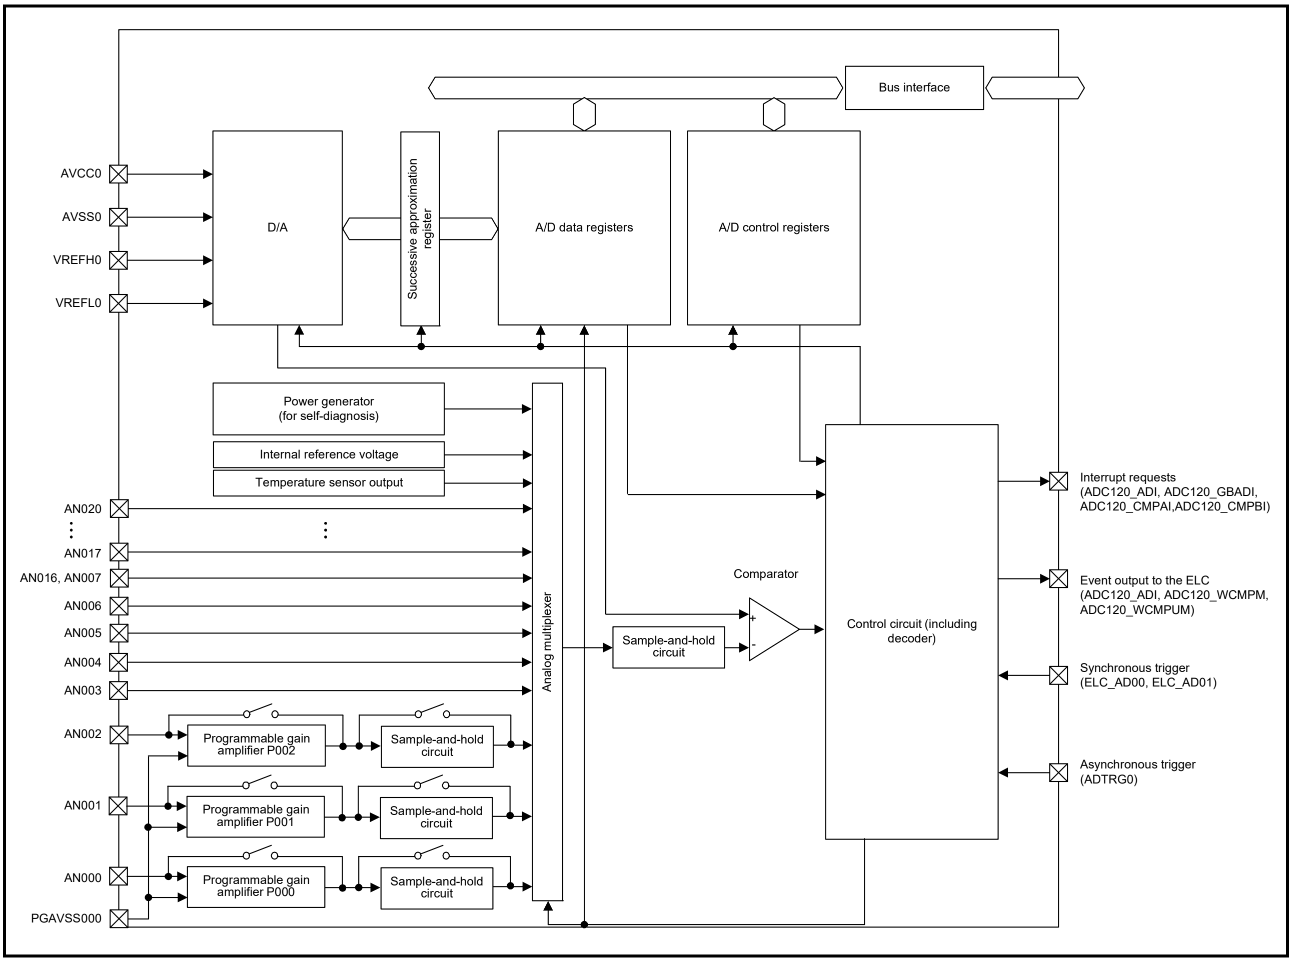

Figure 47.1 ADC12 unit 0 block diagram

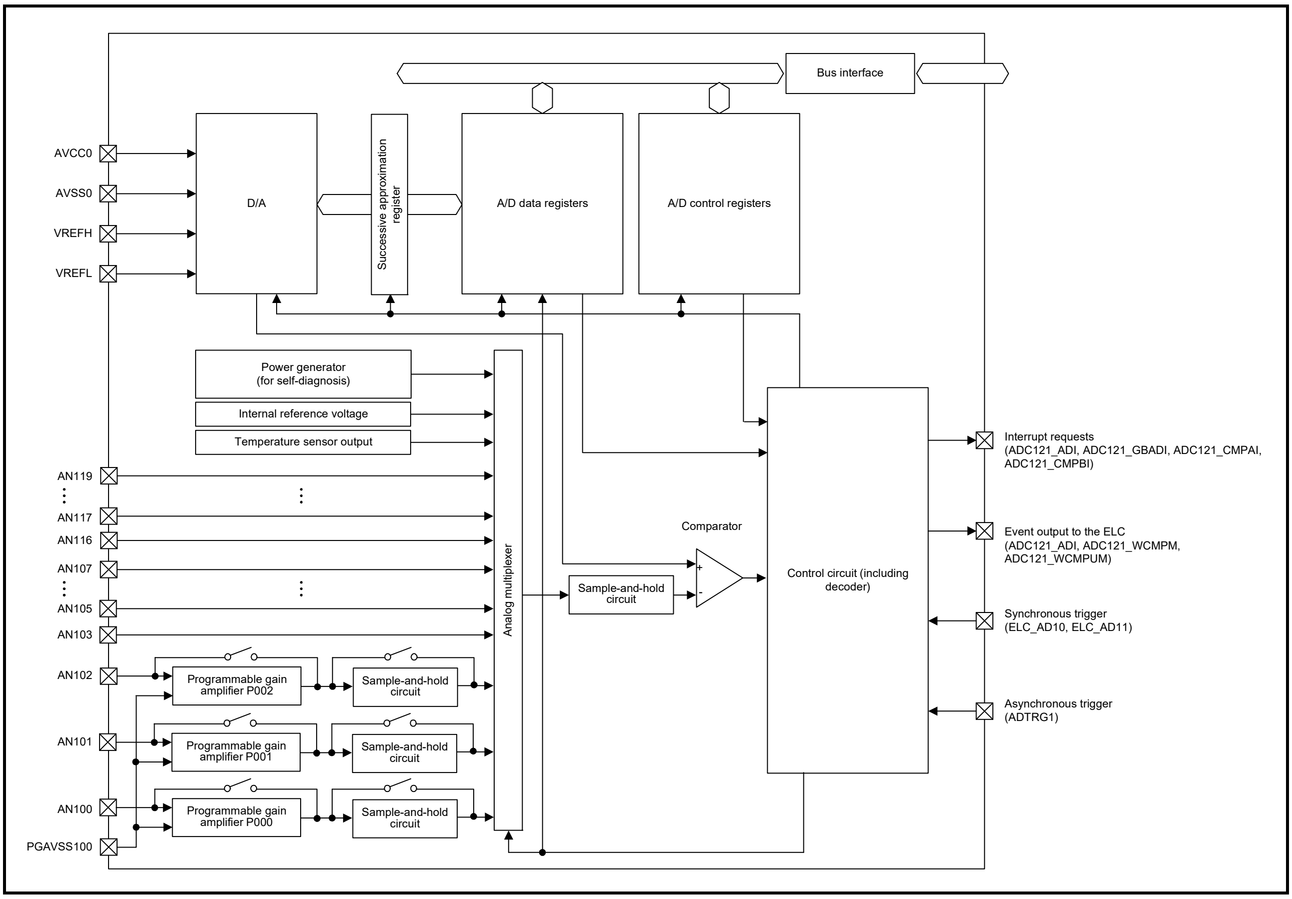

Figure 47.2 ADC12 unit 1 block diagram

Table 47.3 ADC12 I/O pins

Unit	Pin name	I/O	Function
Unit 0	AVCC0	Input	Analog block power supply pin
	AVSS0	Input	Analog block power supply ground pin
	VREFH0	Input	Reference power supply pin
	VREFL0	Input	Reference power supply ground pin
	AN000 to AN007, AN016 to AN020	Input	Analog input pins 0 to 7 and 16 to 20
	ADTRG0	Input	External trigger input pin for starting A/D conversion, active low
	PGAVSS000	Input	Differential input pin
Unit 1	AVCC0	Input	Analog block power supply pin
	AVSS0	Input	Analog block power supply ground pin
	VREFH	Input	Reference power supply pin for ADC12 unit 1 and DAC
	VRELF	Input	Reference power supply ground pin for ADC12 unit 1 and DAC
	AN100 to AN103, AN105 to AN107, AN116 to AN119	Input	Analog input pins 0 to 3, 5 to 7, and 16 to 19
	ADTRG1	Input	External trigger input pin for starting A/D conversion, active low
	PGAVSS100	Input	Differential input pin

47.2 Register Descriptions

47.2.1 A/D Data Registers y (ADDRy), A/D Data Duplexing Register (ADDBLDR), A/D Data Duplexing Register A (ADDBLDRA), A/D Data Duplexing Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR)

The data registers include:

- ADDRy registers (y = 0 to 7, 16 to 20 in unit 0 and y = 0 to 3, 5 to 7, 16 to 19 in unit 1): 16-bit read-only registers for storing the A/D conversion results
- ADDBLDR register: 16-bit read-only register for storing the A/D conversion results in response to the second trigger in double-trigger mode
- ADDBLDRA and ADDBLDRB registers: 16-bit read-only registers for storing the A/D conversion results in response to the respective triggers during extended operation in double-trigger mode
- ADTSDR register: 16-bit read-only register for storing the A/D conversion result of the temperature sensor output
- ADOCDR register: 16-bit read-only register for storing the A/D result of the internal reference voltage.

The following conditions determine the formats for data in these registers:

- The setting in the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right setting)
- The setting in the A/D Conversion Accuracy Specify bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit setting).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

The data formats for each condition are as follows:

Settings for flush-right data with 12-bit accuracy

Address(es): ADC120.ADDR0 4005 C020h to ADC120.ADDR7 4005 C02Eh,
ADC120.ADDR16 4005 C040h to ADC120.ADDR20 4005 C048h,
ADC120.ADDBLDR 4005 C018h, ADC120.ADDBLDRA 4005 C084h, ADC120.ADDBLDRB 4005 C086h,
ADC120.ADTSDR 4005 C01Ah, ADC120.ADOCDR 4005 C01Ch,
ADC121.ADDR0 4005 C220h to ADC121.ADDR3 4005 C226h,
ADC121.ADDR5 4005 C22Ah to ADC121.ADDR7 4005 C22Eh,
ADC121.ADDR16 4005 C240h to ADC121.ADDR19 4005 C246h,
ADC121.ADDBLDR 4005 C218h, ADC121.ADDBLDRA 4005 C284h, ADC121.ADDBLDRB 4005 C286h,
ADC121.ADTSDR 4005 C21Ah, ADC121.ADOCDR 4005 C21Ch

b15 to b8	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value.	R

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in A/D-converted value addition mode. When A/D-converted value average mode is selected, this register indicates the mean of the A/D-converted values on the specified channel. The value is stored in the A/D data register based on the setting in the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 8-, 10-, or 12-bit accuracy (ADPRC bit setting), 1, 2, 3 or 4 times can be selected for A/D-converted value addition. 16 times can also be selected for addition mode, but only with 12-bit accuracy selected. In addition mode, this register indicates the value that is obtained by adding the A/D-converted values on a specific channel. The conversion results sum is retained in the A/D data register as a 2-bit-extended value of the conversion accuracy specified. The value is stored in the A/D data register based on the setting in the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

When converting 1, 2, 3, or 4 times in addition mode with 8-, 10-, or 12-bit accuracy specified, the conversion result is stored in the A/D data register as a 2-bit-extended value of the specified accuracy.

When converting 16 times in addition mode with 12-bit accuracy specified the conversion result is stored in the A/D data register as a 4-bit-extended value of the specified accuracy.

The data formats for each condition are as follows:

Settings for flush-right data with 12-bit accuracy in A/D-converted value addition mode

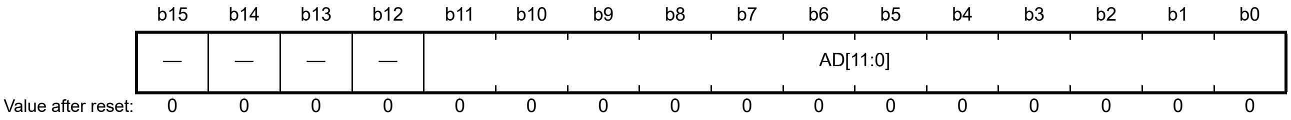
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	AD[15:0]*1															
	—	—	AD[13:0]*2													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	AD[15:0]*1	Added Value 15 to 0	16 -bit sum of A/D conversion results.	R

Bit	Symbol	Bit name	Description	R/W
b13 to b0	AD[13:0]*2	Added Value 13 to 0	14-bit sum of A/D conversion results.	R
b15, b14	—	Reserved	These bits are read as 0.	R

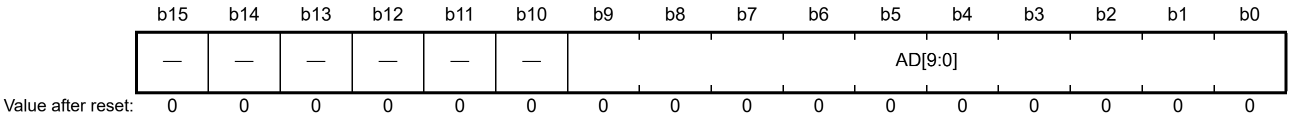
Note 1. Used when 16 conversion times is specified in A/D-converted value addition mode.
Note 2. Used when 1, 2, 3, or 4 conversion times is specified in A/D-converted value addition mode.

Settings for flush-right data with 10-bit accuracy in A/D-converted value addition mode



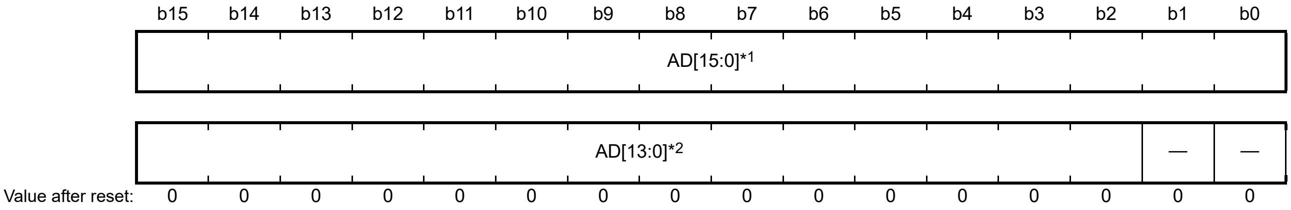
Bit	Symbol	Bit name	Description	R/W
b11 to b0	AD[11:0]	Added Value 11 to 0	12-bit sum of A/D conversion results.	R
b15 to b12	—	Reserved	These bits are read as 0.	R

Settings for flush-right data with 8-bit accuracy in A/D-converted value addition mode



Bit	Symbol	Bit name	Description	R/W
b9 to b0	AD[9:0]	Added Value 9 to 0	10-bit sum of A/D conversion results	R
b15 to b10	—	Reserved	These bits are read as 0.	R

Settings for flush-left data with 12-bit accuracy in A/D-converted value addition mode



Bit	Symbol	Bit name	Description	R/W
b15 to b0	AD[15:0]*1	Added Value 15 to 0	16 -bit sum of A/D conversion results.	R

Bit	Symbol	Bit name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0.	R
b15 to b2	AD[13:0]*2	Added Value 13 o 0	14-bit sum of A/D conversion results.	R

Note 1. Used when 16 conversion times is selected in A/D-converted value addition mode.
Note 2. Used when 1, 2, 3, or 4 conversion times is selected in A/D-converted value addition mode.

Settings for flush-left data with 10-bit accuracy in A/D-converted value addition mode

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0.	R
b15 to b6	AD[9:0]	Added Value 9 to 0	10-bit sum of A/D conversion results.	R

47.2.2 A/D Self-Diagnosis Data Register (ADRD)

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the self-diagnosis status bit (DIAGST).

The following conditions determine the formats for data in this registers:

- The setting in the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right setting)
- The setting in the A/D Conversion Accuracy Specify bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit setting).

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see section 47.2.11, A/D Control Extended Register (ADCER).

This section describes the data formats for each condition.

Settings for flush-right data with 12-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b11 to b0	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value.	R
b13, b12	—	Reserved	These bits are read as 0.	R
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis not executed after power-on 0 1: Self-diagnosis was executed using the 0 V voltage 1 0: Self-diagnosis was executed using the reference power supply*1 voltage x 1/2 1 1: Self-diagnosis was executed using the reference power supply*1 voltage. For details on self-diagnosis, see section 47.2.11, A/D Control Extended Register (ADCER).	R

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

Settings for flush-right data with 10-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

47.2.3 A/D Control Register (ADCSR)

Address(es): ADC120.ADCSR 4005 C000h, ADC121.ADCSR 4005 C200h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADST	ADCS[1:0]		—			TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	DBLANS[4:0]	Double Trigger Channel Select	These bits select one analog input channel for double-triggered operation. The setting is only valid in double-trigger mode.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	GBADIE	Group B Scan End Interrupt and ELC Event Enable	0: Disable ADC12i_GBADI interrupt generation on Group B scan completion 1: Enable ADC12i_GBADI interrupt generation on Group B scan completion. Group B scan only works in group scan mode.	R/W
b7	DBLE	Double Trigger Mode Select	0: Deselect double-trigger mode 1: Select double-trigger mode.	R/W
b8	EXTRG	Trigger Select*1	0: Start A/D conversion by a synchronous trigger (ELC) 1: Start A/D conversion by the asynchronous trigger (ADTRGi).	R/W
b9	TRGE	Trigger Start Enable	0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger.	R/W
b12 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14, b13	ADCS[1:0]	Scan Mode Select	b14 b13 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited.	R/W
b15	ADST	A/D Conversion Start	0: Stop A/D conversion process 1: Start A/D conversion process.	R/W

i = 0 for unit 0, and i = 1 for unit 1.

Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRG0 in unit 0; ADTRG1 in unit 1), write 1 to both the TRGE and EXTRG bits in ADCSR and drive the external pin signals low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0 in unit 0 and ADTRG1 in unit 1. For this configuration, the pulse width of the low-level input must be at least 1.5 PCLKB clock cycles.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double-trigger mode. The A/D conversion results from the specified analog input channel are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when started by the second trigger. Table 47.4 shows the channel selection settings for double-triggered operation.

A/D-converted value addition/average mode can be set with double-trigger mode for the channel selected in the DBLANS[4:0] bits by using the ADADS0 and ADADS1 registers. In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers are invalid, and the channel selected in the DBLANS[4:0] bits is A/D-converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to Group A and not to Group B. This means that multi-channel analog input, temperature sensor output, and internal reference voltage can be selected for Group B even in double-trigger mode.

Only set the DBLANS[4:0] bits while the ADST bit is 0. Do not set them at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, set the channel selected in the DBLANS[4:0] bits in the ADANSA0 and ADANSA1 registers.

Table 47.4 Relationship between DBLANS bit settings and double-trigger enabled channels

Unit 0		Unit 1	
DBLANS[4:0]	**Duplication channel**	**DBLANS[4:0]**	**Duplication channel**
00000	AN000	00000	AN100
00001	AN001	00001	AN101
00010	AN002	00010	AN102
00011	AN003	00011	AN103

00101	AN005	00101	AN105
00110	AN006	00110	AN106
00111	AN007	00111	AN107
Unit 0		**Unit 1**	
DBLANS[4:0]	**Duplication channel**	**DBLANS[4:0]**	**Duplication channel**
10000	AN016	10000	AN116
10001	AN017	10001	AN117
10010	AN018	10010	AN118
10011	AN019	10011	AN119
10100	AN020	10100	—

Note: A/D-converted data from the self-diagnosis function, temperature sensor output, and internal reference voltage cannot be used in double-trigger mode.
Settings other than those listed in Table 47.4 are prohibited.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables Group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When DBLE is set, selecting double-trigger mode, the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for the first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Additionally, do not select double-trigger mode for conversion of the temperature sensor output or internal reference voltage except for Group B scan in group scan mode. Software triggering cannot be set in double-trigger mode. Always clear the ADST bit to 0 before setting the DBLE bit. In other words, do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs, up to a maximum of 13 channels in unit 0 and 11 channels in unit 1, and selected in the ADANSA0 and ADANSA1 registers in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops. When the temperature sensor output or internal reference voltage is selected, A/D conversion of the designated analog input channels is followed by A/D conversion of the temperature sensor output and the internal reference voltage, in that order.

In continuous scan mode, while the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs selected in the ADANSA0 and ADANSA1 registers in ascending order of channel number, and when 1 cycle of A/D conversion completes for all the selected channels, A/D conversion is repeated from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress. When the temperature sensor output or internal reference voltage is selected, A/D conversion of the designated analog input channels is followed by A/D conversion of the temperature sensor output and the internal reference voltage, in that order.

In group scan mode, scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in ADSTRGR. A/D conversion is performed on the Group A analog inputs, up to the maximum channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops. On the same trigger, A/D conversion is also performed on the Group B analog inputs, up to the maximum channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops. If the conversion processes in Group A and Group B occur at the same time, those conversions cannot be controlled separately. In this case, set the Group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to give priority to Group A conversion. When the temperature sensor output or internal reference voltage is selected, A/D conversion of the designated analog input channels is followed by A/D conversion of the temperature sensor output and the internal reference voltage, in that order.

In group scan mode, select different channels and triggers for Group A and Group B. Clear the ADST bit to 0 before setting the ADCS[1:0] bits. In other words, do not set the ADCS[1:0] bits at the same time as writing 1 to the ADST bit.

Table 47.5 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (including Group A)	Analog input (Group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	-	✓	✓
	DBLE = 1	-	✓ (1 ch only)	-	-	-
Continuous scan	DBLE = 0	✓	✓	-	✓	✓
	DBLE = 1	-	-	-	-	-
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	-	✓ (1 ch only)	✓	✓	✓

✓: Selectable. -: Not selectable.

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before setting the ADST bit to 1, set the A/D conversion clock, conversion mode, and analog input for the conversion target.

[Setting conditions]

- 1 is written by software
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 000000b
- When Group A priority control operation mode is enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion of Group B starts.

[Clearing conditions]

- 0 is written by software
- The A/D conversion of all the selected channels, the temperature sensor output or the internal reference voltage completes in single scan mode
- Group A scan completes in group scan mode
- Group B scan completes in group scan mode
- When Group A priority control operation mode is enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1, and each time a scanning of Group B completes.

Note: When Group A priority control operation mode is enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.
When Group A priority control operation mode is enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

Note: If the single scan continuous function is used (ADGSPCR.GBRP = 1) when the group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADST bit is retained to 1.

47.2.4 A/D Channel Select Register A0 (ADANSA0)

Address(es): ADC120.ADANSA0 4005 C004h, ADC121.ADANSA0 4005 C204h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ANSA07	ANSA06	ANSA05	ANSA04	ANSA03	ANSA02	ANSA01	ANSA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	ANSA07 to ANSA00	A/D Conversion Channels Select	0: Do not select associated input channel 1: Select associated input channel.	R/W
b15 to b8	-	Reserved.	These bits are read as 0. The write value should be 0.	R/W

ANSAn bits (n = 00 to 07) (A/D Conversion Channels Select)

The ADANSA0.ANSAn bits select or deselect the analog input channels for A/D conversion for AN000 to AN007 (unit 0) and AN100 to AN103 and AN105 to AN107 (unit 1). The channels and the number of channels can be set arbitrarily. In unit 0, the ANSA00 bit is associated with AN000 and the ANSA07 bit with AN007. In unit 1, the ANSA00 bit is associated with AN100 and the ANSA07 bit with AN107.

In double-trigger mode, the channel selected in the ADANSA0 register is invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in Group A instead.

In group scan mode, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

Only set the ADANSA0 register while the ADCSR.ADST bit is 0.

47.2.5 A/D Channel Select Register A1 (ADANSA1)

Address(es): ADC120.ADANSA1 4005 C006h, ADC121.ADANSA1 4005 C206h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	ANSA20	ANSA19	ANSA18	ANSA17	ANSA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	ANSA20 to ANSA16	A/D Conversion Channels Select	0: Do not select associated input channel 1: Select associated input channel	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ANSAn bits (n = 16 to 20) (A/D Conversion Channels Select)

The ADANSA1.ANSAn bits select or deselect the analog input channels for A/D conversion for AN016 to AN020 (unit 0) and AN116 to AN119 (unit 1). The channels and the number of channels can be set arbitrarily. In unit 0, the ANSA16 bit is associated with AN016 and the ANSA20 bit with AN020. In unit 1, the ANSA16 bit is associated with AN116 and the ANSA19 bit with AN119.

In double-trigger mode, the ANSA1[15:0] bits are invalid, and the channel selected in the ADCSR.DBLANS[15:0] bits is selected in Group A instead.

In group scan mode, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

Only set the ADANSA1 register while the ADCSR.ADST bit is 0.

47.2.6 A/D Channel Select Register B0 (ADANSB0)

Address(es): ADC120.ADANSB0 4005 C014h, ADC121.ADANSB0 4005 C214h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ANSB07	ANSB06	ANSB05	ANSB04	ANSB03	ANSB02	ANSB01	ANSB00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	ANSB07 to ANSB00	A/D Conversion Channels Select	0: Do not select associated input channel 1: Select associated input channel.	R/W
b15 to b8	-	Reserved	These bits are read as 0. The write value should be 0.	R/W

ANSBn bits (n = 00 to 07) (A/D Conversion Channels Select)

The ADANSB0.ANSBn bits select the analog input channels for A/D conversion for AN000 to AN007 (unit 0) and AN100 to AN103 and AN105 to AN107 (unit 1) in Group B in group scan mode. The ADANSB0 register is only used for group scan mode, not for any other modes. Exclude the channels specified in Group A (the channels associated with Group A, selected in the ADANSA0 and ADANSA1 registers and the ADCSR.DBLANS[4:0] bits in double-trigger mode), both the selected channels and the number of channels to be set.

In unit 0, the ANSB00 bit is associated with AN000 and the ANSB07 bit with AN007. In unit 1, the ANSB00 bit is associated with AN100 and the ANSB07 bit with AN107.

Only set the ADANSB0 register while the ADCSR.ADST bit is 0.

47.2.7 A/D Channel Select Register B1 (ADANSB1)

Address(es): ADC120.ADANSB1 4005 C016h, ADC121.ADANSB1 4005 C216h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	ANSB20	ANSB19	ANSB18	ANSB17	ANSB16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	ANSB20 to ANSB16	A/D Conversion Channels Select	0: Do not select associated input channel 1: Select associated input channel.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ANSBn bits (n = 16 to 20) (A/D Conversion Channels Select)

The ADANSB1.ANSBn bits select the analog input channels for A/D conversion for AN016 to AN020 (unit 0) and AN116 to AN119 (unit 1) in Group B in group scan mode. The ADANSB1 register is only used for group scan mode, not for any other modes. Exclude the channels specified in Group A (the channels associated with Group A, selected in the ADANSA0 and ADANSA1 registers and the ADCSR.DBLANS[4:0] bits in double-trigger mode), both the selected channels and the number of channels to be set.

In unit 0, the ANSB16 bit is associated with AN016 and the ANSB20 bit with AN020. In unit 1, the ANSB16 bit is associated with AN116 and the ANSB19 bit with AN119.

Only set the ADANSB1 register bits while the ADST bit is 0.

47.2.8 A/D-Converted Value Addition/Average Channel Select Register 0 (ADADS0)

Address(es): ADC120.ADADS0 4005 C008h, ADC121.ADADS0 4005 C208h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ADS07	ADS06	ADS05	ADS04	ADS03	ADS02	ADS01	ADS00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	ADS07 to ADS00	A/D-Converted Value Addition/Average Channel Select	0: Do not select associated input channel 1: Select associated input channel	R/W
b15 to b8	-	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSn bits (n = 00 to 07) (A/D-Converted Value Addition/Average Channel Select)

When the ADSn bit with the same number as the A/D-converted channel selected in the ANSAn bits (n = 00 to 07) in ADANSA0 or the ADCSR.DBLANS[4:0] bits and the ANSBn bits (n = 00 to 07) in ADANSB0 is set to 1, A/D conversion of the analog input of the selected channels is performed successively 1 to 16 times, as specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. For A/D-converted channels for which addition or average mode is not selected, a normal one-time conversion is executed, and the conversion result is stored in the A/D data register.

In unit 0, the ADS00 bit is associated with AN000 and the ADS07 bit with AN007. In unit 1, the ADS00 bit is associated with AN100 and the ADS07 bit with AN107.

Only set the ADADS0 register bits while the ADCSR.ADST bit is 0.

47.2.9 A/D-Converted Value Addition/Average Channel Select Register 1 (ADADS1)

Address(es): ADC120.ADADS1 4005 C00Ah, ADC121.ADADS1 4005 C20Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	ADS20	ADS19	ADS18	ADS17	ADS16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	ADS20 to ADS16	A/D-Converted Value Addition/Average Channel Select	0: Do not select associated input channel 1: Select associated input channel.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSn bits (n = 16 to 20) (A/D-Converted Value Addition/Average Channel Select)

When the ADSn bit with the same number as the A/D-converted channel selected in the ANSAn bits (n = 16 to 20) in ADANSA1 or ADCSR.DBLANS[4:0] bits and ANSBn bits (n = 16 to 20) in ADANSB1 is set to 1, A/D conversion of the analog input of the selected channels is performed successively 1 to 16 times, as specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. For A/D-converted channels for which addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored in the A/D data register.

In unit 0, the ADS16 bit is associated with AN016 and the ADS20 bit with AN020. In unit 1, the ADS16 bit is associated with AN116 and the ADS19 bit with AN119.

Only set the ADADS1 register while the ADCSR.ADST bit is 0.

Figure 47.3 shows a scanning operation sequence in which both the ADADS0.ADS02 and ADS06 bits are set to 1.

In this example, addition mode is selected (ADADS.AVEE = 0), the time conversion is set to 4 (ADADC.ADC[1:0] = 11b), and the AN000 to AN006 channels are selected (ADANSA0.ANSA0[15:0] = 007Fh) in continuous scan mode (ADCSR.ADCS[1:0] = 10b). The conversion process begins with AN000. The AN002 conversion is performed successively 4 times, and the added (integrated) value is returned to A/D data register ADDR2. Next, the AN003 conversion process starts. The AN006 conversion is performed successively 4 times and the added (integrated) value is returned to A/D data register ADDR6. After conversion of AN006, the conversion operation is once again performed in the same sequence from AN000.

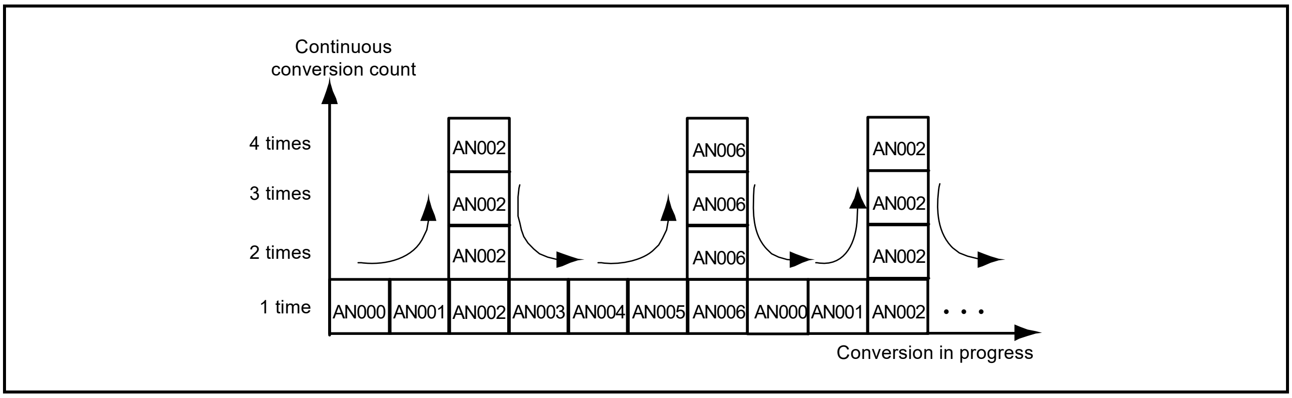

Figure 47.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, ADADS0.ADS02 = 1, and ADS06 = 1

47.2.10 A/D-Converted Value Addition/Average Count Select Register (ADADC)

Address(es): ADC120.ADADC 4005 C00Ch, ADC121.ADADC 4005 C20Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	ADC[2:0]	Count Select	b2 b0 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2 time conversion (one addition) 0 1 0: 3-time conversion (two additions) 0 1 1: 4 time conversion (three additions) 1 0 1: 16-time conversion (15 additions). Other settings are prohibited.	R/W
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	AVEE	Average Mode Enable	0: Disable average mode*1 1: Enable average mode.*2	R/W

Note 1. When average mode is deselected by setting the ADADC.AVEE bit to 0, set the addition count to 1, 2, 3, 4 or 16-time conversion. 16-time conversion can only be used with 12-bit accuracy selected.

Note 2. When average mode is selected by setting the ADADC.AVEE bit to 1, set the addition count to 1-, 2-, or 4-time conversion. Do not set the addition count to 3- or 16-time conversion (ADC[2:0] = 010b or 101b).

ADC[2:0] bits (Count Select)

The ADC[2:0] bits set the count for all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of temperature sensor output and internal reference voltage.

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the count to 3-time conversion

(ADADC.ADC[2:0] = 010b). Additionally, the combination of 16-time conversion (ADADC.ADC[2:0] = 101b) with a conversion accuracy setting of 8 or 10 bits (ADCER.ADPRC[1:0] = 10b or 01b) is a prohibited setting, as described in section 47.2.2.

Only set the ADC[2:0] bits while the ADCSR.ADST bit is 0. When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b. When the conversion accuracy is 8 or 10 bits (ADCER.ADPRC[1:0] = 10b or 01b), do not set the ADC[2:0] bits to 101b.

AVEE bit (Average Mode Enable)

The AVEE bit selects addition or average mode for all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, and internal reference voltage.

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to 3-time conversion (ADADC.ADC[2:0] = 010b).

Only set the AVEE bits while the ADCSR.ADST bit is 0.

47.2.11 A/D Control Extended Register (ADCER)

Address(es): ADC120.ADCER 4005 C00Eh, ADC121.ADCER 4005 C20Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2, b1	ADPRC[1:0]	A/D Conversion Accuracy Specify	b2 b1 0 0: 12-bit accuracy 0 1: 10-bit accuracy 1 0: 8-bit accuracy 1 1: Setting prohibited.	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	ACE	A/D Data Register Automatic Clearing Enable	0: Disable automatic clearing 1: Enable automatic clearing.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select	b9 b8 0 0: Setting prohibited when self-diagnosis is enabled 0 1: 0 V 1 0: Reference power supply voltage*1 x 1/2 1 1: Reference power supply voltage.*1	R/W
b10	DIAGLD	Self-Diagnosis Mode Select	0: Select rotation mode for self-diagnosis voltage 1: Select fixed mode for self-diagnosis voltage.	R/W
b11	DIAGM	Self-Diagnosis Enable	0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis.	R/W
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	ADRFMT	A/D Data Register Format Select	0: Select flush-right for the A/D data register format 1: Select flush-left for the A/D data register format.	R/W

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bits (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy to 8-, 10-, or 12-bit accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see section 47.3.6, Analog Input Sampling and Scan Conversion Time.

Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0s) of ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR after any of these registers is read by the CPU, DTC, or DMAC. Automatic clearing of the A/D data registers enables detection of failures that do not update the A/D data registers.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the ADCER.DIAGLD bit description.

Do not execute self-diagnosis by setting the ADCER.DIAGLD bit to 1 when the ADCER.DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or fixed voltage is used in self-diagnosis. Setting this bit to 0 allows conversion of the voltages in rotation mode where 0 V, the reference power supply × 1/2, and the reference power supply are converted, in that order. After reset, when the self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted when self-diagnosis fixed voltage mode is selected. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion completes. When scan conversion restarts, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit while the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis. Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the internally generated voltage values (0, the reference power supply × 1/2, or the reference power supply) is converted. When conversion completes, information on the converted voltage and the conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). ADRD can be read by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. When the double-trigger mode is set (ADCSR.DBLE = 1), always deselect self-diagnosis (DIAGM = 0). When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately on Group A and Group B.

Only set the DIAGM bit while the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for the data to be stored in ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD.

Only set the ADRFMT bit the ADCSR.ADST bit is 0.

47.2.12 A/D Conversion Start Trigger Select Register (ADSTRGR)

Address(es): ADC120.ADSTRGR 4005 C010h, ADC121.ADSTRGR 4005 C210h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B	These bits specify the A/D conversion start trigger for Group B in group scan mode.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b13 to b8	TRSA[5:0]	A/D Conversion Start Trigger Select	These bits specify the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for Group A is selected.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in Group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for Group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 000000b and set the ADCSR.TRGE bit to 1.

When Group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows Group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 3Fh. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger might have no effect.

When the trigger from a module operated at 120 MHz (GPT) is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see section 47.3.6, Analog Input Sampling and Scan Conversion Time.

Table 47.6 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in Group A is selected. When scanning is executed in group scan mode or double-trigger mode, setting a software trigger or an asynchronous trigger is prohibited.

When using a synchronous trigger (ELC) as the A/D conversion start source, set the TRGE bit in ADCSR to 1 and the EXTRG bit in ADCSR to 0.

When using the asynchronous trigger (ADTRGn), set the TRGE bit in ADCSR to 1 and the EXTRG bit in ADCSR to 1.

The software trigger (ADCSR.ADST) is enabled regardless of the settings in the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger might have no effect.

When the trigger from a module operated at 120 MHz (GPT) is selected as an A/D conversion start trigger, a delay period for synchronization processing occurs. For details, see section 47.3.6, Analog Input Sampling and Scan Conversion Time.

Table 47.7 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

Table 47.6 Selection of A/D conversion start sources in the TRSB[5:0] bits

Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]

b1	OCSAD	Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select	0: Do not select addition/average mode for internal reference voltage 1: Select addition/average mode for internal reference voltage.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TSSA	Temperature Sensor Output A/D Conversion Select	0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output.	R/W
b9	OCSA	Internal Reference Voltage A/D Conversion Select	0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage.	R/W
b10	TSSB	Temperature Sensor Output A/D Conversion Select for Group B	Selection for Group B in group scan mode. 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output.	R/W
b11	OCSB	Internal Reference Voltage A/D Conversion Select for Group B	Selection for Group B in group scan mode. 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. The maximum addition count differs depending on the conversion accuracy (see section 47.2.2, A/D Self-Diagnosis Data Register (ADRD)). When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. The maximum addition count differs depending on the conversion accuracy (see 47.2.2 A/D Self-Diagnosis Data Register (ADRD)). When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for Group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for Group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for Group B in group scan mode.

Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for Group B in group scan mode.

Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1.

Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

47.2.14 A/D Sampling State Register n (ADSSTRn) (n = 00 to 07, L, T, O)

Address(es): ADC120.ADSSTR00 4005 C0E0h to ADC120.ADSSTR07 4005 C0E7h,
ADC120.ADSSTRL 4005 C0DDh, ADC120.ADSSTRT 4005 C0DEh, ADC120.ADSSTRO 4005 C0DFh,
ADC121.ADSSTR00 4005 C2E0h to ADC121.ADSSTR03 4005 C2E3h,
ADC121.ADSSTR05 4005 C2E5h to ADC121.ADSSTR07 4005 C2E7h,
ADC121.ADSSTRL 4005 C2DDh, ADC121.ADSSTRT 4005 C2DEh, ADC121.ADSSTRO 4005 C2DFh

	b7	b6	b5	b4	b3	b2	b1	b0
	SST[7:0]							
Value after reset:	0	0	0	0	1	0	1	1

Bit	Symbol	Bit name	Description	R/W
b7 to b0	SST[7:0]	Sampling Time Setting	These bits set the sampling time in the range from 5 to 255 states.	R/W

The ADSSTRn register sets the sampling time for analog input. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 11 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SST[7:0] bits while the ADCSR.ADST bit is 0.

The lower limit of the sampling time setting depends on the frequency ratio, as follows:

- If the frequency ratio of PCLKB to PCLKC(ADCLK) = 1:1, 2:1, 4:1, or 8:1, the sampling time must be set to a value of more than 5 states

- If the frequency ratio of PCLKB to PCLKC(ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 47.8 shows the relationship between the A/D Sampling State Register and the associated channels.

For details, see section 47.3.6, Analog Input Sampling and Scan Conversion Time.

Table 47.8 Relationship between A/D sampling state register and associated channels

	Associated channels	
Bit name	**Unit 0**	**Unit 1**
ADSSTR00.SST[7:0] bits*[1]	AN000	AN100
ADSSTR01.SST[7:0] bits	AN001	AN101
ADSSTR02.SST[7:0] bits	AN002	AN102
ADSSTR03.SST[7:0] bits	AN003	AN103
ADSSTR04.SST[7:0] bits	AN004	-
ADSSTR05.SST[7:0] bits	AN005	AN105
ADSSTR06.SST[7:0] bits	AN006	AN106
ADSSTR07.SST[7:0] bits	AN007	AN107
ADSSTRL.SST[7:0] bits	AN016 to AN020	AN116 to AN119
ADSSTRT.SST[7:0] bits	Temperature sensor output	Temperature sensor output
ADSSTRO.SST[7:0] bits	Internal reference voltage	Internal reference voltage

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR00.SST[7:0] bits is applied.

47.2.15 A/D Sample and Hold Circuit Control Register (ADSHCR)

Address(es): ADC120.ADSHCR 4005 C066h, ADC121.ADSHCR 4005 C266h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SHANS[2:0]			SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting	Sampling time (4 to 255 states).	R/W
b10 to b8	SHANS[2:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select	Select whether to use or bypass channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0) and AN100 to AN102 (unit 1). 0: Bypass the circuits 1: Use the circuits.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SHANS[2:0] bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[2:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits for AN000 to AN002 (unit 0) and AN100 to AN102 (unit 1). In unit 0, the SHANS[0] bit is associated with AN000, the SHANS[1] bit with AN001, and the SHANS[2] bit with AN002. In unit 1, the SHANS[0] bit is associated with AN100, the SHANS[1] bit with AN101, and the SHANS[2] bit with AN102.

If any channel from among AN000 to AN002 (unit 0) or AN100 to AD102 (unit 1) is selected for Group B while operation is in group scan mode under Group A priority control, use this setting to bypass the dedicated sample-and-hold circuit of the channel.

Only set the SHANS[2:0] bits while the ADCSR.ADST bit is 0 and the ADSHMSR.SHMD bit is 0.

47.2.16 A/D Sample and Hold Operation Mode Selection Register (ADSHMSR)

Address(es): ADC120.ADSHMSR 4005 C07Ch, ADC121.ADSHMSR 4005 C27Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SHMD	Sampling Operation Selection	0: Disable continuous sampling function 1: Enable continuous sampling function.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[2:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and operates holding while the ADC12 is operating.

Note: The ADCSR.ADST bit must become 1 after 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ).

47.2.17 A/D Disconnection Detection Control Register (ADDISCR)

Address(es): ADC120.ADDISCR 4005 C07Ah, ADC121.ADDISCR 4005 C27Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b3 to b0	ADNDIS[3:0]	Disconnection Detection Assist Setting	b3 - b0 0000: The disconnection detection assist function is disabled 0001: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
b4	PCHG	Precharge/discharge select	0: Discharge 1: Precharge.	R/W

Bit	Symbol	Bit name	Description	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0.

If any of the following functions are used, the disconnection detection assist function must be disabled:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- The programmable gain amplifier without bypass enabled.

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

PCHG bit (Precharge/discharge select)

Setting the PCHG bit to 1 selects precharge and setting the PCHG bit to 0 selects discharge.

47.2.18 A/D Group Scan Priority Control Register (ADGSPCR)

Address(es): ADC120.ADGSPCR 4005 C080h, ADC121.ADGSPCR 4005 C280h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GBRP	—	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	PGS	Group A Priority Control Setting[*1]	0: Operate without Group A priority control 1: Operate with Group A priority control.	R/W
b1	GBRSCN	Group B Restart Setting	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Do not restart Group B scanning after it is stopped by Group A priority control 1: Restart Group B scanning after it is stopped by Group A priority control.	R/W
b14 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	GBRP	Group B Single Scan Continuous Start[*2]	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Do not continuously activate single scan for Group B 1: Continuously activate single scan for Group B.	R/W

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for Group B regardless of the setting in the GBRSCN bit.

PGS bit (Group A Priority Control Setting)

Set the PGS bit to 1 to give priority to operation on Group A. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 47.6.2, Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 47.3.4.3, Operation with group A priority control.

GBRSCN bit (Group B Restart Setting)

The GBRSCN bit controls the restarting of scan operation on Group B when operation on Group A is given priority. If a scan operation on Group B is stopped by a Group A trigger input with the GBRSCN bit set to 1, the scan operation is restarted on completion of the Group A conversion. Also, if a Group B trigger is input during A/D conversion on Group A, the scan operation on Group B is restarted on completion of Group A conversion.

When the GBRSCN bit is set to 0, triggers input during A/D conversion are ignored. Only set the GBRSCN bit while the ADCSR.ADST bit is 0.

The setting in the GBRSCN bit is valid when the PGS bit is 1.

GBRP bit (Group B Single Scan Continuous Start)

Set the GBRP bit to perform a single scan operation continuously on Group B. Setting the GBRP bit to 1 starts a single scan on Group B. On completion of the scan, another single scan on Group B starts automatically. If a Group B conversion stops because of an operation on Group A, the Group A operation takes priority, and single scan on Group B restarts automatically on completion of the Group A conversion.

Disable Group B trigger input before setting the GBRP bit to 1. Setting the GBRP bit to 1 invalidates the setting in the GBRSCN bit. Only set the GBRP bit while the ADCSR.ADST is 0.

The setting in the GBRP bit is valid when the PGS bit is 1.

47.2.19 A/D Compare Function Control Register (ADCMPCR)

Address(es): ADC120.ADCMPCR 4005 C090h, ADC121.ADCMPCR 4005 C290h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CMPAB[1:0]	Window A/B Composite Conditions Setting	b1 b0 0 0: Output ADC12i_WCMPM when Window A OR Window B comparison conditions are met; otherwise, output ADC12i_WCMPUM 0 1: Output ADC12i_WCMPM when Window A EXOR Window B comparison conditions are met; otherwise, output ADC12i_WCMPUM 1 0: Output ADC12i_WCMPM when Window A AND Window B comparison conditions are met; otherwise, output ADC12i_WCMPUM 1 1: Setting prohibited. These bits are valid when both Window A and Window B are enabled (CMPAE = 1 and CMPBE = 1).	R/W
b8 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	CMPBE	Compare Window B Operation Enable	0: Disable compare Window B operation Disable ADC12i_WCMPM and ADC12i_WCMPUM outputs. 1: Enable compare Window B operation.	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11	CMPAE	Compare Window A Operation Enable	0: Disable compare Window A operation Disable ADC12i_WCMPM and ADC12i_WCMPUM outputs. 1: Enable compare Window A operation.	R/W
b12	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b13	CMPBIE	Compare B Interrupt Enable	0: Disable ADC12i_CMPBI interrupt when comparison conditions (Window B) are met 1: Enable ADC12i_CMPBI interrupt when comparison conditions (Window B) are met.	R/W
b14	WCMPE	Window Function Setting	0: Disable window function Window A and Window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function. Window A and Window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
b15	CMPAIE	Compare A Interrupt Enable	0: Disable ADC12i_CMPAI interrupt when comparison conditions (Window A) are met 1: Enable ADC12i_CMPAI interrupt when comparison conditions (Window A) are met.	R/W

Note: i = 0: unit 0, i = 1: unit 1.

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both Window A and Window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCONB.

Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare Window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, and B1 (ADANSA0, ADANSA1, ADANSB0, and ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR).

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare Window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, and B1 (ADANSA0, ADANSA1, ADANSB0, and ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (Window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (Window A) are met.

47.2.20 A/D Compare Function Window A Channel Select Register 0 (ADCMPANSR0)

Address(es): ADC120.ADCMPANSR0 4005 C094h, ADC121.ADCMPANSR0 4005 C294h

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI) is generated.

47.2.26 A/D Compare Function Window A Lower-Side Level Setting Register (ADCMPDR0), A/D Compare Function Window A Upper-Side Level Setting Register (ADCMPDR1), A/D Compare Function Window B Lower-Side Level Setting Register (ADWINLLB), A/D Compare Function Window B Upper-Side Level Setting Register (ADWINULB)

Address(es): ADC120.ADCMPDR0 4005 C09Ch, ADC120.ADCMPDR1 4005 C09Eh,
ADC120.ADWINLLB 4005 C0A8h, ADC120.ADWINULB 4005 C0AAh,
ADC121.ADCMPDR0 4005 C29Ch, ADC121.ADCMPDR1 4005 C29Eh,
ADC121.ADWINLLB 4005 C2A8h, ADC121.ADWINULB 4005 C2AAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	—	—	Reference value	R/W

The ADCMPDRy (y = 0,1) register specifies the reference data when the compare Window A function is used. ADCMPDR0 sets the lower reference for Window A, and ADCMPDR1 sets the upper reference for Window A.

ADWINULB and ADWINLLB specify the reference data when the compare Window B function is used. ADWINLLB sets the lower reference for Window B, and ADWINULB sets the upper reference for Window B. The ADCMPDRy, ADWINULB, and ADWINLLB are read/write registers.

ADCMPDRy, ADWINULB, and ADWINLLB can be written to even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0 and ADWINULBB ≥ ADWINLLB). ADCMPDR1 and ADWINULB are not used when the window function is disabled.

The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after a rewrite), and the lower reference (before a rewrite) with the A/D conversion result. (See Figure 47.5.) If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the associated compare window operation enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) is 0.

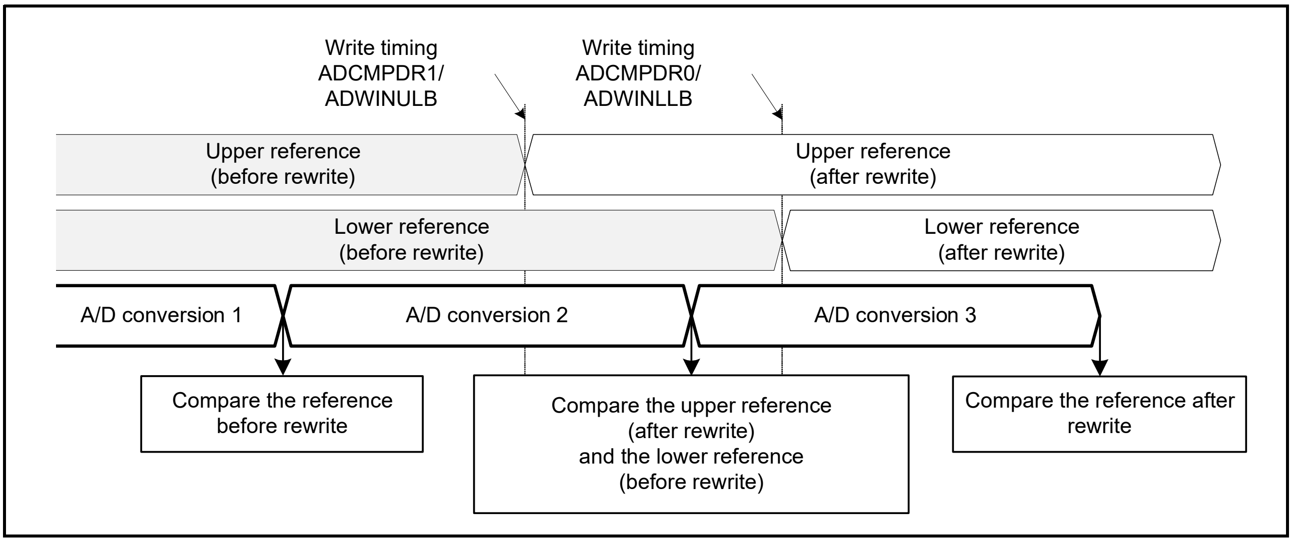

Figure 47.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy, ADWINLLB, and ADWINULB registers use different formats depending on the following conditions:

- The value in the A/D Data Register Format Select bit (flush-right or flush-left)
- The value in the A/D Conversion Accuracy Specify bit (12-bit, 10-bit, or 8-bit)
- The value in the A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are as follows:

(1) When A/D-converted value addition mode is not selected

- Flush-right data with 12-bit accuracy: Lower 12 bits ([11:0]) are valid
- Flush-right data with 10-bit accuracy: Lower 10 bits ([9:0]) are valid
- Flush-right data with 8-bit accuracy: Lower 8 bits ([7:0]) are valid
- Flush-left data with 12-bit accuracy: Upper 12 bits ([15:4]) are valid
- Flush-left data with 10-bit accuracy: Upper 10 bits ([15:6]) are valid
- Flush-left data with 8-bit accuracy: Upper 8 bits ([15:8]) are valid.

(2) When A/D-converted value addition mode is selected

- Flush-right data with 12-bit accuracy: Lower 14 bits ([13:0]) are valid
- Flush-right data with 10-bit accuracy: Lower 12 bits ([11:0]) are valid
- Flush-right data with 8-bit accuracy: Lower 10 bits ([9:0]) are valid
- Flush-left data with 12-bit accuracy: Upper 14 bits ([15:2]) are valid
- Flush-left data with 10-bit accuracy: Upper 12 bits ([15:4]) are valid
- Flush-left data with 8-bit accuracy: Upper 10 bits ([15:6]) are valid.

47.2.27 A/D Compare Function Window A Channel Status Register 0 (ADCMPSR0)

Address(es): ADC120.ADCMPSR0 4005 C0A0h, ADC121.ADCMPSR0 4005 C2A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CMPSTCHA07	CMPSTCHA06	CMPSTCHA05	CMPSTCHA04	CMPSTCHA03	CMPSTCHA02	CMPSTCHA01	CMPSTCHA00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CMPSTCHA07 to CMPSTCHA00	Compare Window A Flag	When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied, selected from AN000 to AN007 (unit 0) and AN100 to AN103, AN105 to AN107 (unit 1). 0: Comparison conditions are not met 1: Comparison conditions are met.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTCHAn flags (n = 00 to 07) (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied, selected from AN000 to AN007 (unit 0) and AN100 to AN103, AN105 to AN107 (unit 1). When a comparison condition set in ADCMPLR0.CMPLCHAn is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1. In unit 0, CMPSTCHA00 is associated with AN000 and CMPSTCHA07 with AN007. In unit 1, CMPSTCHA00 is associated with AN100 and CMPSTCHA07 with AN107.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHAn is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

47.2.28 A/D Compare Function Window A Channel Status Register1 (ADCMPSR1)

Address(es): ADC120.ADCMPSR1 4005 C0A2h, ADC121.ADCMPSR1 4005 C2A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	CMPSTCHA20	CMPSTCHA19	CMPSTCHA18	CMPSTCHA17	CMPSTCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b4 to b0	CMPSTCHA20 to CMPSTCHA16	Compare Window A Flag	When Window A operation is enabled (ADCMPCR.CMPAE = 1), these bits indicate the comparison result of channels to which Window A comparison conditions are applied, selected from AN016 to AN020 (unit 0) and AN116 to AN119 (unit 1). 0: Comparison conditions are not met 1: Comparison conditions are met.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTCHAn flags (n = 16 to 20) (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied, selected from AN016 to AN020 (unit 0) and AN116 to AN119 (unit 1). When the comparison condition set in

ADCMPLR1.CMPLCHAn is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1. In unit 0, CMPSTCHA16 is associated with AN016 and CMPSTCHA20 with AN020. In unit 1, CMPSTCHA16 is associated with AN116 and CMPSTCHA19 with AN119.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHAn is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

47.2.29 A/D Compare Function Window A Extended Input Channel Status Register (ADCMPSER)

Address(es): ADC120.ADCMPSER 4005 C0A4h, ADC121.ADCMPSER 4005 C2A4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPSTOCA	CMPSTTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag	When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
b1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag	When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

47.2.30 A/D Compare Function Window B Channel Select Register (ADCMPBNSR)

Address(es): ADC120.ADCMPBNSR 4005 C0A6h, ADC121.ADCMPBNSR 4005 C2A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	CMPCHB[5:0]	Compare Window B Channel Select	These bits select channels to be compared with the compare Window B conditions. The maximum channel is AN020 in unit 0 and AN119 in unit 1. b5 b0 Unit 0 Unit 1 0 0 0 0 0 0: AN000 AN100 0 0 0 0 0 1: AN001 AN101 0 0 0 0 1 0: AN002 AN102 0 0 0 0 1 1: AN003 AN103 0 0 0 1 0 0: AN004 — 0 0 0 1 0 1: AN005 AN105 0 0 0 1 1 0: AN006 AN106 0 0 0 1 1 1: AN007 AN107 0 1 0 0 0 0: AN016 AN116 : : 0 1 0 0 1 1: AN019 AN119 0 1 0 1 0 0: AN020 — 1 0 0 0 0 0: Temperature sensor 1 0 0 0 0 1: Internal reference voltage 1 1 1 1 1 1: Do no select. Other settings are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Compare Window B Comparison Condition Setting	This bit sets comparison conditions for channels for Window B. The comparison conditions are shown in Figure 47.6. • When window function is disabled (ADCMPCR.WCMPE = 0) 0: CMPLLB value > A/D-converted value 1: CMPLLB value < A/D-converted value. • When window function is enabled (ADCMPCR.WCMPE = 1) 0: A/D-converted value < CMPLLB value, or CMPULB value < A/D-converted value 1: CMPLLB value < A/D-converted value < CMPULB value.	R/W

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN007 and AN016 to AN020 (unit 0), AN100 to AN103, AN105 to AN107, and AN116 to AN119 (unit 1), the temperature sensor, and the internal reference voltage. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the following bits:

Unit 0:

- ADANSA0.ANSA00 to ANSA07 bits
- ADANSA1.ANSA16 to ANSA20 bits
- ADANSB0.ANSB00 to ANSB07 bits
- ADANSB1.ANSB16 to ANSB20 bits.

Unit 1:

- ADANSA0.ANSA00 to ANSA03 bits
- ADANSA0.ANSA05 to ANSA07 bits
- ADANSA1.ANSA16 to ANSA19 bits
- ADANSB0.ANSB00 to ANSB03 bits
- ADANSB0.ANSB05 to ANSB07 bits
- ADANSB1.ANSB16 to ANSB19 bits.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI) (i = 0, 1)) is generated.

Compare conditions when the window function is disabled

CMPLB = 0

ADWINLLB value ≤ A/D converted value	Not met
ADWINLLB value > A/D converted value	Met

CMPLB = 1

ADWINLLB value < A/D converted value	Met
ADWINLLB value ≥ A/D converted value	Not met

Compare conditions when the window function is enabled

CMPLB = 0

A/D converted value > ADWINULB value	Met
ADWINLLB value ≤ A/D converted value ≤ ADWINULB value	Not met
A/D converted value < ADWINLLB value	Met

CMPLB = 1

A/D converted value ≥ ADWINULB value	Not met
ADWINLLB value <A/D converted value < ADWINULB value	Met
A/D converted value ≤ ADWINLLB value	Not met

Figure 47.6 Explanation of compare conditions for compare function Window B

47.2.31 A/D Compare Function Window B Status Register (ADCMPBSR)

Address(es): ADC120.ADCMPBSR 4005 C0ACh, ADC121.ADCMPBSR 4005 C2ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CMPSTB	Compare Window B Flag	When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, selected from AN000 to AN007 and AN016 to AN020 (unit 0), AN100 to AN103, AN105 to AN107, and AN116 to AN119 (unit 1), temperature sensor output, and internal reference voltage. 0: Comparison conditions are not met 1: Comparison conditions are met.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, selected from AN000 to AN007 and AN016 to AN020 (unit 0), AN100 to AN103, AN105 to AN107, and AN116 to AN119 (unit 1), the temperature sensor, and the internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

47.2.32 A/D Compare Function Window A/B Status Monitor Register (ADWINMON)

Address(es): ADC120.ADWINMON 4005 C08Ch, ADC121.ADWINMON 4005 C28Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	MONCOMB	Combination Result Monitor	This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met 1: Window A/B composite conditions are met.	R
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	MONCMPA	Comparison Result Monitor A	0: Window A comparison conditions are not met 1: Window A comparison conditions are met.	R
b5	MONCMPB	Comparison Result Monitor B	0: Window B comparison conditions are not met 1: Window B comparison conditions are met.	R
b7, b6	—	Reserved	These bits are read as 0.	R

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPLR0.CMPLCHAn when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPLR0.CMPLCHAn when ADCMPCR.CMPAE = 1
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

47.2.33 A/D Programmable Gain Amplifier Control Register (ADPGACR)

Address(es): ADC120.ADPGACR 4005 C1A0h, ADC121.ADPGACR 4005 C3A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b11	P002GEN	PGA P002 Gain Setting Enable	0: Disable gain setting 1: Enable gain setting.	R/W
b12	—	Reserved	This bit is read as 1. The write value should be 1.	R/W
b14, b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	—	Reserved	This bit is read as 1. The write value should be 1.	R/W

Note: See section 47.3.12, Programmable Gain Amplifiers, for details on setting these bits.

PnSEL0 bit (PGA Pn Amplifier Bypass Enable) (n = 000 to 002)

The PnSEL0 bit selects whether to output the signal in a path that bypasses the amplifier in the PGA for each programmable gain amplifier Pn.

PnSEL1 bit (PGA Pn Amplifier Transit Enable) (n = 000 to 002)

The PnSEL1 bit selects whether to output the signal in a path through the amplifier in the PGA for each programmable gain amplifier Pn.

PnENAMP bit (PGA Pn Amplifier Enable) (n = 000 to 002)

The PnENAMP bit selects whether to use the amplifier in the PGA for each programmable gain amplifier Pn.

PnGEN bit (PGA Pn Input Resistance Side Gain Selection Signal Enable) (n = 000 to 002)

The PnGEN bit enables or disables the gain setting for each programmable gain amplifier Pn.

47.2.34 A/D Programmable Gain Amplifier Gain Setting Register 0 (ADPGAGS0)

Address(es): ADC120.ADPGAGS0 4005 C1A2h, ADC121.ADPGAGS0 4005 C3A2h

Note 1. For details on setting these bits, see section 47.3.12, Programmable Gain Amplifiers.

PnGAIN[3:0] bits (PGA Pn Gain Setting) (n = 000 to 002)

The PnGAIN[3:0] bits specify the gain of each PGA amplifier Pn. For differential inputs (ADPGADCR0.PnDEN = 1 and ADPGACR.PnGEN = 1), these bits set the gain in combination with ADPGADCR0.PnDG[1:0].

47.2.35 A/D Programmable Gain Amplifier Differential Input Control Register (ADPGADCR0)

Address(es): ADC120.ADPGADCR0 4005 C1B0h, ADC121.ADPGADCR0 4005 C3B0h

b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: For details on setting these bits, see section 47.3.12, Programmable Gain Amplifiers.

PnDG[1:0] bits (Pn Differential Input Gain Setting) (n = 000 to 002)

The PnDG[1:0] bits specify the gain of each PGA amplifier Pn when differential inputs are used. These bits are only valid when the PnDEN bit = 1 and the PnGEN bit = 1.

To use the PGA for differential inputs, set the ADPGADCR0.PnDG[1:0] bits in conjunction with the ADPGAGS0.PnGAIN[3:0] bits.

Example: To set the gain to × 1.5 using P000 for differential input, set:
ADPGAGS0.P000GAIN[3:0] = 0001b
ADPGADCR0.P000DG[1:0] = 00b

PnDEN bit (Pn Differential Input Enable) (n = 000 to 002)

The PnDEN bit enables or disables differential inputs for each PGA amplifier Pn.

47.3 Operation

47.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1 by software. In group scan mode, the selected channels in Group A and the selected channels in Group B are scanned once after scan starts in response to the respective synchronous trigger (ELC).

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in Group A selected in the ADANSA0 and ADANSA1 registers first, and then for the ANn channels in Group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan, and one of the three voltages generated internally in the ADC12 is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double-trigger mode can be used with single scan mode or group scan mode. With double-trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in ADSTRGR. Only Group A in group scan mode can use the double-trigger mode.

The extended operation of double-trigger mode means the A/D conversion operation is generated from the synchronous trigger combination. This trigger combination is selected in ADSTRGR.TRSA[5:0] in double-trigger mode. ELC_AD00 and ELC_AD01 are associated with unit 0. ELC_AD10 and ELC_AD11 are associated with unit 1.

In the extended operation of double-trigger mode, in addition to normal double-trigger operation, A/D conversion data from the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) triggers is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data from the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) triggers is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double-trigger mode, when a combination of triggers occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

When one synchronous trigger is input during the A/D conversion started by another synchronous trigger, the subsequent trigger is input when the other A/D conversion is canceled.

When any of the AN000 to AN002 (unit 0), and AN100 to AN102 (unit 1) channels are set as a channel-dedicated sample-and-hold circuit in the SHANS[2:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

47.3.2 Single Scan Mode

47.3.2.1 Basic operation without channel-dedicated sample-and-hold circuits

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).

4. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state.

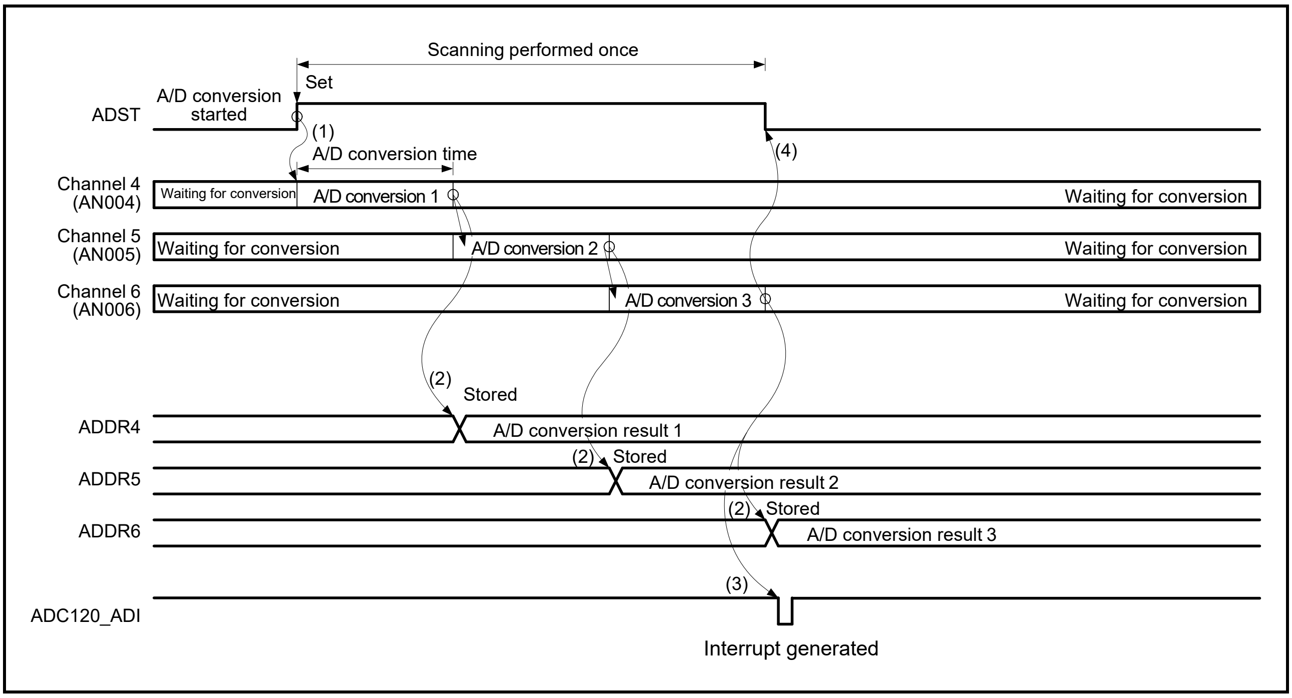

Figure 47.7 Example basic operation in single scan mode when AN004 to AN006 are selected

47.3.2.2 Basic operation with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed once on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state.

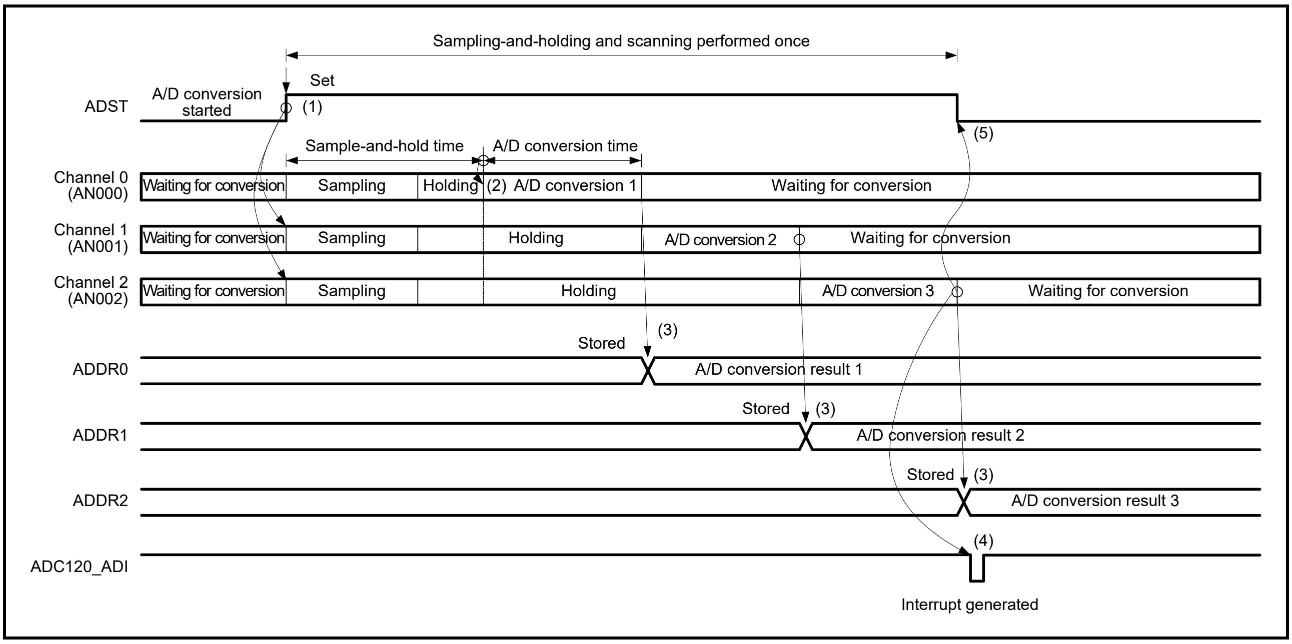

Figure 47.8 **Example operation in single scan mode when the channel-dedicated sample-and-hold circuits are used and AN000 to AN002 are selected**

47.3.2.3 Basic operation with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, and this is followed by A/D conversion once of the analog inputs on all selected channels. The ADSHCR.SHANS[2:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

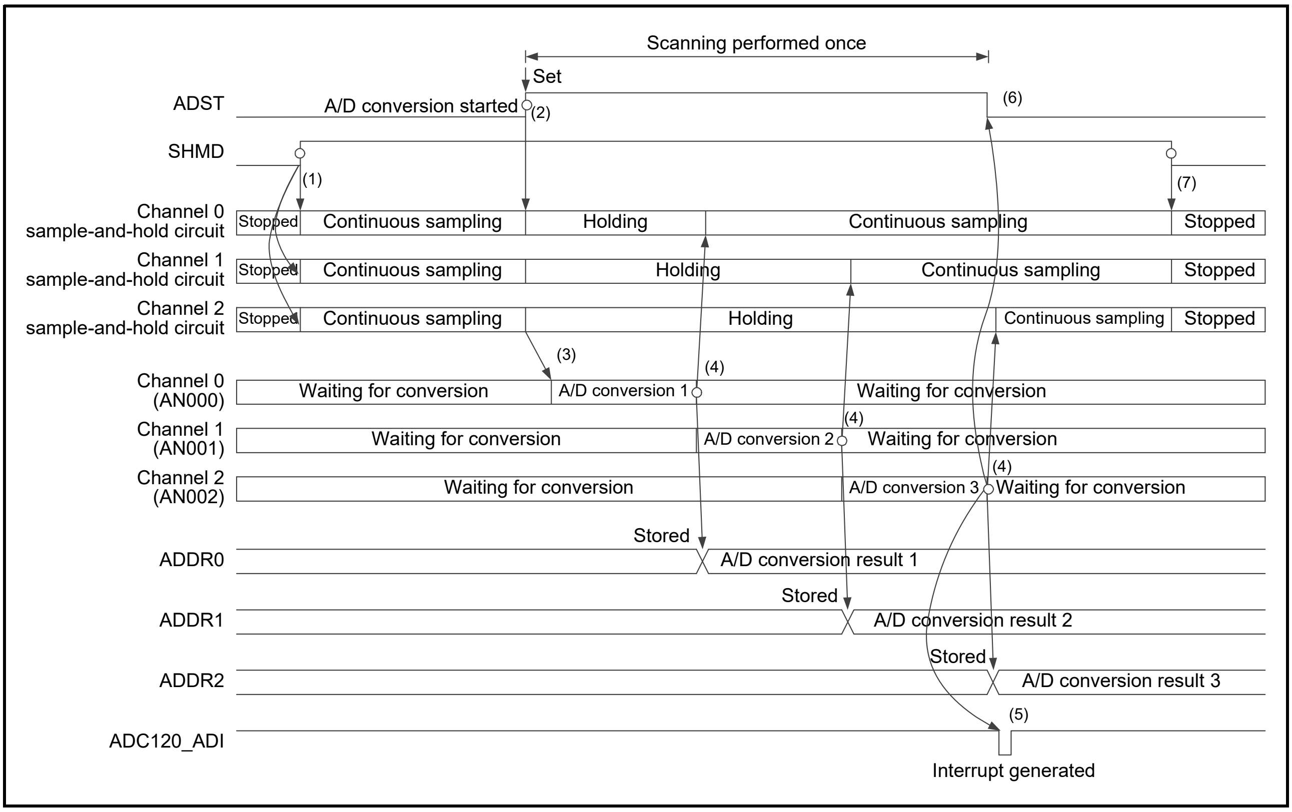

Figure 47.9 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected, and continuous sampling is enabled

47.3.2.4 Channel selection and self-diagnosis without channel-dedicated sample-and-hold circuits

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or VREFH (unit 1) (× 0, × 1/2, or × 1) supplied to the ADC12, and then A/D conversion is performed once on the analog input of the specified channels.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state.

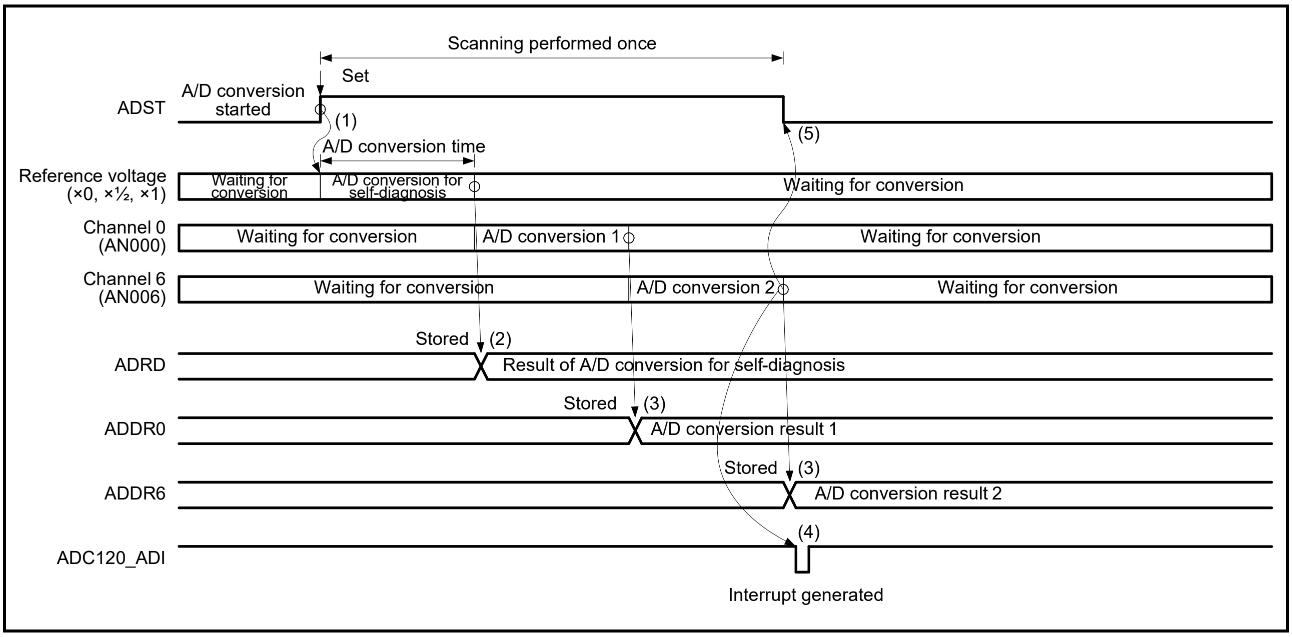

Figure 47.10 Example basic operation in single scan mode when AN000 and AN006 are selected with self-diagnosis

47.3.2.5 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, the sample-and-hold operation is performed first, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) or VREFH (unit 1) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state.

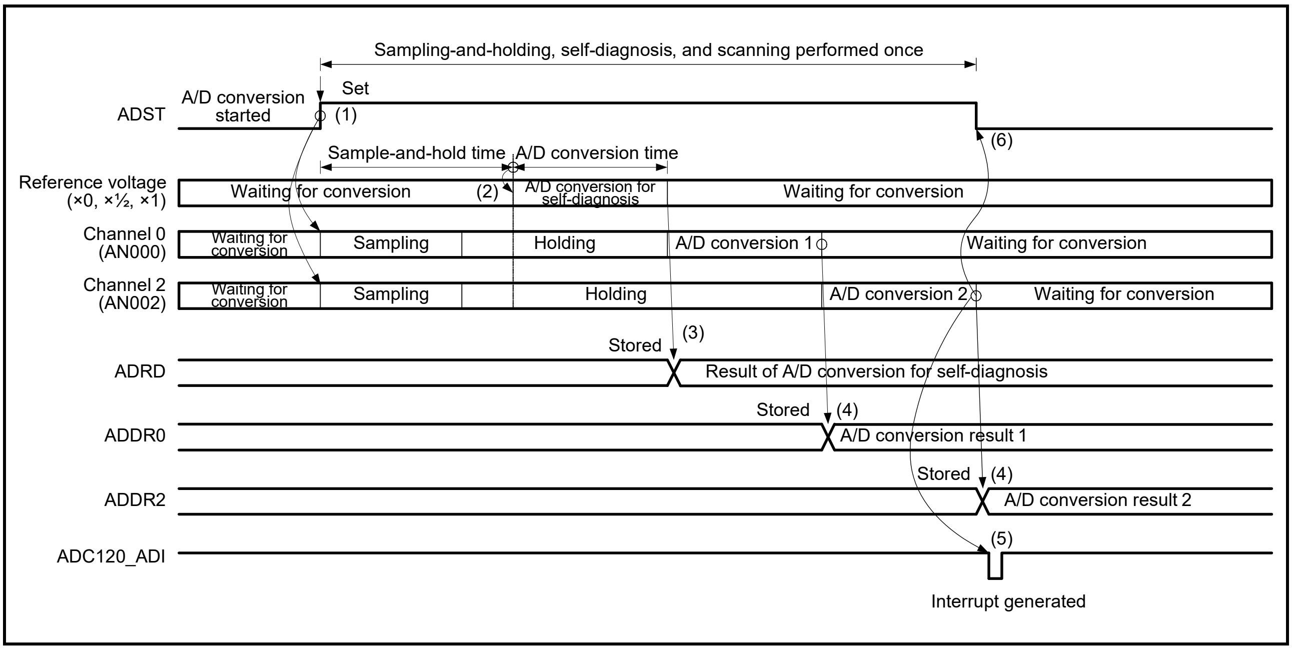

Figure 47.11 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 and AN002 are selected with self-diagnosis, and continuous sampling is disabled

47.3.2.6 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or VREFH (unit 1) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapses after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

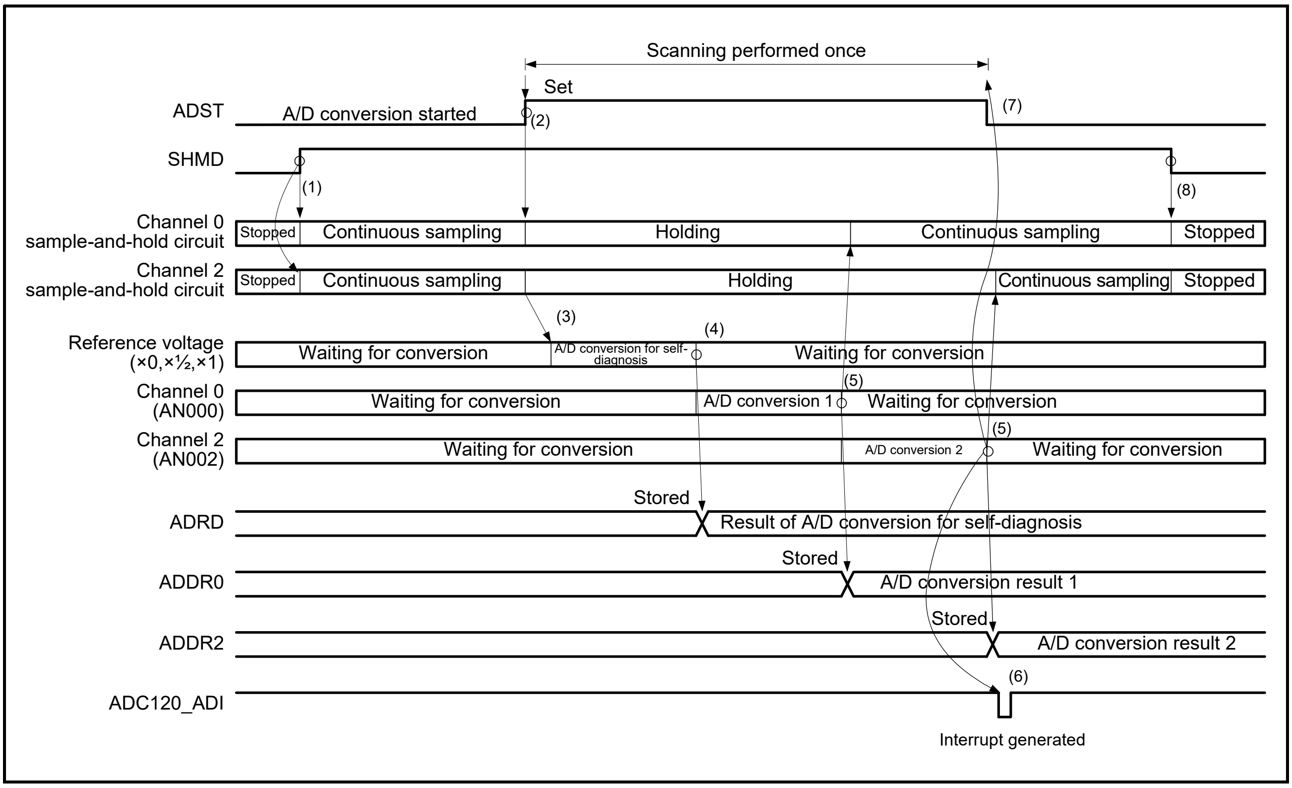

Figure 47.12 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000 to AN002 are selected with self-diagnosis, and continuous sampling is enabled

47.3.2.7 A/D conversion of temperature sensor output or internal reference voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then A/D conversion is performed once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then the ADC12 enters a wait state.

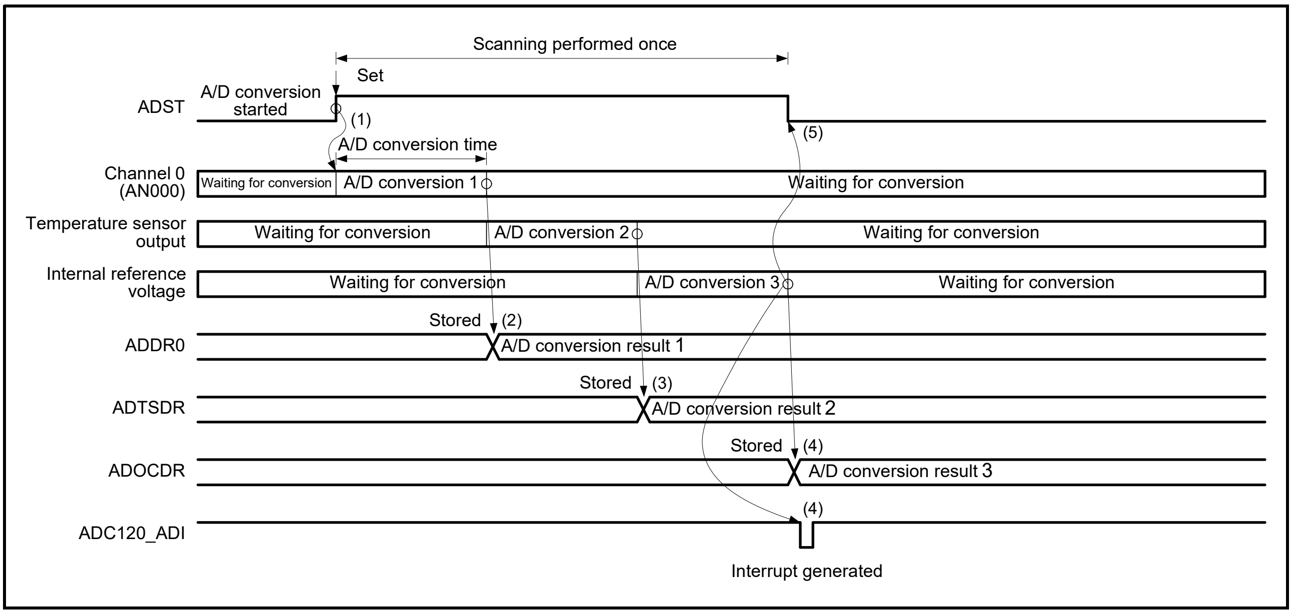

Figure 47.13 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

47.3.2.8 A/D conversion in double-trigger mode

When double-trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.

Deselect self-diagnosis, and set the addition/average mode select bits for both temperature sensor output (ADEXICR.TSSA) and internal reference voltage (ADEXICR.OCSA) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE to 1. When the ADCSR.DBLE is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double-trigger mode, select a synchronous trigger (ELC) using the ADSTRGR.TRSA[5:0] bits, and in ADCSR, set the EXTRG bit to 0 and the TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADST bit is automatically cleared to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
7. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion completes. Then the ADC12 enters a wait state.

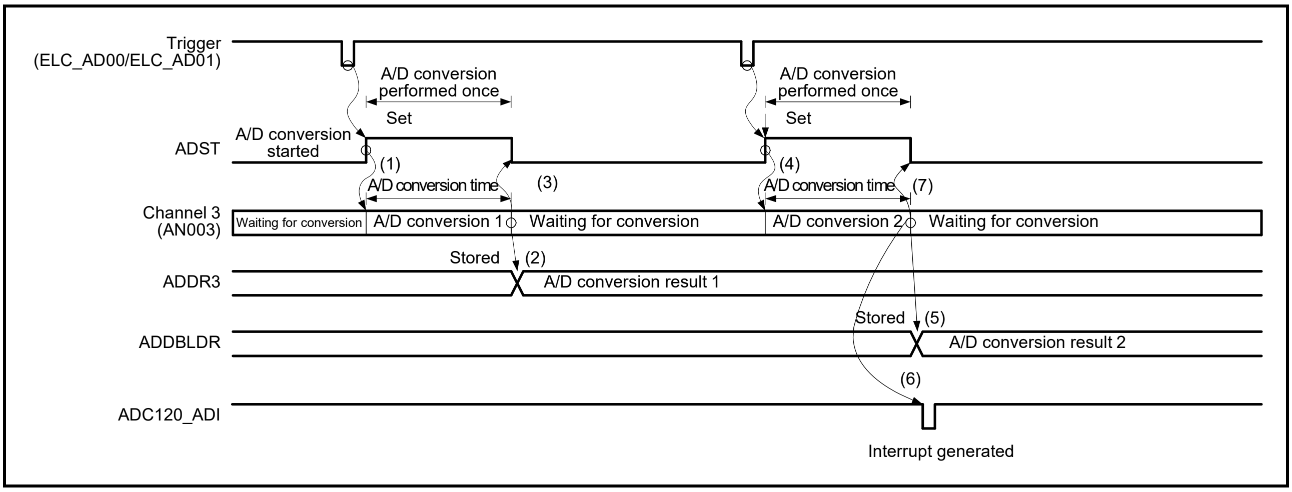

Figure 47.14 **Example operation in single scan mode when double-trigger mode is selected and AN003 is duplicated**

47.3.2.9 Extended operations when double-trigger mode is selected

When double-trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00/ELC_AD01 (unit 0), ELC_AD10/ELC_AD11 (unit 1)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis, and set the addition/average mode select bits for both temperature sensor output (ADEXICR.TSSA and ADEXICR.TSSB) and internal reference voltage (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double-trigger mode, select a synchronous trigger (ELC_AD00/ELC_AD01 (unit 0), ELC_AD10/ELC_AD11 (unit 1)) by setting the ADSTRGR.TRSA[5:0] bits to 0Bh, and in ADCSR, set the EXTRG bit to 0 and the TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC_AD00/ELC_AD01 (unit 0), ELC_AD10/ELC_AD11 (unit 1)), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the trigger of ELC_ADi0 or ELC_ADi1 is input respectively (i=0, 1).
3. The ADCSR.ADST bit is automatically cleared to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input (ELC_AD00/ELC_AD01 (unit 0), ELC_AD10/ELC_AD11 (unit 1)), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the trigger of ELC_ADi0 or ELC_ADi1 is input respectively (i=0, 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically cleared to 0 when A/D conversion completes. Then the ADC12 enters a wait state.

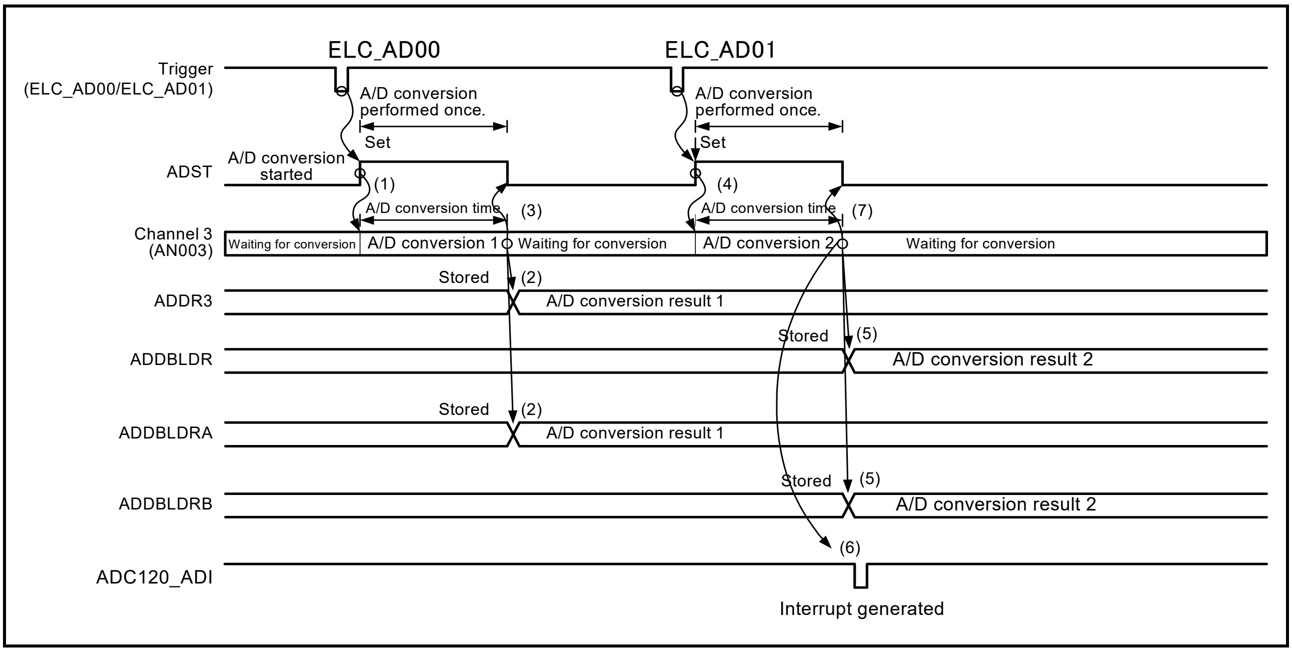

Figure 47.15 **Example extended operation in double-trigger mode (1) when duplication is selected for AN003 and ELC_AD00/ELC_AD01 is selected**

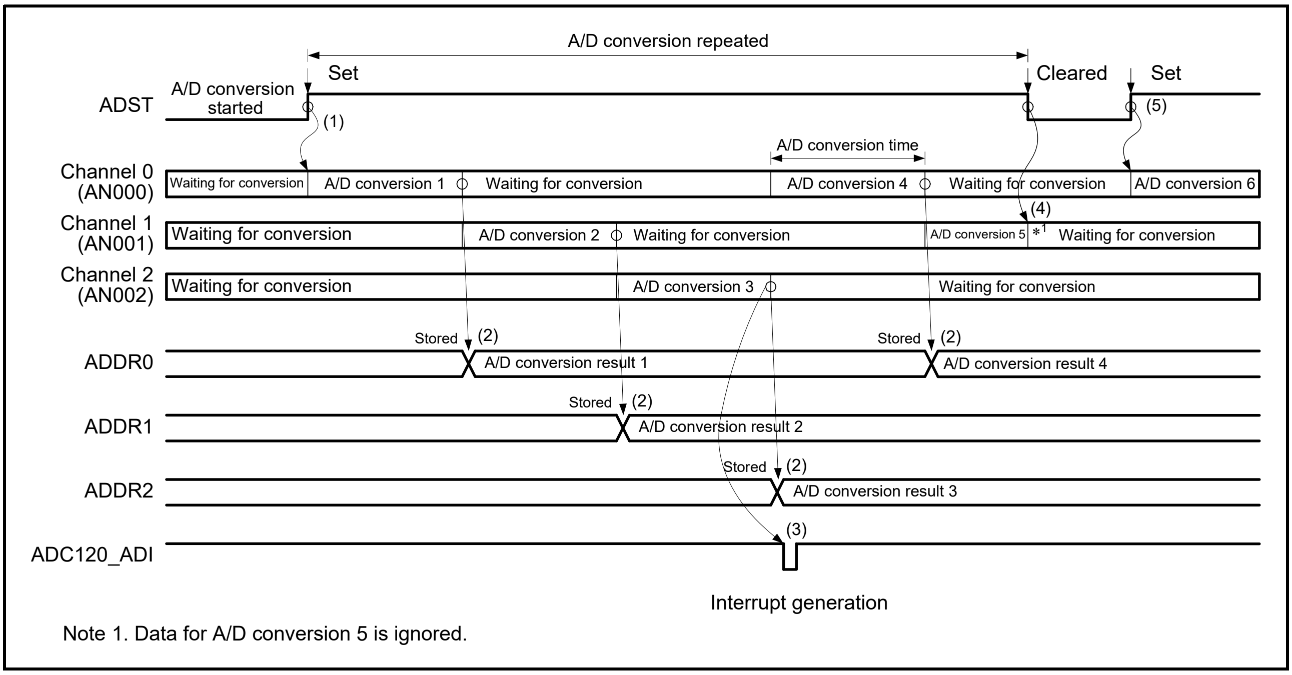
47.3.3 Continuous Scan Mode

47.3.3.1 Basic operation without channel-dedicated sample-and-hold circuits

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0,1) interrupt request is generated (no register setting). The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2 and 3 are repeated as long as the bit remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.



Note 1. Data for A/D conversion 5 is ignored.

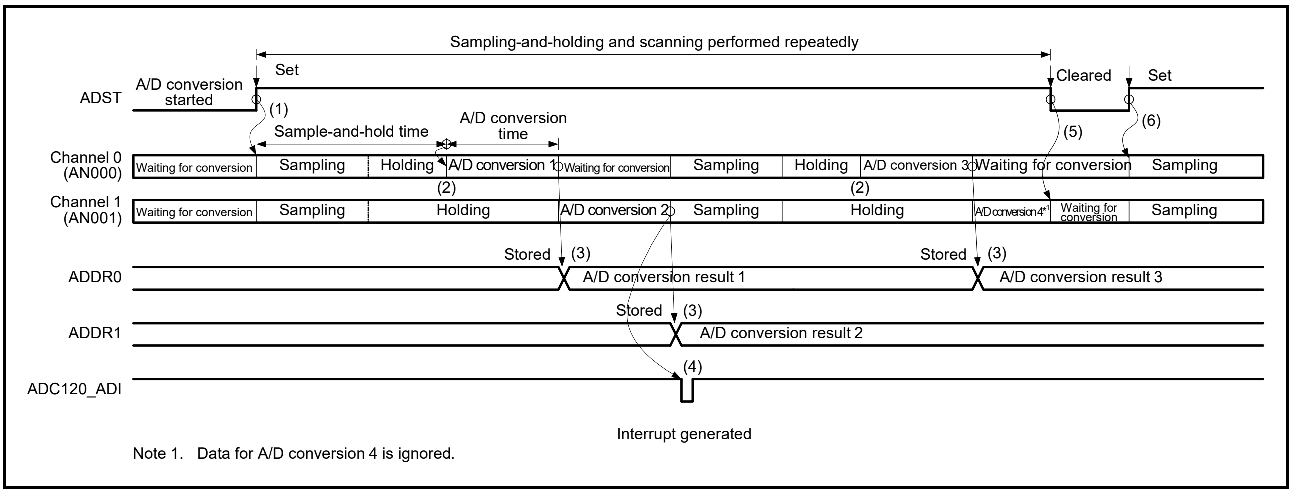
Figure 47.16 **Example basic operation in continuous scan mode when AN000 to AN002 are selected**

47.3.3.2 Basic operation with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When the channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operation is first performed, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[2:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all channels whose dedicated sample-and-hold circuit is to be used.



Note 1. Data for A/D conversion 4 is ignored.

Figure 47.17 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected

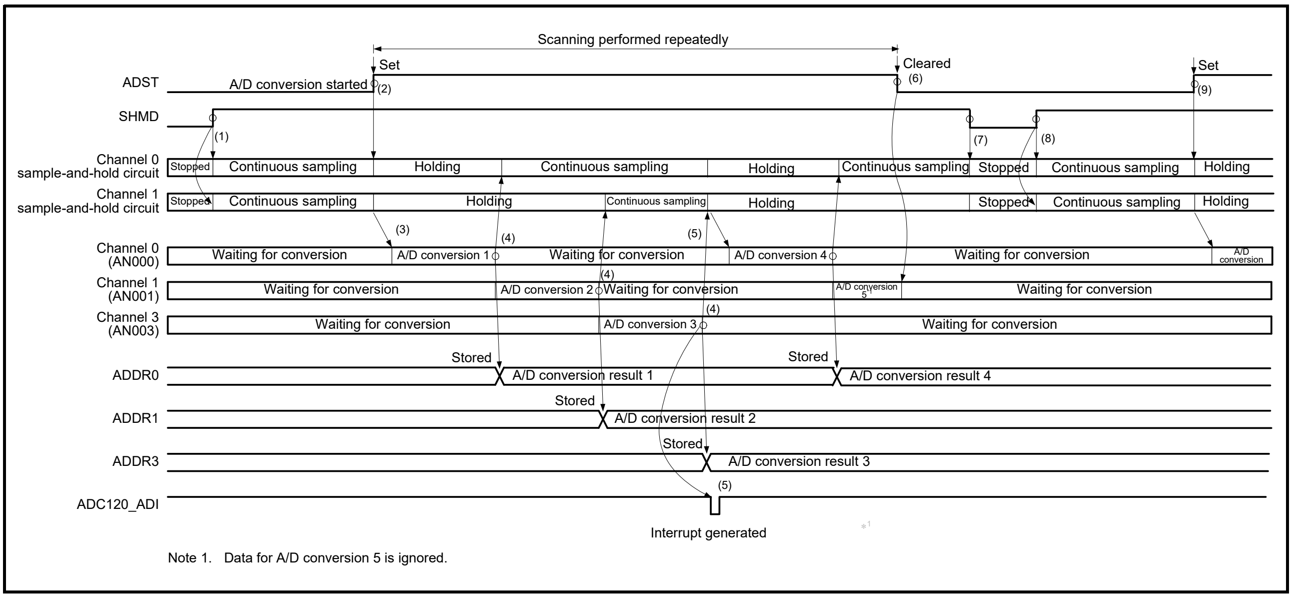
47.3.3.3 Basic operation with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[2:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapses after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only the channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN003 to AN007 and AN016 to AN020, temperature sensor output, and internal reference voltage for unit 0, and AN103, AN105 to AN107 and AN116 to AN119, temperature sensor output, and internal reference voltage for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).



Note 1. Data for A/D conversion 5 is ignored.

Figure 47.18 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN003 are selected, and continuous sampling is enabled

47.3.3.4 Channel selection and self-diagnosis without channel-dedicated sample-and-hold circuits

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or VREFH (unit 1) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting). At the same time, the ADC12 starts A/D conversion for self-diagnosis and then starts A/D conversion on ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then the ADC12 enters a wait state.

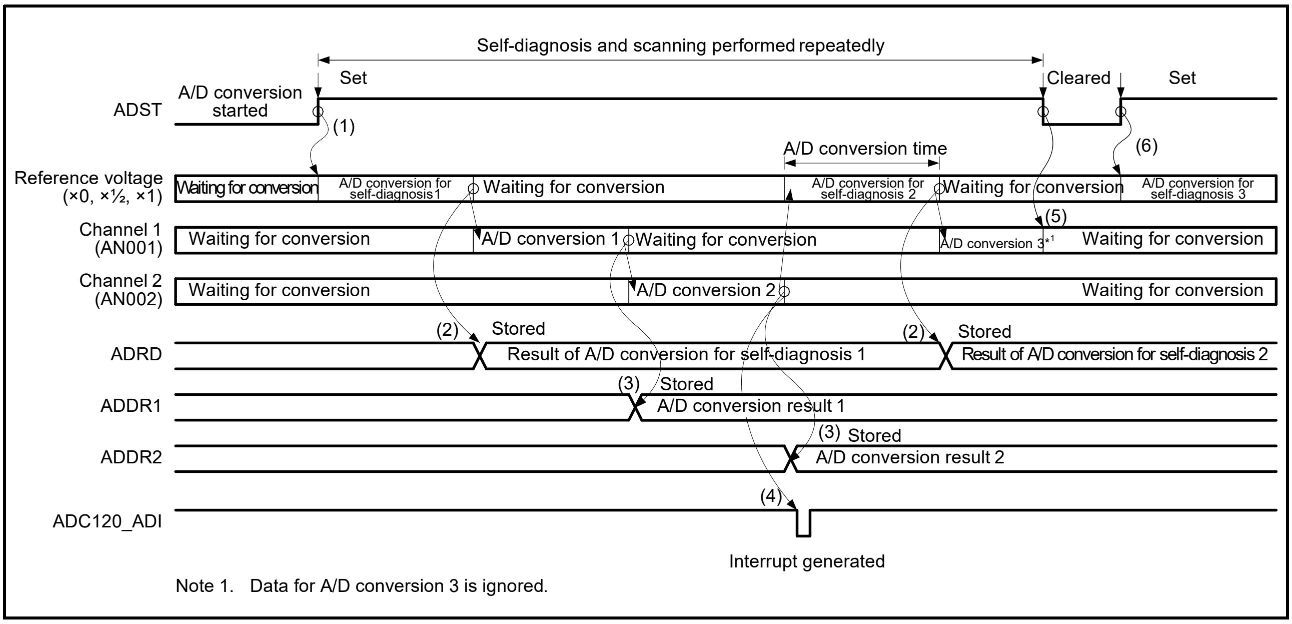


Figure 47.19 Example basic operation in continuous scan mode when AN001 and AN002 are selected with self-diagnosis

47.3.3.5 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling disabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and- hold operation is first performed, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) or VREFH (unit 1) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (ELC), or asynchronous trigger input.
2. After sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
6. The ADST bit is not automatically cleared, and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all channels whose dedicated sample-and-hold circuit is to be used.

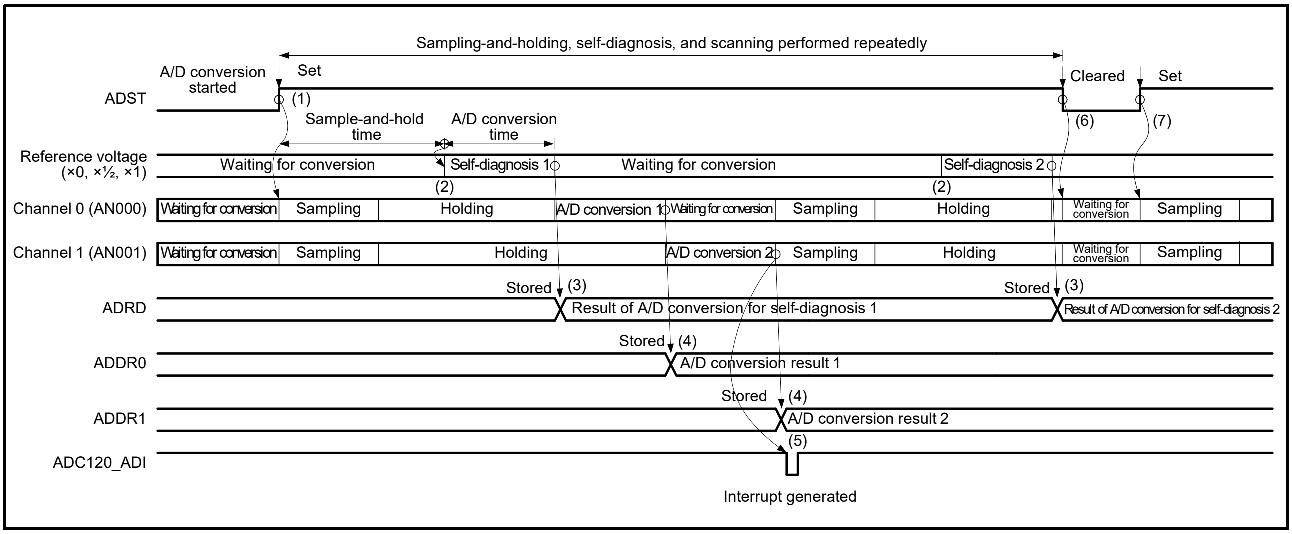

Figure 47.20 **Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected with self-diagnosis**

47.3.3.6 Channel selection and self-diagnosis with channel-dedicated sample-and-hold circuits and continuous sampling enabled

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operation is first performed, and this is followed by A/D conversion of the reference voltage VREFH0 (unit 0) or VREFH (unit 1) (×0, ×1/2, or ×1) supplied to the ADC12. After that, A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapses after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
7. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
9. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[2:0] bits start continuous sampling.
10. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

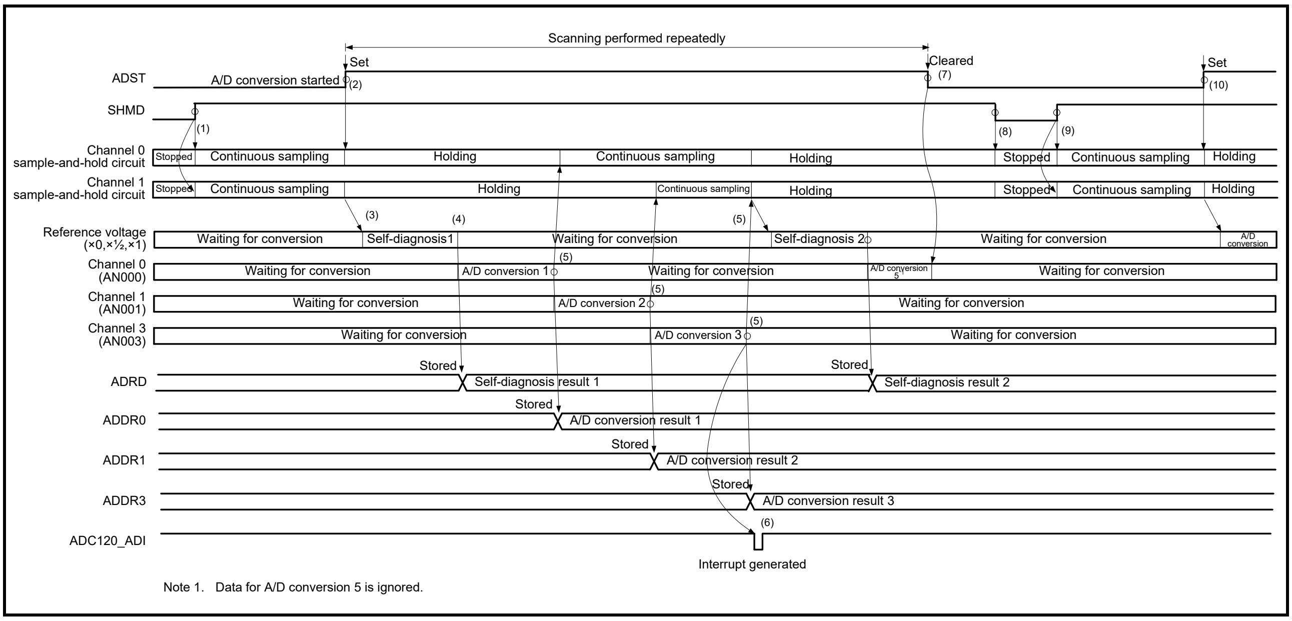

Figure 47.21 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN003 are selected with self-diagnosis, and continuous sampling is enabled

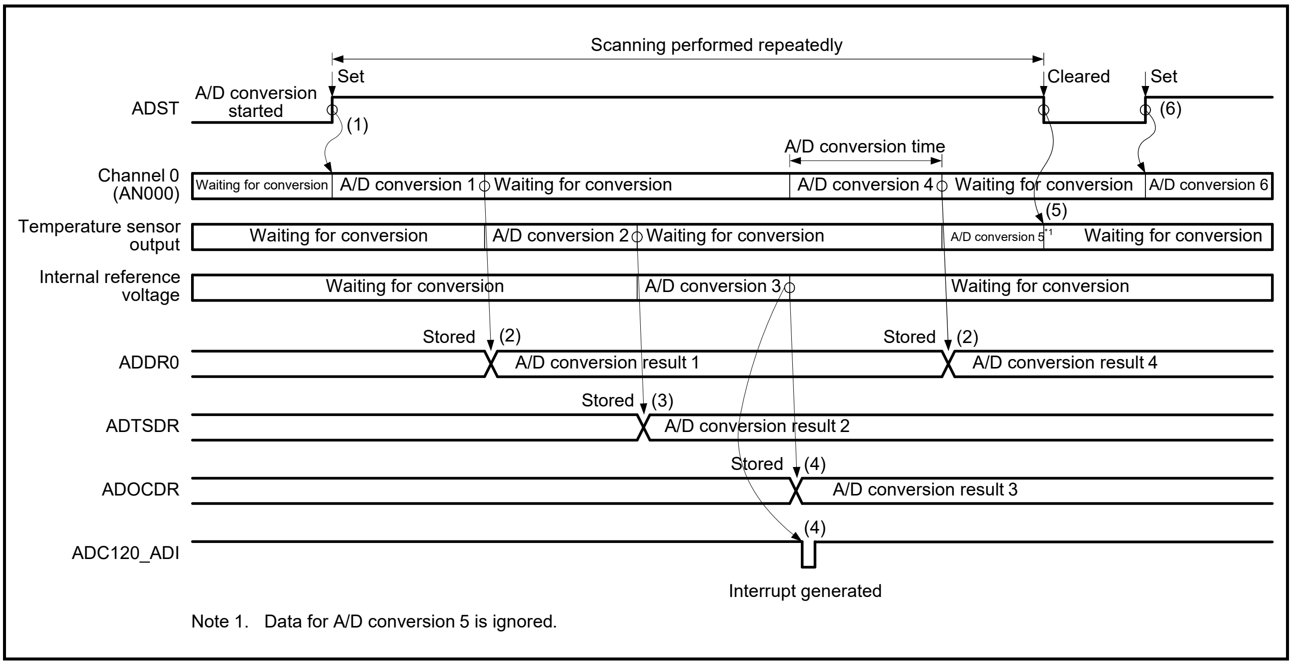
47.3.3.7 A/D conversion of temperature sensor output or internal reference voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.



Note 1. Data for A/D conversion 5 is ignored.

Figure 47.22 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

47.3.4 Group Scan Mode

47.3.4.1 Basic operation

In group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in Group A and Group B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for Group A and in the ADSTRGR.TRSB[5:0] bits for Group B. Use different triggers for Group A and Group B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The Group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits, while the Group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and Group B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and Group B.

The following describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 and ELC_AD01 (unit 0), and ELC_AD10 and ELC_AD11 (unit 1) triggers from the ELC are used to start conversion of Group A and Group B, respectively. Also, ELC_AD00 and ELC_AD01 (unit 0), and ELC_AD10 and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of Group A is started by ELC_AD00 (unit 0) or ELC_AD10 (unit 1).
2. When Group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of Group B is started by ELC_AD01 (unit 0) or ELC_AD11 (unit 1).
4. When Group B scanning completes, an ADC12i_GBADI interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI interrupt when scanning completion is enabled).

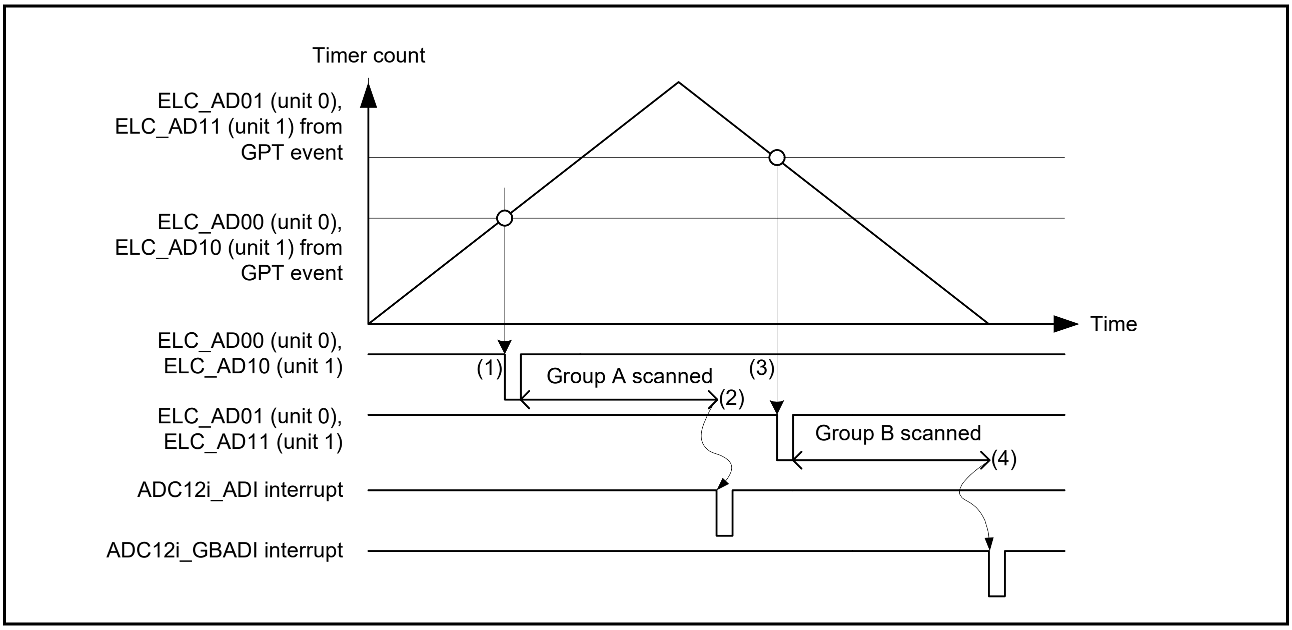


Figure 47.23 Example basic operation in group scan mode when synchronous triggers from the ELC are used

47.3.4.2 A/D conversion in double-trigger mode

When double-trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for Group A. For Group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous triggers can be selected in the TRSA[5:0] bits in ADSTRGR for Group A and in the TRSB[5:0] bits in ADSTRGR for Group B. Use different triggers for Group A and Group B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger (ADTRGn).

When ELC_AD00/ELC_AD01 (unit 0), ELC_AD10/ELC_AD11 (unit 1) is selected as the Group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0Bh, operation proceeds in extended double-trigger mode.

The channels to be A/D-converted are selected in the DBLANS[4:0] bits in the ADCSR register for Group A and in the ADANSB0 and ADANSB1 registers for Group B. The same channels cannot be selected for both groups.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected). Self-diagnosis cannot be selected when double-trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the DBLE bit in ADCSR to 1.

The following describes operation in group scan mode with double-trigger mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 and ELC_AD01 (unit 0), ELC_AD10 and ELC_AD11 (unit 1) triggers from the ELC are used to start conversion of Group A and Group B, respectively. Also, ELC_AD00 and ELC_AD01 (unit 0), ELC_AD10 and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of Group B is started by the ELC_AD00 (unit 0) or ELC_AD10 (unit 1) trigger from the ELC.
2. When Group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI interrupt when scanning completion is enabled).
3. The first scan of Group A is started by the first ELC_AD01 (unit 0) or ELC_AD11 (unit 1) trigger.
4. When the first scan of Group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC12i_ADI interrupt request is not generated, regardless of the ADIE bit setting in ADCSR.
5. The second scan of Group A is started by the second ELC_AD01 (unit 0) or ELC_AD11 (unit 1) trigger.

6. When the second scan of Group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI interrupt is generated.

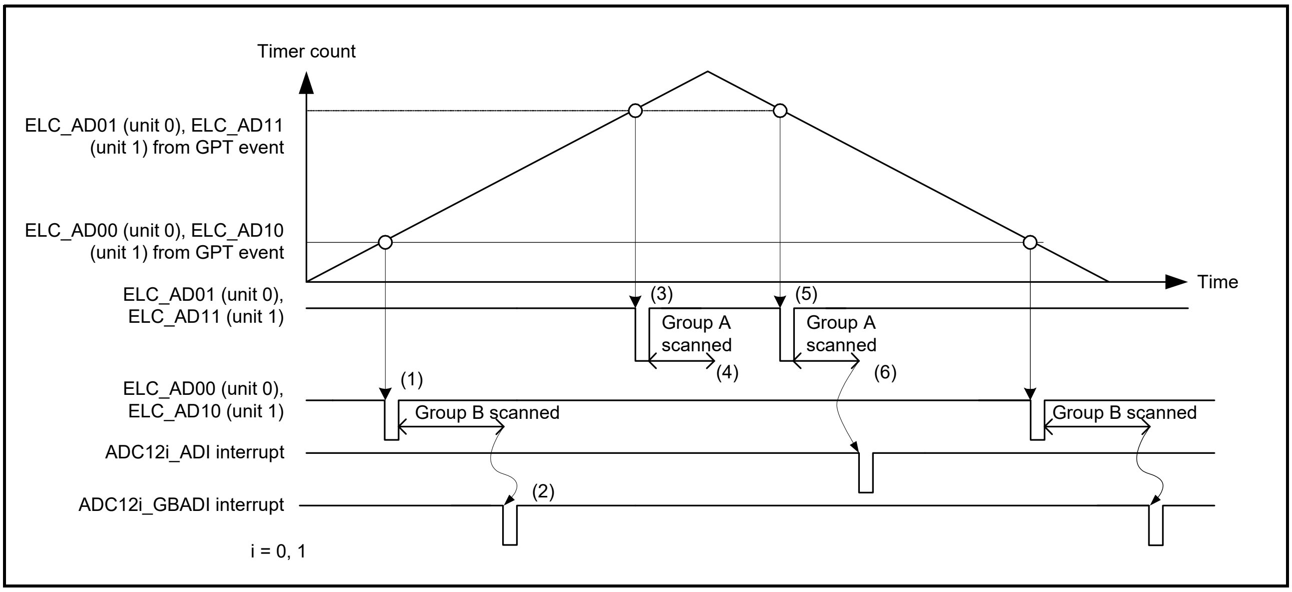

Figure 47.24 **Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used**

47.3.4.3 Operation with group A priority control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under Group A priority control. When setting the PGS bit in the ADGSPCR register to 1, follow the procedure shown in Figure 47.25. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

In basic group scan mode, while A/D conversion is underway for group A or group B, input of the trigger for A/D conversion for the other group is ignored. Under Group A priority control, if a Group A trigger is input during A/D conversion for Group B, A/D conversion for Group B is discontinued and A/D conversion for Group A proceeds. If the setting in the ADGSPCR.GBRSCN bit is 0, the ADC12 enters wait state on completion of the A/D conversion for Group A. If the setting in the ADGSPCR.GBRSCN bit is 1, the ADC12 automatically restarts scanning for Group B from the head of the group after completion of the A/D conversion for Group A. Table 47.9 summarizes operations in response to the input of a trigger during A/D conversion with the settings in the ADGSPCR.GBRSCN bit.

Scan operations in Group A or Group B are the same in single scan mode. Additionally, single scanning continues to proceed if the ADGSPCR.GBRP bit is set to 1 during scanning operations for Group B.

For the trigger settings in group scan mode, select a synchronous trigger for Group A using the ADSTRGR.TRSA[5:0] bits, and select a synchronous trigger for Group B, different from that of Group A, using the ADSTRGR.TRSB[5:0] bits. Set the ADSTRGR.TRSB[5:0] bits to 3Fh when setting the ADGSPCR.GBRP bit to 1.

Additionally, as targets for A/D conversion, select channels for Group A using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits, and for Group B, select channels different from those for Group A using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits.

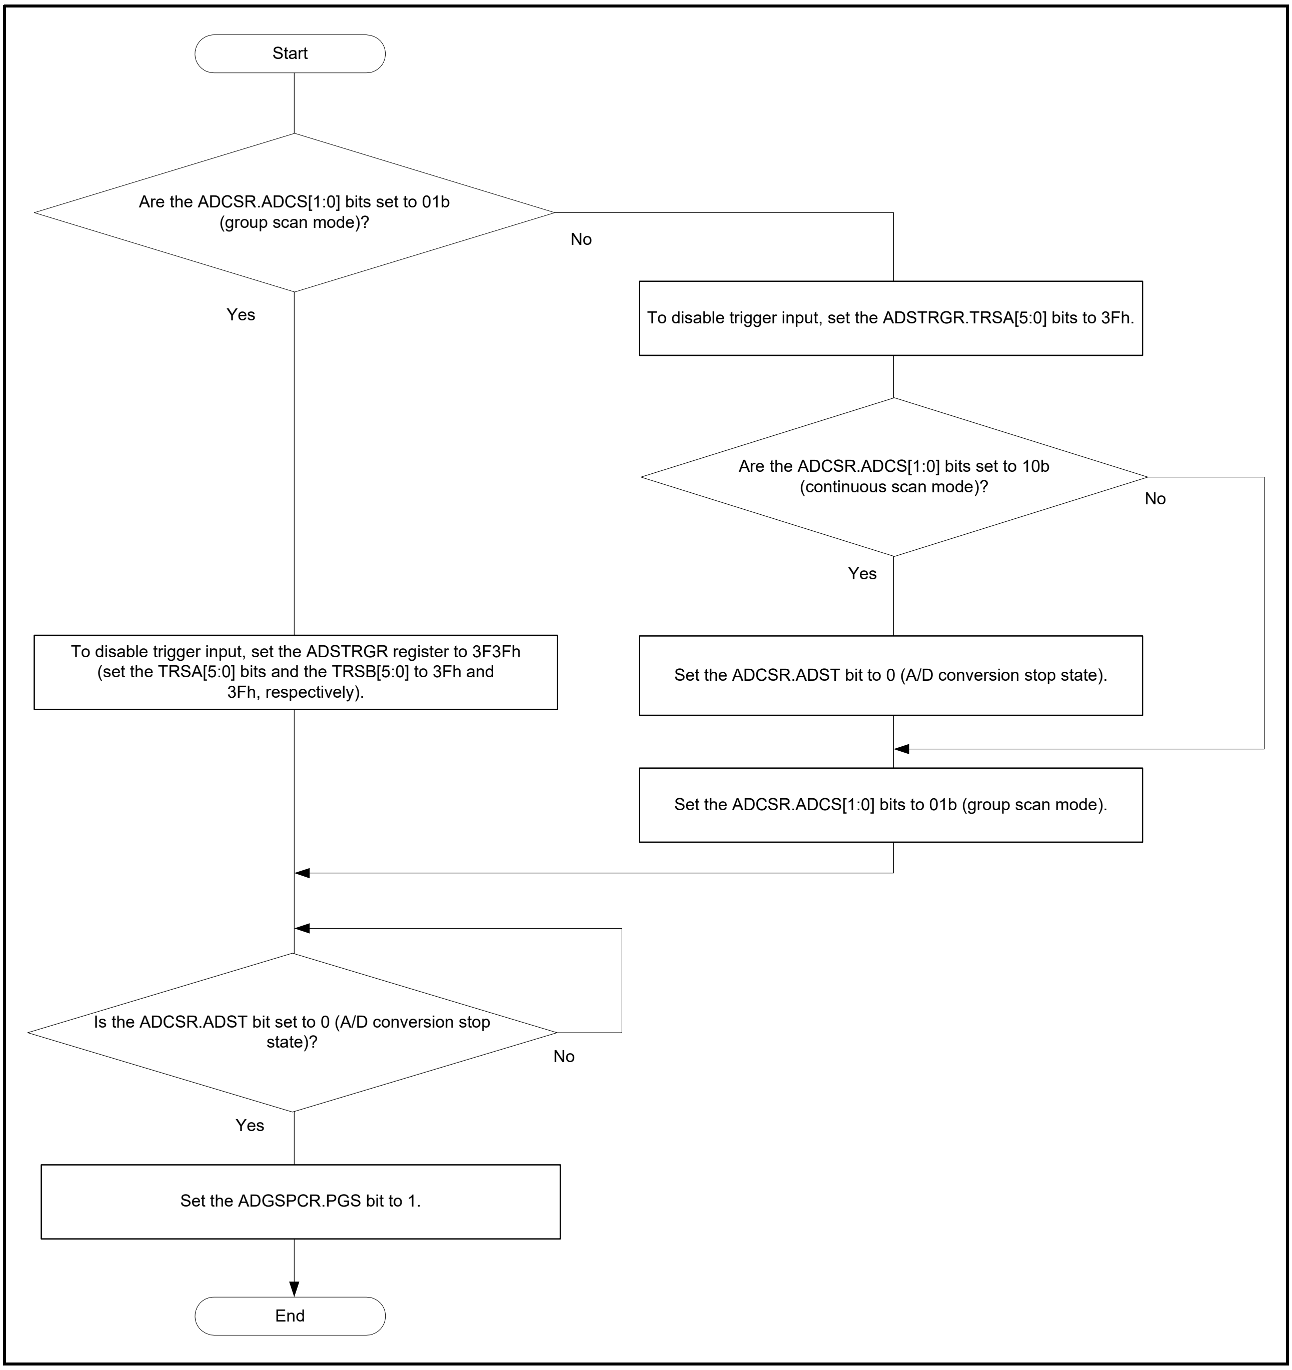

Figure 47.25 Flow for ADGSPCR.PGS bit setting

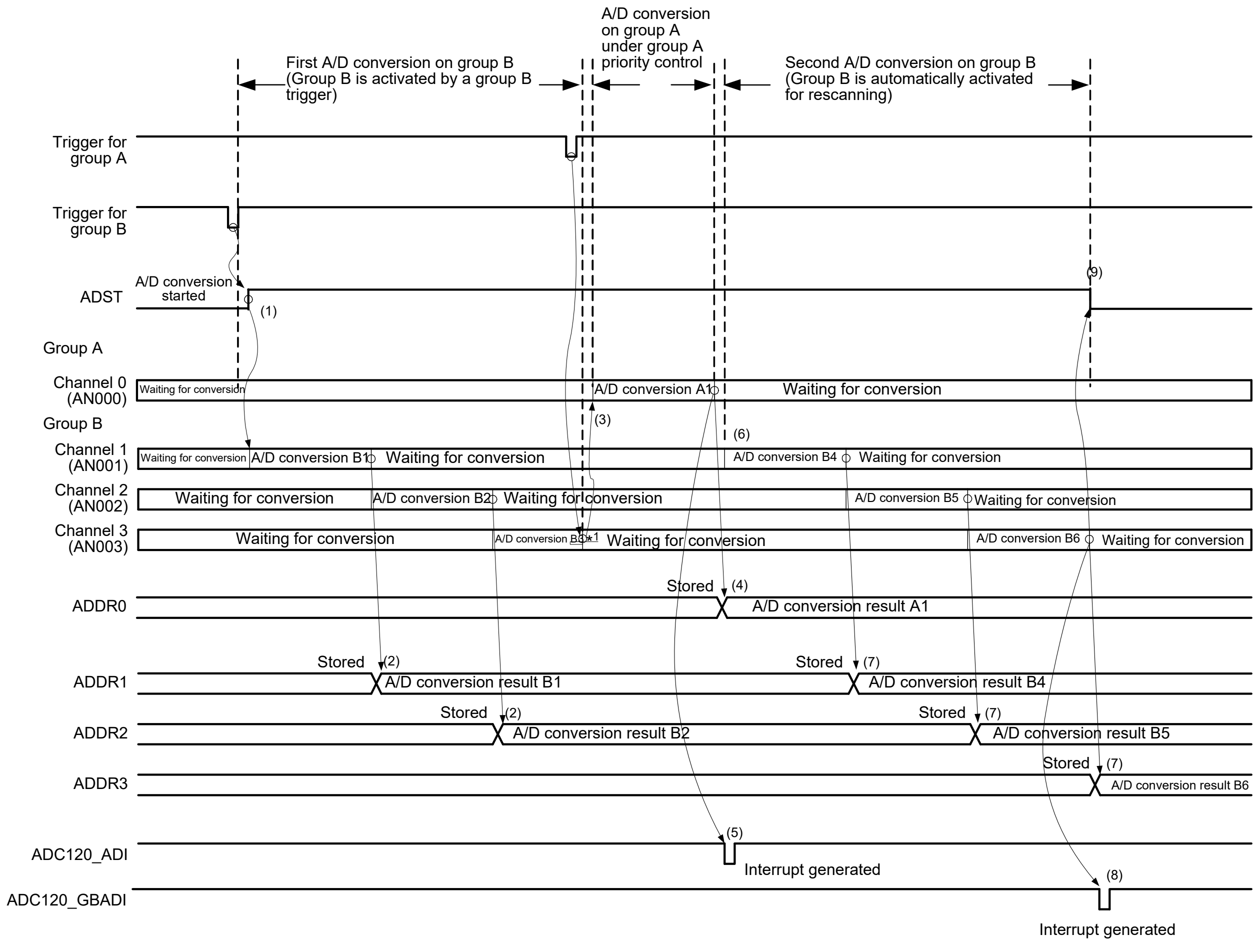
Table 47.9 Control of A/D conversion operations based on the ADGSPCR.GBRSCN bit settings

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for Group A is in progress	Input of Group A trigger	Trigger input is invalid	Trigger input is invalid
	Input of Group B trigger	Trigger input is invalid	Group B is converted after Group A conversion completes
When A/D conversion for Group B is in progress	Input of Group A trigger	Group B conversion stops and Group A conversion starts	• Group B conversion stops and Group A conversion starts • Group B Conversion starts after Group A conversion completes
	Input of Group B trigger	Trigger input is invalid	Trigger input is invalid

The following describes the operations in group scan mode under Group A priority control (ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0) when channel 0 is selected for Group A and channels 1 to 3 are selected for Group B.

The operation is as follows:

1. When input of a trigger for Group B sets the ADCSR.ADST bit to 1 (A/D conversion start), conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n.
2. On completion of A/D conversion, the result is stored in the associated A/D Data Register y (ADDRy).
3. When a group A trigger is input while A/D conversion for group B is in progress, and A/D conversion for group B is discontinued with the ADCSR.ADST bit remains 1, A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest number n. If A/D conversion are not complete when conversion of group B is interrupted, A/D conversion result is not stored in the A/D Data Register (ADDRy).
4. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
5. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
6. A/D conversion for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers restarts in order from the channel with the smallest number n with the ADCSR.ADST bit remains 1.
7. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
8. An ADC12i_GBADI interrupt request is generated if the setting in the ADCSR.GBADIE bit is 1 (ADC12i_GBADI interrupt when Group B scanning completion is enabled).
9. The ADCSR.ADST bit is automatically cleared and ADC12 enters the wait state when A/D conversion completes.



Note 1. Converted data from A/D conversion B3 is ignored.

Figure 47.26 Example operation with Group A priority control (1), when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0

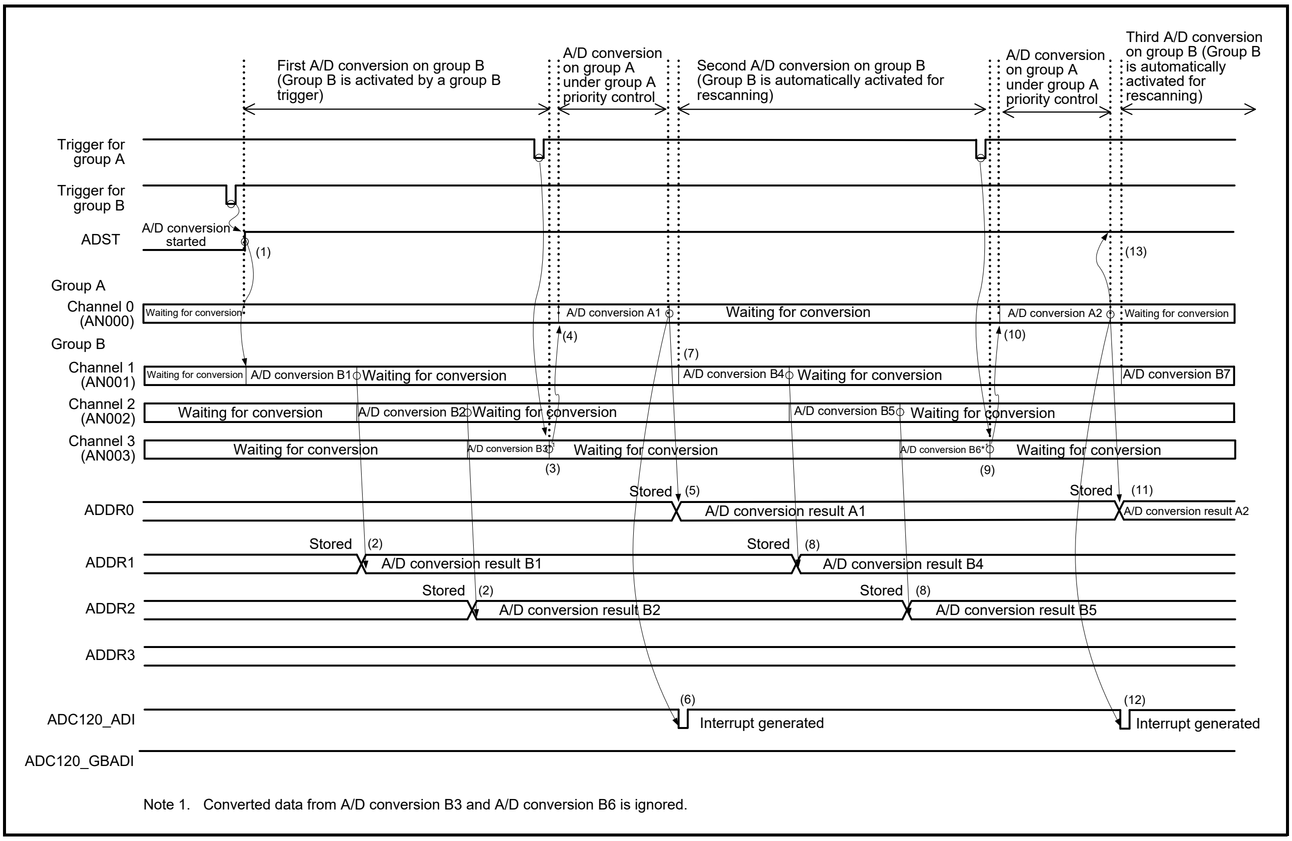
This section provides an example operation when a Group A trigger is input again during rescanning operation on Group B. In this example, channel 0 is selected for Group A and channels 1 to 3 are selected for Group B when operation on Group A is given priority (ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0).

The operation is as follows:

1. When a Group B trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), conversion for the ANn channels in Group B selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n.
2. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
3. When a group A trigger is input while A/D conversion for group B is in progress, and A/D conversion for group B is discontinued with the ADCSR.ADST bit remains 1. If A/D conversion are not complete when the conversion of group B is interrupted, A/D conversion result is not stored in the A/D Data Register (ADDRy).
4. A/D conversion for the ANn Group A channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest number n.
5. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
7. If the ADGSPCR.GBRSCN bit is 1 when the A/D conversion of group A completes, the ADCSR.ADST bit remains

1 and group B is rescanned. A/D conversion for the ANn group B channels selected in the ADANSB0 and ADANSB1 registers starts again in order from the channel with the smallest number n.

8. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
9. If a group A trigger is input during A/D conversion on group B for rescanning, the ADCSR.ADST bit remains 1 and the ongoing A/D conversion on group B is discontinued.
10. The ADCSR.ADST bit is set to 1 automatically, and A/D conversion for the ANn Group A channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest number n.
11. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
12. An ADC12i_ADI interrupt request is generated (no register setting).
13. If the ADGSPCR.GBRSCN bit is 1 when A/D conversion of group A are complete, the ADCSR.ADST bit remains 1 and group B is rescanned. A/D conversion for the ANn group B channels selected in the ADANSB0 and ADANSB1 registers starts again in order from the channel with the smallest number n.
14. If a Group A trigger is input during A/D conversion on Group B for rescanning, steps 9 to 13 are repeated. If a Group A trigger is not input, the ADCSR.ADST bit is cleared automatically on completion of A/D conversion on Group B and ADC12 enters a wait state.



Note 1. Converted data from A/D conversion B3 and A/D conversion B6 is ignored.

Figure 47.27 Example operation with Group A priority control (2), when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0

This section provides an example of a rescanning operation in which a Group B trigger is input during A/D conversion on Group A. In this example, channels 1 to 3 are selected for Group A and channel 0 is selected for Group B when operation on Group A is given priority (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

The operation is as follows:

1. When input of a trigger for Group A sets the ADCSR.ADST bit to 1 (A/D conversion start), conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest

number n.

2. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
3. If a Group B trigger is input during A/D conversion on Group A, A/D conversion on Group B can be performed after the A/D conversion on Group A completes. (However, if Group A triggers are input continuously, the scan operation on Group B is canceled by Group A and is not performed.)
4. On completion of the A/D conversion on Group A, an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. On completion of group A conversion, the ADCSR.ADST bit remains 1 and group B is rescanned. Next, A/D conversion for the ANn channels of group B selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n.
6. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
7. On completion of the rescanning operation on Group B, an ADC12i_GBADI interrupt request is generated if the setting in the ADCSR.GBADIE bit is 1 (ADC12i_GBADI interrupt when scanning completion is enabled).
8. The ADCSR.ADST bit is automatically cleared and ADC12 enters the wait state when A/D conversion completes.

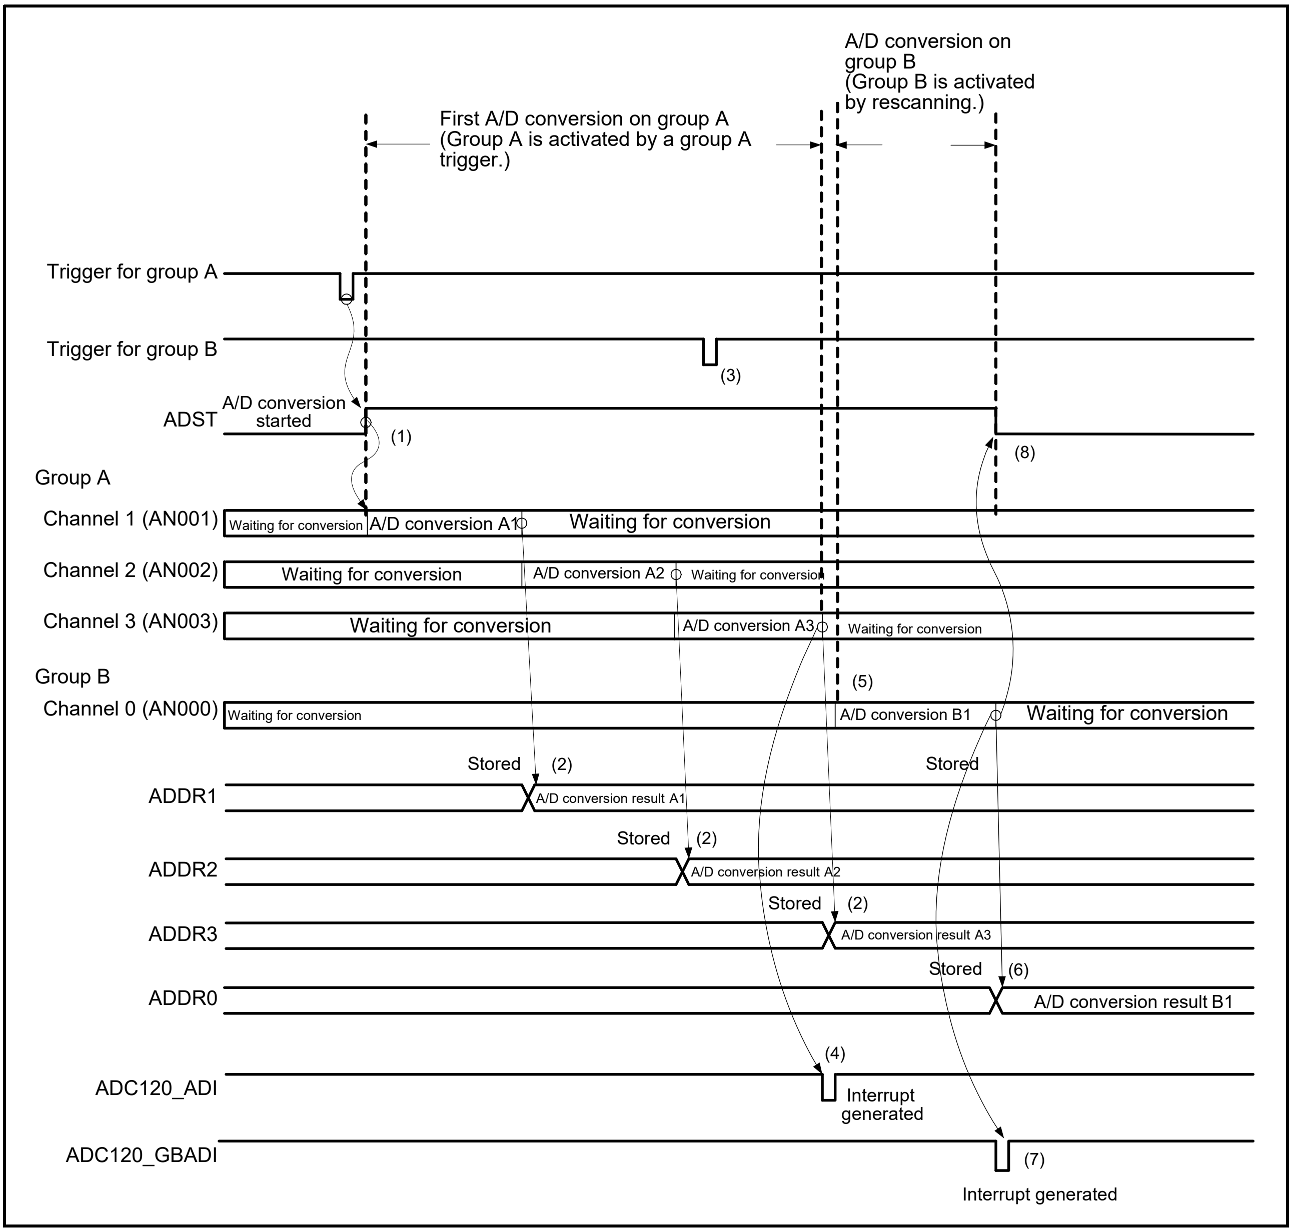


Figure 47.28 Example operation with Group A priority control (3), when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0

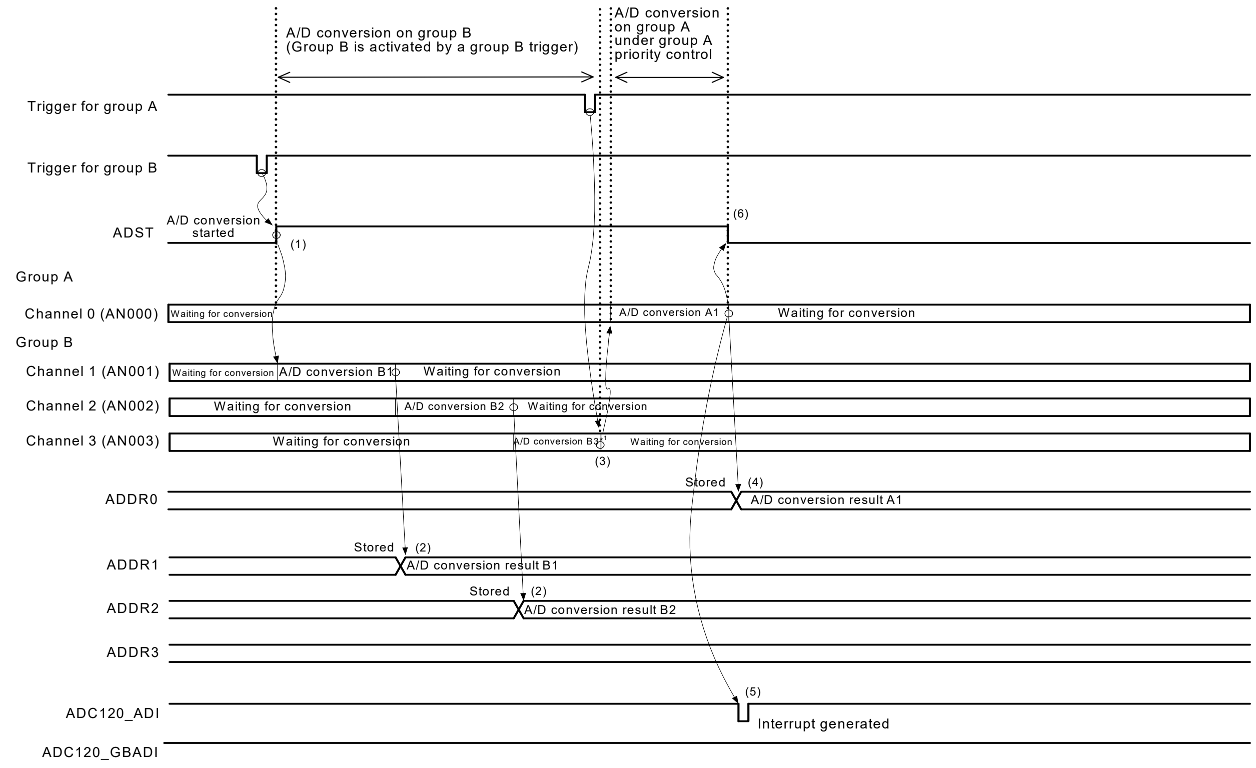
This section provides an example of operation under Group A priority control in which channel 0 is selected for Group A and channels 1 to 3 are selected for Group B (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0).

The operation is as follows:

1. When input of a trigger for Group B sets the ADCSR.ADST bit to 1 (A/D conversion start), conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n.
2. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
3. If a group A trigger is input while A/D conversion for group B is in progress, and A/D conversion for group B is discontinued with the ADCSR.ADST bit remains 1. Next, A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest number n.
4. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).

5. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit is automatically cleared and ADC12 enters the wait state when A/D conversion completes.



Note 1. Converted data of A/D conversion B3 is ignored.

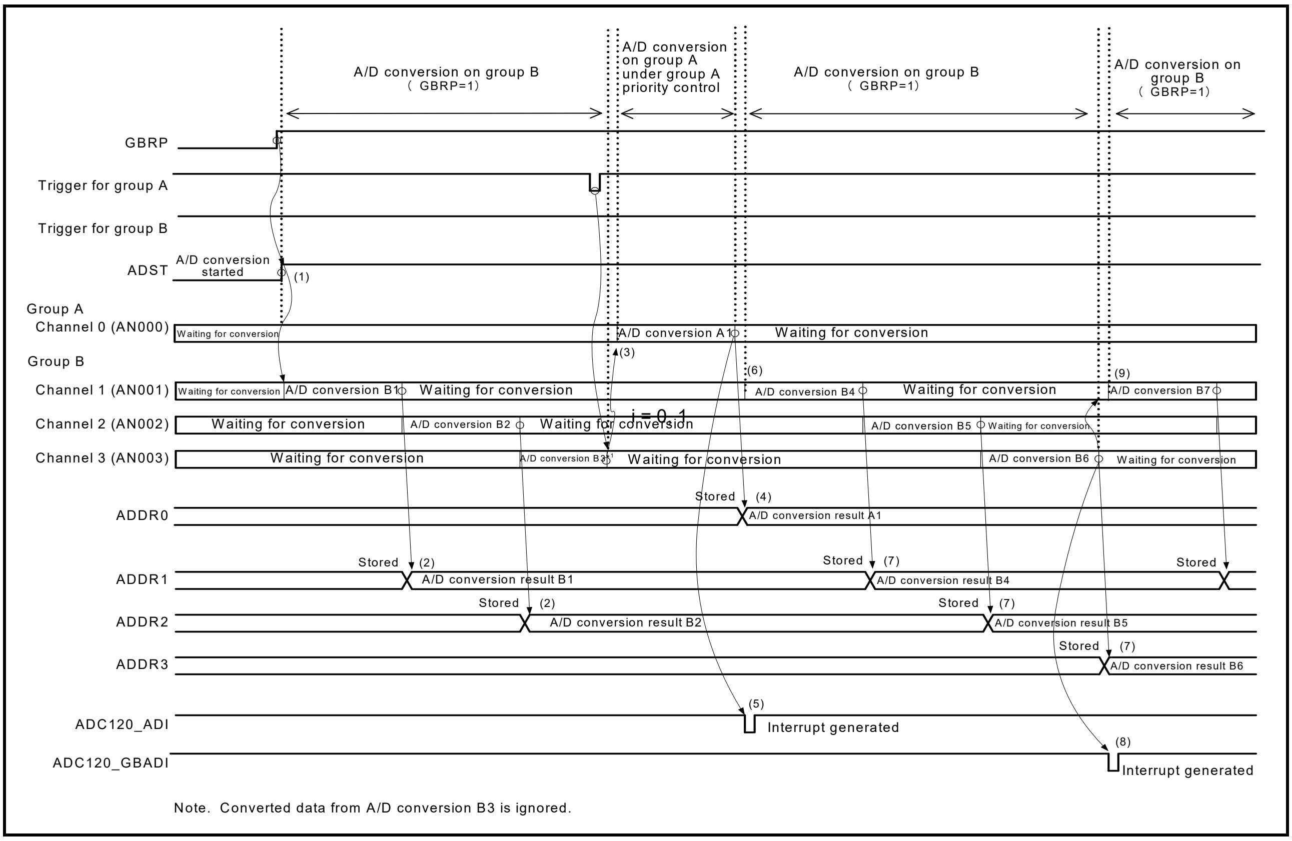
Figure 47.29 Example operation with Group A priority control (4), when ADGSPCR.GBRSCN = 0 and ADGSPCR.GBRP = 0

This section provides an example of operation under Group A priority control in which channel 0 is selected for Group A and channels 1 to 3 are selected for Group B (ADGSPCR.GBRP = 1).

The operation is as follows:

1. The ADCSR.ADST bit is set to 1 (A/D conversion start) when ADGSPCR.GBRP is set to 1, and conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n.
2. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
3. If a group A trigger is input while A/D conversion for group B is in progress, and A/D conversion for group B is discontinued with the ADCSR.ADST bit remains 1. Next, A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers starts in order from the channel with the smallest number n.
4. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
5. An ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
6. A/D conversion for the ANn channels in group B selected in the ADANSB0 and ADANSB1 registers restarts in order from the channel with the smallest number n and with the ADCSR.ADST bit remains 1.
7. On completion of A/D conversion on a single channel, the result is stored in the associated A/D Data Register y (ADDRy).
8. An ADC12i_GBADI interrupt request is generated if the setting in the ADCSR.GBADIE bit is 1.

9. A/D conversion for the ANn channels selected in the ADANSB0 and ADANSB1 registers starts in order from the channel with the smallest number n. Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1. Follow the procedure for clearing the ADCSR.ADST bit operation by software, shown in Figure 47.40, to force A/D conversion to stop while ADGSPCR.GBRP = 1.



Note. Converted data from A/D conversion B3 is ignored.

Figure 47.30 Example operation with Group A priority control (5), when ADGSPCR.GBRP = 1

47.3.5 Compare Function for Windows A and B

47.3.5.1 Compare function windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double-trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

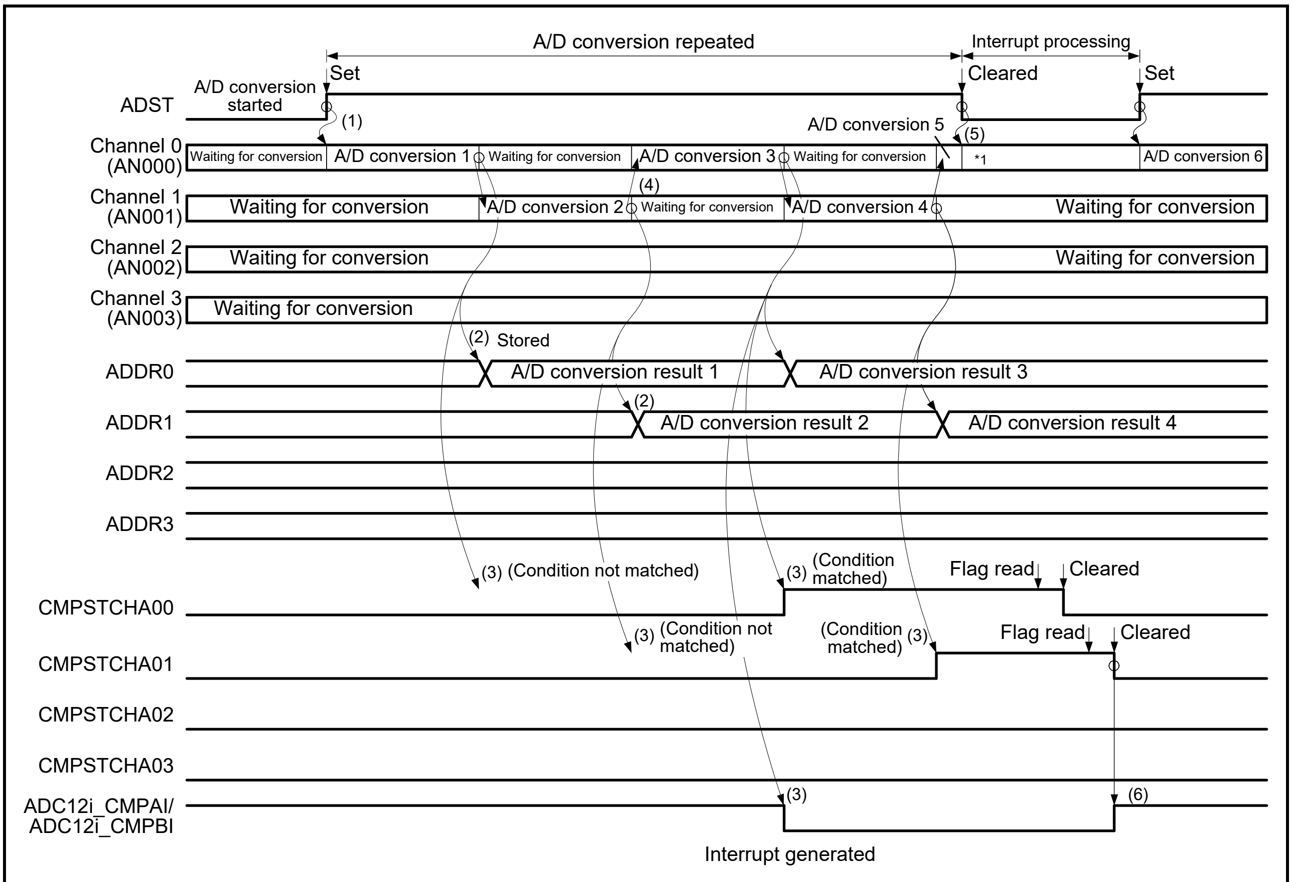
This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts for the selected channels, temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.
3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHA0n, ADCMPSR1.CMPSTCHA1n, ADCMPSER.CMPSTTSA, or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1,

an ADC12i_CMPAI (i = 0, 1) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC12i_CMPBI interrupt request is generated.

4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI and ADC12i_CMPBI interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note 1. Data on conversion is ignored.
i = 0, 1

Figure 47.31 Example of compare function operation, when AN000 to AN003 are compared

47.3.5.2 Event output of compare function

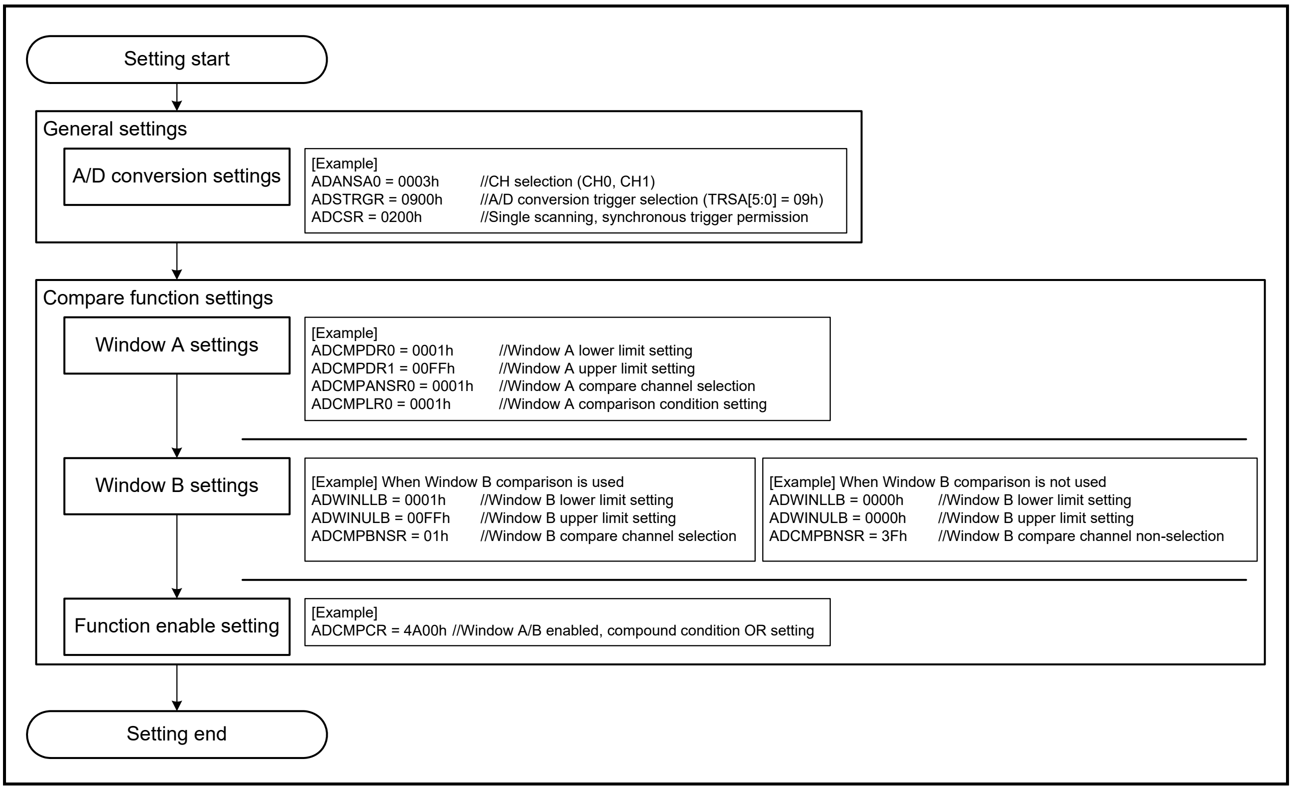
The event output of compare function specifies the upper reference voltage value for Window A and the lower reference voltage value for Window B, compares the A/D-converted value of the selected channel with the upper and lower reference voltage values, and then outputs the ADC12i_WCMPM and ADC12i_WCMPUM (i = 0, 1) events based on the event conditions (A OR B, A AND B, A XOR B) and comparison results of Window A and Window B.

If more than one channel is selected for Window A, and even one channel in Window A meets the comparison condition, the comparison result of Window A becomes met. When using this function, perform A/D conversion in single scan mode. Any channels from AN000 to AN007 and AN016 to AN020 (unit 0), and AN100 to AN103, AN105 to AN107, and AN116 to AN119 (unit 1), internal reference voltage, and temperature sensor output are selectable for Window A.

This section provides the setting procedure and example when using event output of compare function.

To set up event output for the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for Window A in ADCMPANSR0/1 and ADCMPANSER. Set window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper and lower reference values in the ADCMPDR0 and 1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set composite conditions for Window A/B, Window A/B operation enable, and interrupt output enable in ADCMPCR.



```
[Example]
ADANSA0 = 0003h        //CH selection (CH0, CH1)
ADSTRGR = 0900h        //A/D conversion trigger selection (TRSA[5:0] = 09h)
ADCSR = 0200h          //Single scanning, synchronous trigger permission
```

```
[Example]
ADCMPDR0 = 0001h       //Window A lower limit setting
ADCMPDR1 = 00FFh       //Window A upper limit setting
ADCMPANSR0 = 0001h     //Window A compare channel selection
ADCMPLR0 = 0001h       //Window A comparison condition setting
```

```
[Example] When Window B comparison is used
ADWINLLB = 0001h       //Window B lower limit setting
ADWINULB = 00FFh       //Window B upper limit setting
ADCMPBNSR = 01h        //Window B compare channel selection
```

```
[Example] When Window B comparison is not used
ADWINLLB = 0000h       //Window B lower limit setting
ADWINULB = 0000h       //Window B upper limit setting
ADCMPBNSR = 3Fh        //Window B compare channel non-selection
```

```
[Example]
ADCMPCR = 4A00h //Window A/B enabled, compound condition OR setting
```

Figure 47.32 Setting example when using the event output of the compare function

Notes on the event output usage when using only the Window A for compare function:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “Do not select” (ADCMPBNSR.CMPCHB[5:0] = 111111b)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB.CMPLLB[15:0] = ADWINULB.CMPULB[15:0] = 0000h, and ADCMPBNSR.CMPLB = 1)

Figure 47.33 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI) is output with the same timing of one time single scan completion. A match or mismatch event (ADC12i_WCMPM or ADC12i_WCMPUM) is output delayed 1 PCLKB depending on ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

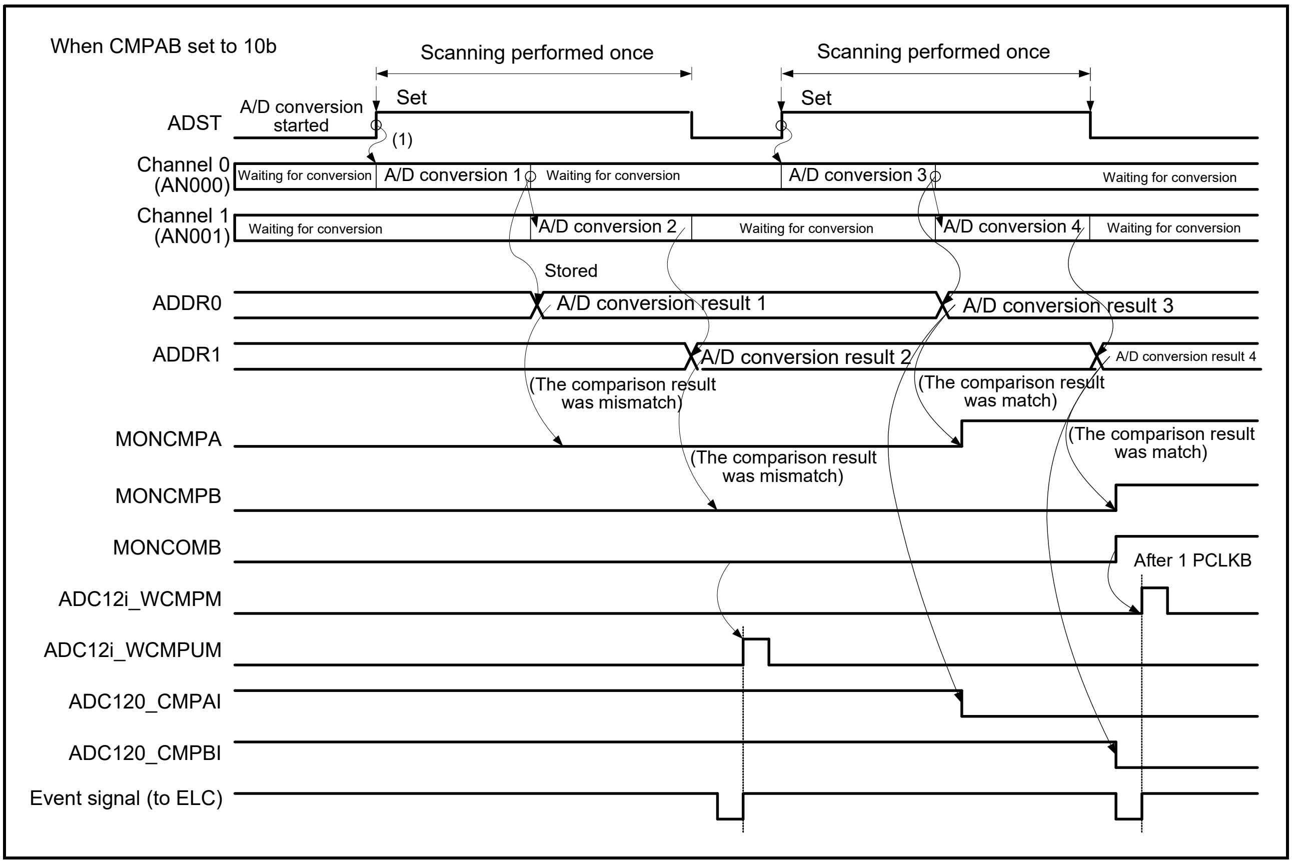


Figure 47.33 Example operation of the compare function event output, when AN000 to AN001 are compared

Note 1. Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note 2. The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

47.3.5.3 Constraints on the compare function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output or internal reference voltage is selected for Window A, Window B operations are disabled.
- When the temperature sensor output or internal reference voltage is selected for Window B, Window A operations are disabled.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low-potential reference voltage value.

47.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRGn). After the start-of-scanning-delay (t_D) elapses, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 47.34 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 47.35 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger, ADTRGn. The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH}),[*1] disconnection detection assistance processing time (t_{DIS}),[*2] self-diagnosis A/D conversion processing time (t_{DIAG}),[*3] A/D conversion processing time (t_{CONV} and t_{DSD}), channel-dedicated sample-and-hold circuit end time (t_{SHED}),[*4] and end-of-scanning-delay (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of the input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the ADC12. If there is not sufficient sampling time because of the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.

The time for conversion by successive approximation (t_{SAM}) is 13 ADCLK states with 12-bit accuracy selected, 11 ADCLK states with 10-bit accuracy selected, and 9 ADCLK states with 8-bit accuracy selected.

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n)^{*5} + t_{ED}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} plus t_{SHED}. The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed at $t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)^{*5} + t_{SHED}$.

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SPLSH} = 0$.

Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$.

Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$, $t_{DSD} = 0$.

Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).

Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals $t_{CONV} \times n$. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 47.10 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKB)

Parameter			Symbol		Type/conditions			Unit
					Synchronous trigger*4	Asynchronous trigger	Software trigger	
Scan start processing time*1, *2	A/D conversion on Group A under Group A priority control.	Group B is to be stopped. (Group A is activated after Group B is stopped by of an A/D conversion source from Group A.)	t_D		3 PCLKB + 6 ADCLK 5 PCLKB + 3 ADCLK *5	-	-	Cycles
		Group B is not to be stopped. (Activation by an A/D conversion source from Group A.)			2 PCLKB + 4 ADCLK	-	-	
	A/D conversion when self-diagnosis is enabled	A/D conversion for self-diagnosis is to be started.			2 PCLKB + 6 ADCLK	4 PCLKB + 6 ADCLK	6 ADCLK	
	All other				2 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	Without continuous sampling: setting in ADSHCR.SSTSH[7:0] (initial value = 18h × ADCLK) With continuous sampling: 0			
	Wait time between sampling and A/D Conversion			t_W	12			
Disconnection detection assistance processing time			t_{DIS}		Setting in ADNDIS[3:0] (initial value = 0h) × ADCLK			
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	Setting in ADSSTR00 (initial value = 0Bh) × ADCLK*3	-	-	
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK	-	-	
		10-bit conversion accuracy			13 ADCLK	-	-	
		8-bit conversion accuracy			11 ADCLK	-	-	
	Wait time between self-diagnosis conversion end and analog channel sampling start			t_{DED}	2 ADCLK			
	Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode		t_{DSD}		2 ADCLK			
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	Setting in ADSSTRn (n = 00 to 07, L, T, O) (initial value = 0Bh) × ADCLK + 0.5 ADCLK			
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK			
		10-bit conversion accuracy			11 ADCLK			
		8-bit conversion accuracy			9 ADCLK			
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK			
Scan end processing time*1			t_{ED}		1 PCLKB + 3 ADCLK 2 PCLKB + 3 ADCLK*5			

Note 1. See Figure 47.34 and Figure 47.35 for an illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. The sampling time setting should satisfy the electrical characteristics.
Note 4. This does not include the time consumed in the path from timer output to trigger input.
Note 5. If ADCLK is faster than PCLKB (PCLKB to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

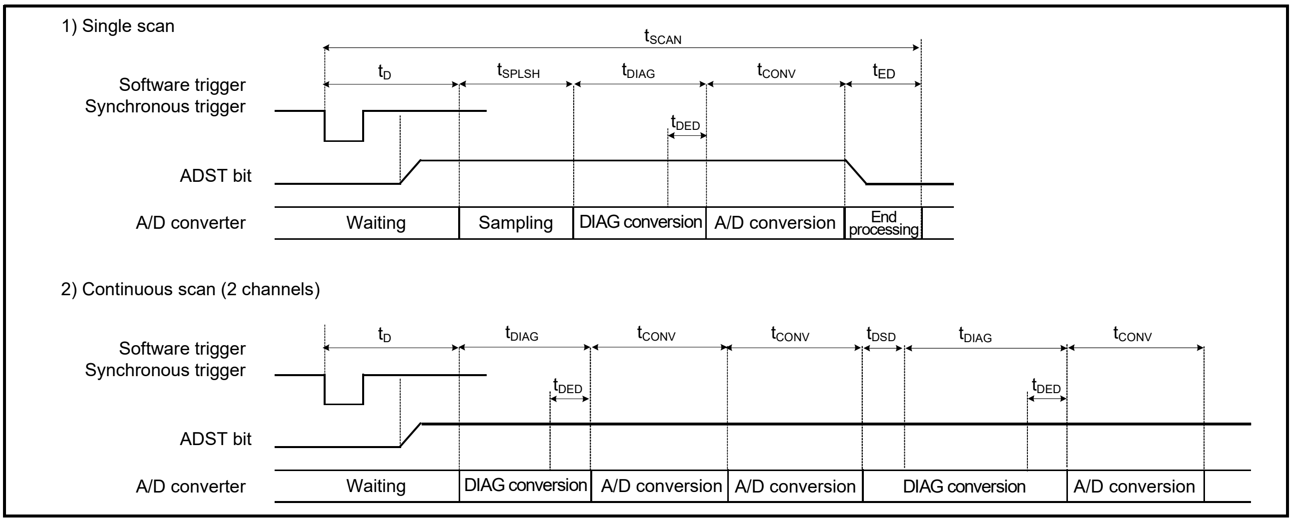

Figure 47.34 Scan conversion timing when activated by software or a synchronous trigger input (ELC)

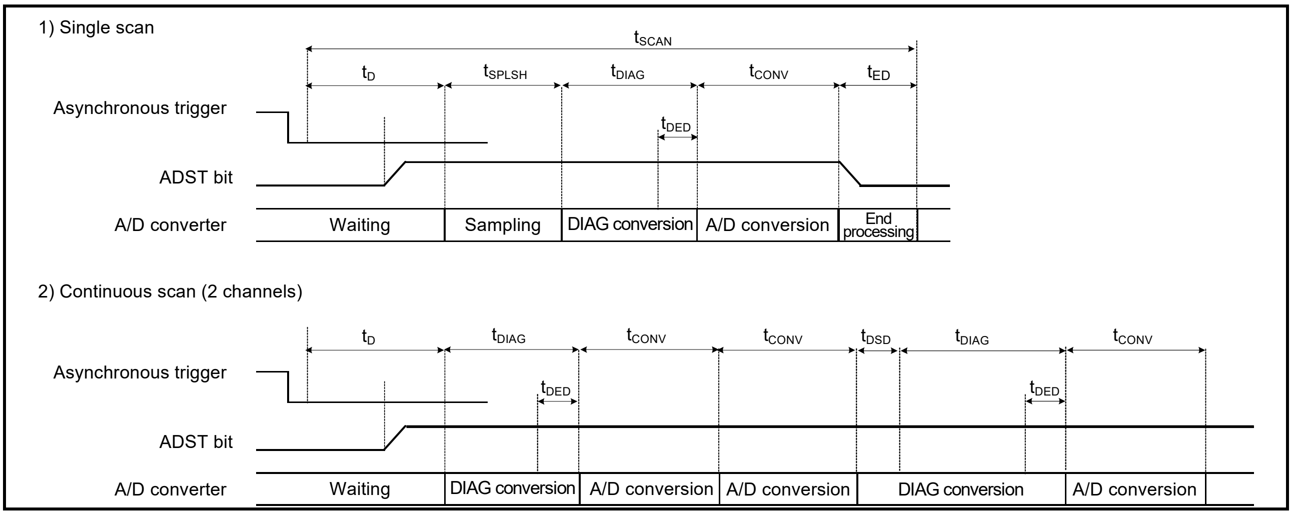

Figure 47.35 Scan conversion timing when activated by an asynchronous trigger input (ADTRG0)

47.3.7 Usage Example of A/D Data Register Automatic Clearing Function

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, temperature sensor output, or internal reference voltage is selected.

Setting the ACE bit in ADCER to 1 automatically clears the data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, and ADOCDR) to 0000h when the data registers are read by the CPU, DTC, or DMAC. This function enables detection of update failures by the data registers. In the following examples, the function to automatically clear the ADDRy register is enabled and disabled.

If the ACE bit in ADCER is 0 (automatic clearing disabled) and for some reason the A/D conversion result (0222h) is not written to the ADDRy register, the ADDRy value retains the old data (0111h). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0111h) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.

If the ACE bit in ADCER is 1 (automatic clearing enabled), when ADDRy = 0111h is read by the CPU, DTC, or DMAC, ADDRy is automatically cleared to 0000h. Next, if the A/D conversion result 0222h cannot be transferred to ADDRy for some reason, the cleared data (0000h) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt at this point, 0000h is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0000h.

47.3.8 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16*1 consecutive times, and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. However, this function cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition or average mode can be specified for A/D conversion of the channel select analog input, temperature sensor output, or internal reference voltage.

Note 1. The addition count can be set to 16 only when 12-bit accuracy is selected.

47.3.9 Disconnection Detection Assist Function

This converter incorporates a function that fixes the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set ADSHMSR.SHMD bit to 0 (select disable continuous sampling function).

If any of the following functions are used, the disconnection detection assist function must be disabled:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- The programmable gain amplifier without bypass enabled.

Figure 47.36 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 47.37 shows an example of disconnection detection when precharge is selected. Figure 47.38 shows an example of disconnection detection when discharge is selected.

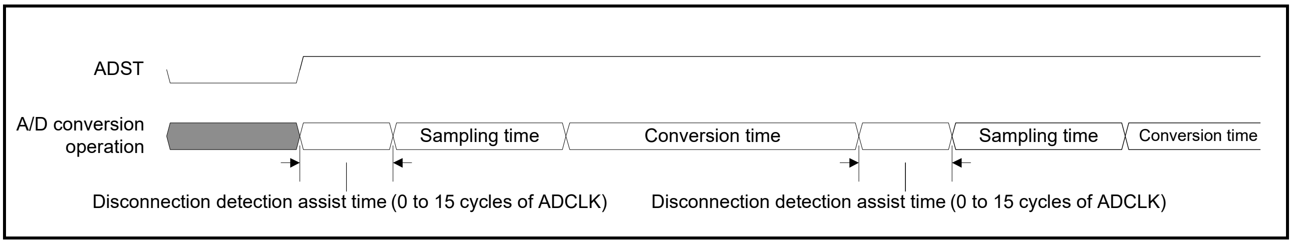

Figure 47.36 A/D conversion operation when the disconnection detection assist function is used

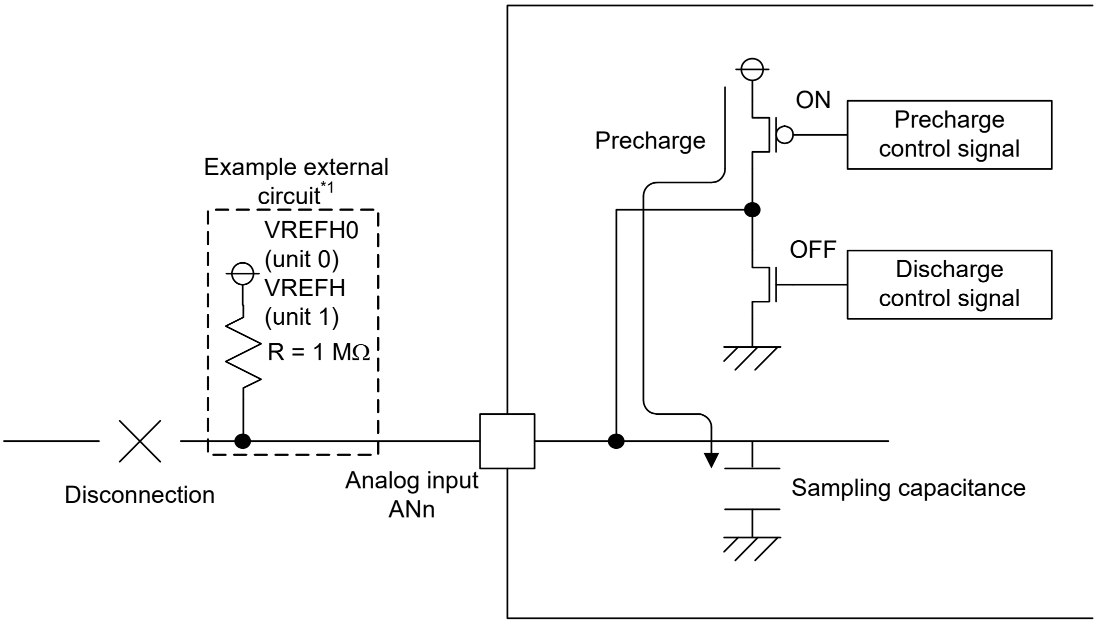
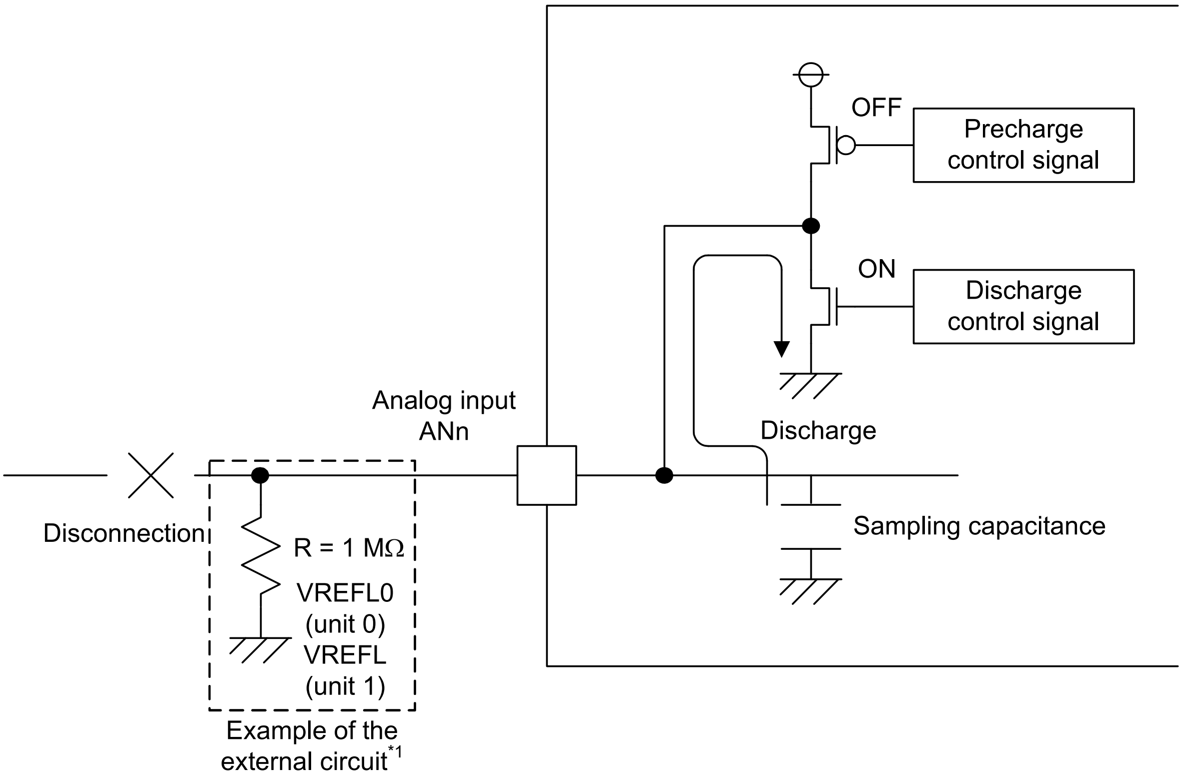


Note 1. The converted result should be only used after full evaluation, because the data result when disconnection occurs varies depending on the external circuit.

Figure 47.37 Example of disconnection detection when precharge is selected



Note 1. The converted result should only be used after full evaluation, because the data result when disconnection occurs varies depending on the external circuit.

Figure 47.38 Example of disconnection detection when discharge is selected

47.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start the ADC12 by an asynchronous trigger, first set the pin function in the PmnPFS register, next set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 000000b, and then input a high-level signal to the asynchronous trigger (ADTRGn pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 47.39 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger select bits (ADSTRGR.TRSB[5:0]) for Group B used in group scan mode. For details on setting the pin function, see section 20, I/O Ports.

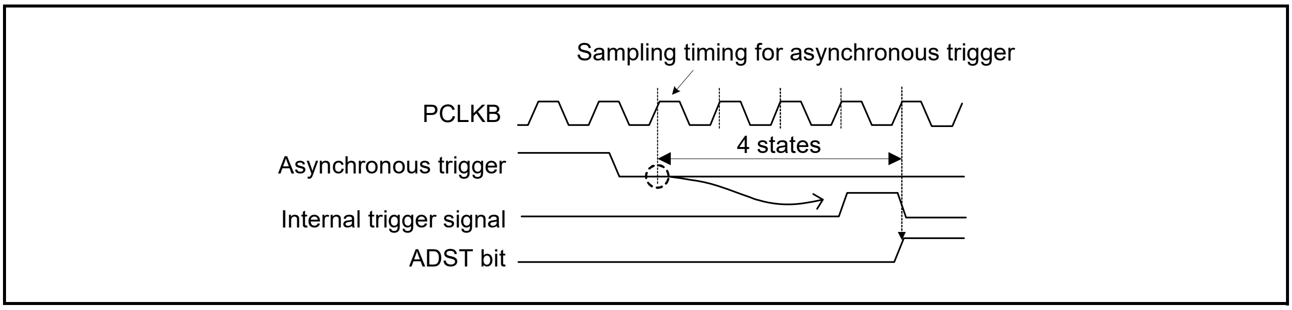


Figure 47.39 Asynchronous trigger input timing

47.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To start the A/D conversion by a synchronous trigger, set the ADCSR.TRGE bit to 1, clear the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] and ADSTRGR.TRSB[5:0] bits.

47.3.12 Programmable Gain Amplifiers

Up to three programmable gain amplifiers (PGAs) can be used in each unit. Select a gain in the ADPGAGS.PnGAIN[3:0] bits (n = 000 to 002) and select an operational amplifier to be used in the ADPGACR.PnSEL bits.

These PGAs accept differential inputs. Pins that accept differential inputs are PGAVSS000 for AN000 to AN002 (unit 0), PGAVSS100 for AN100 to AN102 (unit 1). To use differential inputs, set the differential input gain in the ADPGADCR0.PnDG[2:0] bits, enable the differential input gain setting in the ADPGADCR0.PnGEN bits, and then select the differential input amplifier in the ADPGADCR0.PnDEN bits. The PGA register is selectable as shown in Table 47.11.

Table 47.11 Setting of PGA register and available related functions

	Setting of corresponding Register				related function ✓: available x: unavailable			
	PmnPFS	ADPGACR	ADPGAGS0	ADPGADCR0				
		PGA P002: bits [11:8]	bits [11:8]	bits [11:8]		ACMPHS*2		
		PGA P001: bits [7:4]	bits [7:4]	bits [7:4]		IVCMP 2	IVCMP 3	
Selectable value for each condition	ASEL*3	PGA P000: bit [3:0]	bit [3:0]	bit [3:0]	Ports*1			ADC12
When using Ports	0	Leave these bits with initial values			✓	x	x	x
When using ACMPHS or ADC12(PGA bypass)*4	1	9	0	0	x	✓	x	✓
When using PGA Differential input disabled	1	Eh	0 to Eh	0	x	✓	✓	✓
When using PGA Differential input enabled	1	Eh	1, 5, 9, Bh	8 to Bh	x	x	✓	✓

Note 1. Ports: When using input ports.
Note 2. ACMPHS IVCMP2: When using input through the PGA. ACMPHS IVCMP3: When using input of PGA output.
Note 3. For detail on the configuration of PmnPFS registers, see section 20, I/O Ports.
Note 4. Ports and ACMPHS cannot be used at the same time. Ports and ADC12 cannot be used at the same time.

Table 47.12 shows the calculation formula for the PGA output voltage.

Table 47.12 PGA output voltage

Mode	PGA output voltage
Single	Gain × Vin
Differential	Gain (Vin - Vs) + 0.5 × AVCC

Vin: AN000 to AN002, AN100 to AN102
Vs: PGAVSS00, PGAVSS001

47.4 Interrupt Sources and DTC/DMAC Transfer Requests

47.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests, ADC12i_ADI (i = 0, 1) and ADC12i_GBADI, to the CPU. The module also generates the ADC12i_CMPAI and ADC12i_CMPBI interrupts to the CPU in response to matches with a comparison condition.

An ADC12i_ADI interrupt is always generated. An ADC12i_GBADI interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI and ADC12i_CMPBI interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI or ADC12i_GBADI interrupt, or ADC12i_WCMPM or ADC12i_WCMPUM event is generated. Using these interrupts or events to allow the DTC or DMAC to read the converted data enables continuous conversion without burdening the software.

For details on the DTC settings, see section 18, Data Transfer Controller (DTC), and for details on the DMAC settings, see section 17, DMA Controller (DMAC).

Table 47.13 describes the interrupt sources and ELC events available for the ADC12.

Table 47.13 ADC12 events (1 of 2)

✓: available x: unavailable

Operation		**Interrupt request or ELC event**			**Interrupt request**	**DTC/DMAC activation**	**ELC event request**	**Function**

			ADC120_GBADI	ADC121_GBADI	✓	✓	x	ADC12i_GBADI dedicated to Group B generated at the end of Group B scan

Note: i = 0: unit 0, i = 1: unit 1.

47.5 Event Link Function

47.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI interrupt request signal as an event signal, enabling link operation for the preset module. The ADC12i_GBADI interrupt and ADC12i_CMPAI/ADC12i_CMPBI interrupts cannot be used as event signals. For details, see Table 47.13.

47.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register
- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC_ADi0 or ELC_ADi1 event occurs during A/D conversion, the event is disabled.

47.6 Usage Notes

47.6.1 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register.

If a register is read twice in byte units, that is, the upper byte and bytes are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

47.6.2 Constraints on Stopping A/D Conversion

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 47.40.

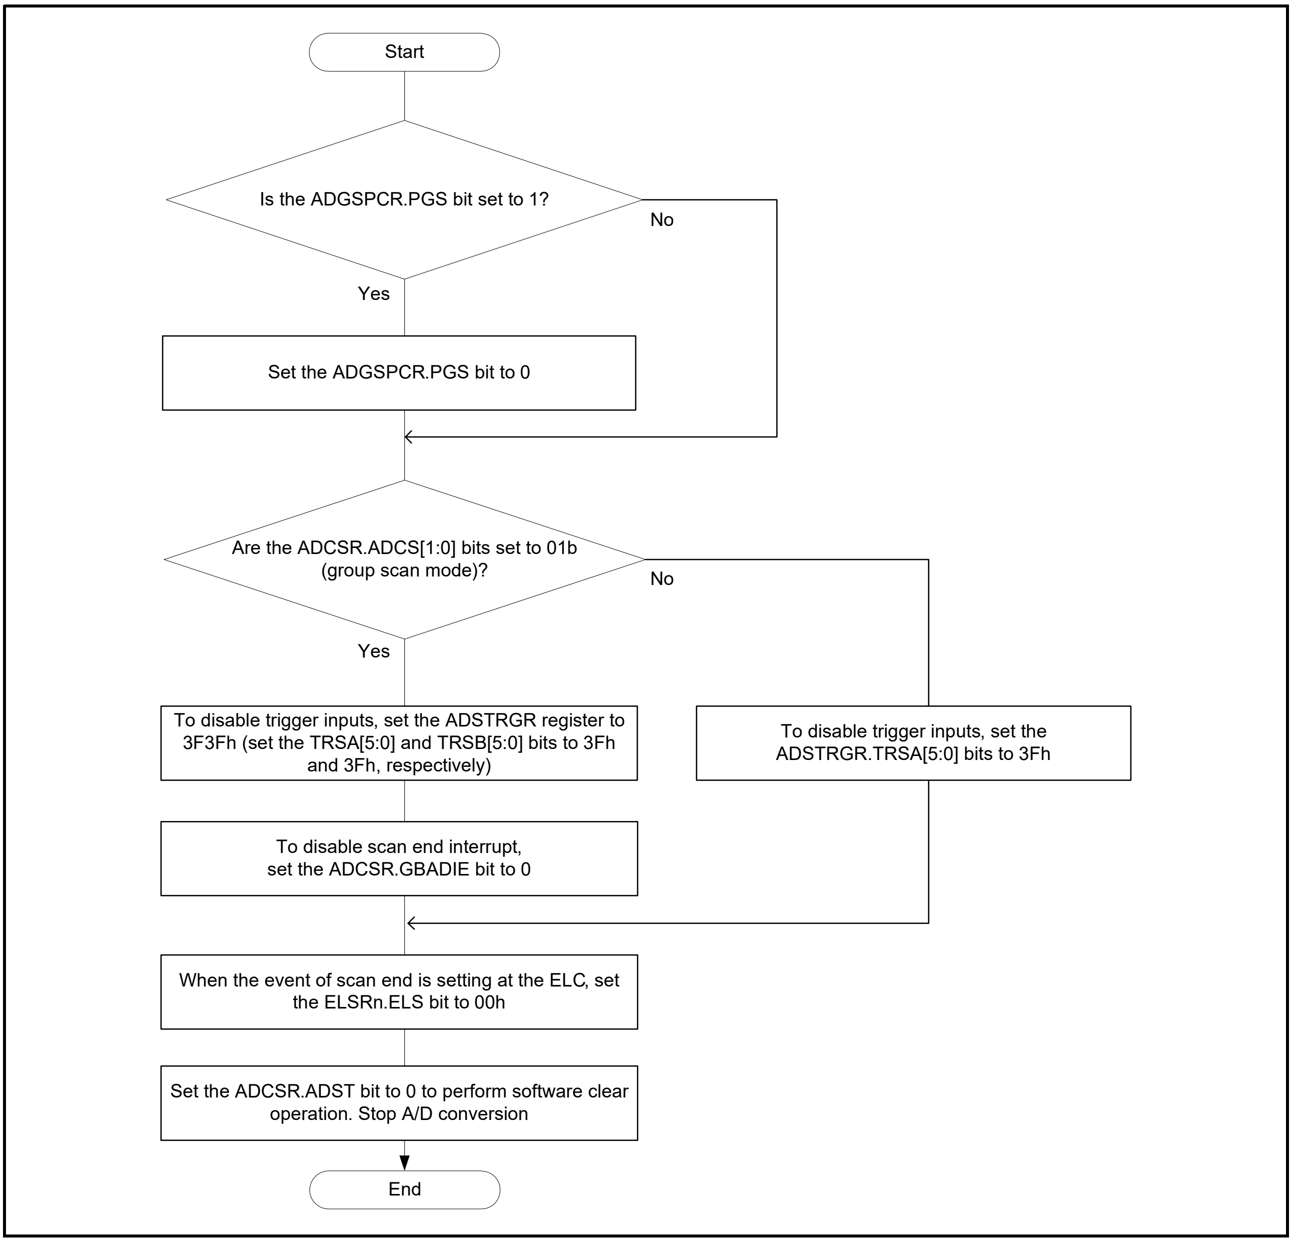

Figure 47.40 Procedures for clearing the ADCSR.ADST bit by software

47.6.3 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to be terminate on setting the ADCSR.ADST bit to 0.

47.6.4 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data if the CPU does not finish reading the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

47.6.5 Settings for the Module-Stop Function

ADC12 operation can be disabled or enabled using the Module Stop Control Register. The ADC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. After release from the module-stop state, wait for at least 1 μs before starting A/D conversion. For details, see section 11.4, Module-Stop Function.

47.6.6 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, you must stop A/D conversion. Here, set the ADCSR.ADST bit to 0 and secure a period of time until the analog unit of the ADC12 stops.

To secure this time, follow the procedure shown in Figure 47.40 for clearing the ADCSR.ADST bit by software. Next, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

47.6.7 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in the absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins because of the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula.

Maximum error in absolute accuracy (LSB) = $(2^{\text{Resolution}} -1) \times \text{Rs} / (\text{Rs} + \text{Rp})$, Resolution = 12, 10, 8

Only use disconnection detection assistance after thorough evaluation.

47.6.8 Available Functions and Register Settings of AN000 to AN002, AN007, AN100 to AN102, and AN107

Table 47.14 shows the available functions and register setting of AN000 to AN002, AN007, AN100 to AN102, and AN107. Figure 47.41 shows the setting procedure of registers. To use each function, set the register value shown in Table 47.14.

When the PGA is used with differential input enabled, a negative voltage can be input for AN000 to AN002 and PGAVSS000 for unit 0, and AN100 to AN102 and PGAVSS100 for unit 1 pin after setting the registers.

When the PGA is used with differential input enabled, all PGA amplifiers in each unit must be set to differential input in the ADPGADCR0 register.

When the PGA is used with differential input disabled, the associated PGAVSS pin must be connected to AVSS0. When the PGA is not used, the associated PGAVSS can be used as an input port.

When transitioning to the ADC module-stop state or Software Standby mode from the state of using PGA or sample-and-hold circuit, if 0 is set to the associated bit of ADPGACR or ADSHCR register of each ADC12 before transitioning, power consumption can be reduced.

The initial value of the ASEL bit of P003 and P007 is 1. When these pins are not used as an analog function, to reduce the input leakage current, set the ASEL bit to 0.

Table 47.14 Available functions and register setting

Available functions						Register setting

✓: Available
x: Don’t care

Note 1. Ports: P000 to P007 can be used as port inputs.

Note 2. IRQ: P000 to P002 and P003 to P005 can be used as IRQ pins.

Note 3. S/H: sample-and-hold circuit.

Note 4. PGA-S: When the PGA setting is Differential input disabled. Corresponding PGAVSS must be set as ASEL to 1, and connect to AVSS0.

Note 5. PGA-D: When the PGA setting is Differential input enabled. Corresponding PGAVSS must set as ASEL to 1.

Note 6. P0nPFS: Port 0 Pin Function Select register (n = 00 to 07) corresponding to analog input pin.

Note 7. It indicates the corresponding Differential Input Enable bit (bit [11] or bit [7] or bit [3]) in the ADPGADCR0 register.

Note 8. It indicates the corresponding Amplifier Control bits (bits [11:8] or bits [7:4], or bits [3:0]) in the ADPGACR register.

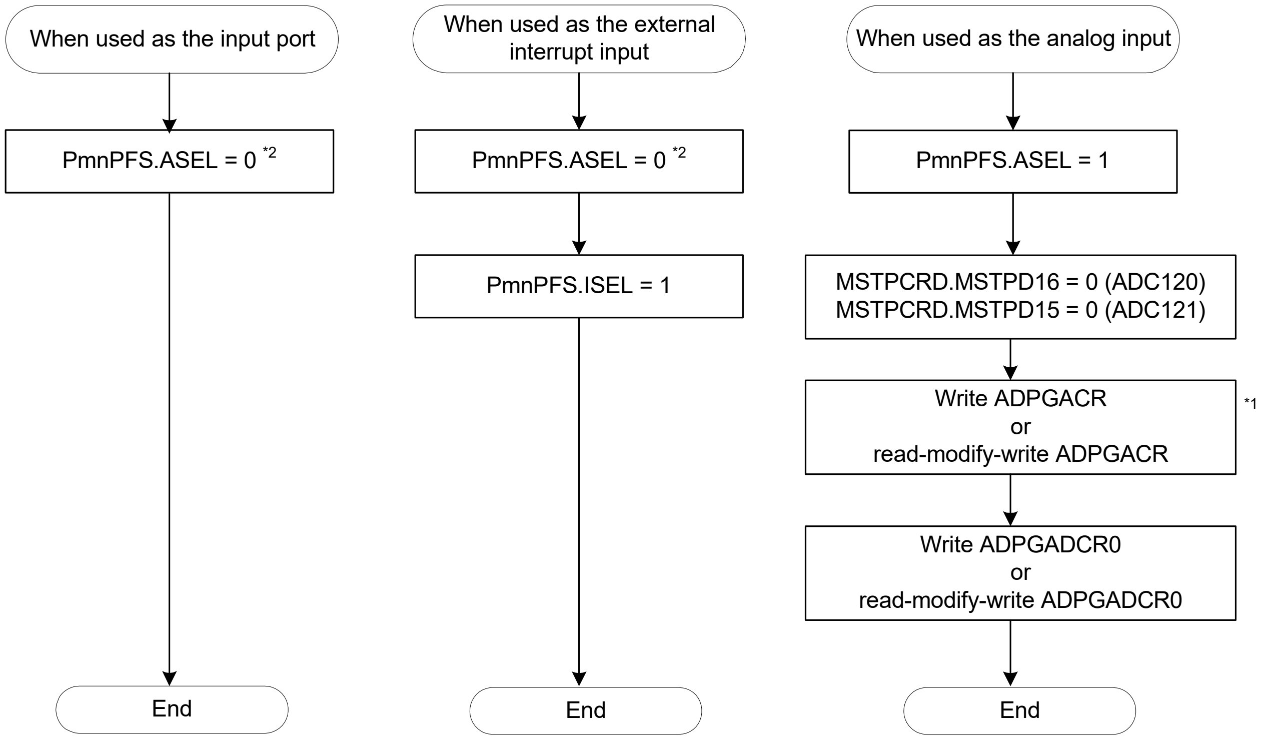
Note 9. It indicates the corresponding Bypass Select bit (bit [10] or bit [9] or bit [8]) in ADSHCR register.

Note 10. When using AN000 to AN002 or AN100 to AN102.

Note 11. When using AN007 or AN107. Set all corresponding bits (ADPGADCR0 bit [11], bit [7], and bit [3] to 0.

Note 12. Power consumption of the PGA can be reduced by setting 0h to the corresponding bit of the ADPGACR register before transitioning to the ADC12 module-stop state or Software Standby mode.

Note 13. Power consumption of the S/H can be reduced by setting 0 to the corresponding bit of the ADSHCR register before transitioning to the ADC12 module-stop state or Software Standby mode.



Note 1. For AN007 and AN107, this step can be skipped.

Note 2. The initial value of the ASEL bit of P003 and P007 is 1. When these pins are not used as an analog function to reduce the input leakage current, set the ASEL bit to 0.

Figure 47.41 Setting procedure of registers

47.6.9 Constraints on Operating Modes and Status Bits

The voltage values in self-diagnosis, the determination of first or second scan in double-trigger mode, and the data buffer pointer and status monitor in the compare function initialize or set it again individually, if required.

- The voltage values in self-diagnosis can be selected in ADCER.DIAGVAL[1:0] after ADCER.DIAGLD is set to 1.
- The double-trigger mode operates as the first scan after ADCSR.DBLE is set to 1 from 0.
- The status monitor bits (MONCMPA, MONCMPB, and MONCOMB) in the compare function are initialized after ADCMPCR.CMPAE and ADCMPCR.CMPBE are cleared to 0.
- The constant sampling function (ADSHMSR.SHMD = 1) is initialized after ADSHMSR.SHMD is cleared to 0. When the constant sampling function is used (setting ADSHMSR.SHMD = 1) again, a wait of 1ADCLK or more waiting is required.

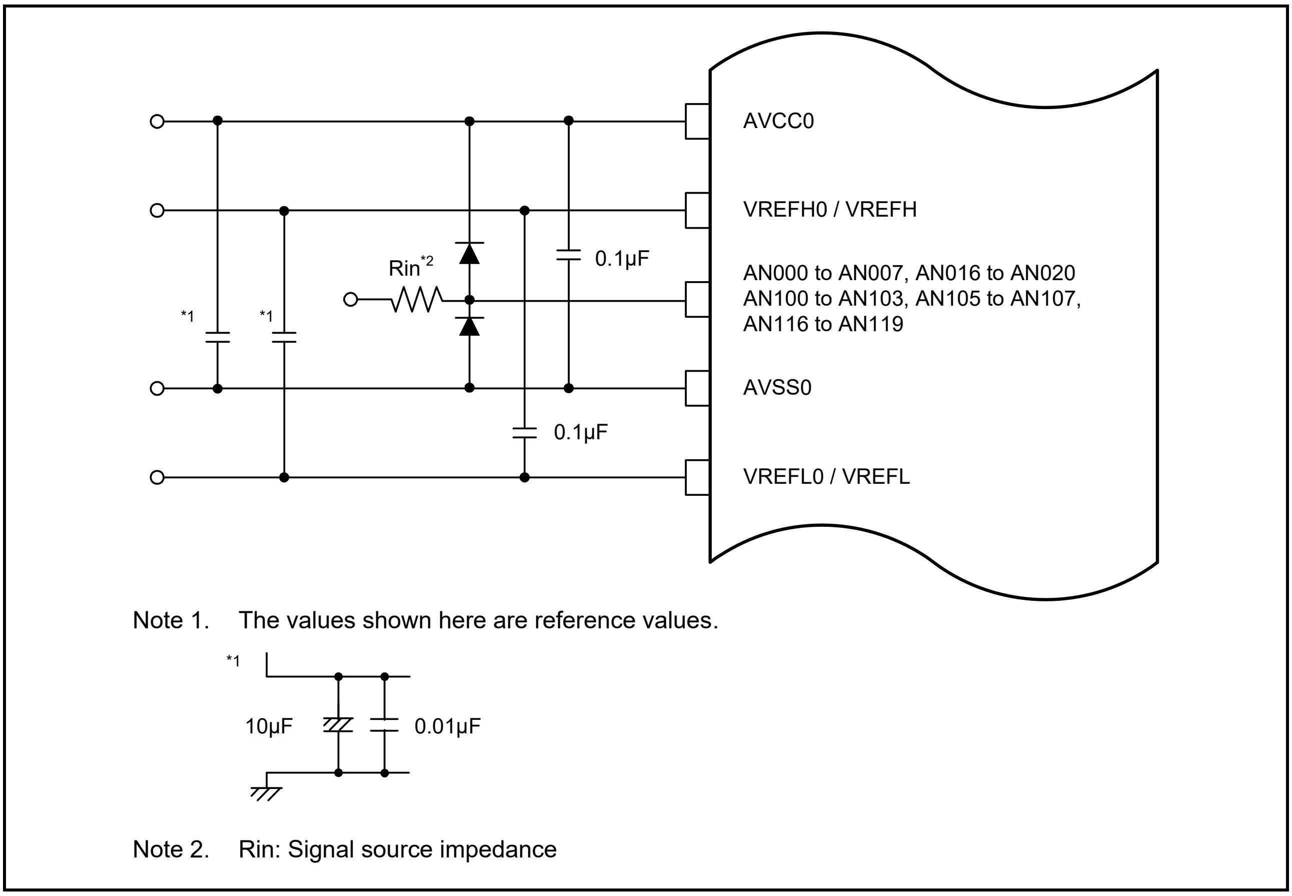
47.6.10 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible.

In addition, digital circuit signal lines and analog circuit signal lines should not intersect or placed near each other. If these rules are not followed, noise will be produced on analog signals and A/D conversion accuracy will be affected. The analog input pins (AN000 to AN007, AN016 to AN020, AN100 to AN103, AN105 to AN107, AN116 to AN119), reference power supply pin (VREFH0/VREFH), reference ground pin (VREFL0/VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

47.6.11 Constraints on Noise Prevention

To prevent the analog input pins (AN000 to AN007, AN016 to AN020, AN100 to AN103, AN105 to AN107, and AN116 to AN119) from being destroyed by abnormal voltage such as excessive surges, insert a capacitor between AVCC0 and AVSS0, between VREFH0 and VREFL0, and between VREFH and VREFL, and connect a protection circuit to protect the analog input pins (AN000 to AN007, AN016 to AN020, AN100 to AN103, AN105 to AN107, and AN116 to AN119) as shown Figure 47.42.



Note 1. The values shown here are reference values.

Note 2. Rin: Signal source impedance

Figure 47.42 Example protection circuit for analog inputs

47.6.12 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use ports 0 as digital output ports. Renesas also recommends not using the digital output that is also used as the A/D analog input, if normal-precision channels is used. If the digital output that is also used as the A/D analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

47.6.13 Relationship between ADC12 Units 0 and 1 and the ACMPHS

For the A/D conversion targets in Table 47.15, unit 0 and 1 should not perform A/D conversion at the same time.

Table 47.15 A/D conversion targets that are mutually exclusive with each other

A/D conversion target	
Unit 0	**Unit 1**
Temperature sensor	
Internal reference voltage	
AN005/DA0	AN105/DA0
AN006/DA1	AN106/DA1

The A/D conversion targets in Table 47.16 should not be selected as ACMPHS input during A/D conversion, because these pins are multiplexed with the ADC12 and ACMPHS.

Table 47.16 A/D conversion targets that are mutually exclusive with ACMPHS

A/D conversion target		
Unit 0	**Unit 1**	**ACMPHS**
AN000	-	ACMPHS0.IVCMP2
AN001	-	ACMPHS1.IVCMP2
AN002	-	ACMPHS2.IVCMP2

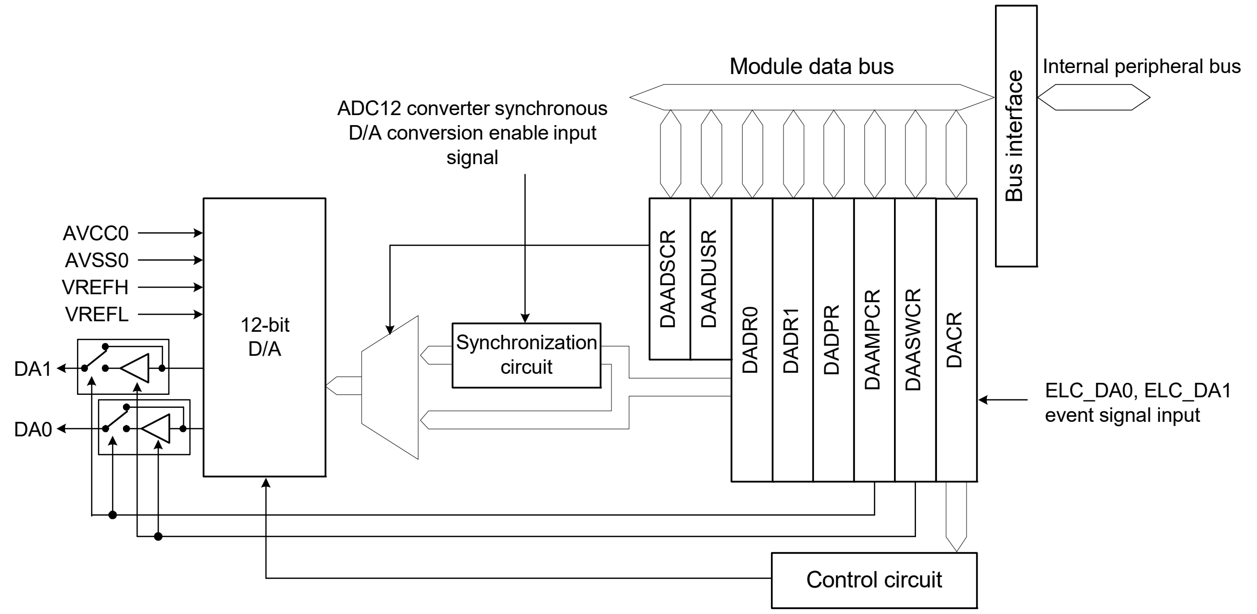
48. 12-Bit D/A Converter (DAC12)

48.1 Overview

The MCU provides a 12-Bit D/A Converter (DAC12) with an output amplifier. Table 48.1 lists the DAC12 specifications, Figure 48.1 shows a block diagram, and Table 48.2 lists the I/O pins.

Table 48.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	2 channels
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: • D/A converted data update timing is controlled by the ADC12 synchronous D/A conversion enable input signal from the ADC12 (unit 1) • Degradation of A/D conversion accuracy caused by interference is reduced by controlling DAC12 inrush current generation timing with the enable signal
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	DA0 and DA1 conversion can be started when an event signal is input
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used



DADR0: D/A Data Register 0
DADR1: D/A Data Register 1
DACR: D/A Control Register
DADPR: DADRm Format Select Register
DAADSCR: D/A A/D Synchronous Start Control Register
DAAMPCR: D/A Output Amplifier Control Register
DAASWCR: D/A Amplifier Stabilization Wait Control Register
DAADUSR: D/A A/D Synchronous Unit Select Register

Figure 48.1 DAC12 block diagram

Table 48.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	Analog power supply pin for ADC12, DAC12, and comparator Connect to VCC when these modules are not used.
AVSS0	Input	Analog ground pin for ADC12, DAC12, and comparator Connect to VSS when these modules are not used.

Table 48.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12
DA0	Output	Channel 0 analog output pin
DA1	Output	Channel 1 analog output pin

48.2 Register Descriptions

48.2.1 D/A Data Register m (DADRm) (m = 0, 1)

Address(es): DAC12.DADR0 4005 E000h, DAC12.DADR1 4005 E002h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DADRm registers are 16-bit read/write registers that store data for D/A conversion. Whenever an analog output is enabled, the values in DADRm are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

For information on using the output amplifier, see section 48.6.5, Initialization Procedure with the Output Amplifier.

48.2.2 D/A Control Register (DACR)

Address(es): DAC12.DACR 4005 E004h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b5	DAE	D/A Enable*1	0: Control D/A conversion of channels 0 and 1 individually 1: Control D/A conversion of channels 0 and 1 collectively.	R/W
b6	DAOE0	D/A Output Enable 0	0: Disable analog output of channel 0 (DA0) 1: Enable D/A conversion of channel 0 (DA0).	R/W
b7	DAOE1	D/A Output Enable 1	0: Disable analog output of channel 1 (DA1) 1: Enable D/A conversion of channel 1 (DA1).	R/W

Note 1. This bit controls D/A conversion in combination with the DAOEi bit (i = 0, 1), which controls output of the conversion results. For details, see Table 48.3.

Table 48.3 D/A conversion controls

b5	b7	b6	
DAE	DAOE1	DAOE0	Description
0	0	0	Disable D/A conversion and analog output pins (DA0, DA1)*1
		1	• Enable D/A conversion of channel 0 and disable D/A conversion of channel 1 • Enable analog output of channel 0 (DA0) and disable analog output of channel 1 (DA1)*1
	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*1 and enable analog output of channel 1 (DA1)
		1	• Enable D/A conversion of channels 0 and 1 • Enable analog output of channels 0 and 1 (DA0, DA1)
1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

x: Don't care

Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 unit 1.

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1) and the DAMMPCR.DAAMPi bit (i = 0, 1). See Table 48.4.

When interference prevention between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 (unit 1) to 0. Then select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAMMPCR.DAAMPi bit (i = 0, 1). See Table 48.4.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference prevention between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit sets to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit sets to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

Table 48.4 D/A conversion and analog output control (1 of 2)

DACR		DAAMPCR

		1	Run	Run	Amplifier output
	1	0	Run	Stop	Amplifier-through
		1	Run	Run	Amplifier output

i = 0, 1

48.2.3 DADRm Format Select Register (DADPR)

Address(es): DAC12.DADPR 4005 E005h

	b7	b6	b5	b4	b3	b2	b1	b0
	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DPSEL	DADRm Format Select	0: Right-justified format 1: Left-justified format.	R/W

48.2.4 D/A A/D Synchronous Start Control Register (DAADSCR)

Address(es): DAC12.DAADSCR 4005 E006h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	DAADST	D/A A/D Synchronous Conversion	0: Do not synchronize DAC12 operation with ADC12 (unit 1) operation (disable interference prevention between D/A and A/D conversion) 1: Synchronize DAC12 operation with ADC12 (unit 1) operation (enable interference prevention between D/A and A/D conversion).	R/W

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1.

Set bit [1] in the DAADUSR register to 1 to select unit 1. The MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRm register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronous D/A conversion with the ADC12 synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even if the DADRm register value is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set bit [1] in the DAADUSR register to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

48.2.5 D/A Output Amplifier Control Register (DAAMPCR)

Address(es): DAC12.DAAMPCR 4005 E008h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAAMP 1	DAAMP 0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	DAAMP0	Amplifier Control 0	0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier.	R/W
b7	DAAMP1	Amplifier Control 1	0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier.	R/W

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DAE and DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 48.4 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DAE and DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 48.4 for details.

48.2.6 D/A Amplifier Stabilization Wait Control Register (DAASWCR)

Address(es): DAC12.DAASWCR 4005 E01C

	b7	b6	b5	b4	b3	b2	b1	b0
	DAAS W1	DAAS W0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	DAASW0	D/A Amplifier Stabilization Wait 0	0: Amplifier stabilization wait off (output) for channel 0 1: Amplifier stabilization wait on (high-Z) for channel 0.	R/W
b7	DAASW1	D/A Amplifier Stabilization Wait 1	0: Amplifier stabilization wait off (output) for channel 1 1: Amplifier stabilization wait on (high-Z) for channel 1.	R/W

The DAASWCR register controls D/A output with the output amplifier. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the

DAE bit and the DAOEi (i = 0, 1) bit in the DACR register are 0. See section 48.6.5, Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for stabilization of the output amplifier of D/A channel 0. When DAASW0 is set to 1, D/A conversion operates, but the conversion result D/A is not output from channel 0. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for stabilization of the output amplifier of D/A channel 1. When DAASW1 is set to 1, D/A conversion operates, but the conversion result D/A is not output from channel 1. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is output through the output amplifier.

48.2.7 D/A A/D Synchronous Unit Select Register (DAADUSR)

Address(es): DAC12.DAADUSR 4005 F0C0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	AMADSEL1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	AMADSEL1	A/D Unit 1 Select	0: Do not select unit 1 1: Select unit 1.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set bit [1] to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

48.3 Operation

The DAC12 includes D/A conversion circuits for two channels, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following is an example of D/A conversion on channel 0. Figure 48.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADPR.DPSEL bit and the DADR0 register.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time tDCONV elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is cleared to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADRm}}{4096} \times \text{VREFH}$$

3. To start conversion again, write to DADR0 again. The conversion result is output after the conversion time tDCONV elapses.
When the DAADSCR.DAADST bit is 1 (interference prevention between D/A and A/D conversion is enabled), a

maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time period might be required.

4. To disable analog output, set the DAOE0 bit to 0.

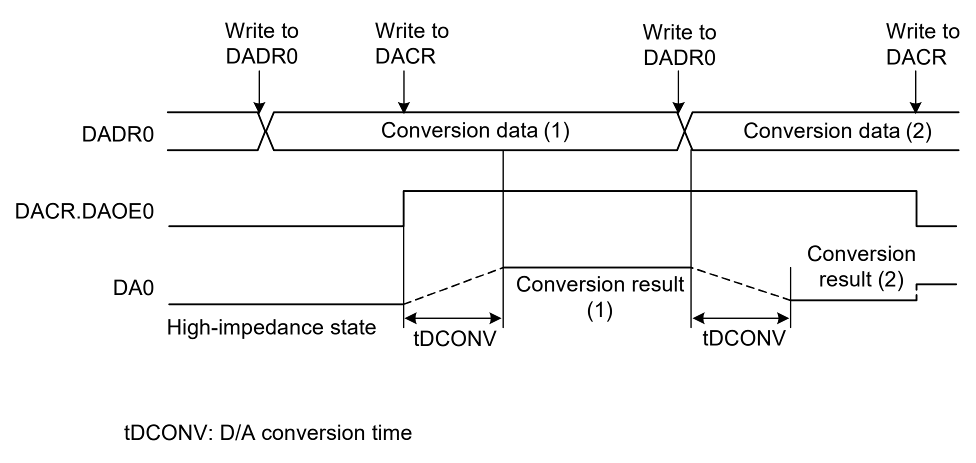

Figure 48.2 Example of DAC12 operation

48.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the same analog power supply is shared by the DAC12 and ADC12 (unit 1), the generated inrush current might interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, even if the DADRm register data is changed during ADC12 (unit 1) operation, D/A conversion does not start immediately but starts synchronously with A/D conversion completion. A maximum of one A/D conversion time is required for the DADRm register data update to be reflected as the D/A conversion circuit input. Before reflection, the DADRm register value does not correspond to the analog output value.

When this function is enabled, it is impossible to check by any software means whether the DADRm register value was D/A converted. When the DADRm register data is changed while the ADC12 (unit 1) is halted, D/A conversion starts in 1 PCLKB cycle, even if DAADSCR.DAADST is 1.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 operates synchronously with the ADC12 (unit 1).

To process D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMADSEL1 bit to 1.
2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. When ADCLK is faster than the peripheral clock, a period longer than one A/D conversion time might be required.

- If the 12-bit A/D conversion is halted (ADCSR.ADST bit = 0) when the DADR0 register is changed, D/A conversion starts in 1 PCLKB cycle.
- If the 12-bit A/D conversion is in progress (ADCSR.ADST bit = 1) when the DADR0 register is changed, D/A conversion starts on A/D conversion completion. If the DADR0 register is changed twice during A/D conversion, the first update might not be converted.

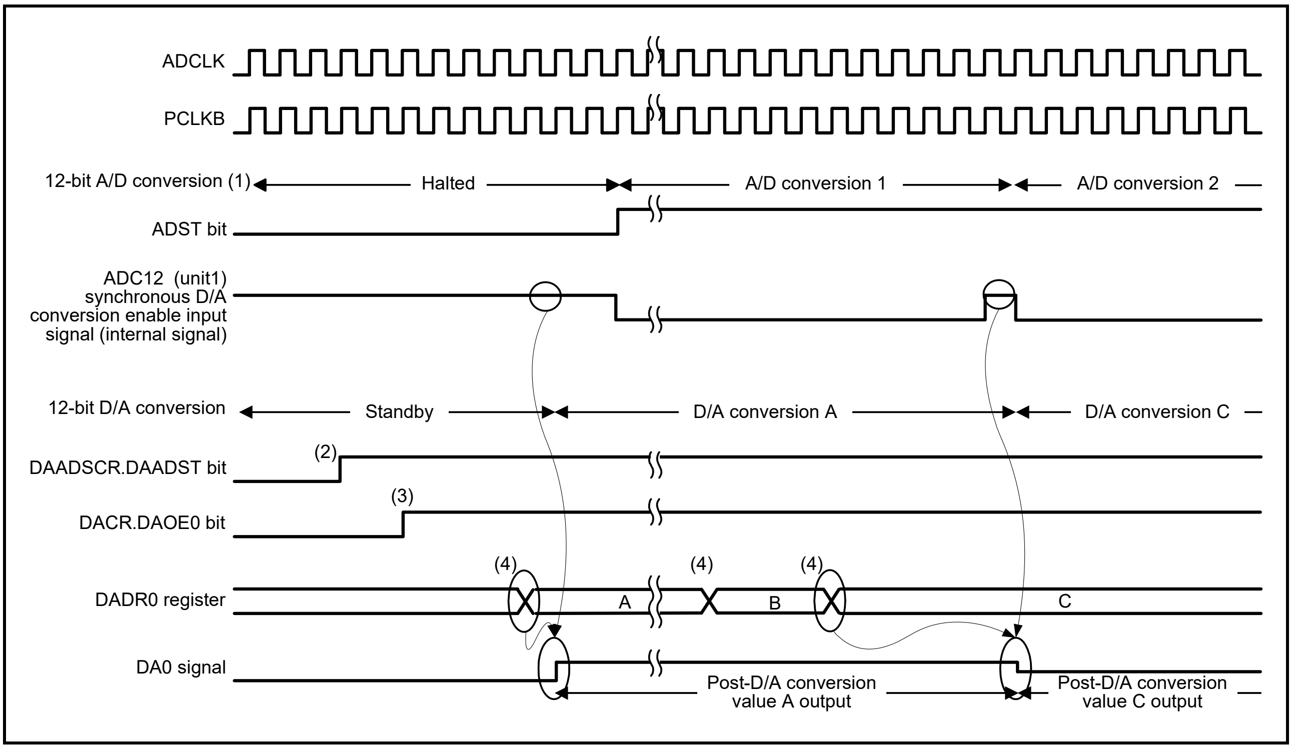

Figure 48.3 Example of conversion when the DAC12 is synchronized with the ADC12

When ADCLK is faster than PCLKB, the DAC12 might not be able to capture an ADC12 (unit 1) synchronous D/A conversion enable input signal for the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2. Figure 48.4 shows an example of this. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

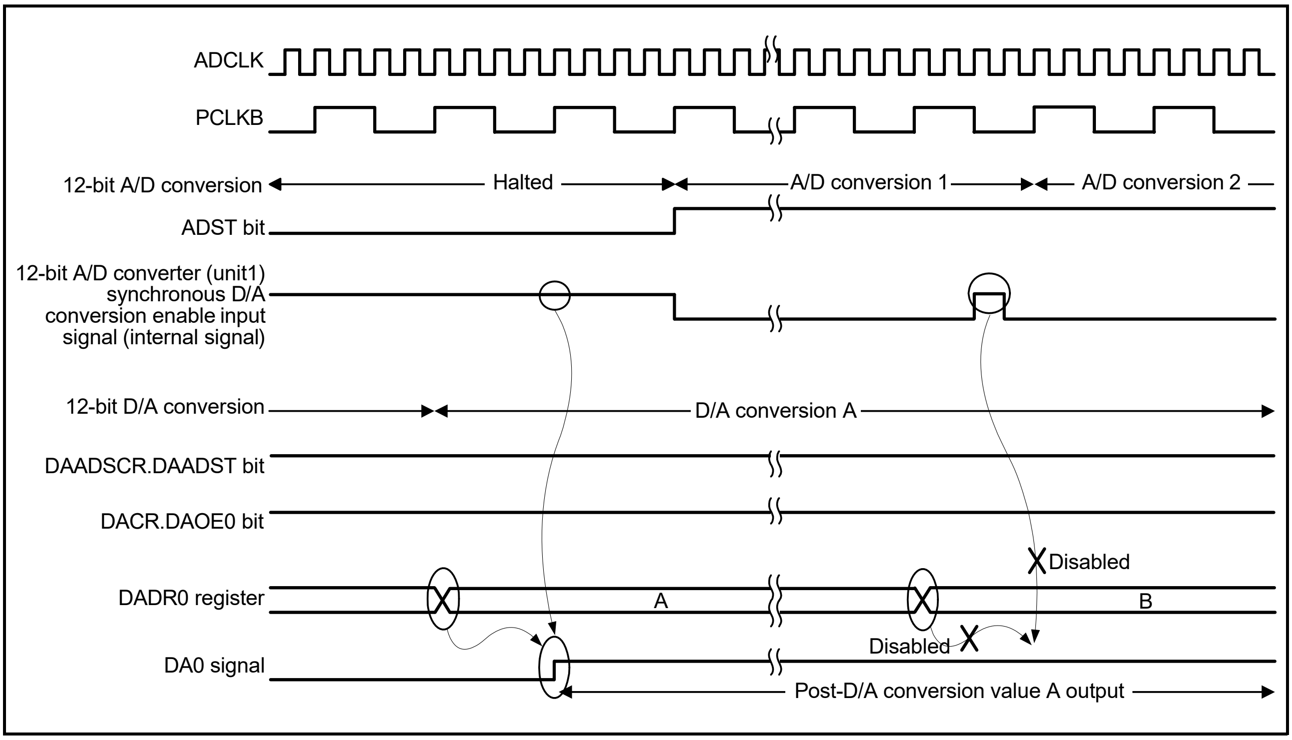

Figure 48.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

48.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

48.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit sets to 1, and D/A conversion starts on channel 0.
5. Set the ELSR12.ELS[8:0] bits to 000h to stop event link operation on DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

48.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit sets to 1, and D/A conversion starts on channel 1.
5. Set the ELSR13.ELS[8:0] bits to 000h to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

48.5 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while the write cycle is performed on the DACR.DAOE0 bit, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while the write cycle is performed on the DACR.DAOE1 bit, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

48.6 Usage Notes

48.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

48.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

48.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

48.6.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

48.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 000h to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting D/A conversion time tCONV.
6. Write the value to be converted in the DADR0 register.

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat procedures 1 to 6.

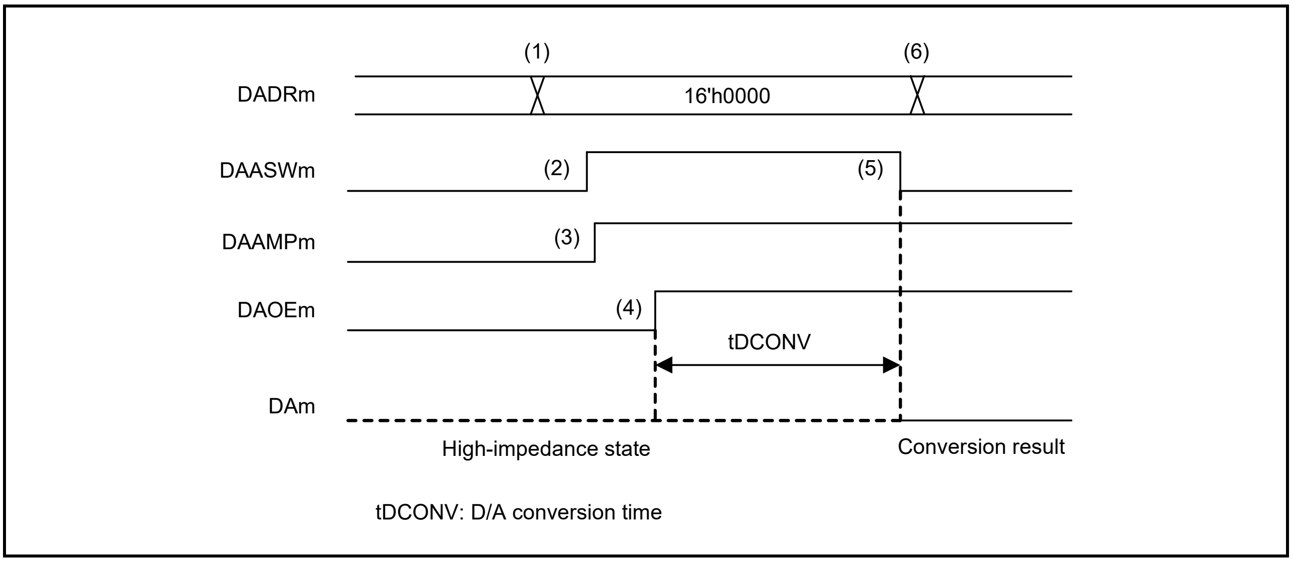

Figure 48.5 Example of the initial flow with the output amplifier in DAC12

48.6.6 Constraints on Usage When Interference Prevention between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1 (interference prevention between D/A and A/D conversion is enabled), do not place the ADC12 in the module-stop state. This might halt D/A conversion in addition to A/D conversion.

49. Temperature Sensor (TSN)

49.1 Overview

The on-chip temperature sensor can be used to determine and monitor the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can also be used by the end application. Table 49.1 lists the temperature sensor specifications and Figure 49.1 shows a block diagram.

Table 49.1 Temperature sensor specifications

Parameter	Specifications
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-Bit A/D Converter (ADC12).
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each MCU at factory shipment is stored

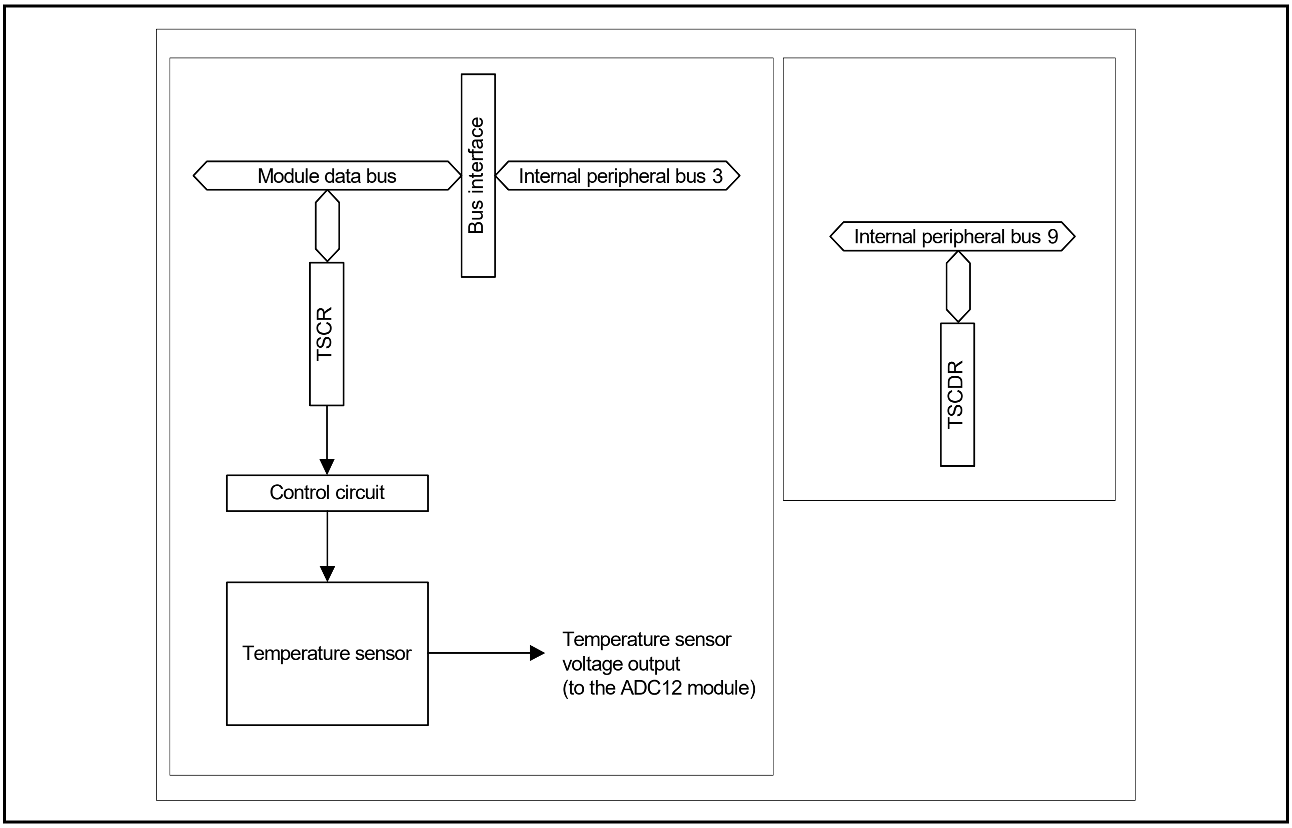

Figure 49.1 Temperature sensor block diagram

49.2 Register Descriptions

49.2.1 Temperature Sensor Control Register (TSCR)

Address(es): TSN.TSCR 4005 D000h

	b7	b6	b5	b4	b3	b2	b1	b0
	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	**Symbol**	**Bit name**	**Description**	**R/W**
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TSOE	Temperature Sensor Output Enable	0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSEN	Temperature Sensor Enable	0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

The timing constraints shown in Figure 49.3 apply to the settings of the TSCR register.

49.2.2 Temperature Sensor Calibration Data Register(TSCDR)

Address(es): TSD.TSCDR 407F B17Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each MCU											

The TSCDR register stores temperature sensor calibration data measured for each MCU at factory shipment. Temperature sensor calibration data is a digital value obtained using the 12-bit A/D converter unit 0 to convert the voltage output by the temperature sensor under the condition Ta = Tj = 127°C and AVCC0 = 3.3 V.

The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.

49.3 Using the Temperature Sensor

The temperature sensor outputs a voltage which varies with the temperature. This voltage is converted to a digital value by the ADC12. You can then obtain the die temperature by converting the value into the temperature.

49.3.1 Preparation for Using the Temperature Sensor

The temperature (T) is proportional to the sensor voltage output (Vs), so temperature is calculated with the following formula:

$T = (Vs - V1) / Slope + T1$

T: Measured temperature (°C)

Vs: Voltage output by the temperature sensor when temperature is measured (V)

T1: Temperature experimentally measured at one point (°C)

V1: Voltage output by the temperature sensor when T1 is measured (V)

T2: Temperature at the experimental measurement of another point (°C)

V2: Voltage output by the temperature sensor when T2 is measured (V)

Slope: Temperature gradient of the temperature sensor (V / °C), Slope = (V2 - V1) / (T2 - T1)

Determine the values for formula parameter (V1, T1, Slope) measurement. These values vary from sensor to sensor, and Renesas recommends making the following experimental measurement at two different temperatures to determine the values for these parameters:

1. Use the ADC12 to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Use the ADC12 to measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature gradient (Slope = (V2 - V1) / (T2 - T1)) from these results.
3. Obtain subsequent temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs - V1) / Slope + T1).

If you are using the temperature slope given in Table 60.45 of section 60, Electrical Characteristics, use the 12-bit A/D converter unit 0 to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic by using the following formula:

T = (Vs - V1) / Slope + T1

T: Measured temperature (°C)

Vs: Voltage output by the temperature sensor when the temperature is measured (V)

T1: Sample temperature measurement at first point (°C)

V1: Voltage output by the temperature sensor when T1 is measured (V)

Slope: Temperature slope given in Table 60.45 ÷ 1000 (V / °C)

In this MCU, the TSCDR register stores the temperature value (CAL127) of the temperature sensor measured under the condition Ta = Tj = 127°C and AVCC0 = 3.3 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.

If V1 is calculated from CAL127:

V1 = 3.3 × CAL127 / 4096 [V]

Using this, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / Slope + 127 [°C]

T: Measured temperature (°C)

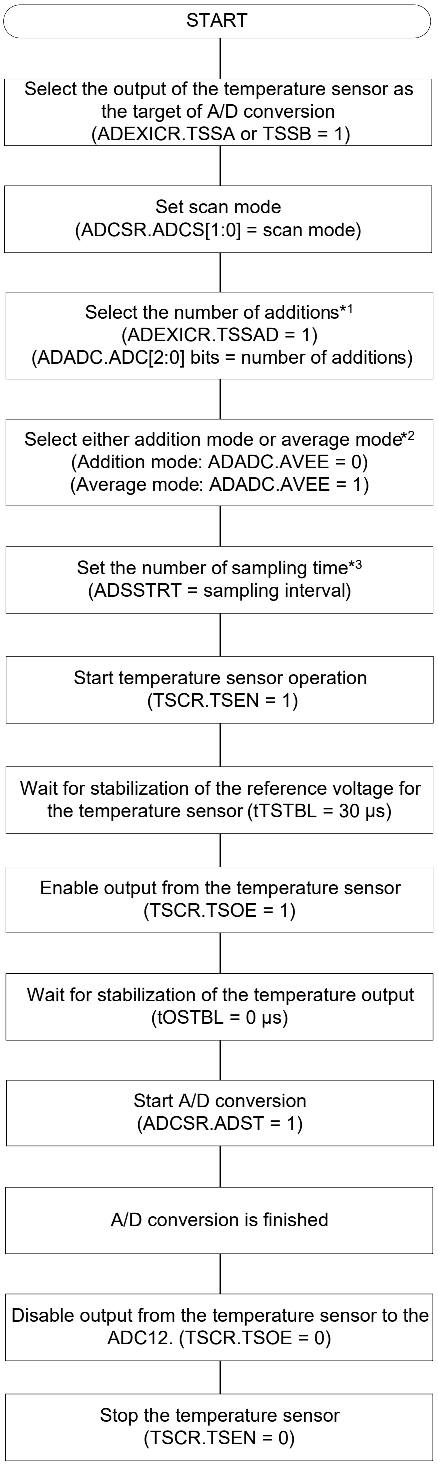
Vs: Voltage output by the temperature sensor when the temperature is measured (V)

V1: Voltage output by the temperature sensor when Ta = Tj = 127°C and AVCC0 = 3.3 V (V)

Slope: Temperature slope given in Table 60.45 ÷ 1000 (V / °C)

49.3.2 Procedures for Using the Temperature Sensor

Figure 49.2 shows the procedure for using the temperature sensor. For the procedure to configure the ADC12, see section 47, 12-Bit A/D Converter (ADC12).



Note 1. The ADADC.ADC[2:0] setting is limited to some values in average mode. For details on available ADADC.ADC[2:0] settings in average mode, see section 47.2.10, A/D-Converted Value Addition/Average Count Select Register (ADADC).

Note 2. This setting is not required if addition/average mode is not set.

Note 3. Set the sampling time to more than the value described in section 60.7, TSN Characteristics.

Figure 49.2 Procedure for using the temperature sensor

Figure 49.3 shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in Table 49.2.

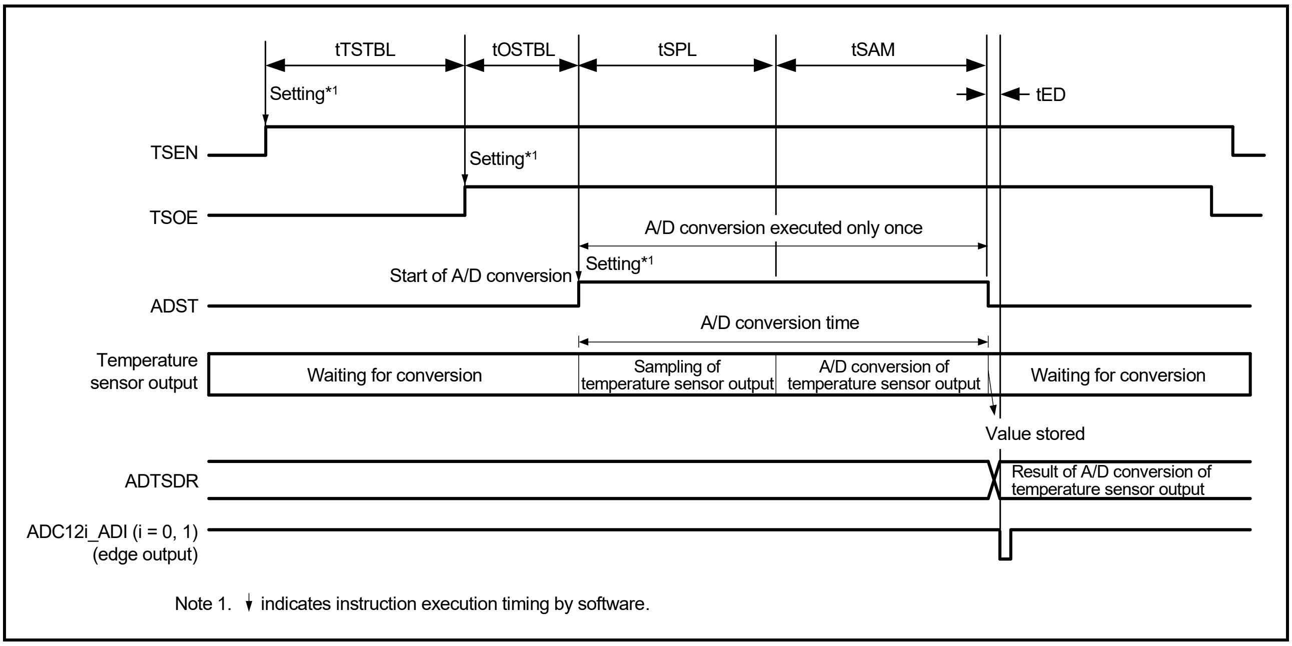


Figure 49.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 49.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	tTSTBL	30 µs (min)
Wait time for temperature sensor output stabilization	tOSTBL	0 µs (min)
ADC12 input sampling time	tSPL	ADSSTRT setting × ADCLK cycles
A/D conversion time	tSAM	See Table 47.10, Conversion times during scanning (in numbers of cycles of ADCLK and PCLKB)
Scan conversion end delay	tED	

49.4 Usage Notes

49.4.1 Settings for the Module-Stop Function

Temperature sensor operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The temperature sensor is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

49.4.2 Constraints

It is prohibited to use both channels of the ADC12 simultaneously for temperature sensor measurement.

50. High-Speed Analog Comparator (ACMPHS)

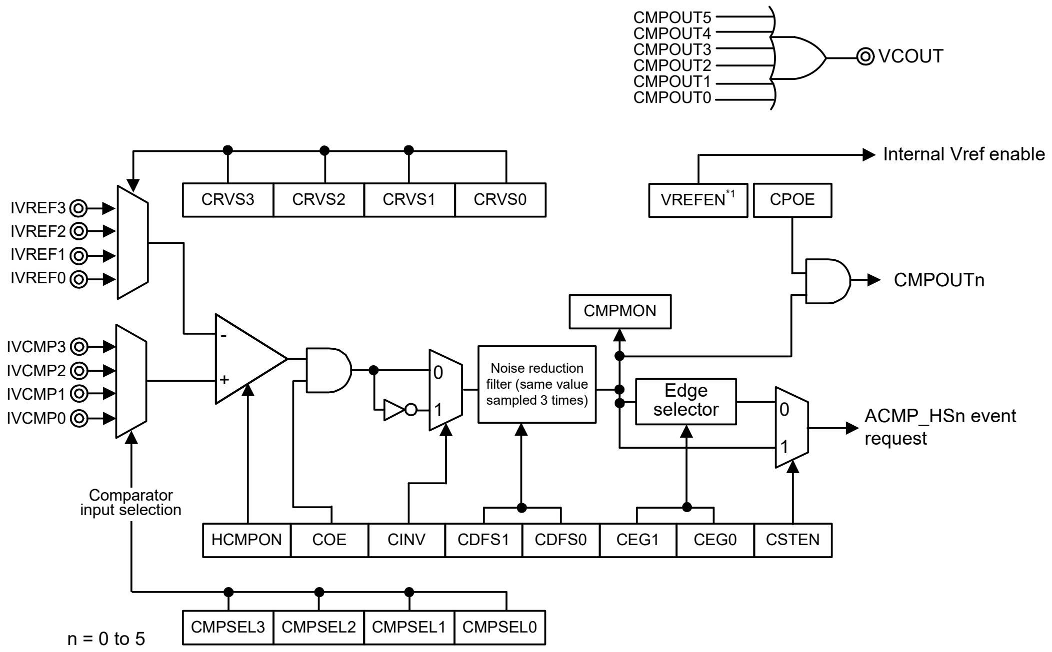
50.1 Overview

The High-Speed Analog Comparator (ACMPHS) can be used to compare a test voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the test voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output and internal reference voltage) and an external source (with or without an internal PGA). Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

Table 50.1 lists the ACMPHS specifications, Figure 50.1 shows a block diagram, and Table 50.2 shows the input source configurations.

Table 50.1 ACMPHS 0 to 5 specifications

Parameter	Specifications
Number of channels	6 channels: ACMPHS 0 to ACMPHS 5
Analog input voltage	• Output from internal PGA • Output from internal D/A converter • Input from internal A/D converter input pin (one selectable).
Reference voltage	• Internal reference voltage (Vref) • Output from internal D/A converter • Input from internal A/D converter input pin (one selectable).
ACMPHS output	• Comparison result • Generation of ELC event output • Monitor output from register.
Interrupt request signal	• Interrupt request generated on valid edge detection from comparison result • Selectable to rising edge, falling edge, or both edges.
Digital filter function	• Selectable to one of three sampling frequencies • Not using the filter function is selectable.



CMPSEL3 to CMPSEL0: Bits in CMPSEL0 register
CRVS3 to CRVS0: Bits in CMPSEL1 register
CPOE, VREFEN: Bits in CPIOC register
CMPMON: Bit in CMPMON register
HCMPON, COE, CINV, CDFS1, CDFS0, CEG1, CEG0, CSTEN: Bits in CMPCTL register

Note: VREFEN exists only in ACMPHS0.

Figure 50.1 ACMPHS block diagram

Table 50.2 Input source configuration of the ACMPHS

	Reference voltage input source				Analog voltage input source				
Comparator	**IVREF3**	**IVREF2**	**IVREF1**	**IVREF0**	**IVCMP3**	**IVCMP2**	**IVCMP1**	**IVCMP0**	**Output pin**
ACMPHS0	DA0*1	Vref*2	AN116	AN016	PGA0 output*6	AN000*3, *6	DA1*4	AN017	VCOUT*5
ACMPHS1	DA0*1	Vref*2	AN116	AN016	PGA1 output*6	AN001*3, *6	DA1*4	AN017	
ACMPHS2	DA0*1	Vref*2	AN116	AN016	PGA2 output*6	AN002*3, *6	DA1*4	AN017	
ACMPHS3	DA0*1	Vref*2	AN116	AN016	PGA3 output*6	AN100*3, *6	DA1*4	AN017	
ACMPHS4	DA0*1	Vref*2	AN116	AN016	PGA4 output*6	AN101*3, *6	DA1*4	AN017	
ACMPHS5	DA0*1	Vref*2	AN116	AN016	PGA5 output*6	AN102*3, *6	DA1*4	AN017	

Note 1. When D/A converter 0 output is not used, the signal can be used as AN005/AN105 analog input.
Note 2. Internal voltage reference.
Note 3. Because input is through PGA, the associated Module Stop bit, MSTPCRD.MSTPD16 (unit 0) or MSTPCRD.MSTPD15 (unit 1) should be set to 0.
Note 4. When D/A converter 1 output is not used, the signal can be used as AN006/AN106 analog input.
Note 5. ACMPHS0 to ACMPHS5 compare outputs are bundled with the VCOUT pin.
Note 6. Setting of the ADC12 is required. For details, see section 47.6.8, Available Functions and Register Settings of AN000 to AN002, AN007, AN100 to AN102, and AN107.

50.2 Register Descriptions

50.2.1 Comparator Control Register (CMPCTL)

Address(es): ACMPHS0.CMPCTL 4008 5000h,ACMPHS1.CMPCTL 4008 5100h, ACMPHS2.CMPCTL 4008 5200h,
ACMPHS3.CMPCTL 4008 5300h, ACMPHS4.CMPCTL 4008 5400h, ACMPHS5.CMPCTL 4008 5500h

	b7	b6	b5	b4	b3	b2	b1	b0
	HCMPON	CDFS[1:0]		CEG1	CEG0	CSTEN	COE	CINV
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CINV	Comparator Output Polarity Selection*2, *3	0: Do not invert comparator output 1: Invert comparator output.	R/W
b1	COE	Comparator Output Enable	0: Disable comparator output (output signal is low level) 1: Enable comparator output.	R/W
b2	CSTEN	Interrupt Select*1	0: Output through the edge selector 1: Output directly.	R/W
b4, b3	CEG1/CEG0	Selection of Valid Edge (Edge Selector)	b4 b3 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges.	R/W
b6, b5	CDFS[1:0]	Noise Filter Selection*1, *2, *3, *4	b6 b5 0 0: Do not use noise filter. 0 1: Use noise filter sampling frequency of PCLKB/2^3 1 0: Use noise filter sampling frequency of PCLKB/2^4 1 1: Use noise filter sampling frequency of PCLKB/2^5.	R/W
b7	HCMPON	Comparator Operation Control*5	0: Stop operation (comparator outputs a low-level signal) 1: Enable operation (enables input to the comparator pins).	R/W

Note 1. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes release of Software Standby or Snooze modes. CTSEN is supported only by the ACMPHS0. ACMPHSn.CMPCTL.CTESN (n = 1 to 5) must be set to 0.

Note 2. Disable the ACMPHS output (COE = 0) before changing the CDFS[1:0] and CINV bits.

Note 3. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.

Note 4. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.

Note 5. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCMPON = 1). The operation stabilization wait time for ACMPHS modules 0 to 5 is 300 ns.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt. A reset clears this register to 00h.

50.2.2 Comparator Input Select Register (CMPSEL0)

Address(es): ACMPHS0.CMPSEL0 4008 5004h, ACMPHS1.CMPSEL0 4008 5104h, ACMPHS2.CMPSEL0 4008 5204h, ACMPHS3.CMPSEL0 4008 5304h, ACMPHS4.CMPSEL0 4008 5404h, ACMPHS5.CMPSEL0 4008 5504h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CMPSEL[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b3 to b0	CMPSEL[3:0]	Comparator Input Selection*1	b3 b0 0 0 0 0: Do not input 0 0 0 1: Select IVCMP0*2 0 0 1 0: Select IVCMP1*2 0 1 0 0: Select IVCMP2*2 1 0 0 0: Select IVCMP3.*2 Other settings are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Use the following procedure to change the CMPSEL[3:0] bits. Writing a value other than 0000 0000b while the value of the CMPSEL0 register is not 0000 0000b is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CMPSEL[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL0 register to 0000 0000b.
3. Set a new value in the CMPSEL[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 50.2.

50.2.3 Comparator Reference Voltage Select Register (CMPSEL1)

Address(es): ACMPHS0.CMPSEL1 4008 5008h, ACMPHS1.CMPSEL1 4008 5108h, ACMPHS2.CMPSEL1 4008 5208h, ACMPHS3.CMPSEL1 4008 5308h, ACMPHS4.CMPSEL1 4008 5408h, ACMPHS5.CMPSEL1 4008 5508h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CRVS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b3 to b0	CRVS[3:0]	Reference Voltage Selection*1	b3 b0 0 0 0 0: Do not input 0 0 0 1: Select IVREF0*2 0 0 1 0: Select IVREF1*2 0 1 0 0: Select IVREF2*2 1 0 0 0: Select IVREF3*2 Other settings are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Use the following procedure to change the CRVS[3:0] bits. Writing a value other than 0000 0000b while the value of the CMPSEL1 register is not 0000 0000b is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.
To change the CRVS[3:0] bits:
1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL1 register to 0000 0000b.
3. Set a new value to the CRVS[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns)
5. Set the CMPCTL.COE bit to 1.

6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see Table 50.2.

50.2.4 Comparator Output Monitor Register (CMPMON)

Address(es): ACMPHS0.CMPMON 4008 500Ch, ACMPHS1.CMPMON 4008 510Ch, ACMPHS2.CMPMON 4008 520Ch, ACMPHS3.CMPMON 4008 530Ch, ACMPHS4.CMPMON 4008 540Ch, ACMPHS5.CMPMON 4008 550Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPMON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CMPMON	Comparator Output Monitor*1	0: Comparator output is low 1: Comparator output is high.	R
b7 to b1	—	Reserved	These bits are read as 0.	R

Note 1. When ACMPHS operation is enabled (HCMPON = COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the CMPMON bit is read twice and the values are only used after the two consecutive values match.

50.2.5 Comparator Output Control Register (CPIOC)

Address(es): ACMPHS0.CPIOC 4008 5010h, ACMPHS1.CPIOC 4008 5110h, ACMPHS2.CPIOC 4008 5210h, ACMPHS3.CPIOC 4008 5310h, ACMPHS4.CPIOC 4008 5410h, ACMPHS5.CPIOC 4008 5510h

	b7	b6	b5	b4	b3	b2	b1	b0
	VREFEN	—	—	—	—	—	—	CPOE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CPOE	Comparator Output Selection	0: Disable VCOUT pin output of the comparator (output signal is low) 1: Enable VCOUT pin output of the comparator.	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	VREFEN	Internal Vref Enable*1	0: Disable internal Vref 1: Enable internal Vref.	R/W

Note 1. For ACMPHS modules 0 to 5, VREFEN exists only in ACMPHS0.CPIOC. When using the internal Vref in COMP0 to COMP5, set the VREFEN bit in ACMPHS0.CPIOC to 1. Bit [7] in ACMPHS1.CPIOC to ACMPHS5.CPIOC should be 0 regardless of whether or not the internal Vref is used.

50.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 50.3 shows the procedures for setting the registers associated with ACMPHS.

Table 50.3 Procedure for setting registers associated with ACMPHSn (n = 0 to 5) (1 of 2)

Step	Register	Bit	Setting
1	Associated MSTPCRD register	MSTPD28 to MSTPD23	0: Input clock supply.
2	Associated Port mn Pin Function Select register (PmnPFS)	ASEL	1: Select the function of pins IVREF and IVCMP.
3	ACMPHS0.CPIOC	VREFEN	1: When using the internal Vref.

Table 50.3 Procedure for setting registers associated with ACMPHSn (n = 0 to 5) (2 of 2)

Step	Register	Bit	Setting
4	Associated D/A convertor		When using the D/A convertor, select in the register.
5	CMPSEL0, CMPSEL1	CMPSEL0 to CMPSEL3, CRVS0 to CRVS3	Select the ACMPHSn input, with 1 set in only one of the bits.
6	CMPCTL	CDFS[1:0], CEG1, CEG0, and CINV	Set up ACMPHSn control.
		HCMPON	1: Enable ACMPHSn operation.
7	Waiting for the ACMPHS stabilization time (minimum 300 ns).		
8	CMPCTL	COE	1: Enable ACMPHSn output.
9	CPIOC	CPOE	Set the VCOUT output
	Associated Port mn Pin Function Select register (PmnPFS)	PSEL, PMR	Select the VCOUT port function.
10	IELSRn	IR, IELS[8:0]	When using an interrupt, select the interrupt status flag and the ICU event link.*1
11	ELSRn	ELS[8:0]	When using an ELC, select the event link.*2
12	Operation started		
13	CMPCTL	COE	0: When changing IVREF or IVCMP, to disable ACMPHSn output.
14	CMPSEL1	CRVS0 to CRVS3	Change the CMPSEL1 bits as follows: 1. Set bits CMPSEL1 to 0000 0000b. 2. Set a new value to the CMPSEL1 bits, with 1 set in only one of the bits.
	CMPSEL0	CMPSEL0 to CMPSEL3	Change the CMPSEL0 bits as follows: 1. Set bits CMPSEL0 to 0000 0000b. 2. Set a new value to the CMPSEL0 bits, with 1 set in only one of the bits.
15	Waiting for the ACMPHS switching stabilization time (minimum 200 ns).		
16	CMPCTL	COE	1: Enable ACMPHSn output.
17	Operation restarted		

Note 1. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the interrupt flag.
Note 2. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the event link select.

Figure 50.2 shows an example of ACMPHS operation. The VCOUT output becomes 1 when the analog input voltage is higher than the ACMPHS reference input voltage, and the VCOUT output becomes 0 when the analog input voltage is lower than the reference voltage. When the ACMPHS output changes, an interrupt request and an ELC event are output.

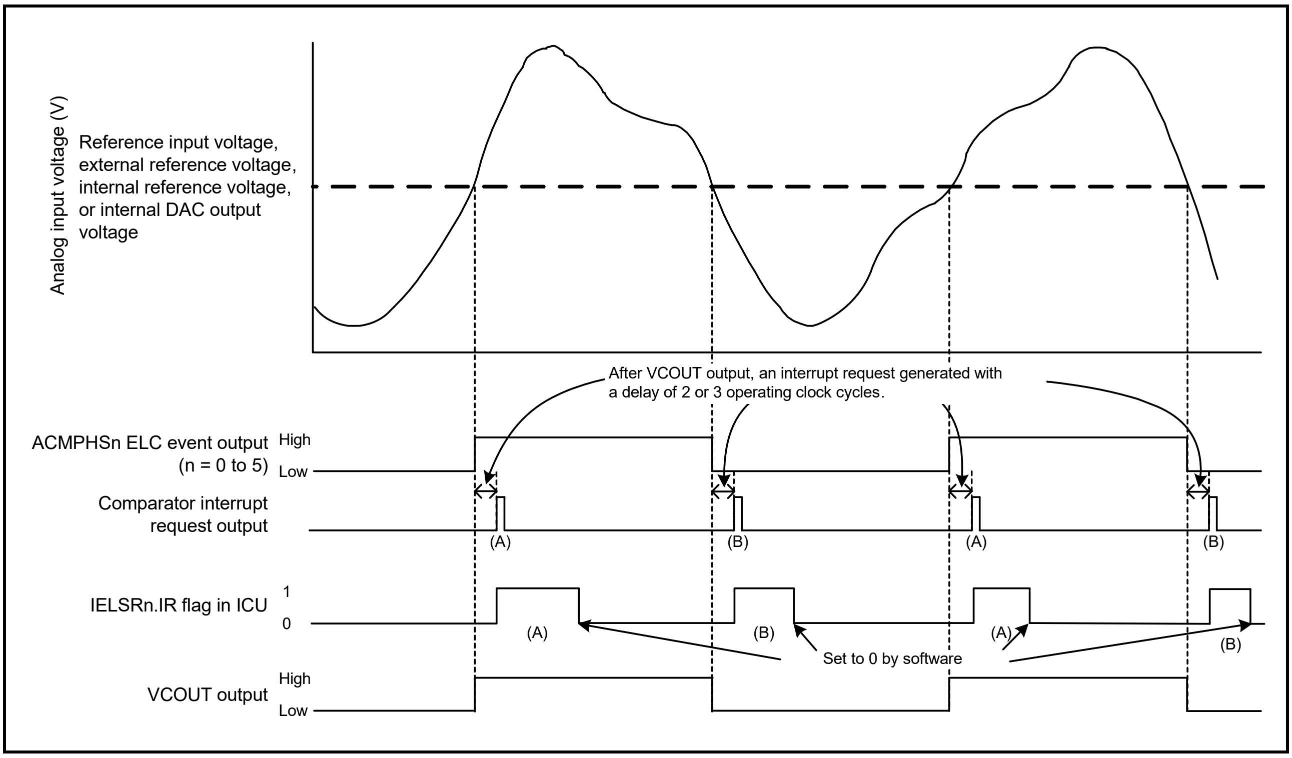


Figure 50.2 ACMPHS operation example

Figure 50.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG1 = CEG0 = 1 (both-edge detection selected). When CINV = 0, CEG0 = 1, and CEG1 = 0 (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG0 = 0, and CEG1 = 1 (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only. When CPOE = 1, VCOUT directly outputs the ELC event output.

50.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The ACMPHS signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 50.3 shows the configuration of the noise filter and edge detector, and Figure 50.4 shows an example of noise filter and interrupt operation.

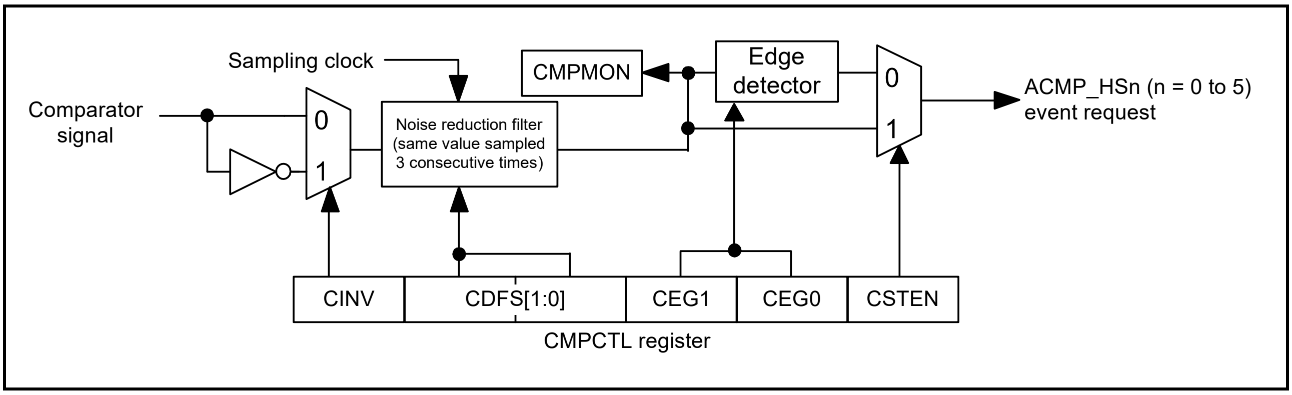

Figure 50.3 Noise filter and edge detection configuration

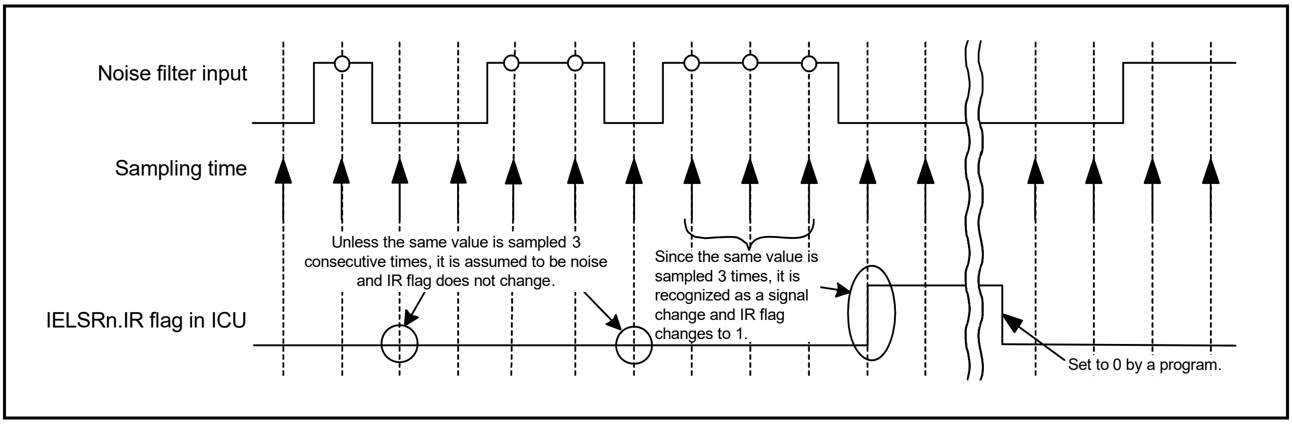

Figure 50.4 Noise filter and interrupt operation example

The operation example in Figure 50.4 applies when the CMPCTL.CDFS[1:0] bits are 01b, 10b, or 11b (noise filter used).

50.5 ACMPHS Interrupts

The ACMPHS generates six interrupt requests from sources ACMPHS0 to ACMPHS5. To use an ACMPHS interrupt, select it in the IELSR register in the Interrupt Controller Unit (ICU). Select the interrupt request in the CMPCTL.CSTEN bit, either through the edge selector, or not.

When using the ACMPHS interrupt through the edge selector, set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection). In most cases, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Setting this bit to 1 is only permitted to release Software Standby or Snooze mode.

To use the ACMPHS interrupt in Software Standby or Snooze mode, set the CMPCTL.CSTEN bit to 1 (direct output), set the CMPCTL.CDFS[1:0] bits to 00b (digital noise filter not used), and set CMPCTL.CINV as follows:

- When detecting compare result 1 to 0, set CMPCTL.CINV to 0 (comparator output not inverted)
- When detecting compare result 0 to 1, set CMPCTL.CINV to 1 (comparator output inverted).

An ACMPHS0 interrupt request can be used to release Software Standby or Snooze modes. (ACMPHS1 to ACMPHS5 cannot be used.)

For details on the register settings related to ACMPHS interrupt requests, see section 50.2.1, Comparator Control Register (CMPCTL).

50.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the ELSRn register in the ELC. When using the ELC event request, set the CMPCTL.CSTEN bit to 0 (output through the edge selector). Also set at least one of the CMPCTL.CEG0 and CMPCTL.CEG1 bits to 1 (to a value other than 00b for no edge selection).

50.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the CMPCTL.CINV and CPIOC.CPOE bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the VCOUT output pin, set the associated Port mn Pin Function Select register (PmnPFS) in the I/O register.

50.8 Usage Notes

50.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

50.8.2 Relationship with the ADC12

Constraints apply on the simultaneous use of ACMPHS analog input and ADC12 analog input. For details, see section 47, Relationship between ADC12 Units 0 and 1 and the ACMPHS.

51. Capacitive Touch Sensing Unit (CTSU)

51.1 Overview

The Capacitive Touch Sensing Unit (CTSU) measures the electrostatic capacitance of the touch sensor. Changes in the electrostatic capacitance are determined by software that enables the CTSU to detect whether a finger is in contact with the touch sensor. The electrode surface of the touch sensor is usually enclosed with an electrical insulator so that a finger does not come into direct contact with the electrode.

As Figure 51.1 shows, electrostatic capacitance (parasitic capacitance) exists between the electrode and the surrounding insulators. Because the human body is an electrical conductor, when a finger is placed close to the electrode, the value of electrostatic capacitance increases.

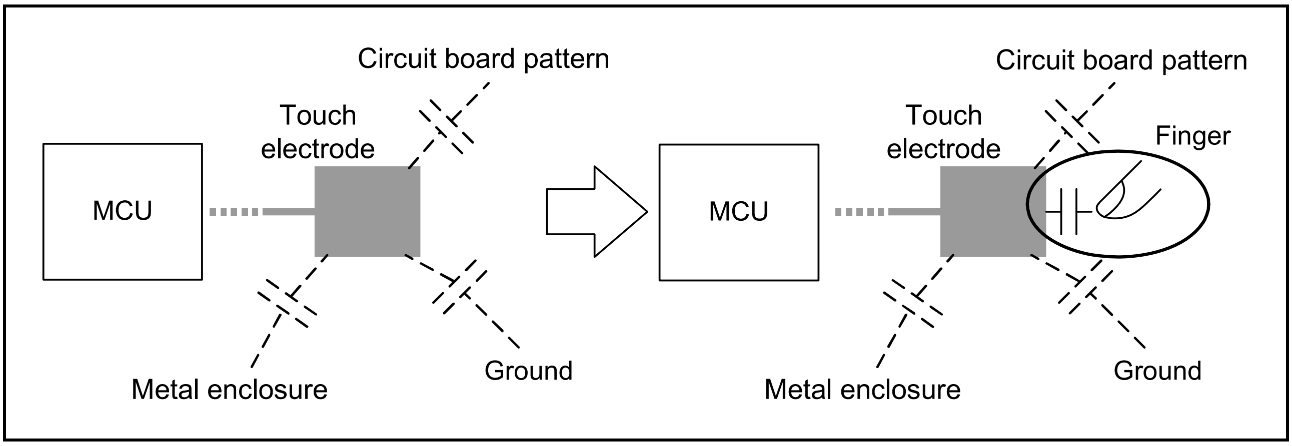

Figure 51.1 Increased electrostatic capacitance because of the presence of a finger

Electrostatic capacitance is detected by the self-capacitance and mutual capacitance methods. In the self-capacitance method, the CTSU detects electrostatic capacitance generated between a finger and a single electrode. In the mutual capacitance method, two electrodes are used as a transmit electrode and a receive electrode, and the CTSU detects the change in the electrostatic capacitance generated between the two when a finger is placed close to them.

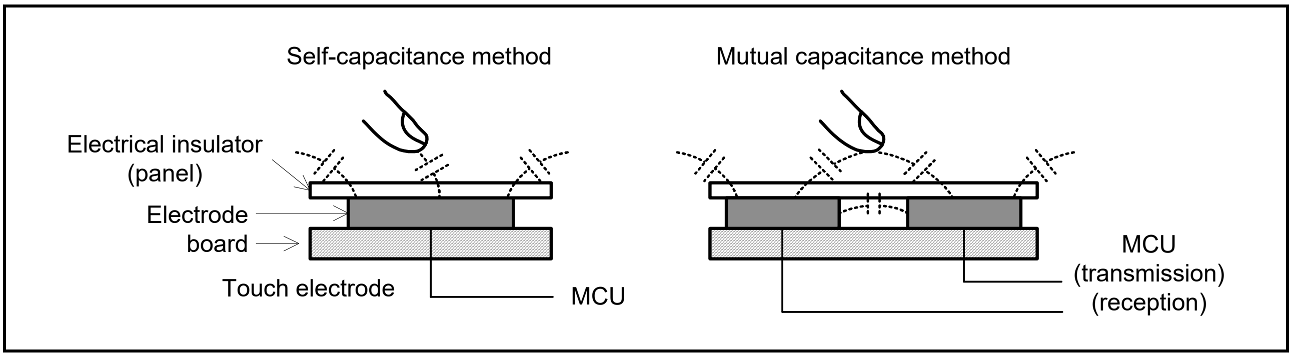

Figure 51.2 Self-capacitance and mutual capacitance methods

Electrostatic capacitance is measured by counting a clock signal whose frequency changes according to the amount of charged or discharged current, for a specified period. For details on the measurement principles of the CTSU, see section 51.3.1, Principles of Measurement Operation. Table 51.1 lists the CTSU specifications and Figure 51.3 shows a block diagram.

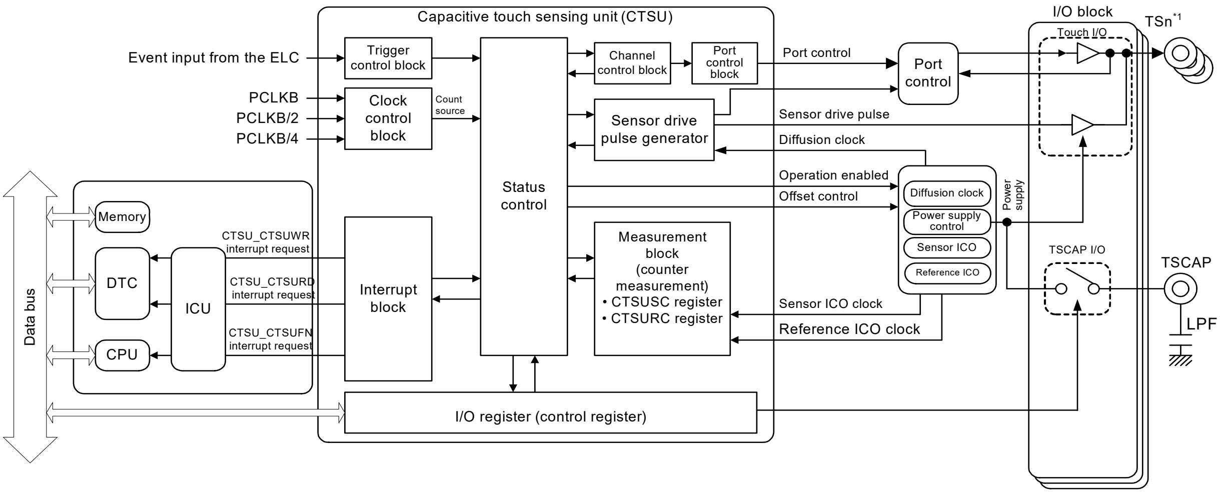
Table 51.1 CTSU specifications (1 of 2)

Parameter	Specifications
Operating clock	PCLKB, PCLKB/2, or PCLKB/4

Table 51.1 CTSU specifications (2 of 2)

Parameter		Specifications
Pins	Electrostatic capacitance measurement	18 channels (TS00 to TS17)
	TSCAP	Low Pass Filter (LPF) connection pin
Measurement modes	Self-capacitance single scan mode	Electrostatic capacitance is measured on one channel using the self-capacitance method
	Self-capacitance multiscan mode	Electrostatic capacitance is measured successively on multiple channels using the self-capacitance method
	Mutual capacitance full scan mode	Electrostatic capacitance is measured successively on multiple channels using the mutual capacitance method
Noise prevention		Synchronous noise prevention, high-pass noise prevention
Measurement start conditions		• Software trigger • External trigger (ELC_CTSU from the Event Link Controller (ELC))

As Figure 51.3 shows, the CTSU consists of a status control block, trigger control block, clock control block, channel control block, port control block, sensor drive pulse generator, measurement block, interrupt block, and I/O registers.



ICO: Intensity of Current Controlled Oscillator

Note 1. n = 00 to 17

Figure 51.3 CTSU block diagram

Table 51.2 CTSU I/O pins

Pin name	I/O	Function
TS00 to TS17	Input	Electrostatic capacitive measurement pins (touch pins)
TSCAP	-	LPF connection pin

51.2 Register Descriptions

51.2.1 CTSU Control Register 0 (CTSUCR0)

Address(es): CTSU.CTSUCR0 4008 1000h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUTXVSEL	—	—	CTSUINIT	—	CTSUSNZ	CTSUCAP	CTSUSTRT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CTSUSTRT	CTSU Measurement Operation Start	0: Stop measurement operation*1 1: Start measurement operation.	R/W
b1	CTSUCAP	CTSU Measurement Operation Start Trigger Select	0: Software trigger 1: External trigger.	R/W
b2	CTSUSNZ	CTSU Wait State Power-Saving Enable	0: Disable power-saving function during wait state 1: Enable power-saving function during wait state.	R/W
b3	—	Reserved	This bit read as 0. The write value should be 0.	R/W
b4	CTSUINIT	CTSU Control Block Initialization	Writing 1 to this bit initializes the CTSU control block and CTSUSC, CTSURC, CTSUMCH0, CTSUMCH1, and CTSUST registers. This bit is read as 0.	W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CTSUTXVSEL	CTSU Transmission Power Supply Select	0: VCC selected 1: Internal logic power supply selected.	R/W

Note 1. When the CTSU is not used, set the value of this bit to 0.

Only set the CTSUCAP and CTSUSNZ bits when the CTSUSTRT bit is 0. These bits can be set at the same time that measurement operation starts.

CTSUSTRT bit (CTSU Measurement Operation Start)

The CTSUSTRT bit specifies whether CTSU operation starts or stops. When the CTSUCAP bit is 0, measurement starts when the software writes 1 to the CTSUSTRT bit (software trigger) and stops when the hardware clears the CTSUSTRT bit to 0. When the CTSUCAP bit is 1, the CTSU waits for an external trigger by writing 1 to the CTSUSTRT bit, and measurement starts on the rising edge of the external trigger. When measurement is stopped, the CTSU waits for the next external trigger and operation continues.

Table 51.3 lists the CTSU states.

Table 51.3 CTSU states

CTSUSTRT bit	CTSUCAP bit	CTSU state
0	0	Stopped
0	1	Stopped
1	0	Measurement in progress
1	1	Measurement in progress and waiting for an external trigger*1

Note 1. The state can be read from the CTSUST.CTSUSTC[2:0] flags as follows:
During measurement: CTSUST.CTSUSTC[2:0] flags ≠ 000b
While waiting for an external trigger: CTSUST.CTSUSTC[2:0] flags = 000b

If the software sets the CTSUSTRT bit to 1 when the bit is already 1, the write is ignored and operation continues. To force operation to stop through the software when the CTSUSTRT bit is 1, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 at the same time.

CTSUCAP bit (CTSU Measurement Operation Start Trigger Select)

The CTSUCAP bit specifies the measurement start condition. For details, see CTSUSTRT bit (CTSU Measurement Operation Start).

CTSUSNZ bit (CTSU Wait State Power-Saving Enable)

The CTSUSNZ bit enables or disables power-saving operation during a wait state. It can also suspend the CTSU power supply, which decreases power consumption during the wait state. In the suspended state, the CTSU power supply is turned off while the external TSCAP is still charged.

Table 51.4 shows the CTSU power supply state control.

Table 51.4 CTSU power supply state control

CTSUCR1.CTSUPON bit	CTSUSNZ bit	CTSUCAP bit	CTSUSTRT bit	CTSU power supply state
0	0	0	0	Stopped
1	0	—	—	Operating
1	1	0	0	Suspended

Note: Other settings are prohibited.

To start measurement from the suspended state, set the CTSUSNZ bit to 0, and then set the CTSUSTRT bit to 1. To suspend the module after measurement stops, set the CTSUSNZ bit to 1.

CTSUINIT bit (CTSU Control Block Initialization)

Write 1 to the CTSUINIT bit to initialize the internal control registers. To force the current operation to stop, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 at the same time. This stops the operation and initializes the internal control registers.

Do not write 1 to the CTSUINIT bit when the CTSUSTRT bit is 1.

CTSUTXVSEL bit (CTSU Transmission Power Supply Select)

This bit is used to switch the power supply for the transmit buffer in mutual capacitance full scan mode. Set this bit to 0 for any other mode or when the VCC voltage is lower than 2.7 V. This bit switches the power supply for touch I/O which is set for transmission by the CTSUCHTRCn registers. Table 51.5 lists the power supply for TSm pin. When the VCC voltage fluctuates greatly due to the switching of the output buffer, switching to the internal logic power supply can reduce the effect on the voltage fluctuation.

Table 51.5 Power supplied to the TSm pins

Setting of CTSUCHTRCn Register	CTSUTXVSEL bit	Power supply of TSm pins
0 (Reception)	*	VCC
1 (Transmission)	0 (VCC)	
	1 (Internal logic power supply)	Internal logic power supply

51.2.2 CTSU Control Register 1 (CTSUCR1)

Address(es): CTSU.CTSUCR1 4008 1001h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUMD[1:0]		CTSUCLK[1:0]		CTSUATUNE1	—	CTSUCSW	CTSUPON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CTSUPON	CTSU Power Supply Enable	0: Power off the CTSU 1: Power on the CTSU.	R/W
b1	CTSUCSW	CTSU LPF Capacitance Charging Control	This bit controls charging of the LPF capacitance connected to the TSCAP pin. 0: Turn off capacitance switch 1: Turn on capacitance switch.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CTSUATUNE1	CTSU Power Supply Capacity Adjustment	0: Normal output 1: High-current output.	R/W
b5, b4	CTSUCLK[1:0]	CTSU Operating Clock Select	b5 b4 0 0: PCLKB 0 1: PCLKB/2 (PCLKB divided by 2) 1 0: PCLKB/4 (PCLKB divided by 4) 1 1: Setting prohibited.	R/W
b7, b6	CTSUMD[1:0]	CTSU Measurement Mode Select	b7 b6 0 0: Self-capacitance single scan mode 0 1: Self-capacitance multiscan mode 1 0: Setting prohibited 1 1: Mutual capacitance full scan mode.	R/W

Only set the CTSUCR1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPON bit (CTSU Power Supply Enable)

The CTSUPON bit controls the power supply to the CTSU. Set the CTSUPON and CTSUCSW bits to the same value.

CTSUCSW bit (CTSU LPF Capacitance Charging Control)

The CTSUCSW bit controls charging of the LPF capacitor connected to the TSCAP pin by turning the capacitance switch on or off. After the capacitance switch is turned on, wait until the capacitance connected to the TSCAP pin is charged for the specified time before starting measurement by setting CTSUCR0.CTSUSTRT to 1. Before starting measurement, use an I/O port to output low to the TSCAP pin, and discharge the existing LPF capacitance. Set the CTSUPON and CTSUCSW bits to the same value.

CTSUATUNE1 bit (CTSU Power Supply Capacity Adjustment)

The CTSUATUNE1 bit sets the capacity of the CTSU power supply. Normally, set this bit to 0.

CTSUCLK[1:0] bits (CTSU Operating Clock Select)

The CTSUCLK[1:0] bits select the operating clock.

CTSUMD[1:0] bits (CTSU Measurement Mode Select)

The CTSUMD[1:0] bits set the measurement mode. For details, see section 51.3.2, Measurement Modes.

51.2.3 CTSU Synchronous Noise Reduction Setting Register (CTSUSDPRS)

Address(es): CTSU.CTSUSDPRS 4008 1002h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	CTSUSOFF	CTSUPRMODE[1:0]		CTSUPRRATIO[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b3 to b0	CTSUPRRATIO[3:0]	CTSU Measurement Time and Pulse Count Adjustment	These bits set the measurement time and the measurement pulse count setting. Recommended setting: 3 (0011b).	R/W
b5, b4	CTSUPRMODE[1:0]	CTSU Base Period and Pulse Count Setting	These bits set the base pulse count. b5 b4 0 0: 510 pulses 0 1: 126 pulses 1 0: 62 pulses (recommended setting) 1 1: Setting prohibited.	R/W
b6	CTSUSOFF	CTSU High-Pass Noise Reduction Function Off Setting	This bit turns spectrum diffusion on or off to reduce high-pass noise. 0: Turn on 1: Turn off.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Only set the CTSUSDPRS register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPRRATIO[3:0] bits (CTSU Measurement Time and Pulse Count Adjustment)

The CTSUPRRATIO[3:0] bits are used to determine the measurement time and the measurement pulse count. These values are calculated using the following formulas, where the base pulse count is determined by the CTSUPRMODE[1:0] setting:

Measurement pulse count = base pulse count × (CTSUPRRATIO[3:0] bits + 1)

Measurement time = (base pulse count × (CTSUPRRATIO[3:0] bits + 1) + base pulse count - 2) × 0.25 × base clock cycle

Note: For details on the base clock cycle, see section 51.2.17, CTSU Sensor Offset Register 1 (CTSUSO1).

CTSUPRMODE[1:0] bits (CTSU Base Period and Pulse Count Setting)

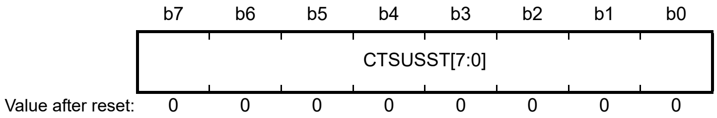
The CTSUPRMODE[1:0] bits select the number of base pulses that occur during measurement.

CTSUSOFF bit (CTSU High-Pass Noise Reduction Function Off Setting)

The CTSUSOFF bit turns on or off the function for reducing high-pass noise. Set this bit to 1 to turn the function off.

51.2.4 CTSU Sensor Stabilization Wait Control Register (CTSUSST)

Address(es): CTSU.CTSUSST 4008 1003h



Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSUSST[7:0]	CTSU Sensor Stabilization Wait Control	Fix the value of these bits to 00010000b.	R/W

Only set the CTSUSST register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSST[7:0] bits (CTSU Sensor Stabilization Wait Control)

The CTSUSST[7:0] bits set the stabilization wait time for the TSCAP pin voltage. Always fix these bits to 00010000b. If these bits are not set, the TSCAP voltage will be unstable at the start of measurement, and the CTSU will be unable to obtain correct touch measurement results.

51.2.5 CTSU Measurement Channel Register 0 (CTSUMCH0)

Address(es): CTSU.CTSUMCH0 4008 1004h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CTSUMCH0[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b4 to b0	CTSUMCH0[4:0]	CTSU Measurement Channel 0	In self-capacitance single scan mode, these bits set the channel to be measured. b4 b0 0 0 0 0 0: TS00 0 0 0 0 1: TS01 0 0 0 1 0: TS02 0 0 0 1 1: TS03 0 0 1 0 0: TS04 0 0 1 0 1: TS05 0 0 1 1 0: TS06 0 0 1 1 1: TS07 0 1 0 0 0: TS08 0 1 0 0 1: TS09 0 1 0 1 0: TS10 0 1 0 1 1: TS11 0 1 1 0 0: TS12 0 1 1 0 1: TS13 0 1 1 1 0: TS14 0 1 1 1 1: TS15 1 0 0 0 0: TS16 1 0 0 0 1: TS17. Other than when specified, starting measurement operation by setting CTSUCR0.CTSUSTRT to 1 is prohibited after these bits are set. In other measurement modes, these bits indicate the channel that is currently being measured. b4 b0 0 0 0 0 0: TS00 0 0 0 0 1: TS01 0 0 0 1 0: TS02 0 0 0 1 1: TS03 0 0 1 0 0: TS04 0 0 1 0 1: TS05 0 0 1 1 0: TS06 0 0 1 1 1: TS07 0 1 0 0 0: TS08 0 1 0 0 1: TS09 0 1 0 1 0: TS10 0 1 0 1 1: TS11 0 1 1 0 0: TS12 0 1 1 0 1: TS13 0 1 1 1 0: TS14 0 1 1 1 1: TS15 1 0 0 0 0: TS16 1 0 0 0 1: TS17 1 1 1 1 1: Measurement is being stopped.	R/W*[1]
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only enabled in self-capacitance single scan mode (CTSUCR1.CTSUMD[1:0] bits = 00b).

Only set the CTSUMCH0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUMCH0[4:0] bits (CTSU Measurement Channel 0)

In self-capacitance single scan mode, the CTSUMCH0[4:0] bits set the channel to be measured. In this mode, only specify enabled channels (00000b to 10001b). In other modes, these indicate the receive channel that is being measured, and writing to these bits has no effect.

51.2.6 CTSU Measurement Channel Register 1 (CTSUMCH1)

Address(es): CTSU.CTSUMCH1 4008 1005h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CTSUMCH1[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit name	Description	R/W
b4 to b0	CTSUMCH1[4:0]	CTSU Measurement Channel 1	b4 b0 0 0 0 0 0: TS00 0 0 0 0 1: TS01 0 0 0 1 0: TS02 0 0 0 1 1: TS03 0 0 1 0 0: TS04 0 0 1 0 1: TS05 0 0 1 1 0: TS06 0 0 1 1 1: TS07 0 1 0 0 0: TS08 0 1 0 0 1: TS09 0 1 0 1 0: TS10 0 1 0 1 1: TS11 0 1 1 0 0: TS12 0 1 1 0 1: TS13 0 1 1 1 0: TS14 0 1 1 1 1: TS15 1 0 0 0 0: TS16 1 0 0 0 1: TS17 1 1 1 1 1: Measurement is being stopped.	R
b7 to b5	—	Reserved	These bits are read as 0.	R

CTSUMCH1[4:0] bits (CTSU Measurement Channel 1)

In full scan mode, the CTSUMCH1[4:0] bits indicate the transmit channel that is being measured. They are always 11111b when measurement is stopped, or in self-capacitance single scan and multi-scan modes.

51.2.7 CTSU Channel Enable Control Register 0 (CTSUCHAC0)

Address(es): CTSU.CTSUCHAC0 4008 1006h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUCHAC0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSUCHAC0[7:0]	CTSU Channel Enable Control 0	These bits select whether the associated TS pin is measured. 0: Do not measure 1: Measure. These bits specify the TS00 to TS07 pins.	R/W

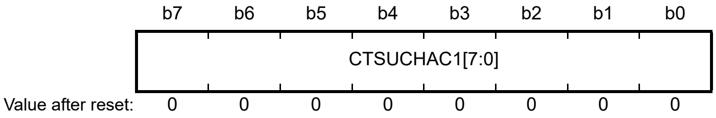
Only set the CTSUCHAC0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC0[7:0] bits (CTSU Channel Enable Control 0)

The CTSUCHAC0[7:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured. CTSUCHAC0[0] is associated with TS00 and CTSUCHAC0[7] with TS07.

51.2.8 CTSU Channel Enable Control Register 1 (CTSUCHAC1)

Address(es): CTSU.CTSUCHAC1 4008 1007h



Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSUCHAC1[7:0]	CTSU Channel Enable Control 1	These bits select whether the associated TS pin is measured. 0: Do not measure 1: Measure. These bits specify the TS08 to TS15 pins.	R/W

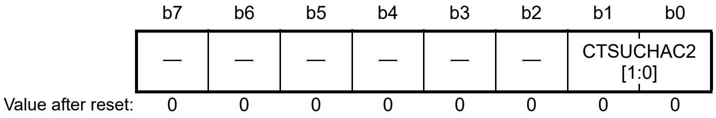
Only set the CTSUCHAC1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC1[7:0] bits (CTSU Channel Enable Control 1)

The CTSUCHAC1[7:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured. CTSUCHAC1[0] is associated with TS08 and CTSUCHAC1[7] with TS15.

51.2.9 CTSU Channel Enable Control Register 2 (CTSUCHAC2)

Address(es): CTSU.CTSUCHAC2 4008 1008h



Bit	Symbol	Bit name	Description	R/W
b1 to b0	CTSUCHAC2 [1:0]	CTSU Channel Enable Control 2	These bits select whether the associated TS pin is measured. 0: Do not measure 1: Measure. These bits specify the TS16 to TS17 pins.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

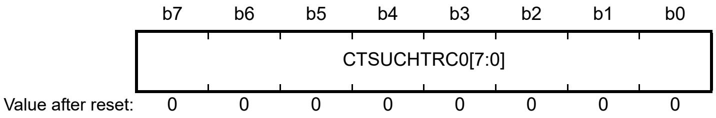
Only set the CTSUCHAC2 register when the CTSUCR0.CTSUSTRT bit = 0.

CTSUCHAC2 [1:0] bits (CTSU Channel Enable Control 2)

The CTSUCHAC2 [1:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured. CTSUCHAC2[0] is associated with TS16 and CTSUCHAC2[1] with TS17.

51.2.10 CTSU Channel Transmit/Receive Control Register 0 (CTSUCHTRC0)

Address(es): CTSU.CTSUCHTRC0 4008 100Bh



Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSUCHTRC0[7:0]	CTSU Channel Transmit/Receive Control 0	0: Reception 1: Transmission. These bits specify the TS00 to TS07 pins.	R/W

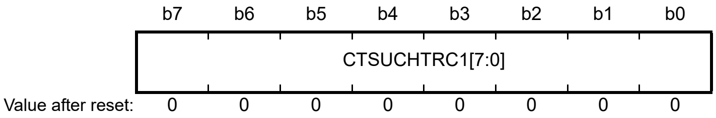
Only set the CTSUCHTRC0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC0[7:0] bits (CTSU Channel Transmit/Receive Control 0)

In full scan mode, the CTSUCHTRC0[7:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multi-scan modes. CTSUCHTRC0[0] is associated with TS00 and CTSUCHTRC0[7] with TS07.

51.2.11 CTSU Channel Transmit/Receive Control Register 1 (CTSUCHTRC1)

Address(es): CTSU.CTSUCHTRC1 4008 100Ch



Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSUCHTRC1[7:0]	CTSU Channel Transmit/Receive Control 1	0: Reception 1: Transmission. These bits specify the TS08 to TS15 pins.	R/W

Only set the CTSUCHTRC1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC1[7:0] bits (CTSU Channel Transmit/Receive Control 1)

In full scan mode, the CTSUCHTRC1[7:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multiscan modes. CTSUCHTRC1[0] is associated with TS08 and CTSUCHTRC1[7] with TS15.

51.2.12 CTSU Channel Transmit/Receive Control Register 2 (CTSUCHTRC2)

Address(es): CTSU.CTSUCHTRC2 4008 100Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CTSUCHTRC2 [1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1 to b0	CTSUCHTRC2 [1:0]	CTSU Channel Transmit/Receive Control 2	0: Reception 1: Transmission. These bits specify the TS16 to TS17 pins.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Only set the CTSUCHTRC2 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC2 [1:0] bits (CTSU Channel Transmit/Receive Control 2)

In full scan mode, the CTSUCHTRC2 [1:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multiscan modes. CTSUCHTRC2[0] is associated with TS16 and CTSUCHTRC2 [1] with TS17.

51.2.13 CTSU High-Pass Noise Reduction Control Register (CTSUDCLKC)

Address(es): CTSU.CTSUDCLKC 4008 1010h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CTSUSSCNT[1:0]		—	—	CTSUSSMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	CTSUSSMOD[1:0]	CTSU Diffusion Clock Mode Select	Set these bits to 00b.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	CTSUSSCNT[1:0]	CTSU Diffusion Clock Mode Control	Set these bits to 11b.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Only set the CTSUDCLKC register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSSMOD[1:0] bits (CTSU Diffusion Clock Mode Select)

The CTSUSSMOD[1:0] bits set the mode of the spectrum diffusion clock for high-pass noise reduction. When using the high-pass function, always fix these bits to 00b. If these bits are not set, the CTSU will be unable to effectively reduce high-pass noise.

CTSUSSCNT[1:0] bits (CTSU Diffusion Clock Mode Control)

The CTSUSSCNT[1:0] bits adjust the amount of spectrum diffusion applied to reduce high-pass noise. When using the high-pass noise reduction function, always fix these bits to 11b. If these bits are not set, touch measurement might be performed incorrectly.

51.2.14 CTSU Status Register (CTSUST)

Address(es): CTSU.CTSUST 4008 1011h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUPS	CTSUROVF	CTSUSOVF	CTSUDTSR	—	CTSUSTC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	CTSUSTC[2:0]	CTSU Measurement Status Counter	These counters indicate the current measurement status. b2 b0 0 0 0: Status 0 0 0 1: Status 1 0 1 0: Status 2 0 1 1: Status 3 1 0 0: Status 4 1 0 1: Status 5.	R
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	CTSUDTSR	CTSU Data Transfer Status Flag	This flag indicates whether the measurement result stored in the sensor counter and the reference counter was read. 0: Read 1: Not read.	R
b5	CTSUSOVF	CTSU Sensor Counter Overflow Flag	This flag indicates an overflow on the sensor counter. 0: No overflow occurred 1: Overflow occurred.	R/W
b6	CTSUROVF	CTSU Reference Counter Overflow Flag	This flag indicates an overflow on the reference counter. 0: No overflow occurred 1: Overflow occurred.	R/W
b7	CTSUPS	CTSU Mutual Capacitance Status Flag	This flag indicates the measurement status in mutual capacitance full scan mode. 0: First measurement 1: Second measurement.	R

When using the CTSUCR0.CTSUINIT bit to clear an overflow flag, make sure that the CTSUCR0.CTSUSTRT bit is 0.

CTSUSTC[2:0] flags (CTSU Measurement Status Counter)

The CTSUSTC[2:0] flags are a counter indicating the current measurement status. For details on each status, see section 51.3.2.2, Status counter.

CTSUDTSR flag (CTSU Data Transfer Status Flag)

The CTSUDTSR flag indicates whether the measurement result stored in the sensor counter and the reference counter was read. The flag sets to 1 when measurement completes and 0 when the reference counter is read by software or the DTC. The flag can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUSOVF flag (CTSU Sensor Counter Overflow Flag)

The CTSUSOVF flag sets to 1 when the sensor counter, CTSUSC, overflows. On overflow, the counter value reads as FFFFh. Measurement processing continues for the specified period.

No interrupt occurs on an overflow. To determine the channel on which the overflow occurred, read the measurement result of each channel after measurement completes, signaled by a measurement end interrupt.

This flag is cleared when 0 is written after 1 is read by software. It can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUROVF flag (CTSU Reference Counter Overflow Flag)

The CTSUROVF flag sets to 1 when the reference counter, CTSURC, overflows. On overflow, the counter value reads as FFFFh. Measurement processing continues for the specified period.

No interrupt occurs on an overflow. To determine the channel on which the overflow occurred, read the measurement result of each channel after measurement completes, signaled by a measurement end interrupt.

This flag is cleared when 0 is written after 1 is read by software. It can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUPS flag (CTSU Mutual Capacitance Status Flag)

In mutual capacitance full scan mode, when CTSUCR1.CTSUMD[1:0] = 11b, the CTSUPS flag indicates whether the measurement is the first or second of two measurements for each channel. When measurement is stopped or in other measurement modes, this flag is always 0.

51.2.15 CTSU High-Pass Noise Reduction Spectrum Diffusion Control Register (CTSUSSC)

Address(es): CTSU.CTSUSSC 4008 1012h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CTSUSSDIV[3:0]				—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	CTSUSSDIV[3:0]	CTSU Spectrum Diffusion Frequency Division Setting	These bits specify the spectrum diffusion frequency division setting based on the base clock frequency division setting.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CTSUSSDIV[3:0] bits (CTSU Spectrum Diffusion Frequency Division Setting)

The CTSUSSDIV[3:0] bits specify the spectrum diffusion frequency derived from the base clock frequency division setting. To calculate the correct setting for CTSUSSDIV[3:0], see the relationship between base clock frequencies and the settings in Table 51.6.

Table 51.6 Relationship between base clock frequencies and CTSUSSDIV[3:0] bit settings (1 of 2)

Base clock frequency fb (MHz)	CTSUSSDIV[3:0] bit setting
4.00 ≤ fb	0000b
2.00 ≤ fb < 4.00	0001b
1.33 ≤ fb < 2.00	0010b
1.00 ≤ fb < 1.33	0011b
0.80 ≤ fb < 1.00	0100b
0.67 ≤ fb < 0.80	0101b
0.57 ≤ fb < 0.67	0110b
0.50 ≤ fb < 0.57	0111b
0.44 ≤ fb < 0.50	1000b
0.40 ≤ fb < 0.44	1001b
0.36 ≤ fb < 0.40	1010b
0.33 ≤ fb < 0.36	1011b
0.31 ≤ fb < 0.33	1100b

Table 51.6 Relationship between base clock frequencies and CTSUSSDIV[3:0] bit settings (2 of 2)

Base clock frequency fb (MHz)	CTSUSSDIV[3:0] bit setting
0.29 ≤ fb < 0.31	1101b
0.27 ≤ fb < 0.29	1110b
fb < 0.27	1111b

51.2.16 CTSU Sensor Offset Register 0 (CTSUSO0)

Address(es): CTSU.CTSUSO0 4008 1014h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUSNUM[5:0]						CTSUSO[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	CTSUSO[9:0]	CTSU Sensor Offset Adjustment	These bits adjust the electronic capacitance when the electrode is not being touched. b9 b0 0 0 0 0 0 0 0 0 0 0: Current offset is 0 0 0 0 0 0 0 0 0 0 1: Current offset is 1 0 0 0 0 0 0 0 0 1 0: Current offset is 2 : : 1 1 1 1 1 1 1 1 1 0: Current offset is 1022 1 1 1 1 1 1 1 1 1 1: Current offset is maximum.	R/W
b15 to b10	CTSUSNUM[5:0]	CTSU Measurement Count Setting	These bits set the number of measurements.	R/W

CTSUSO[9:0] bits (CTSU Sensor Offset Adjustment)

The CTSUSO[9:0] bits offset the sensor ICO input current generated from electrostatic capacitance during touch measurement when the electrode is not being touched. This prevents the CTSU sensor counter from overflowing. Set the TS pin that is to be measured next after a CTSU_CTSUWR interrupt occurs.

CTSUSNUM[5:0] bits (CTSU Measurement Count Setting)

The CTSUSNUM[5:0] bits specify how many times the measurement pulse count specified in the CTSUSDPRS.CTSUPRRATIO[3:0] and CTSUSDPRS.CTSUPRMODE[1:0] bits is repeated during the measurement time. The measurement pulse count is repeated (CTSUSNUM[5:0] bits + 1) times. Set the TS pin that is to be measured next after a CTSU_CTSUWR interrupt is generated.

51.2.17 CTSU Sensor Offset Register 1 (CTSUSO1)

Address(es): CTSU.CTSUSO1 4008 1016h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CTSUICOG[1:0]		CTSUSDPA[4:0]					CTSURICOA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CTSURICOA[7:0]	CTSU Reference ICO Current Adjustment	These bits adjust the input current of the reference ICO. b7 b0 0 0 0 0 0 0 0 0: Current offset is 0 0 0 0 0 0 0 0 1: Current offset is 1 0 0 0 0 0 0 1 0: Current offset is 2 : : 1 1 1 1 1 1 1 0: Current offset is 254 1 1 1 1 1 1 1 1: Current offset is maximum.	R/W
b12 to b8	CTSUSDPA[4:0]	CTSU Base Clock Setting	These bits are used to generate the base clock. b12 b8 0 0 0 0 0: Operating clock divided by 2*1 0 0 0 0 1: Operating clock divided by 4 0 0 0 1 0: Operating clock divided by 6 0 0 0 1 1: Operating clock divided by 8 0 0 1 0 0: Operating clock divided by 10 0 0 1 0 1: Operating clock divided by 12 0 0 1 1 0: Operating clock divided by 14 0 0 1 1 1: Operating clock divided by 16 0 1 0 0 0: Operating clock divided by 18 0 1 0 0 1: Operating clock divided by 20 0 1 0 1 0: Operating clock divided by 22 0 1 0 1 1: Operating clock divided by 24 0 1 1 0 0: Operating clock divided by 26 0 1 1 0 1: Operating clock divided by 28 0 1 1 1 0: Operating clock divided by 30 0 1 1 1 1: Operating clock divided by 32 1 0 0 0 0: Operating clock divided by 34 1 0 0 0 1: Operating clock divided by 36 1 0 0 1 0: Operating clock divided by 38 1 0 0 1 1: Operating clock divided by 40 1 0 1 0 0: Operating clock divided by 42 1 0 1 0 1: Operating clock divided by 44 1 0 1 1 0: Operating clock divided by 46 1 0 1 1 1: Operating clock divided by 48 1 1 0 0 0: Operating clock divided by 50 1 1 0 0 1: Operating clock divided by 52 1 1 0 1 0: Operating clock divided by 54 1 1 0 1 1: Operating clock divided by 56 1 1 1 0 0: Operating clock divided by 58 1 1 1 0 1: Operating clock divided by 60 1 1 1 1 0: Operating clock divided by 62 1 1 1 1 1: Operating clock divided by 64.	R/W
b14, b13	CTSUICOG[1:0]	CTSU ICO Gain Adjustment	These bits adjust the output frequency gain of the sensor ICO and the reference ICO. b14 b13 0 0: 100% gain 0 1: 66% gain 1 0: 50% gain 1 1: 40% gain.	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Do not set the CTSUSDPA[4:0] bits set to 00000b while the high-pass noise reduction function is turned off (CTSUSDPRS.CTSUSOFF bit = 1) in mutual capacitance full scan mode (CTSUCR1.CTSUMD[1:0] bits = 11b).

After a CTSU_CTSUWR interrupt occurs, write first to the CTSUSSC register, next to the CTSUSO0 register, and then to the CTSUSO1 register. The write to the CTSUSO1 register causes a transition to Status 3. (See Table 51.7 and Table 51.8.) Set all of the bits in a single operation when writing to the CTSUSO1 register.

CTSURICOA[7:0] bits (CTSU Reference ICO Current Adjustment)

The CTSURICOA[7:0] bits adjust the oscillation frequency using the input current of the reference ICO.

CTSUSDPA[4:0] bits (CTSU Base Clock Setting)

The CTSUSDPA[4:0] bits select the base clock used as the source for the sensor drive pulse by dividing the operating clock. For details on the setting procedure, see section 51.3.2.1, Initial settings flow.

CTSUICOG[1:0] bits (CTSU ICO Gain Adjustment)

The CTSUICOG[1:0] bits adjust the output frequency gain of the sensor ICO and the reference ICO. Normally, set these bits to 00b for the maximum gain. If changes in the capacitance between when the electrode is touched and when it is not touched greatly exceed the dynamic range of the sensor ICO, adjust the gain appropriately with this setting.

51.2.18 CTSU Sensor Counter (CTSUSC)

Address(es): CTSU.CTSUSC 4008 1018h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUSC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	CTSUSC[15:0]	CTSU Sensor Counter	These bits indicate the measurement result of the sensor ICO. They read FFFFh when an overflow occurs.	R

After a CTSU_CTSURD interrupt occurs, read first from the CTSUSC counter and then from the CTSURC counter.

CTSUSC[15:0] bits (CTSU Sensor Counter)

The CTSUSC[15:0] bits are configured as an increment counter for the sensor ICO clock. Read these bits after a CTSU_CTSURD interrupt occurs. After the CTSURC counter is read, these bits are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. They can also be cleared using the CTSUCR0.CTSUINIT bit.

51.2.19 CTSU Reference Counter (CTSURC)

Address(es): CTSU.CTSURC 4008 101Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSURC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	CTSURC[15:0]	CTSU Reference Counter	These bits indicate the measurement result of the reference ICO. They read FFFFh when an overflow occurs.	R

After a CTSU_CTSURD interrupt occurs, read first from the CTSUSC counter and then from the CTSURC counter. Status 3 continues until the CTSURC counter is read, even if the stabilization time specified for Status 3 elapses.

CTSURC[15:0] bits (CTSU Reference Counter)

The CTSURC[15:0] bits are configured as an increment counter for the reference ICO clock. The reference ICO optimizes touch measurement performed by the sensor ICO. There is some deviation depending on the internal sensor ICO and the reference ICO in the CTSU, but both ICOs have almost the same characteristics, including the dynamic range and the current-to-frequency characteristics. The range of current amount that can be set in the reference ICO current adjustment bits is about the same as the dynamic range of both ICOs, and the current amount input to the sensor ICO must be within this dynamic range. To ensure this, use the reference ICO to check the differences between the ICOs and measure the current-to-oscillation frequency characteristics. Because the reference ICO oscillation frequency can be obtained from the reference ICO counter, the ICO oscillation frequency (counter value/measurement time) for the input current amount can be measured by setting the value in the reference ICO current adjustment bits and measuring the reference ICO counter. The reference ICO counter value measured using the maximum value in the reference ICO current adjustment bits is the maximum value of the ICO dynamic range. The current to the sensor ICO must be offset in the offset adjustment bits so that the sensor ICO counter value does not exceed this value.

Read the CTSURC[15:0] bits after a CTSU_CTSURD interrupt occurs. After these bits are read, they are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. They can also be cleared using the CTSUCR0.CTSUINIT bit.

51.2.20 CTSU Error Status Register (CTSUERRS)

Address(es): CTSU.CTSUERRS 4008 101Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUICOMP	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b14 to b0	—	Reserved	These bits are read as 0.	R
b15	CTSUICOMP	TSCAP Voltage Error Monitor	This bit monitors the error status of the TSCAP voltage. 0: Normal TSCAP voltage 1: Abnormal TSCAP voltage.*1	R

Note 1. When CTSUCR1.CTSUPON bit is 0, this bit is set to 1.

CTSUICOMP bit (TSCAP Voltage Error Monitor)

If the offset current amount set in the CTSUSO1 register exceeds the sensor ICO input current during touch measurement, the TSCAP voltage becomes abnormal and touch measurement cannot be performed correctly. The CTSUICOMP bit monitors the TSCAP voltage and it sets to 1 if the voltage becomes abnormal.

If the TSCAP voltage becomes abnormal, the sensor ICO counter value becomes undefined, but touch measurement completes normally, so it is difficult to detect an abnormality by reading the sensor ICO counter value. If the CTSU reference ICO current adjustment bits (CTSURICOA[7:0]) in the CTSUSO1 register are set to any value other than 0, always check this bit when touch measurement completes.

This bit is cleared by writing 0 to the CTSUCR1.CTSUPON bit and turning off the power supply.

51.3 Operation

51.3.1 Principles of Measurement Operation

Figure 51.4 shows the measurement circuit.

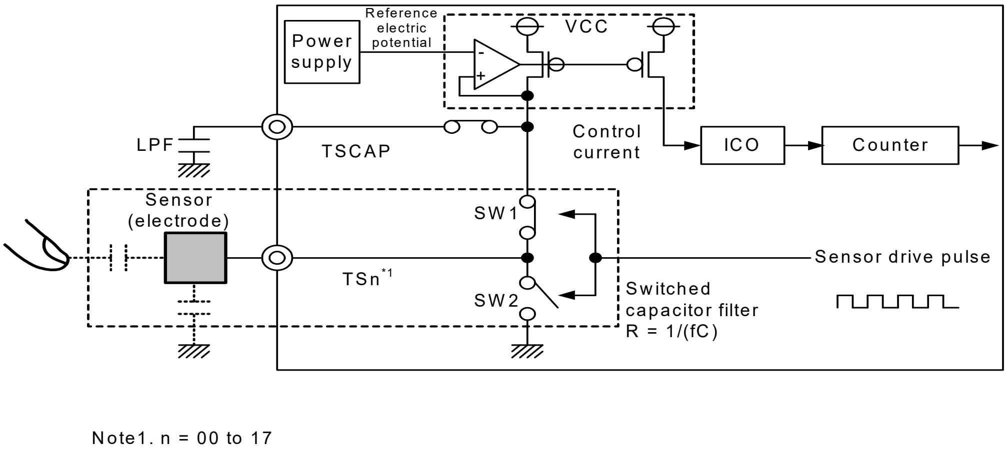


Figure 51.4 Measurement circuit

Figure 51.5 to Figure 51.7 explain the electrostatic capacitance measurement operation principles of the CTSU current frequency conversion method.

The electrostatic capacitance of the electrode is charged by turning SW1 on and SW2 off (Figure 51.5).

The charged capacitance is discharged by turning SW1 off and SW2 on (Figure 51.6).

Current flows to the switched capacitor filter by switching between charging and discharging. At this point, if a finger is in close proximity, the capacitance and the flowing current change. A clock is generated by supplying the control current, which is proportional to the amount of current flowing through the switched capacitor filter, from the circuit that generates the TSCAP power supply to the ICO. The counter measures the clock frequency that changes depending on whether a finger is in close proximity. The software uses the value read from the counter to determine contact with a finger (Figure 51.7).

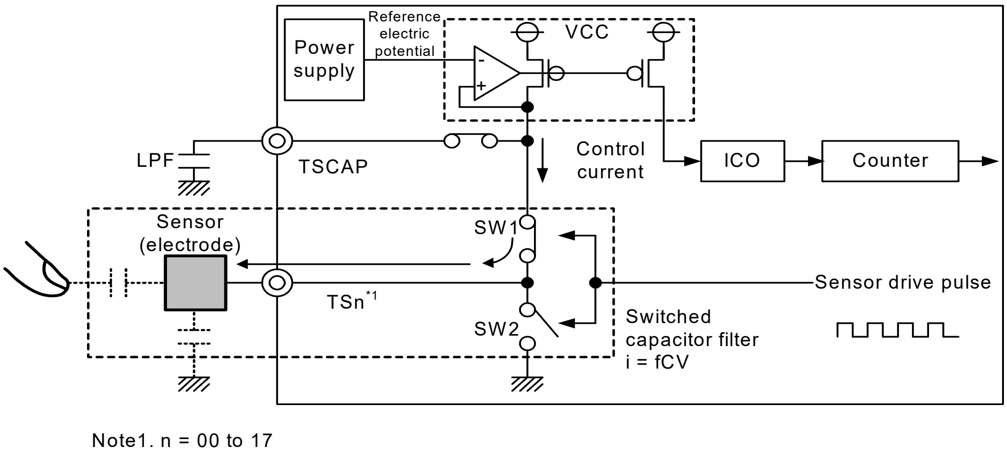

Figure 51.5 Charging operation

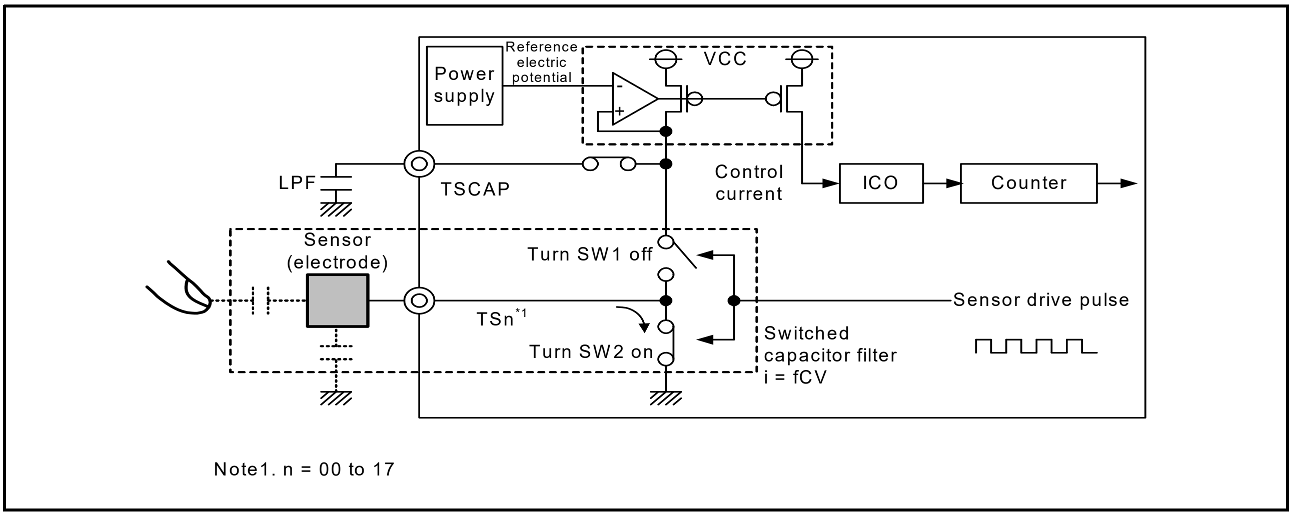

Figure 51.6 Discharging operation

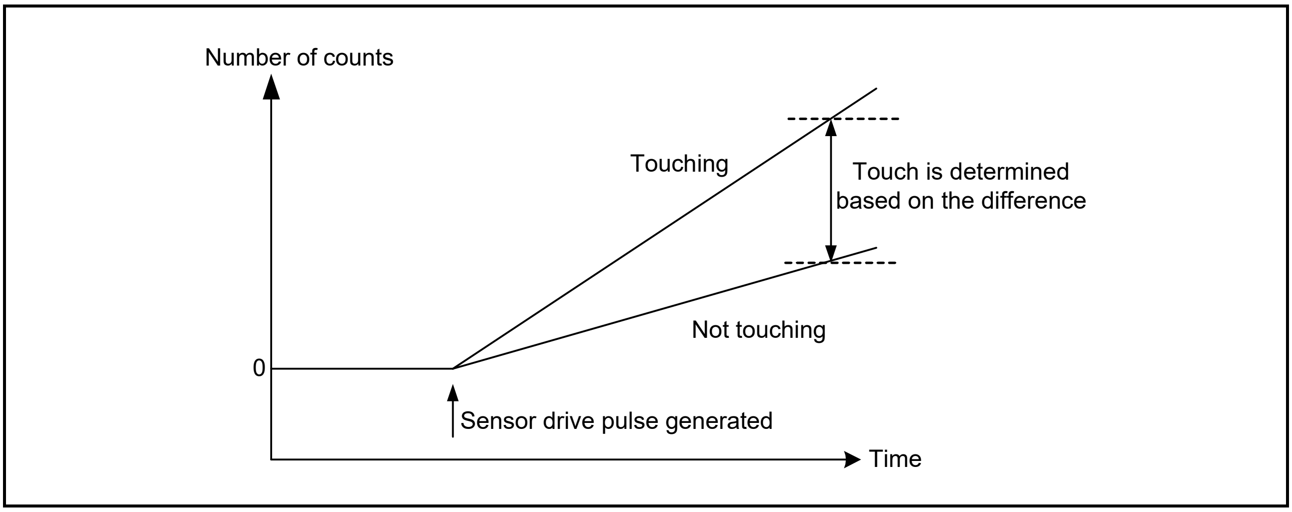

Figure 51.7 Change in measured value when finger is touching and not touching

51.3.2 Measurement Modes

The CTSU supports self-capacitance and mutual capacitance methods. Figure 51.8 illustrates these methods.

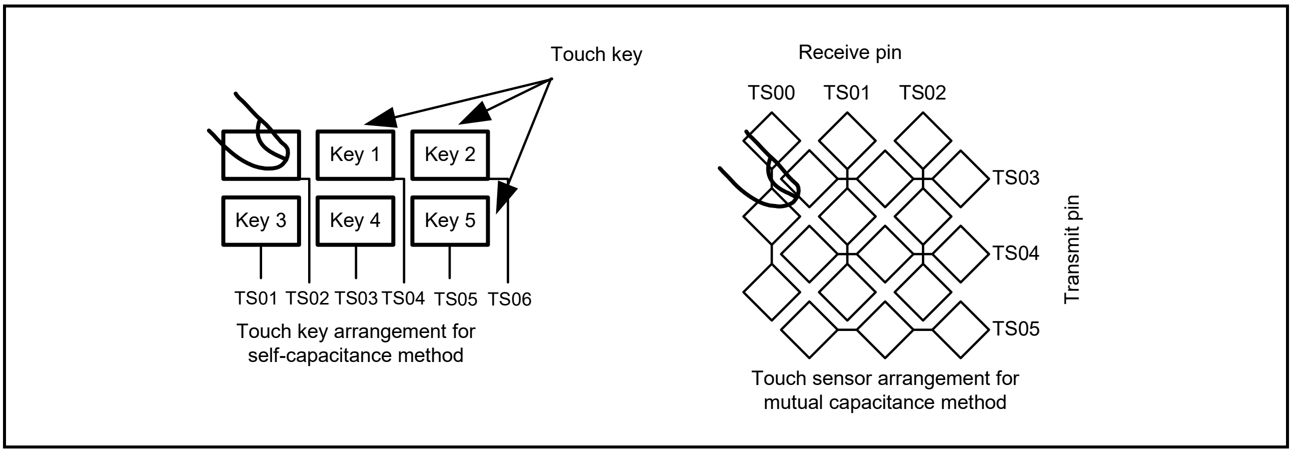

Figure 51.8 Overview of self-capacitance method and mutual capacitance method

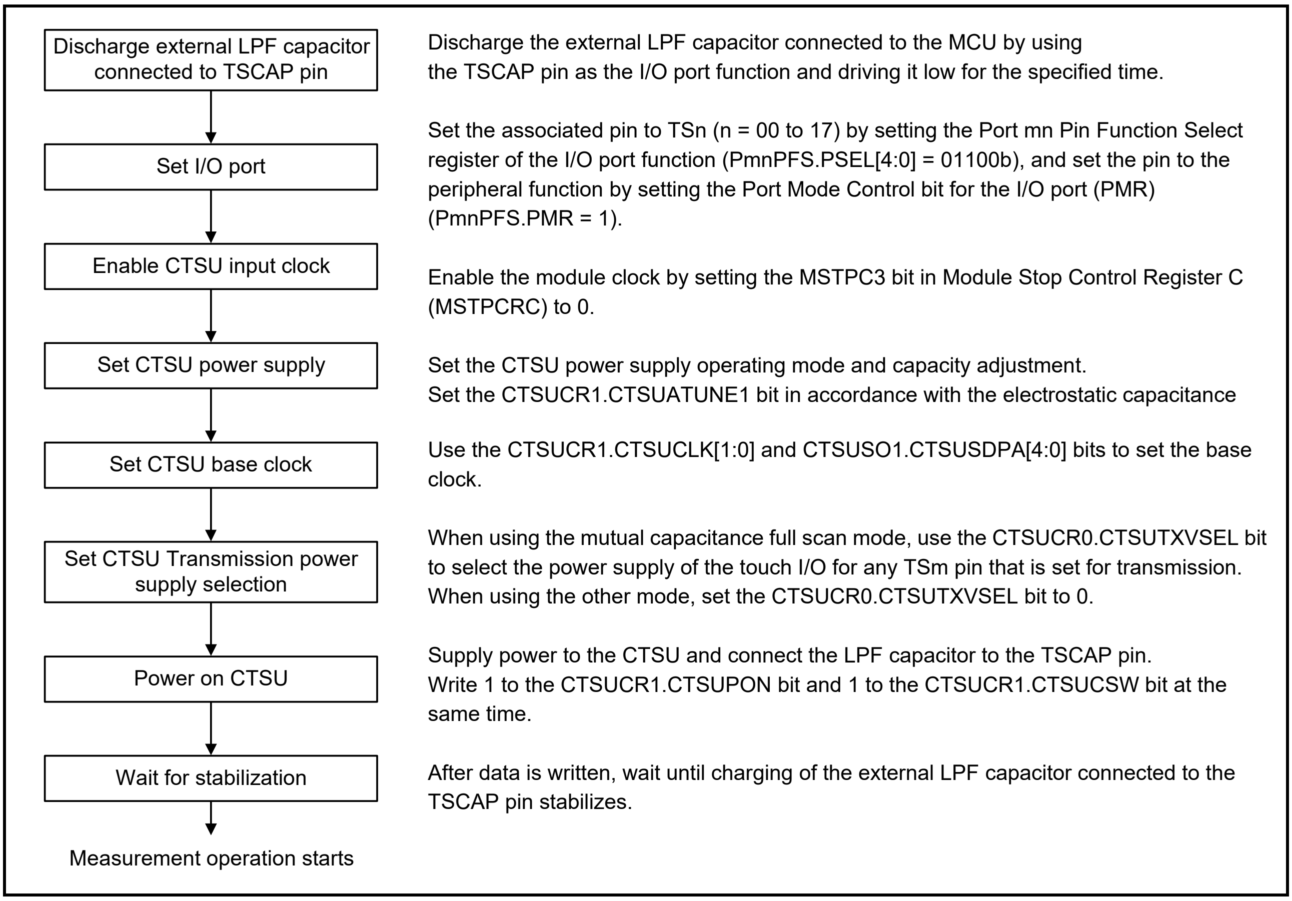
In the self-capacitance method, a single touch pin is allocated to a single touch key to measure individual electrostatic capacitance when a finger is in close proximity. In this method, capacitance can be measured in both single scan and multiscan modes. In the mutual capacitance method, the capacitance between two opposing electrodes (transmit and receive pins) is measured.

51.3.2.1 Initial settings flow

Figure 51.9 shows the flow for the CTSU initial settings.



Discharge the external LPF capacitor connected to the MCU by using the TSCAP pin as the I/O port function and driving it low for the specified time.

Set the associated pin to TSn (n = 00 to 17) by setting the Port mn Pin Function Select register of the I/O port function (PmnPFS.PSEL[4:0] = 01100b), and set the pin to the peripheral function by setting the Port Mode Control bit for the I/O port (PMR) (PmnPFS.PMR = 1).

Enable the module clock by setting the MSTPC3 bit in Module Stop Control Register C (MSTPCRC) to 0.

Set the CTSU power supply operating mode and capacity adjustment.
Set the CTSUCR1.CTSUATUNE1 bit in accordance with the electrostatic capacitance

Use the CTSUCR1.CTSUCLK[1:0] and CTSUSO1.CTSUSDPA[4:0] bits to set the base clock.

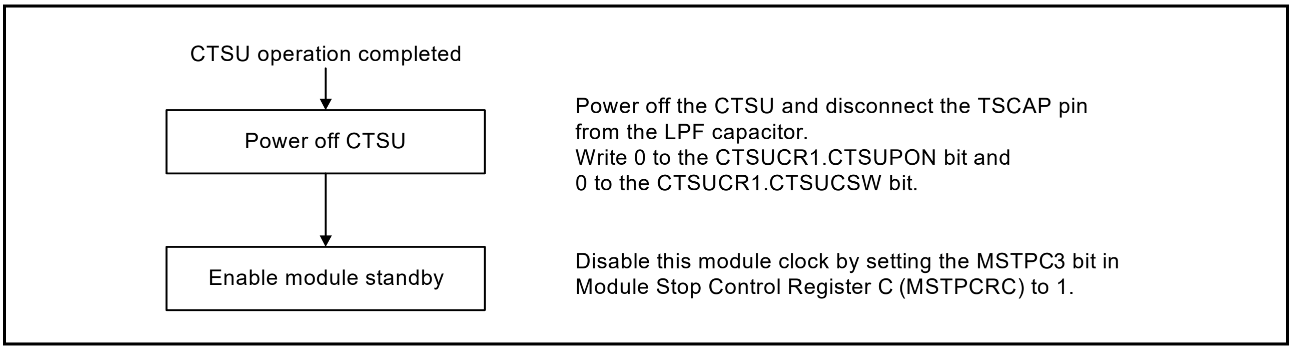
When using the mutual capacitance full scan mode, use the CTSUCR0.CTSUTXVSEL bit to select the power supply of the touch I/O for any TSm pin that is set for transmission. When using the other mode, set the CTSUCR0.CTSUTXVSEL bit to 0.

Supply power to the CTSU and connect the LPF capacitor to the TSCAP pin.
Write 1 to the CTSUCR1.CTSUPON bit and 1 to the CTSUCR1.CTSUCSW bit at the same time.

After data is written, wait until charging of the external LPF capacitor connected to the TSCAP pin stabilizes.

Figure 51.9 CTSU initial settings flow

Figure 51.10 shows the flow for stopping CTSU operation and invoking the standby state.



Power off the CTSU and disconnect the TSCAP pin from the LPF capacitor.
Write 0 to the CTSUCR1.CTSUPON bit and 0 to the CTSUCR1.CTSUCSW bit.

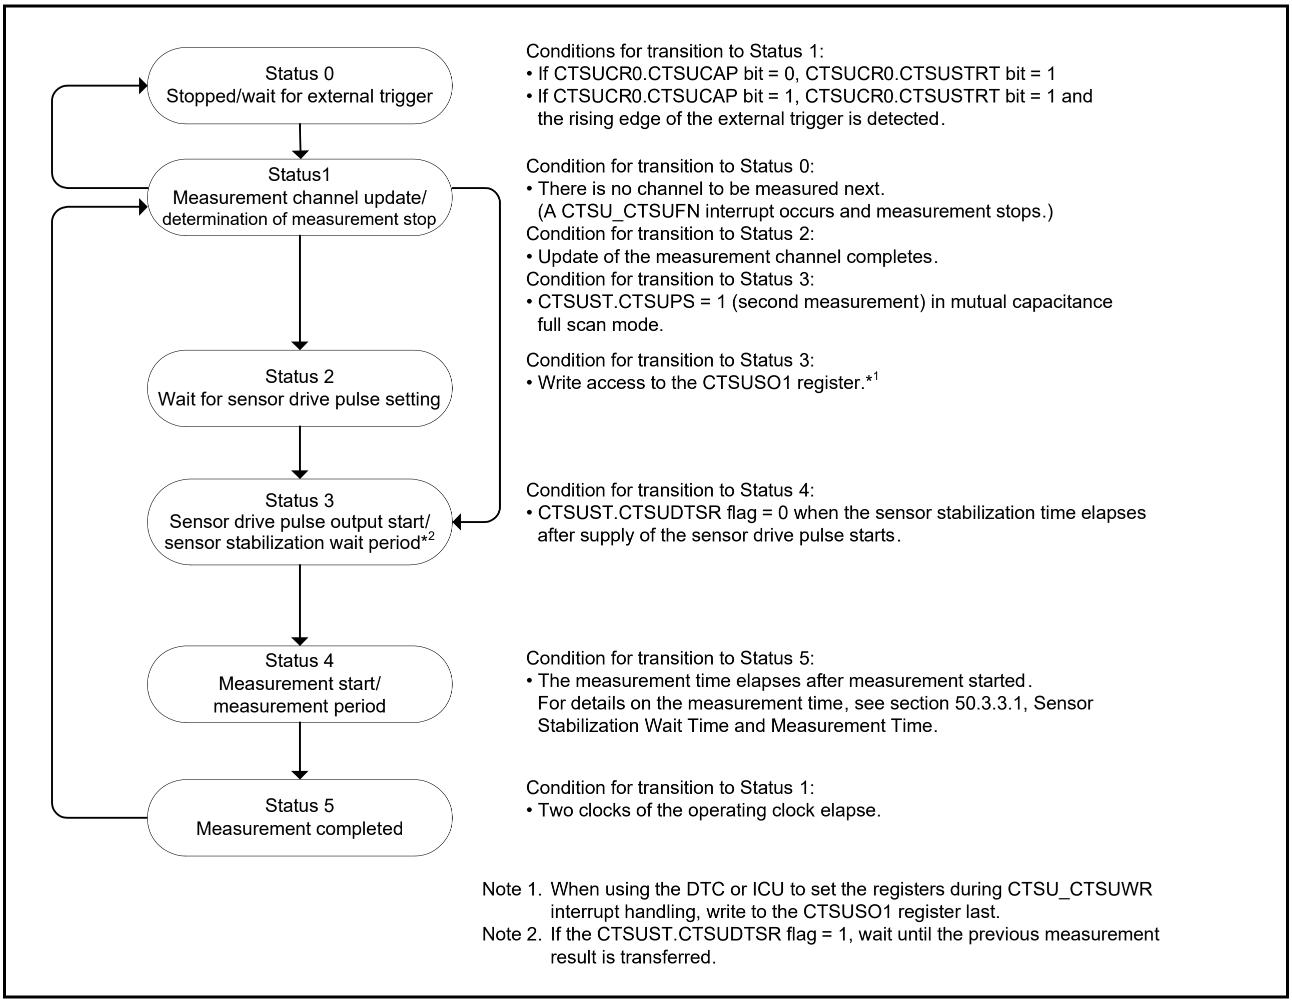
Disable this module clock by setting the MSTPC3 bit in Module Stop Control Register C (MSTPCRC) to 1.

Figure 51.10 CTSU stopping flow

When restarting operation after it stops, follow the initial settings flow shown in Figure 51.9.

51.3.2.2 Status counter

The measurement status counter of the CTSU Status Register (CTSUST) indicates the current measurement status. The measurement status is shared by all three modes. Figure 51.11 shows the status operation transitions.



Conditions for transition to Status 1:
- If CTSUCR0.CTSUCAP bit = 0, CTSUCR0.CTSUSTRT bit = 1
- If CTSUCR0.CTSUCAP bit = 1, CTSUCR0.CTSUSTRT bit = 1 and the rising edge of the external trigger is detected.

Condition for transition to Status 0:
- There is no channel to be measured next. (A CTSU_CTSUFN interrupt occurs and measurement stops.)

Condition for transition to Status 2:
- Update of the measurement channel completes.

Condition for transition to Status 3:
- CTSUST.CTSUPS = 1 (second measurement) in mutual capacitance full scan mode.

Condition for transition to Status 3:
- Write access to the CTSUSO1 register.*1

Condition for transition to Status 4:
- CTSUST.CTSUDTSR flag = 0 when the sensor stabilization time elapses after supply of the sensor drive pulse starts.

Condition for transition to Status 5:
- The measurement time elapses after measurement started. For details on the measurement time, see section 50.3.3.1, Sensor Stabilization Wait Time and Measurement Time.

Condition for transition to Status 1:
- Two clocks of the operating clock elapse.

Note 1. When using the DTC or ICU to set the registers during CTSU_CTSUWR interrupt handling, write to the CTSUSO1 register last.

Note 2. If the CTSUST.CTSUDTSR flag = 1, wait until the previous measurement result is transferred.

Figure 51.11 Status operation transitions

The status counter transitions to Status 0 when all of the specified measurement channels are measured.

The CTSUCR0.CTSUSTRT bit is cleared to 0 by hardware when a software trigger is used. When an external trigger is used, the value of 1 is retained, and the CTSU waits for the next trigger.

When operation is forced to stop during measurement or the trigger wait state, by a simultaneous 0 write to the CTSUCR0.CTSUSTRT bit and a 1 write to the CTSUCR0.CTSUINIT bit, the status transitions to Status 0 and measurement stops.

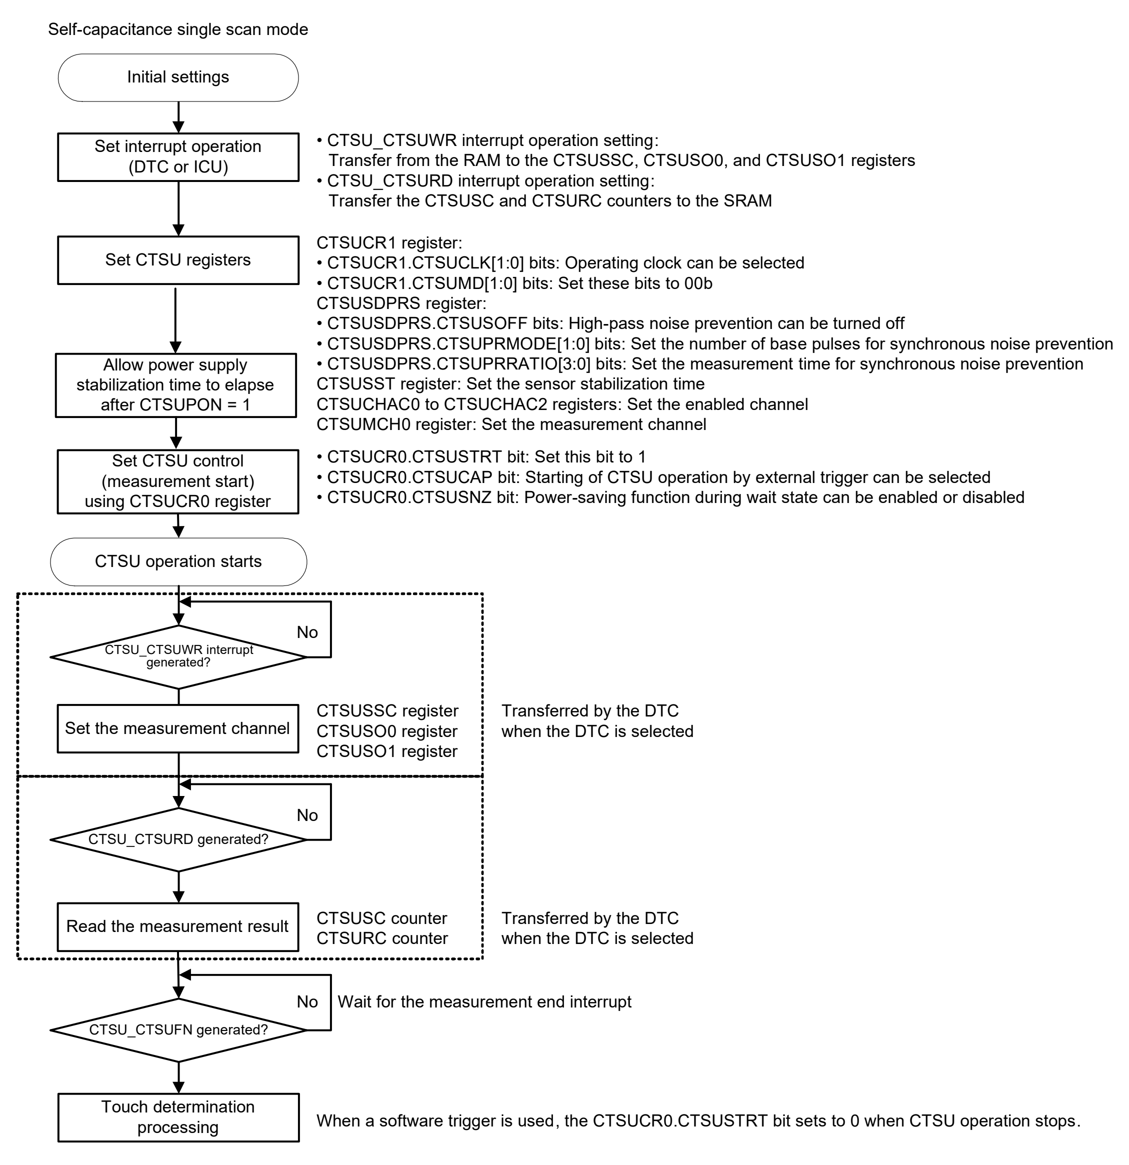
If the channel to be measured is not set in the CTSUCHAC0 to CTSUCHAC2 or CTSUCHTRC0 to CTSUCHTRC2 registers, a CTSU_CTSUFN interrupt occurs immediately after a transition to Status 1, and then the status transitions to Status 0.

In the following situations, there is no channel to be measured:

- No measurement target channel is specified in the CTSUCHAC0 to CTSUCHAC2 registers.
- In self-capacitance single scan mode, the channel specified in the CTSUMCH0 register is not a measurement target in the CTSUCHAC0 to CTSUCHAC2 registers.
- In full scan modes, there is no transmit channel or receive channel to be measured based on the combined settings of the CTSUCHAC0 to CTSUCHAC2 and CTSUCHTRC0 to CTSUCHTRC2 registers.

51.3.2.3 Self-capacitance single scan mode operation

In self-capacitance single scan mode, electrostatic capacitance on one channel is measured. Figure 51.12 shows the software flow and an operation example, and Figure 51.13 shows the timing.



- CTSU_CTSUWR interrupt operation setting:
  Transfer from the RAM to the CTSUSSC, CTSUSO0, and CTSUSO1 registers
- CTSU_CTSURD interrupt operation setting:
  Transfer the CTSUSC and CTSURC counters to the SRAM

CTSUCR1 register:
- CTSUCR1.CTSUCLK[1:0] bits: Operating clock can be selected
- CTSUCR1.CTSUMD[1:0] bits: Set these bits to 00b

CTSUSDPRS register:
- CTSUSDPRS.CTSUSOFF bits: High-pass noise prevention can be turned off
- CTSUSDPRS.CTSUPRMODE[1:0] bits: Set the number of base pulses for synchronous noise prevention
- CTSUSDPRS.CTSUPRRATIO[3:0] bits: Set the measurement time for synchronous noise prevention

CTSUSST register: Set the sensor stabilization time
CTSUCHAC0 to CTSUCHAC2 registers: Set the enabled channel
CTSUMCH0 register: Set the measurement channel

- CTSUCR0.CTSUSTRT bit: Set this bit to 1
- CTSUCR0.CTSUCAP bit: Starting of CTSU operation by external trigger can be selected
- CTSUCR0.CTSUSNZ bit: Power-saving function during wait state can be enabled or disabled

Transferred by the DTC when the DTC is selected

Transferred by the DTC when the DTC is selected

Wait for the measurement end interrupt

When a software trigger is used, the CTSUCR0.CTSUSTRT bit sets to 0 when CTSU operation stops.

Figure 51.12 Software flow and example operation for self-capacitance single scan mode

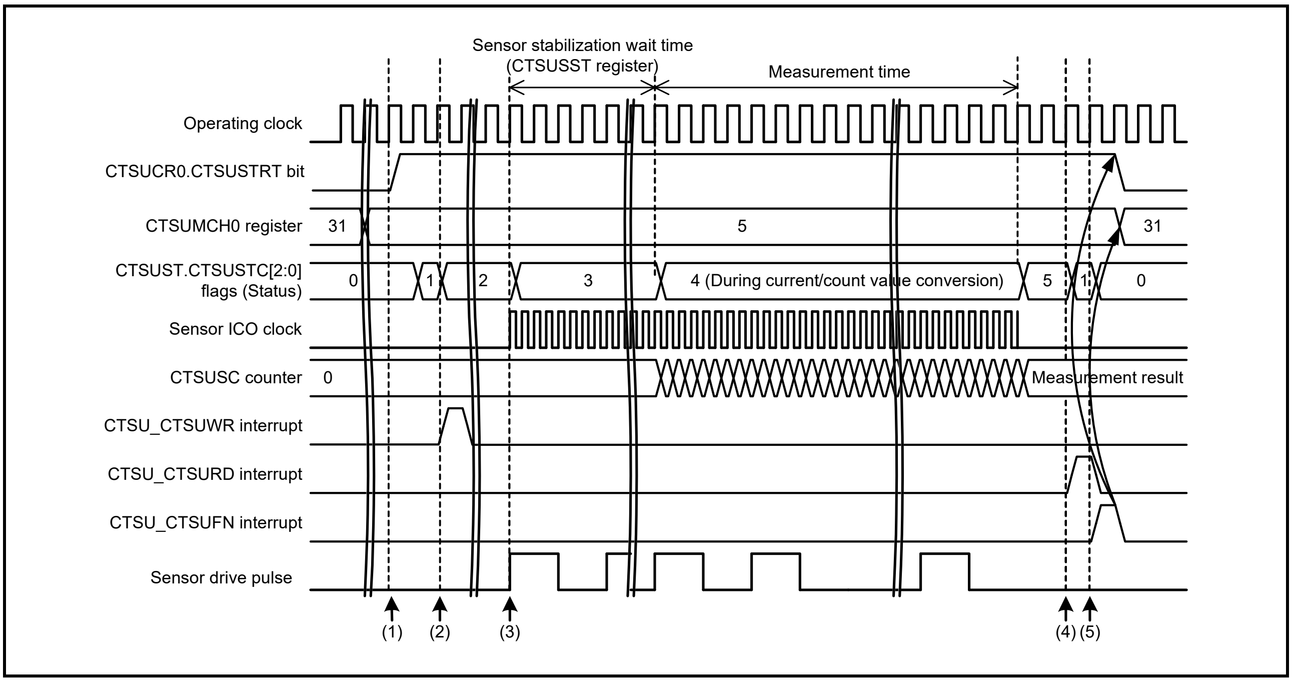


Figure 51.13 Timing of self-capacitance single scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 51.13.

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and reference ICO clock operate.
4. After the sensor stabilization wait time and the measurement time elapse, and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. A measurement end interrupt (CTSU_CTSUFN) is output and measurement stops (transition to Status 0).

Table 51.7 lists the touch pin states in self-capacitance single scan mode.

Table 51.7 Touch pin states in self-capacitance single scan mode

	Touch pin	
Status	**Measured channel**	**Non-measured channel**
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

51.3.2.4 Self-capacitance multi-scan mode operation

In self-capacitance multi-scan mode, electrostatic capacitance on all channels that are specified as measurement targets in the CTSUCHAC0 to CTSUCHAC2 registers is measured sequentially in ascending order. Figure 51.14 shows the software flow and an operation example, and Figure 51.15 shows the timing.

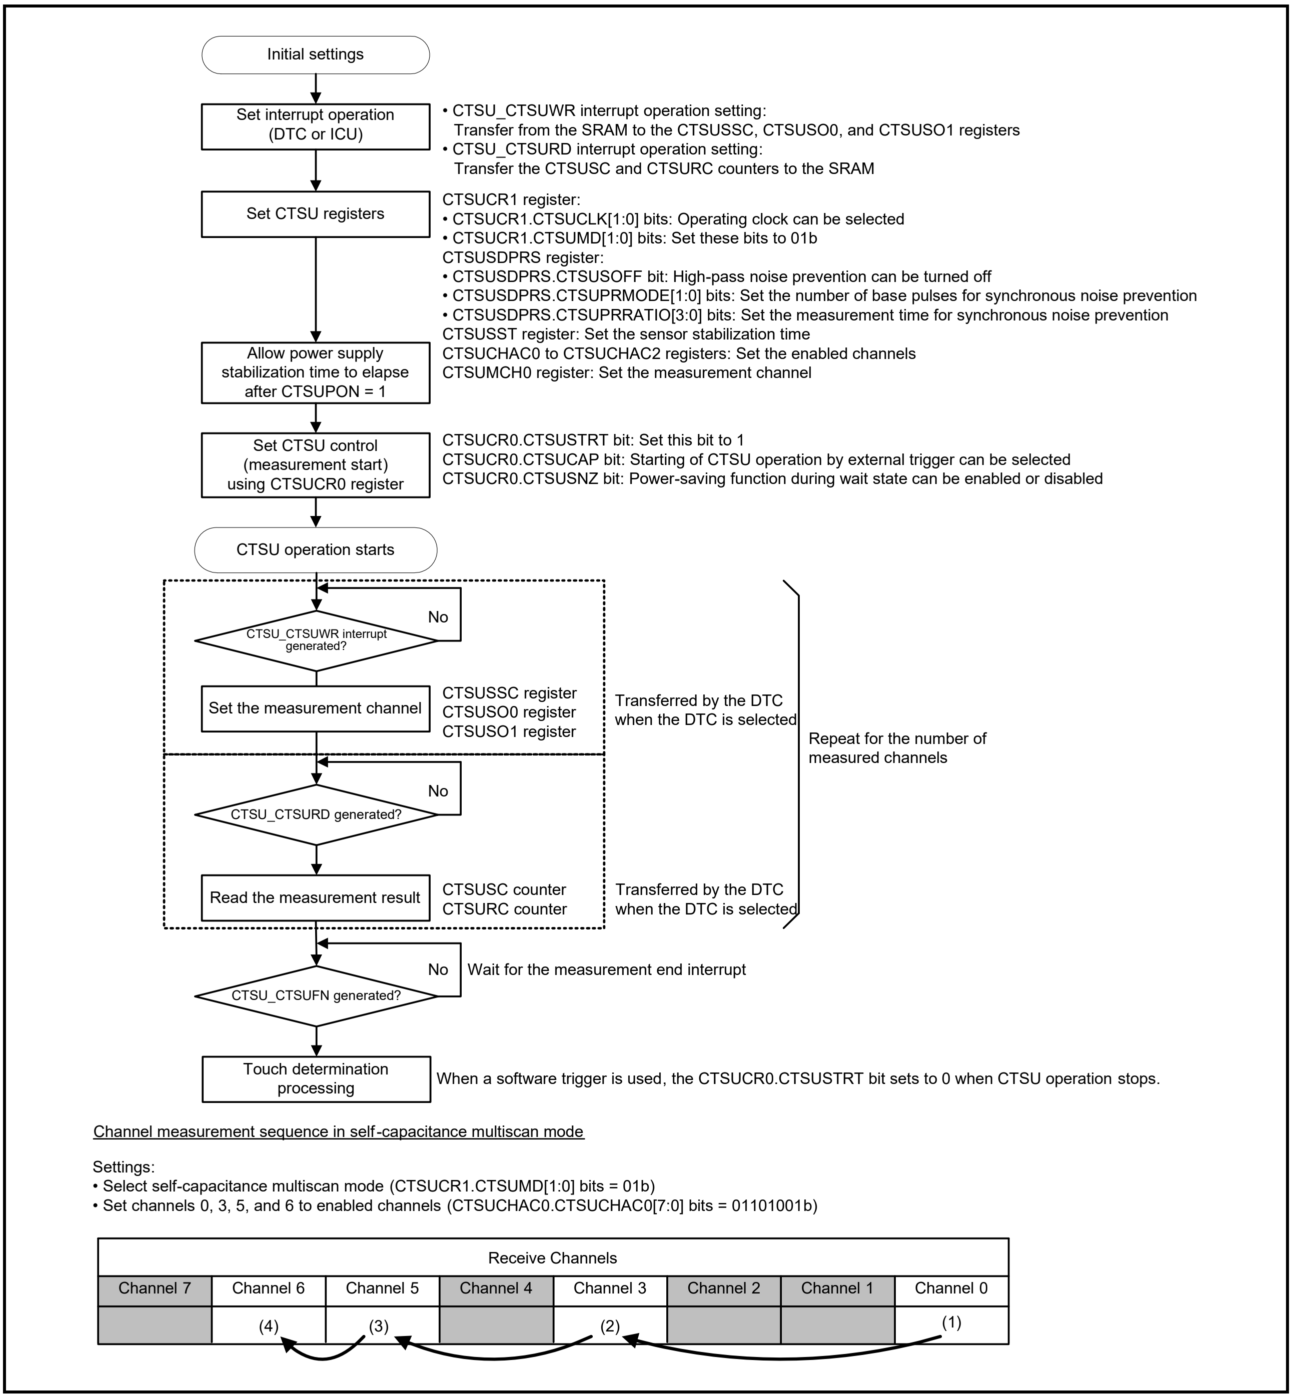

Figure 51.14 Software flow and example operation for self-capacitance multi-scan mode

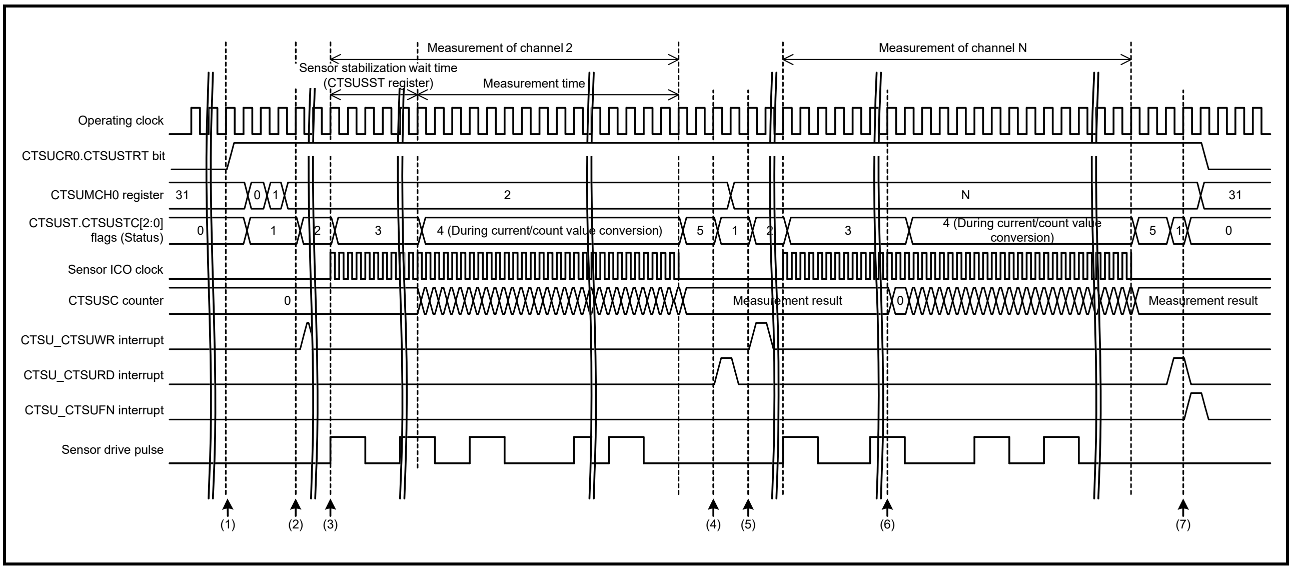

Figure 51.15 Timing of self-capacitance multi-scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 51.15:

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate.
4. After the sensor stabilization wait time and the measurement time elapse, and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. After the channel to be measured next is determined, a measurement channel setting request (CTSU_CTSUWR) is output.
6. After the stabilization wait time elapses and when the previous measurement is read, the result is cleared and measurement starts.
7. On completion of all measurement channels, a measurement end interrupt (CTSU_CTSUFN) is output and measurement is stopped (transition to Status 0).

Table 51.8 lists the touch pin states in self-capacitance multi-scan mode.

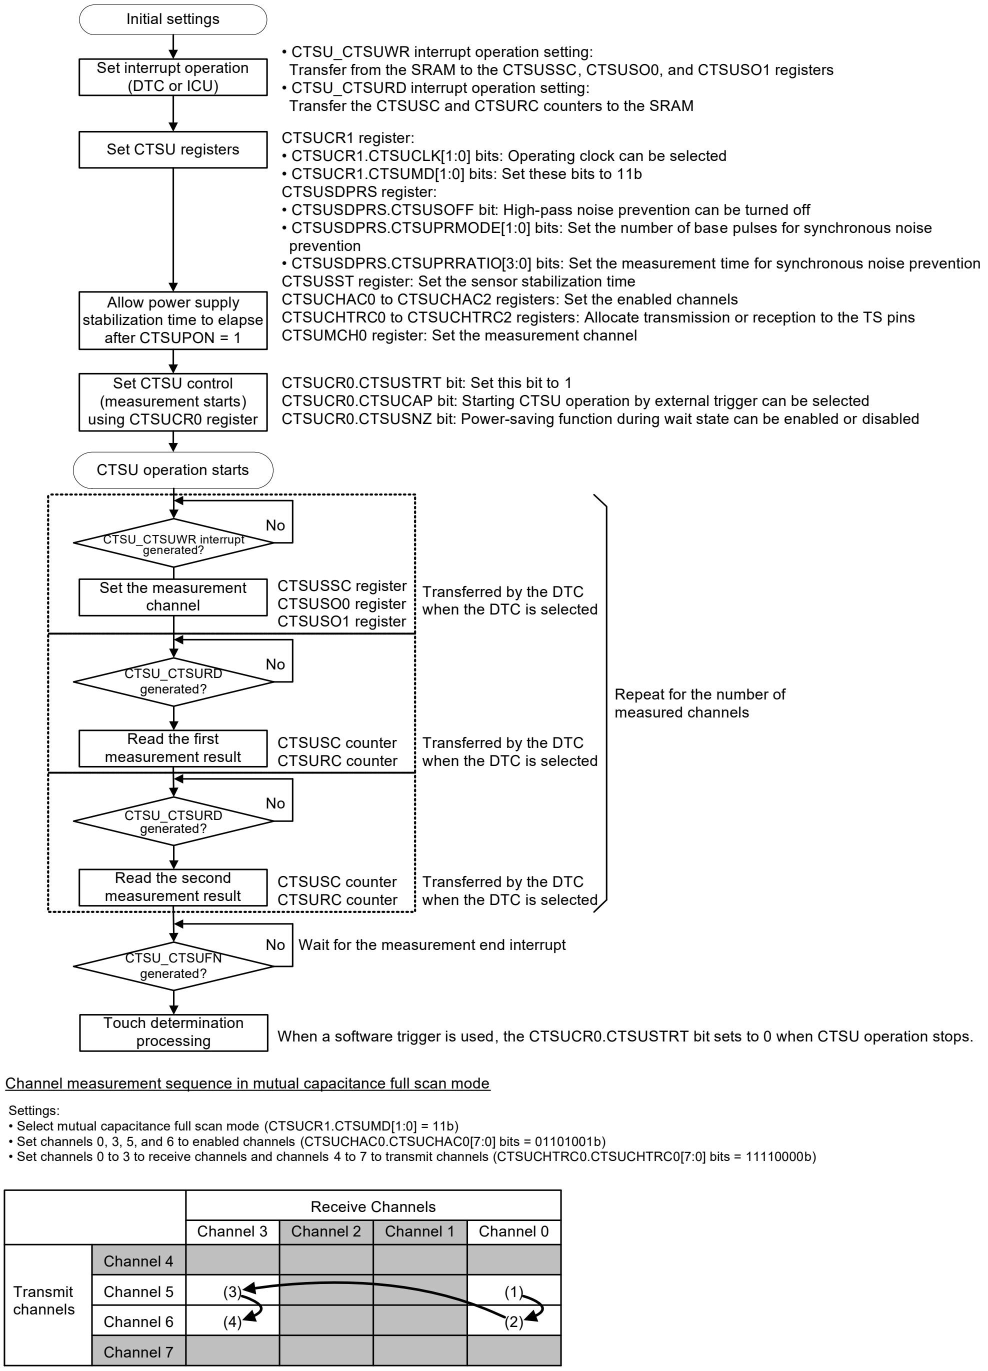
Table 51.8 Touch pin states in self-capacitance multi-scan mode

	Touch pin	
Status	**Measured channel**	**Non-measured channel**
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

51.3.2.5 Mutual capacitance full scan mode operation

In mutual capacitance full scan mode, measurement is performed during the high-level period of the sensor drive pulse on the receive channel by applying the edge to the target transmit channel to be measured. A single measurement target is measured twice, on the rising and falling edges. The difference between the data of these two measurements determines whether or not the electrode was touched, which results in a higher touch sensitivity.

Electrostatic capacitance is measured sequentially on channels set to transmission or reception in the CTSUCHTRC0 to CTSUCHTRC2 registers, and specified as measurement targets in the CTSUCHAC0 to CTSUCHAC2 registers. The capacitance is measured by combining these signals. Figure 51.16 shows the software flow and an operation example, and Figure 51.17 shows the timing.



- CTSU_CTSUWR interrupt operation setting:
  Transfer from the SRAM to the CTSUSSC, CTSUSO0, and CTSUSO1 registers
- CTSU_CTSURD interrupt operation setting:
  Transfer the CTSUSC and CTSURC counters to the SRAM

CTSUCR1 register:
- CTSUCR1.CTSUCLK[1:0] bits: Operating clock can be selected
- CTSUCR1.CTSUMD[1:0] bits: Set these bits to 11b

CTSUSDPRS register:
- CTSUSDPRS.CTSUSOFF bit: High-pass noise prevention can be turned off
- CTSUSDPRS.CTSUPRMODE[1:0] bits: Set the number of base pulses for synchronous noise prevention
- CTSUSDPRS.CTSUPRRATIO[3:0] bits: Set the measurement time for synchronous noise prevention

CTSUSST register: Set the sensor stabilization time
CTSUCHAC0 to CTSUCHAC2 registers: Set the enabled channels
CTSUCHTRC0 to CTSUCHTRC2 registers: Allocate transmission or reception to the TS pins
CTSUMCH0 register: Set the measurement channel

CTSUCR0.CTSUSTRT bit: Set this bit to 1
CTSUCR0.CTSUCAP bit: Starting CTSU operation by external trigger can be selected
CTSUCR0.CTSUSNZ bit: Power-saving function during wait state can be enabled or disabled

CTSUSSC register
CTSUSO0 register
CTSUSO1 register
Transferred by the DTC when the DTC is selected

CTSUSC counter
CTSURC counter
Transferred by the DTC when the DTC is selected

CTSUSC counter
CTSURC counter
Transferred by the DTC when the DTC is selected

Repeat for the number of measured channels

Wait for the measurement end interrupt

When a software trigger is used, the CTSUCR0.CTSUSTRT bit sets to 0 when CTSU operation stops.

Channel measurement sequence in mutual capacitance full scan mode

Settings:
- Select mutual capacitance full scan mode (CTSUCR1.CTSUMD[1:0] = 11b)
- Set channels 0, 3, 5, and 6 to enabled channels (CTSUCHAC0.CTSUCHAC0[7:0] bits = 01101001b)
- Set channels 0 to 3 to receive channels and channels 4 to 7 to transmit channels (CTSUCHTRC0.CTSUCHTRC0[7:0] bits = 11110000b)

		Receive Channels			
		Channel 3	Channel 2	Channel 1	Channel 0
Transmit channels	Channel 4				
	Channel 5	(3)			(1)
	Channel 6	(4)			(2)
	Channel 7				

Figure 51.16 Software flow and example operation for mutual capacitance full scan mode

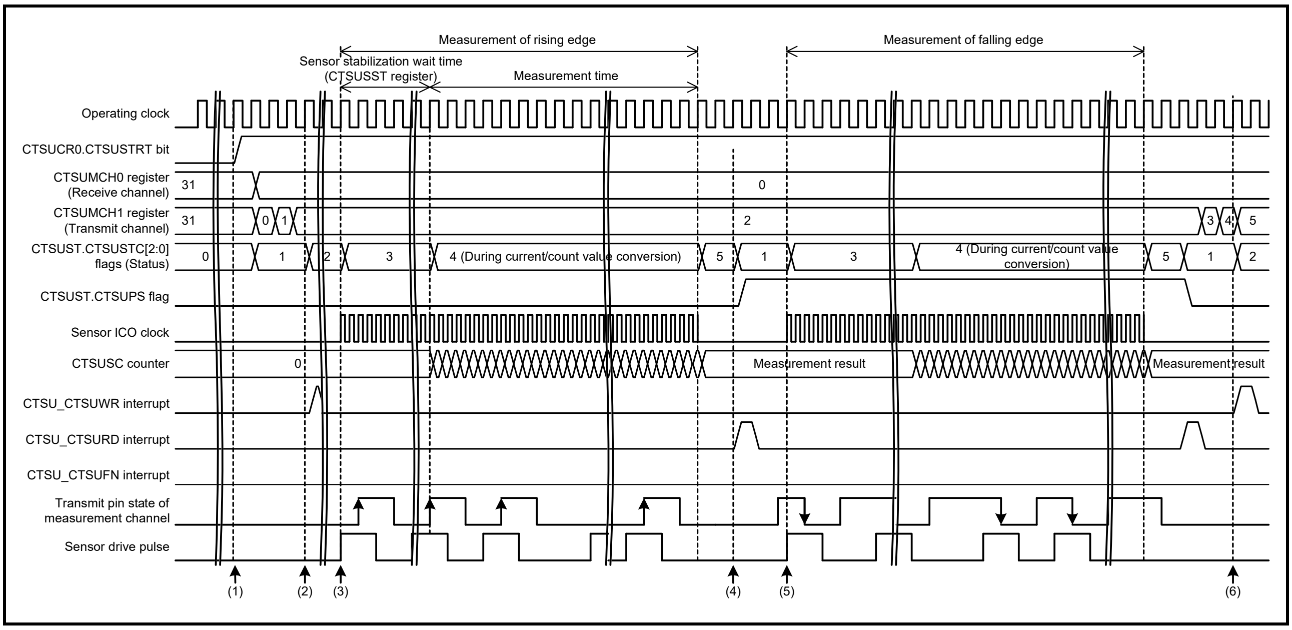


Figure 51.17 Timing of mutual capacitance full scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 51.17.

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate. At the same time, a pulse detected on the rising edge is output to the transmit pin on the measurement channel during the high-level period of the sensor drive pulse.
4. After the sensor stabilization wait time and the measurement time elapsed and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. The same channel is measured by outputting a pulse detected on the falling edge during the high-level period of the sensor drive pulse.
6. After the same channel is measured twice, the channel to be measured next is determined and measured in the same way.
7. On completion of all measurement channels, a measurement end interrupt (CTSU_CTSUFN) is output and measurement stops (transition to Status 0).

The CTSU mutual capacitance status flag (CTSUST.CTSUPS bit) changes when Status 5 transitions to Status 1.

Table 51.9 lists the touch pin states in mutual capacitance full scan mode.

Table 51.9 Touch pin states in mutual capacitance full scan mode (1 of 2)

	Touch pins for receive channels		Touch pins for transmit channels		
Status	Measured channel	Non-measured channel	Measured channel	Non-measured channel	Remarks
0	Low	Low	Low	Low	-
1	Low	Low	Low/high	Low	-
2	Low	Low	Low	Low	-

Table 51.9 Touch pin states in mutual capacitance full scan mode (2 of 2)

	Touch pins for receive channels		Touch pins for transmit channels		
Status	**Measured channel**	**Non-measured channel**	**Measured channel**	**Non-measured channel**	**Remarks**
3	Pulse	Low	Pulse	Low	The phase pulse is the same as that of the receive channel on the first measurement and opposite on the second measurement.
4	Pulse	Low	Pulse	Low	-
5	Low	Low	Low	Low	-

51.3.3 Parameters Common to Multiple Modes

51.3.3.1 Sensor stabilization wait time and measurement time

Figure 51.18 shows the timing of the sensor stabilization wait and measurement.

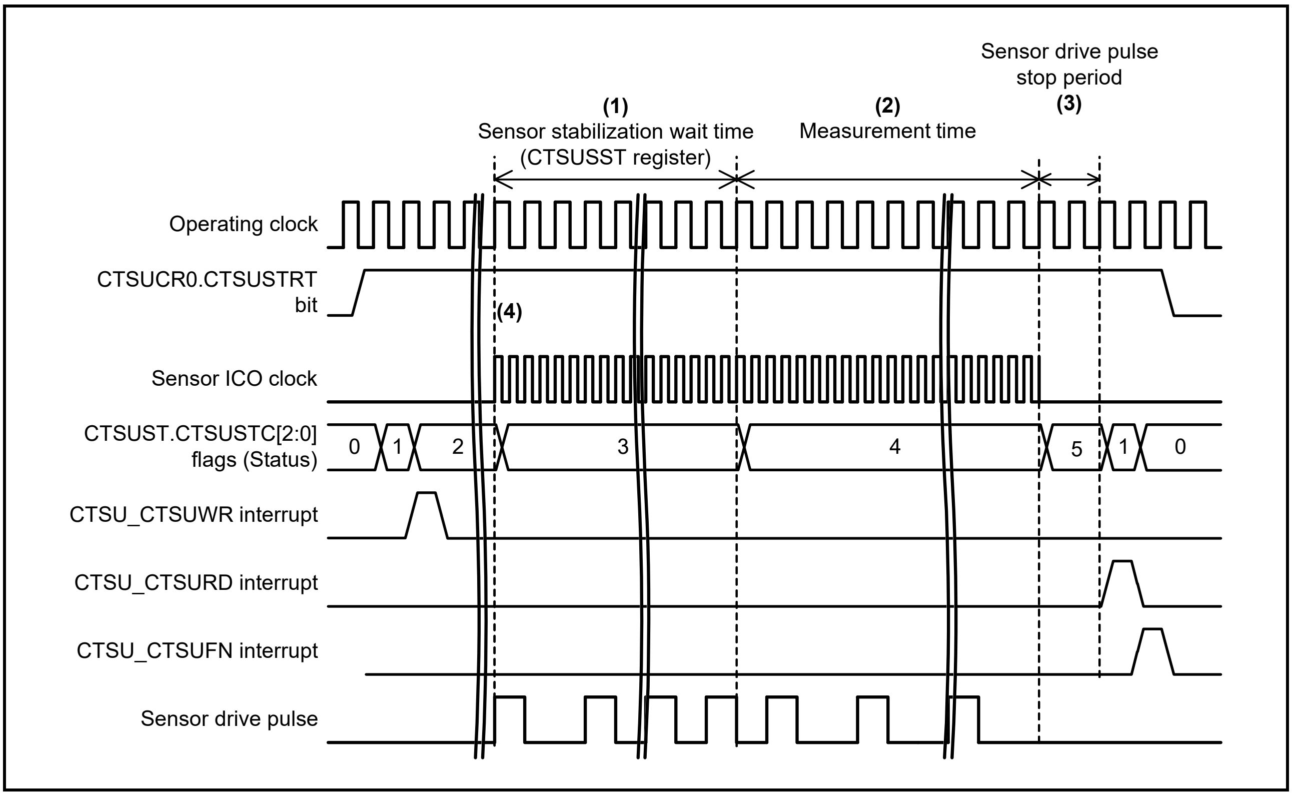

Figure 51.18 Sensor stabilization wait and measurement timing

The following describes the operation shown in Figure 51.18:

1. In response to the CTSU_CTSUWR interrupt request, output of the sensor drive pulse is started by a write access to the CTSUSO1 register. The CTSU waits for the stabilization time set in the CTSUSST register.
2. When the sensor stabilization time elapses and the CTSUST.CTSUDTSR flag clears to 0, measurement starts on transition to Status 4. The measurement time is determined by the base clock cycle setting and the CTSUSDPRS.CTSUPRMODE[1:0], CTSUPRRATIO[3:0], and CTSUSO0.CTSUSNUM[5:0] bits. When the measurement time elapses, measurement of the channel stops.
3. After the measurement time elapses, the status transitions to Status 1 after two operating clock cycles, and a CTSU_CTSURD interrupt occurs. Read the data from the CTSUSC and CTSURC counters. At this time, the sensor drive pulse is output at the low level. When measurement of all specified channels is completed, the CTSUCR0.CTSUSTRT bit clears to 0.
4. The sensor ICO clock oscillates while the CTSUST.CTSUSTC[2:0] flags = 011b (Status 3) or 100b (Status 4).

51.3.3.2 Interrupts

The CTSU supports the following interrupts:

- Write request interrupt for setting registers for each channel (CTSU_CTSUWR)
- Measurement data transfer request interrupt (CTSU_CTSURD)
- Measurement end interrupt (CTSU_CTSUFN).

(1) Write request interrupt for setting registers for each channel (CTSU_CTSUWR)

Store the settings for each measurement channel in the SRAM, and set up the DTC or ICU transfer associated with the CTSU_CTSUWR interrupt in advance. The CTSU_CTSUWR interrupt is output when Status 1 transitions to Status 2. Write the settings for the selected channel from the SRAM to the CTSUSSC, CTSUSO0, and CTSUSO1 registers (Figure 51.19). Because write access to the CTSUSO1 register controls the transition to the next status, you must set this register last.

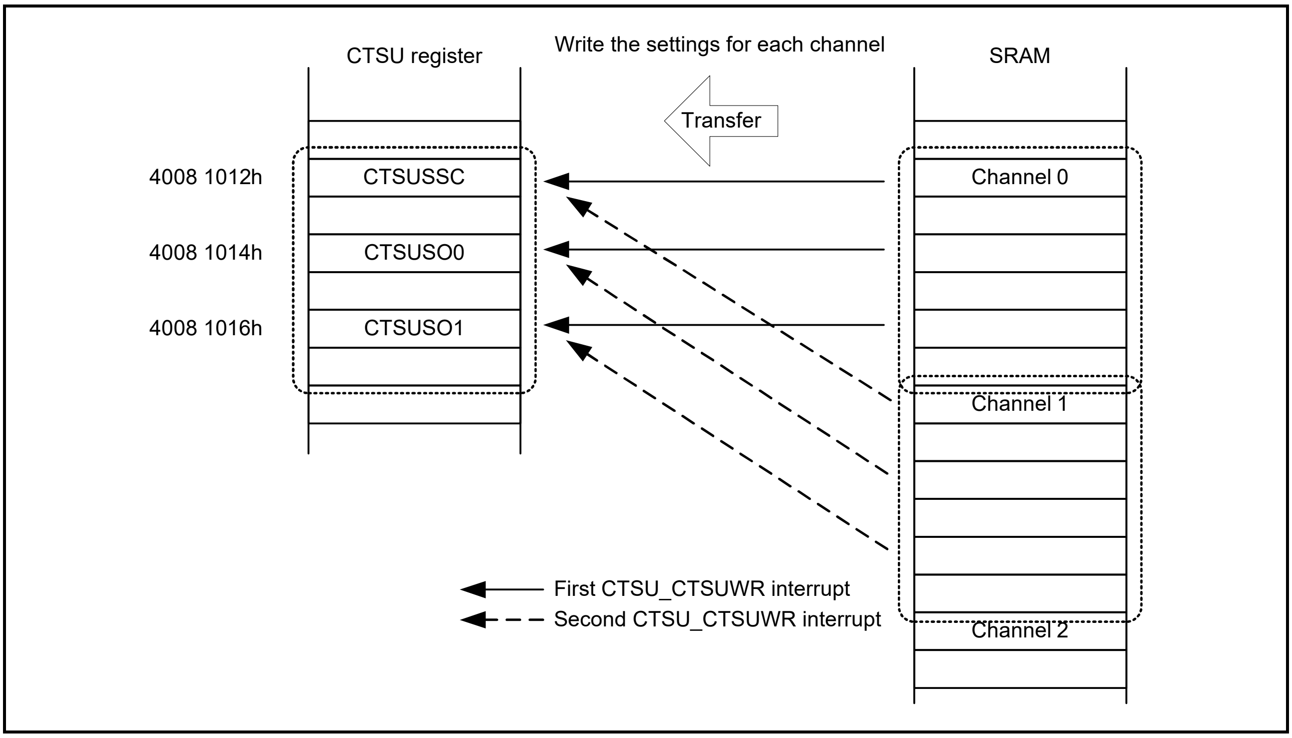

Figure 51.19 Example of DTC transfer operation using the CTSU_CTSUWR interrupt

The registers to be set (CTSUSSC, CTSUSO0, and CTSUSO1) are allocated at sequential addresses. On CTSU_CTSUWR interrupt generation, set up the operation as follows:

- Transfer destination address: CTSUSSC register address
- Handling at the transfer destination address: Transfer 2-byte data three times with a single interrupt. The address of the start byte is fixed
- Transfer source address: CTSUSSC register data storage address for the lowest number channel in the settings stored in the SRAM
- Handling at the transfer source address: Transfer 2-byte data three times with a single interrupt. The address of the first byte is continued from the previous interrupt handling
- Number of transfers per interrupt: Specify the number of measurements.

(2) Measurement data transfer request interrupt (CTSU_CTSURD)

Set up the DTC or ICU transfer associated with the CTSU_CTSURD interrupt in advance. The CTSU_CTSURD interrupt is output when Status 5 transitions to Status 1. Read the measurement result from the CTSUSC and CTSURC counters (Figure 51.20).

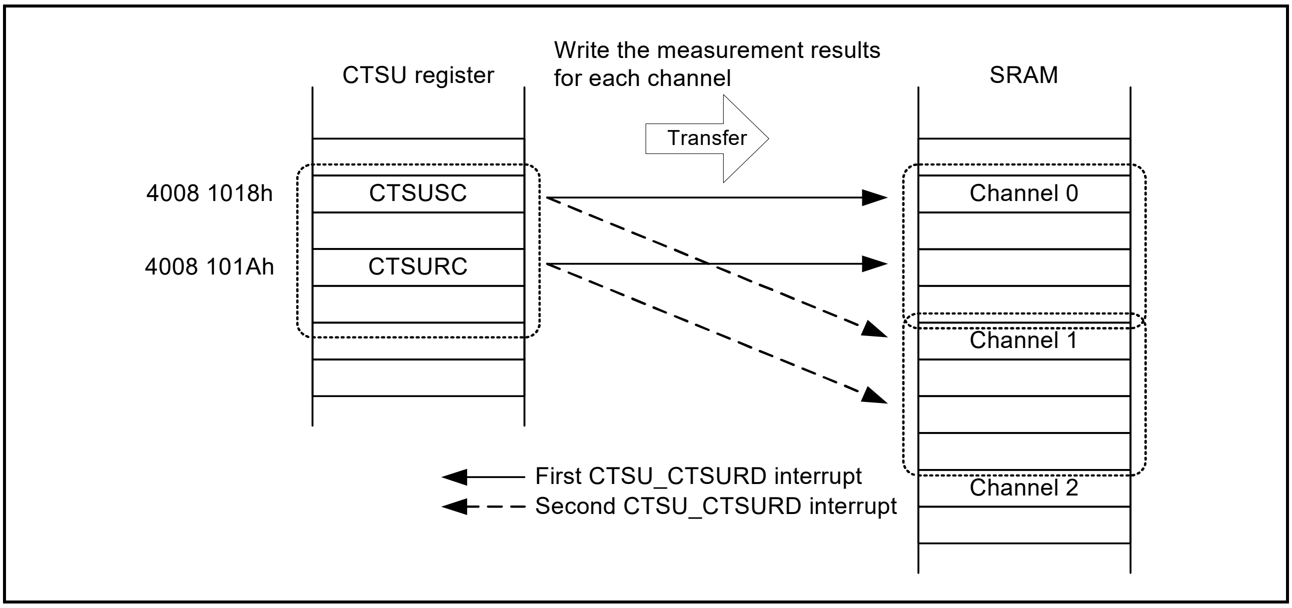

Figure 51.20 Example of DTC transfer operation using the CTSU_CTSURD interrupt

The measurement result registers (CTSUSC and CTSURC counters) used as transfer sources are allocated at sequential addresses. On CTSU_CTSURD interrupt generation, set up the operation as follows:

- Transfer source address: CTSUSC counter address
- Handling at the transfer source address: Transfer 2-byte data twice with a single interrupt. The start address is fixed
- Transfer destination address: CTSUSC counter data storage address for the lowest number channel in the settings stored in the SRAM
- Handling at the transfer destination address: Transfer 2-byte data twice with a single interrupt. The start address is continued from the previous interrupt handling
- Number of transfers per interrupt: Specify the number of measurements.

(3) Measurement end interrupt (CTSU_CTSUFN)

When all channels are measured, an interrupt occurs when Status 1 transitions to Status 0. In the software, check the overflow flags (CTSUST.CTSUSOVF and CTSUROVF) and read the measurement results to determine whether or not the electrode was touched. Interrupt requests are accepted or disabled in the interrupt control block.

51.4 Usage Notes

51.4.1 Measurement Result Data (CTSUSC and CTSURC Counters)

Read access during measurement is prohibited. If the measurement result data is accessed, an incorrect value might be read because of asynchronous operation.

51.4.2 Constraint on Software Trigger

When 10b (PCLKB/4) is selected in the CTSUCR1.CTSUCLK[1:0] bits, to restart measurement by writing 1 to the CTSUR0.CTSUSTRT bit after measurement is complete, wait for at least 3 cycles to elapse after an interrupt occurs, and then write to the CTSUCR0.CTSUSTRT bit.

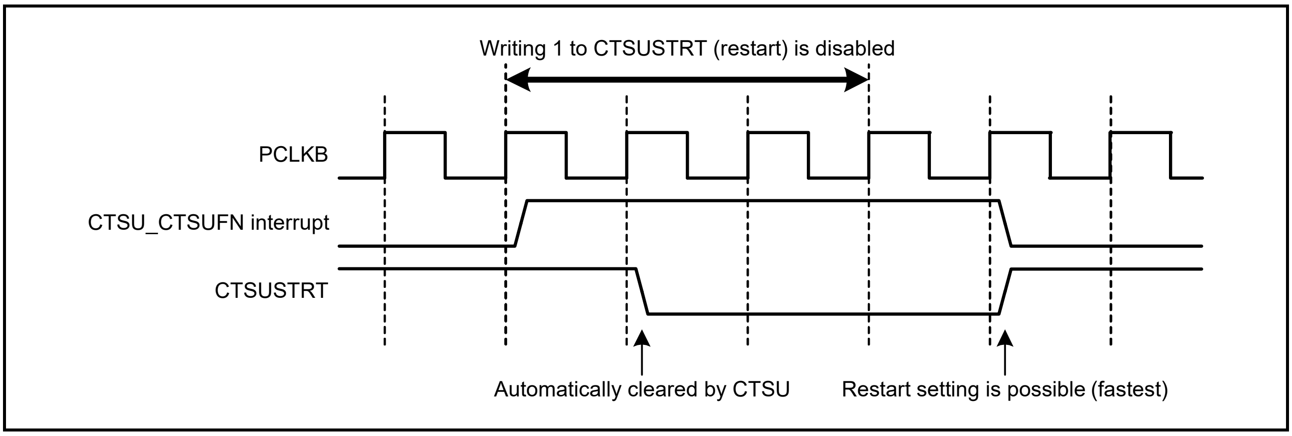

Figure 51.21 Notes on restarting measurement

51.4.3 Constraints on External Triggers

- If an external trigger is input during the measurement time, measurement does not start. The next external event is enabled after 1 cycle of the operating clock when a CTSU_CTSUFN interrupt occurs.
- To stop external trigger mode, write 0 to the CTSUCR0.CTSUSTRT bit and 0 to the CTSUCR0.CTSUINIT bit at the same time (forced stop).

51.4.4 Constraints on Forced Stops

To force the current operation to stop, write 0 to the CTSUCR0.CTSUSTRT bit and 1 to the CTSUCR0.CTSUINIT bit at the same time. After this setting, the operation is stopped and the internal control registers are initialized.

When the CTSUCR0.CTSUINIT bit is used for initialization, the following registers are initialized in addition to the initialization of the internal measurement state.

- CTSUMCH0 register
- CTSUMCH1 register
- CTSUST register
- CTSUSC counter
- CTSURC counter.

If operation is forced to stop, an interrupt request might be generated depending on the internal state. After a forced stop, also perform the processing for stopping and disabling the DTC or ICU. If a DTC transfer is stopped in an installed system for some reason, also perform the processing for forcing stop to and initializing the CTSU.

51.4.5 TSCAP Pin

The TSCAP pin requires an external decoupling capacitor to stabilize CTSU internal voltage. The traces between the TSCAP pin and the capacitor, and the capacitor and ground should be as short and wide as physically possible.

The capacitor connected to the TSCAP pin should be fully discharged using I/O port control to output a low level, before turning on the switch (CTSUCR1.CTSUCSW bit = 1) to establish a connection.

51.4.6 Constraints on Measurement Operation (CTSUCR0.CTSUSTRT Bit = 1)

During measurement (CTSUCR0.CTSUSTRT bit = 1), do not use the settings for stopping the peripheral clock or changing the port settings related to the touch pins (TSn and TSCAP pins) and Transmission power supply selection (CTSUCR0.CTSUTXVSEL) in the higher layers of the system.

If control settings non-compliant with these constraints are made, operation is forced to stop (CTSUCR0.CTSUSTRT bit = 0 and CTSUCR0.CTSUINIT bit = 1), write 0 to the CTSUCR1.CTSUPON bit and 0 to the CTSUCR1.CTSUCSW bit at the same time, and set the CTSUCR0.CTSUSNZ bit to 0. Next, restart from the initial settings flow shown in Figure 51.9.

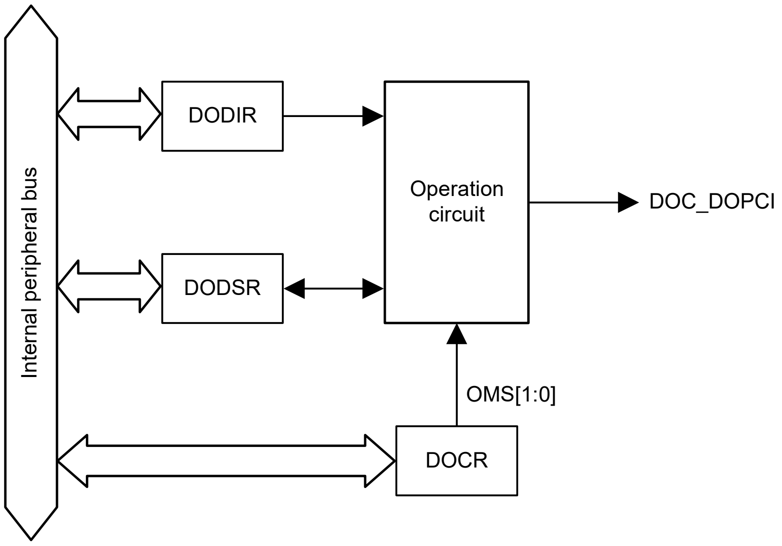
52. Data Operation Circuit (DOC)

52.1 Overview

The Data Operation Circuit (DOC) is used to compare, add, and subtract 16-bit data. When a selected condition applies, 16-bit data is compared and an interrupt can be generated. Table 52.1 lists the DOC specifications and Figure 52.1 shows a block diagram.

Table 52.1 DOC specifications

Parameter	Specifications
Data operation function	16-bit data comparison, addition, and subtraction
Module-stop function	Module-stop state can be set to reduce power consumption
Interrupts and event link function (DOC_DOPCI)	An interrupt occurs on the following conditions: • Compared values either match or mismatch • Data addition result is greater than FFFFh • Data subtraction result is less than 0000h



DOCR: DOC Control Register
DODIR: DOC Data Input Register
DODSR: DOC Data Setting Register

Figure 52.1 DOC block diagram

52.2 Register Descriptions

52.2.1 DOC Control Register (DOCR)

Address(es): DOC.DOCR 4005 4100h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	DOPCFCL	DOPCF	—	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited.	R/W
b2	DCSEL*1	Detection Condition Select	0: Set DOPCF when data mismatch detected 1: Set DOPCF when data match detected.	R/W
b4, b3	—	Reserved	There bits are read as 0. The write value should be 0.	R/W
b5	DOPCF	Data Operation Circuit Flag	Indicates the result of an operation.	R
b6	DOPCFCL	DOPCF Clear	0: Retain DOPCF flag state 1: Clear DOPCF flag.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Only valid when data comparison mode is selected.

OMS[1:0] bits (Operating Mode Select)

The OMS[1:0] bits select the operating mode of the DOC.

DCSEL bit (Detection Condition Select)

The DCSEL bit selects the detection condition in data comparison mode. This bit is only valid when data comparison mode is selected.

DOPCF flag (Data Operation Circuit Flag)

The DOPCF flag indicates the result of an operation.

[Setting conditions]

- The condition selected in the DCSEL bit is met
- A data addition result is greater than FFFFh
- A data subtraction result is less than 0000h.

[Clearing condition]

- Writing 1 to the DOPCFCL bit.

DOPCFCL bit (DOPCF Clear)

Setting the DOPCFCL bit to 1 clears the DOPCF flag. This bit is read as 0.

52.2.2 DOC Data Input Register (DODIR)

Address(es): DOC.DODIR 4005 4102h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DODIR is a 16-bit read/write register that stores 16-bit data used in the operations.

52.2.3 DOC Data Setting Register (DODSR)

Address(es): DOC.DODSR 4005 4104h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DODSR is a 16-bit read/write register that stores 16-bit data used as a reference in data comparison mode. This register also stores the results of operations in data addition and subtraction modes.

52.3 Operation

52.3.1 Data Comparison Mode

Figure 52.2 shows an example of the steps involved in data comparison mode operation by the DOC. The following is an example operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison):

1. Write 00b to the DOCR.OMS[1:0] bits to select data comparison mode.
2. Set 16-bit reference data in DODSR.
3. Write 16-bit data for comparison to DODIR.
4. Continue writing 16-bit data until all data for comparison is written to DODIR.
5. If a value written to DODIR does not match that in DODSR,[*1] the DOCR.DOPCF flag sets to 1.

Note 1. When DOCR.DCSEL = 0

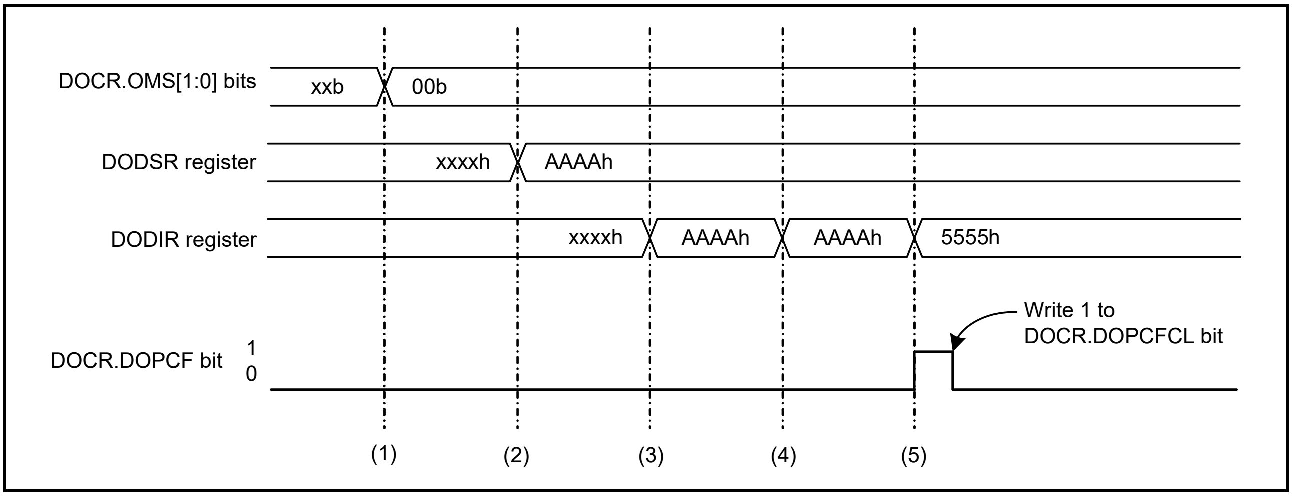


Figure 52.2 Example of operation in data comparison mode

52.3.2 Data Addition Mode

Figure 52.3 shows an example of the steps involved in data addition mode operation by the DOC:

1. Write 01b to the DOCR.OMS[1:0] bits to select data addition mode.
2. Set 16-bit data in the DODSR register as the initial value.
3. Write 16-bit data to be added to DODIR. The result of the operation is stored in DODSR.
4. Continue writing 16-bit data until all data for addition is written to DODIR.
5. If the result of an operation is greater than FFFFh, the DOCR.DOPCF flag sets to 1.

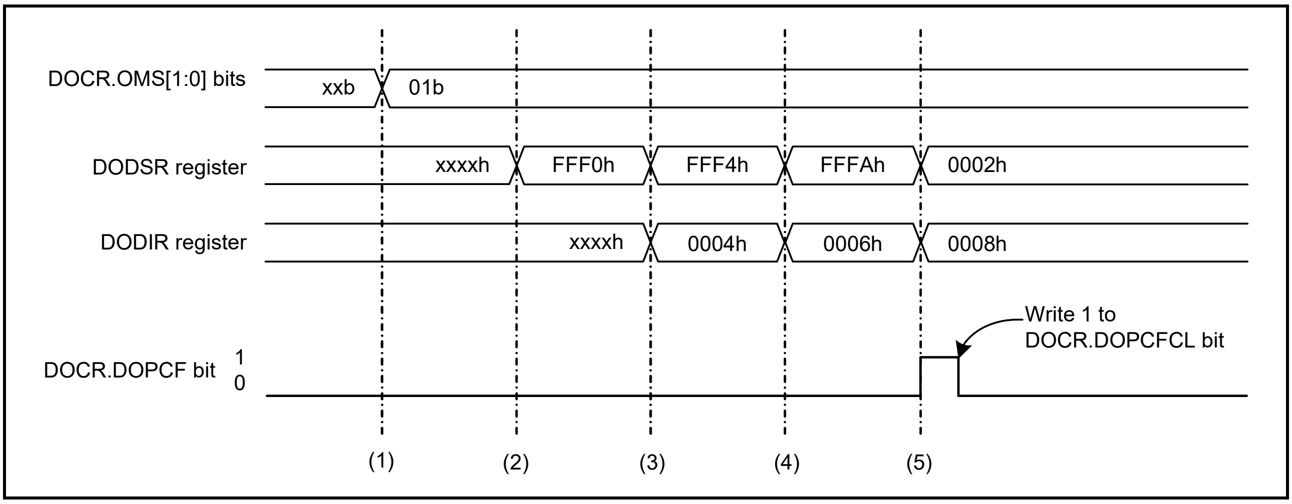

Figure 52.3 Example of operation in data addition mode

52.3.3 Data Subtraction Mode

Figure 52.4 shows an example of the steps involved in data subtraction mode operation by the DOC:

1. Write 10b to the DOCR.OMS[1:0] bits to select data subtraction mode.
2. Set 16-bit data in the DODSR register as the initial value.
3. Write 16-bit data to be subtracted to DODIR. The result of the operation is stored in DODSR.
4. Continue writing 16-bit data until all data for subtraction is written to DODIR.
5. If the result of an operation is less than 0000h, the DOCR.DOPCF flag sets to 1.

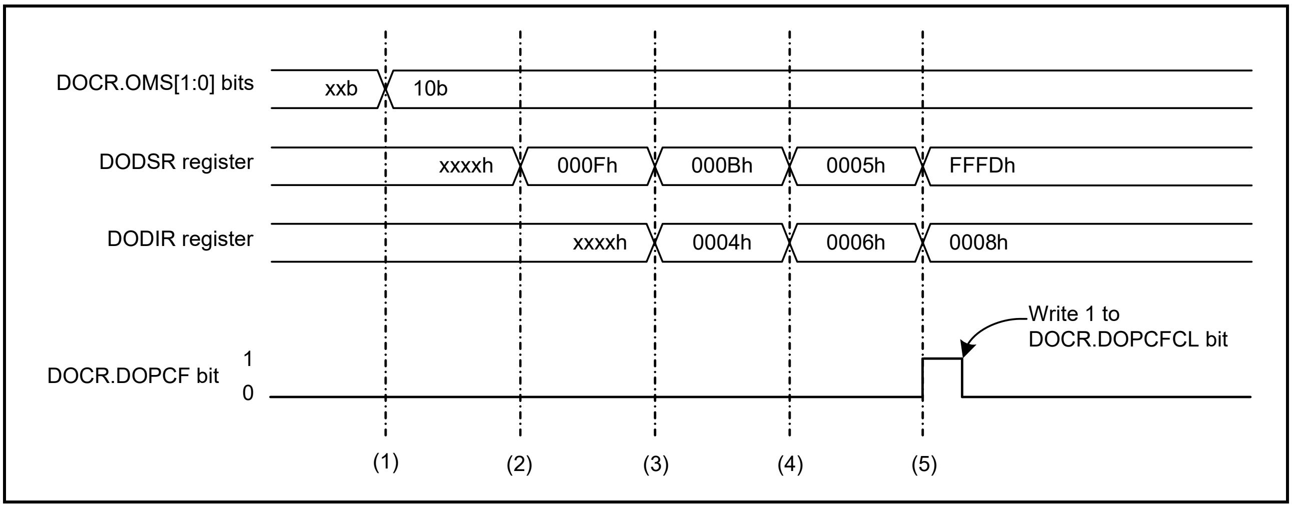

Figure 52.4 Example of operation in data subtraction mode

52.4 Interrupt Request and Output to the Event Link Controller (ELC)

The DOC outputs an event signal for the ELC under the following conditions:

- The compared values either match or mismatch
- The data addition result is greater than FFFFh
- The data subtraction result is less than 0000h.

This signal can be used to initiate operations by other modules selected in advance and also can be used as an interrupt request. When an event signal is generated, the Data Operation Circuit Flag (DOCR.DOPCF) sets to 1.

52.5 Usage Notes

52.5.1 Settings for the Module-Stop Function

DOC operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 11, Low Power Modes.

53. SRAM

53.1 Overview

The MCU provides on-chip high-speed SRAM modules with either parity-bit checking or ECC (Error Correction Code). The area of the first 32 KB of SRAM0 is subject to ECC. Parity check is performed on other areas. Table 53.1 lists the SRAM specifications.

Table 53.1 SRAM specifications

Parameter	Specifications without ECC	Specifications with ECC	SRAMHS specifications
SRAM capacity	SRAM0: 224 KB SRAM1: 256 KB	SRAM0 (ECC area): 32 KB	SRAMHS: 128 KB
SRAM addresses*2	SRAM0: 2000 8000h to 2003 FFFFh SRAM1: 2004 0000h to 2007 FFFFh	SRAM0 (ECC area): 2000 0000h to 2000 7FFFh	SRAMHS: 1FFE 0000h to 1FFF FFFFh
Access*1	Wait states are inserted into the read cycle by default. If the ICLK frequency is faster than 60 (up to 120) MHz, a wait state is required. If the ICLK frequency is 60 MHz or less, a wait state is not required. For details, see section 53.4, Usage Notes.	Wait states are inserted into the read cycle by default. If the ICLK frequency is faster than 60 (up to 120) MHz, wait state is required. If the ICLK frequency is 60 MHz or less, a wait state is not required. For details, see section 53.4, Usage Notes.	Access to the SRAMHS is always no wait state.
Data retention	Not available in Deep Software Standby mode		
Module-stop function	Module-stop state can be set to reduce power consumption		
Parity	Even-parity (data: 8 bits, parity: 1 bit)	No parity	Even-parity (data: 8 bits, parity: 1 bit)
Error checking	Even-parity error check	Detection up to 2-bit errors	Even-parity error check

Note 1. For details, see section 53.3.7, Access Cycles.

Note 2. The Cortex®-M4 processor supports Arm®v7 unaligned accesses. In this product, SRAMHS and SRAM0 are adjacent to each other and there is an access boundary between them. Therefore, when SRAMHS and SRAM0 are used as a continuous area of memory space, access that straddles the boundary must not be produced as this might lead to access of data other than what is intended. For details, see the *ARM® Cortex®-M4 Processor Technical Reference Manual*.

53.2 Register Descriptions

53.2.1 SRAM Parity Error Operation After Detection Register (PARIOAD)

Address(es): SRAM.PARIOAD 4000 2000h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	OAD	Operation after Detection	1: Reset 0: Non-maskable interrupt.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writing. Set the SRAMPRCR bit in the SRAMPRCR register to the enabled setting before writing to this register. Do not write to the PARIOAD register while access to the SRAM is in progress.

OAD bit (Operation after Detection)

The OAD bit specifies generation of either a reset or non-maskable interrupt when a parity error is detected. The OAD bit in the PARIOAD register is shared by SRAM0 (without ECC), SRAM1, SRAMHS, and the Standby SRAM.

53.2.2 SRAM Protection Register (SRAMPRCR)

Address(es): SRAM.SRAMPRCR 4000 2004h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW[6:0]							SRAMPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	SRAMPRCR	Register Write Control	0: Disable writes to protected registers 1: Enable writes to protected registers.	R/W
b7 to b1	KW[6:0]	Write Key Code	These bits enable or disable writing of the SRAMPRCR bit.	R/W

SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the SRAMWTSC and PARIOAD registers. When the bit is set to 1, writing to the SRAMWTSC and PARIOAD registers is enabled. When you write to this bit, write 78h to the KW[6:0] bits simultaneously.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, write 78h to the KW[6:0] bits simultaneously. When a value other than 78h is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0.

53.2.3 SRAM Wait State Control Register (SRAMWTSC)

Address(es): SRAM.SRAMWTSC 4000 2008h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SRAM1WTEN	SRAM0WTEN	SRAM0ERDWTEN	—
Value after reset:	0	0	0	0	1	1	1	0

Bit	Symbol	Bit name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	SRAM0ERDWTEN	SRAM0 (ECC area) Read Wait Enable	1: Add wait state in read access cycle to SRAM0 (ECC area) 0: Do not add wait state in read access cycle to SRAM0 (ECC area).	R/W
b2	SRAM0WTEN	SRAM0 Wait Enable	1: Add wait state in read access cycle to SRAM0 0: Do not add wait state in read access cycle to SRAM0.	R/W
b3	SRAM1WTEN	SRAM1 Wait Enable	1: Add wait state in read access cycle to SRAM1 0: Do not add wait state in read access cycle to SRAM1.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SRAMWTSC register controls the wait states in the SRAM modules. The SRAM Protection Register (SRAMPRCR) protects this register against writing. Set the SRAMPRCR bit in the SRAMPRCR register to the enabled setting before writing to this register. Do not write to the SRAMWTSC register while access to the SRAM is in progress.

SRAM0ERDWTEN bit (SRAM0 (ECC area) Read Wait Enable)

The SRAM0ERDWTEN bit enables the wait cycle for reads from the ECC area in SRAM0. When this bit is set to 1, one wait cycle is inserted into the read cycle of the ECC area in SRAM0. When the read access frequency is more than 60 MHz, this one-wait cycle setting is required.

SRAM0WTEN bit (SRAM0 Wait Enable)

The SRAM0WTEN bit enables the wait cycle for reads from SRAM0. When this bit is set to 1, one wait cycle is inserted into the read cycle of SRAM0. When the read access frequency is more than 60 MHz, this one-wait cycle setting is required.

SRAM1WTEN bit (SRAM1 Wait Enable)

The SRAM1WTEN bit enables the wait cycle for reads from SRAM1. When this bit is set to 1, one wait cycle is inserted into the read cycle of SRAM1. When the read access frequency is more than 60 MHz, this one-wait cycle setting is required.

53.2.4 ECC Operating Mode Control Register (ECCMODE)

Address(es): SRAM.ECCMODE 4000 20C0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	ECCMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	ECCMOD[1:0]	ECC Operating Mode Select	b1 b0 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECCMODE register specifies the ECC operating mode. The ECC Protection Register (ECCPRCR) protects this register against writing. Set the ECCPRCR bit in the ECCPRCR register to the enabled setting before writing to this register. Do not write to the ECCMODE register while access to the SRAM is in progress.

ECCMOD[1:0] bit (ECC Operating Mode Select)

The ECCMOD[1:0] bit sets the access mode for the ECC area in SRAM0.

53.2.5 ECC 2-Bit Error Status Register (ECC2STS)

Address(es): SRAM.ECC2STS 4000 20C1h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECC2ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ECC2ERR	ECC 2-Bit Error Status	0: No 2-bit ECC error occurred 1: 2-bit ECC error occurred.	R(/W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the bit.

ECC2ERR bit (ECC 2-Bit Error Status)

The ECC2ERR bit indicates whether a 2-bit ECC error occurred in the ECC area of the SRAM. When ECC operations are enabled and error correction is selected, this bit sets to 1 if a 2-bit error is detected. The SRAM error signal is also asserted. Writing 0 to the ECC2ERR bit negates the SRAM error signal triggered by the 2-bit ECC error.

The SRAM error can be specified as a non-maskable interrupt or reset in the ECCOAD register. Do not access the ECC area in the SRAM while writing 0 to this register.

53.2.6 ECC 1-Bit Error Information Update Enable Register (ECC1STSEN)

Address(es): SRAM.ECC1STSEN 4000 20C2h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	E1STSEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	E1STSEN	ECC 1-Bit Error Information Update Enable	0: Disable updating of 1-bit ECC error information 1: Enable updating of 1-bit ECC error information.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECC1STSEN register enables or disables updating of the ECC 1-Bit Error Status Register (ECC1STS) in response to a 1-bit ECC error in the SRAM (ECC area). The ECC Protection Register (ECCPRCR) protects this register against writing. Set the ECCPRCR bit in the ECCPRCR register to the enabled setting before writing to this bit.

E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the SRAM (ECC area) 1-Bit Error Status Register (ECC1STS) in response to a 1-bit error in the ECC area of SRAM. The register also functions as an interrupt and reset mask.

53.2.7 ECC 1-Bit Error Status Register (ECC1STS)

Address(es): SRAM.ECC1STS 4000 20C3h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECC1ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ECC1ERR	ECC 1-Bit Error Status	0: No 1-bit ECC error occurred 1: 1-bit ECC error occurred.	R(/W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the bit.

ECC1ERR bit (ECC 1-Bit Error Status)

The ECC1ERR bit indicates whether a 1-bit ECC error occurred in the ECC area of the SRAM. When ECC operations are enabled and error correction is selected, and updating of the 1-bit error information is enabled, this bit sets to 1 if a 1-bit error is detected. The SRAM error signal is also asserted. Writing 0 to the ECC1ERR bit negates the SRAM error signal triggered by the 1-bit ECC error.

The SRAM error can be specified as a non-maskable interrupt or reset in the ECCOAD register. Do not access the ECC area in the SRAM while writing 0 to this register.

53.2.8 ECC Protection Register (ECCPRCR)

Address(es): SRAM.ECCPRCR 4000 20C4h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW[6:0]							ECCPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ECCPRCR	Registers Write Control	0: Disable writes to protected registers 1: Enable writes to protected registers.	R/W
b7 to b1	KW[6:0]	Write Key Code	These bits enable or disable writes to the ECCPRCR bit.	R/W

ECCPRCR bit (Registers Write Control)

The ECCPRCR bit controls the write mode of the ECCMODE, ECC1STSEN, and ECCOAD registers. When the bit is set to 1, writing to the ECCMODE, ECC1STSEN, and ECCOAD registers is enabled. When you write to this bit, write 78h to the KW[6:0] simultaneously.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the ECCPRCR bit. When you write to the ECCPRCR bit, write 78h to the KW[6:0] bits simultaneously. When a value other than 78h is written to KW[6:0], the ECCPRCR bit is not updated. The KW[6:0] bits are always read as 0.

53.2.9 ECC Test Control Register (ECCETST)

Address(es): SRAM.ECCETST 4000 20D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	TSTBYP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSTBYP	ECC Bypass Select	0: ECC bypass disabled 1: ECC bypass enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECC Protection Register (ECCPRCR2) protects this register against writing. Change the ECCPRCR2 bit in the ECCPRCR2 register to the enabled setting before writing to this bit. Do not write to the ECCETST register while access to SRAM is in progress.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to the ECC code by bypassing ECC function. The ECC bypass function is used with the ECCMOD[1:0] bits in the ECCMODE register to 00b. Access the same address with 32-bit access size as the data that is checked by ECC. The lower 7 bits of 32-bit write data can be written as an ECC code when the ECC bypass is enabled. The higher 25 bits in the write data are then ignored. The lower 7 bits of the 32-bit read data can be used as ECC code. The higher 25 bits in the read data are unknown.

Note: For details of ECC test, see section 53.3.4, ECC Decoder Testing.

53.2.10 SRAM ECC Error Operation After Detection Register (ECCOAD)

Address(es): SRAM.ECCOAD 4000 20D8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	OAD	Operation after Detection	1: Reset 0: Non-maskable interrupt.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ECCOAD register controls the operation on detection of a ECC error. The ECC Protection Register (ECCPRCR) protects this register against writing. Set the ECCPRCR bit in the ECCPRCR register to the enabled setting before writing to this register. Do not write to the ECCOAD register while access to the SRAM is in progress.

OAD bit (Operation after Detection)

The OAD bit specifies generation of either a reset or a non-maskable interrupt when a ECC error is detected. The OAD bit in the ECCOAD register is used for the SRAM (ECC area).

53.3 Operation

53.3.1 Low-Power Functions

Power consumption can be reduced by setting Module Stop Control Register A (MSTPCRA) to stop supply of the clock signal to the SRAM. The control bits are as follows for each module:

- Setting both the MSTPA0 and MSTPA6 bits in the MSTPCRA to 1 stops supply of the clock signal to SRAM0*1
- Setting the MSTPA1 bit in the MSTPCRA to 1 stops supply of the clock signal to SRAM1
- Setting the MSTPA5 bit in MSTPCRA to 1 stops supply of the clock signal to the SRAMHS
- Setting the MSTPA7 bit in the MSTPCRA to 1 stops supply of the clock signal to the Standby SRAM.

Stopping the clock signal supply places the SRAM in the module-stop state. The SRAM operates after a reset.

The SRAM is not accessible in the module-stop state. Do not transition to the module-stop state while access to the SRAM is in progress. Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 11, Low Power Modes.

Note 1. The settings in the MSTPA0 and MSTPA6 bits in the MSTPCRA register must be the same.

53.3.2 ECC Function

Enabling and disabling of ECC error correction can be selected through ECCMODE register setting. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 7-bit check bits are appended to 32-bit data for writing. For reading, 39-bit (data: 32 bits, check bits: 7 bits) data is read out from the SRAM (ECC area).

When ECC function is enabled and error checking is enable, error correction is done if a 1-bit error occurs and the ECC1ERR bit in the ECC1STS register is set to 1 if the E1STSEN bit in the ECC1STSEN register is 1; if a 2-bit error occurs, error detection is done and the ECC2ERR bit in the ECC2STS register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but

ECC1ERR bit in the ECC1STS register is not updated although E1STSEN bit in the ECC1STSEN register is 1; if a 2-bit error occurs, this error is detected but the ECC2ERR bit in the ECC2STS register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur. So ECC1ERR bit and ECC2ERR bit are not updated.

There is no way to confirm the location where the error was found. Therefore, when after the occurrence of an error, update all the data.

When updating all the data after the occurrence of an error, the only support of 32-bit data writing.

Because the SRAM data is undefined after power on and release from deep software standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 32-bit data size to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, please do not perform the read access in a row after the write access.

53.3.3 ECC Error Generation

When ECC function is enabled and error checking is applied to the SRAM (ECC area), an ECC error occurs when either the ECC2ERR bit in the ECC2STS register or the ECC1ERR bit in the ECC1STS register becomes 1 to indicate that ECC checking revealed a 2-bit error or a 1-bit error, respectively.

An ECC error is output with a pulse width of ICLK. When the ECC 1-bit error is to be masked, set the ECC1STSEN.E1STSEN bit to 0 to disable updating of the ECC1ERR bit. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected.

ECC error can choose non maskable interrupt or reset by ECCOAD register. When set 1 in the OAD bit of the ECCOAD register, ECC error is output to the reset function. When set 0 in the OAD bit of the ECCOAD register, ECC Error interrupt is output to the ICU as non-maskable interrupt.

53.3.4 ECC Decoder Testing

Figure 53.1 shows the ECC decoder testing.

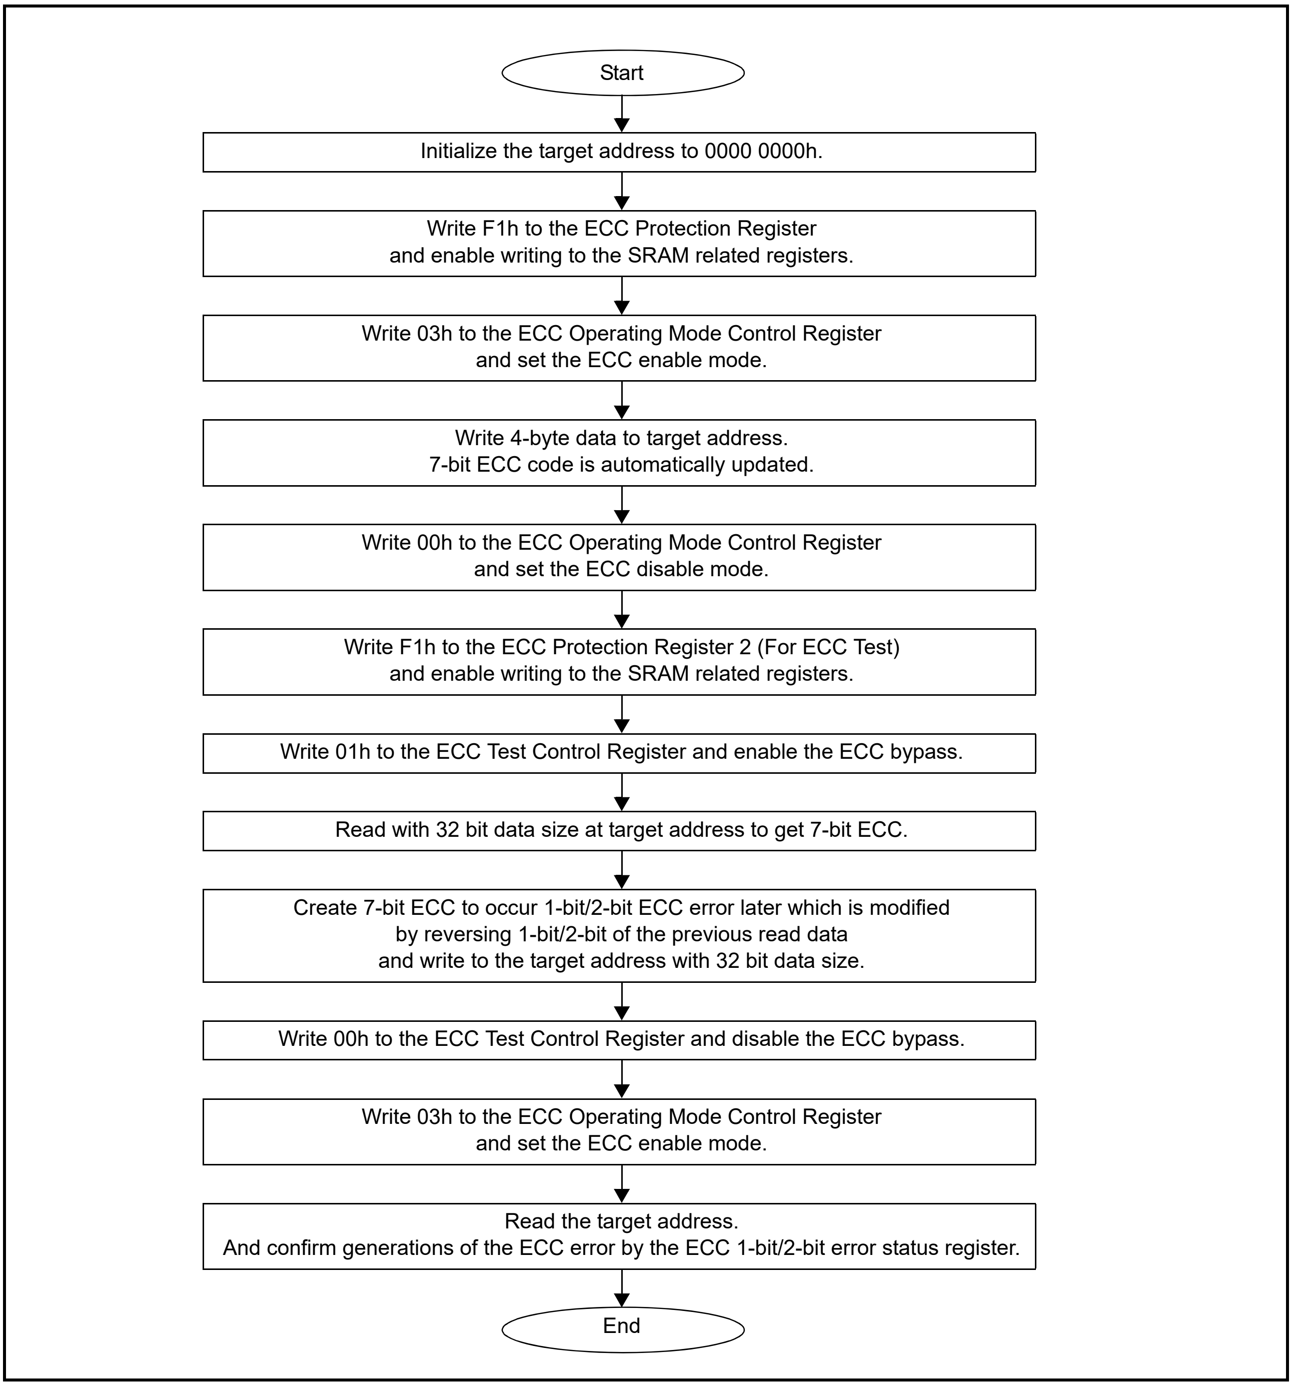

Figure 53.1 ECC Decoder Testing

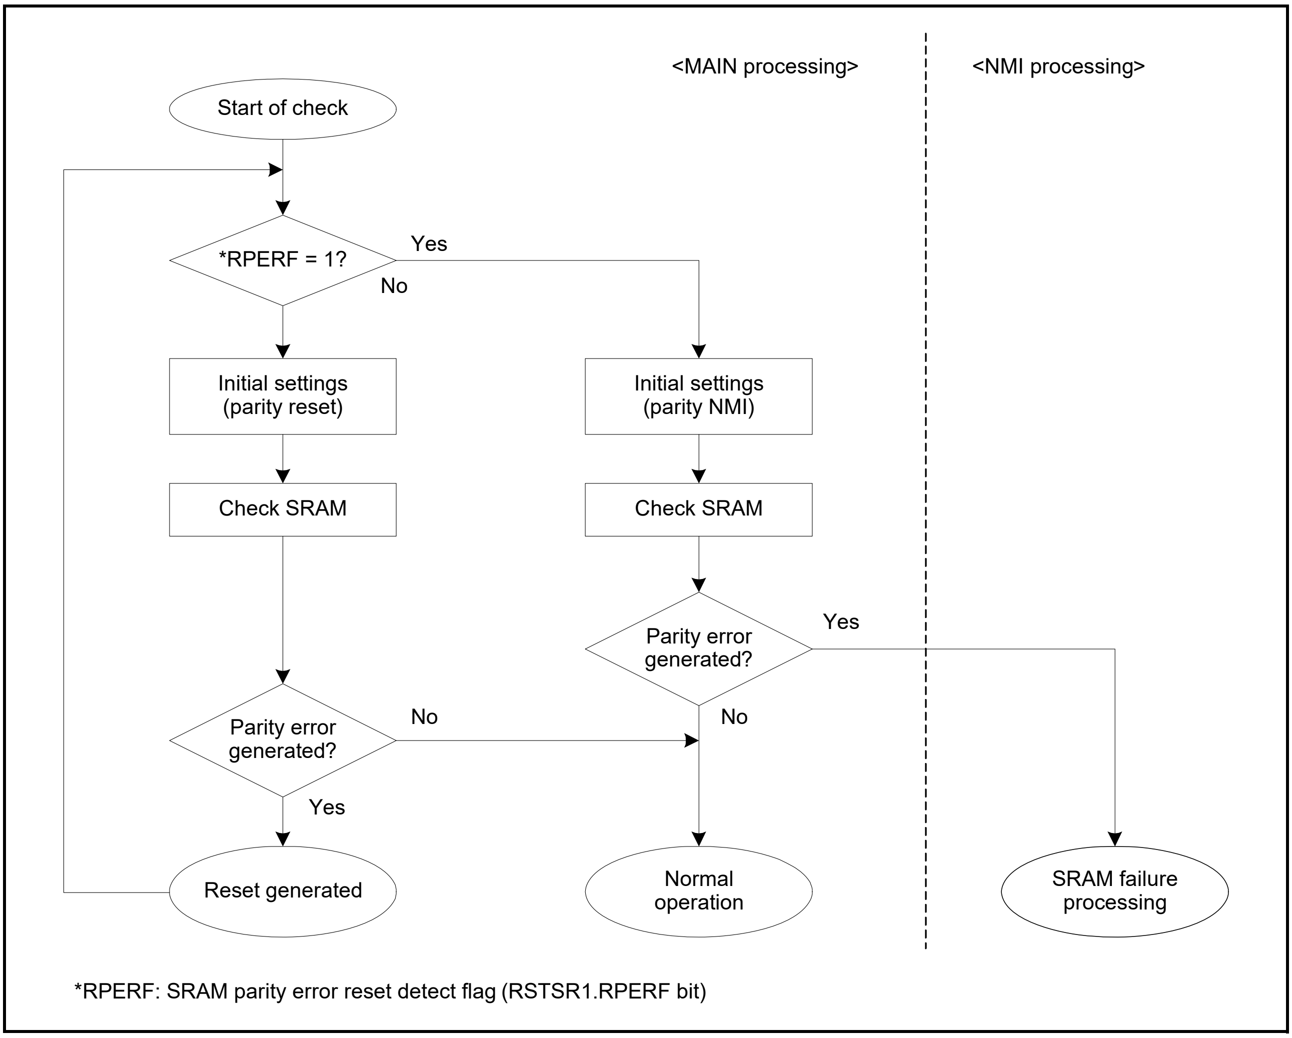
53.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. A parity bit is therefore added to every 8-bit data unit in the SRAM modules that have 32-bit data width. With this SRAM parity error detection function, the parity bit is appended when data is written, and the parity is checked when the data is read. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset. The specification for SRAM0 without ECC, SRAM1, SRAMHS, and Standby SRAM is even parity.

Parity error notification can be specified as either a non-maskable interrupt or reset in the PARIOAD register. When the OAD bit in the PARIOAD register is set to 1, a parity error is output to the reset function. When the OAD bit in the PARIOAD register is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors often occur because of noise. To confirm whether the cause is noise or corruption, follow the parity check flows shown in Figure 53.2 and Figure 53.3.



*RPERF: SRAM parity error reset detect flag (RSTSR1.RPERF bit)

Figure 53.2 Flow of SRAM parity check when SRAM parity reset is enabled

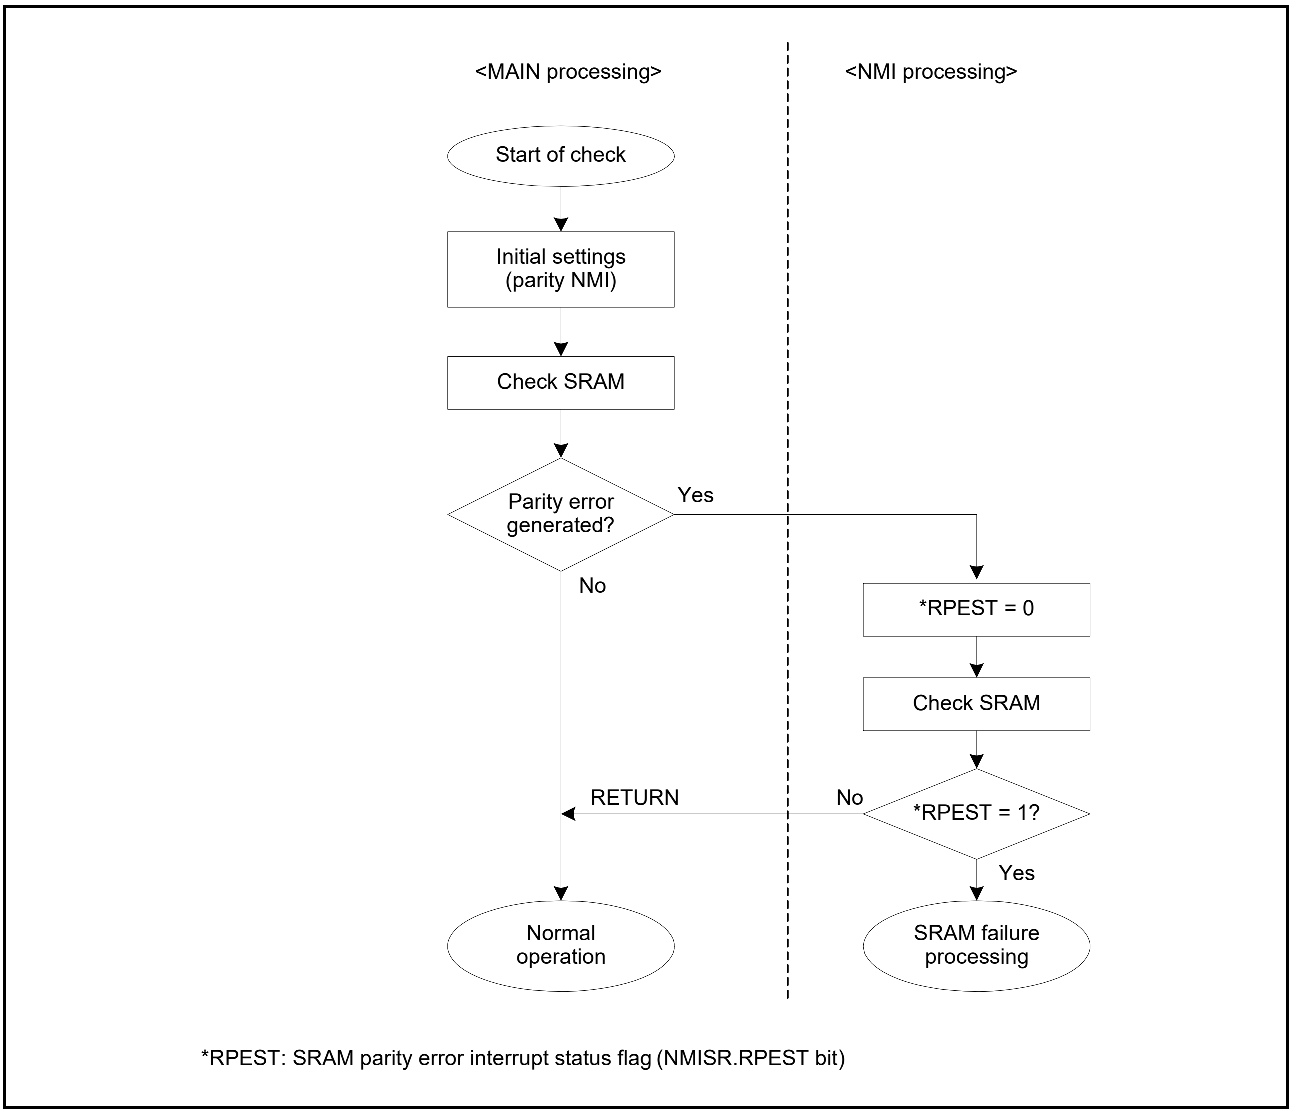


Figure 53.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

53.3.6 SRAM Error Sources

The SRAM error sources are ECC errors and parity errors. ECC errors can be specified as non-maskable interrupts or resets in the OAD bit in the ECCOAD register, and parity errors can be specified as non-maskable interrupts or resets in the PARIOAD register.

Table 53.2 SRAM error sources

Interrupt source	DTC activation	DMAC activation
ECC error (SRAM0 area with ECC)	Not possible	Not possible
Parity error (SRAM0 area without ECC, SRAM1, SRAMHS	Not possible	Not possible

53.3.7 Access Cycles

Table 53.3 SRAMHS (parity area 1FFE 0000h to 1FFF FFFFh)

Read (cycles)		Write (cycles)	
Word access	Halfword/byte access	Word access	Halfword/byte access
2		2	

Table 53.4 SRAM0 (ECC area 2000 0000h to 2000 7FFFh)

Bit settings		Read (cycles)		Write (cycles)	
		Word access	Halfword or byte access	Word access	Halfword or byte access
ECC Off ECCMOD[1] = 0	SRAM0ERDWTEN = 0	2		2	
	SRAM0ERDWTEN = 1	3		2	
ECC On ECCMOD[1] = 1	SRAM0ERDWTEN = 0	2		2	4
	SRAM0ERDWTEN = 1	3		2	4

Table 53.5 SRAM0 (parity area 2000 8000h to 2003 FFFFh)

Bit settings	Read (cycles)		Write (cycles)	
	Word access	Halfword or byte access	Word access	Halfword or byte access
SRAM0WTEN = 0	2		2	
SRAM0WTEN = 1	3		2	

Table 53.6 SRAM1 (parity area 2004 0000h to 2007 FFFFh)

Bit settings	Read (cycles)		Write (cycles)	
	Word access	Halfword or byte access	Word access	Halfword or byte access
SRAM1WTEN = 0	2		2	
SRAM1WTEN = 1	3		2	

53.4 Usage Notes

53.4.1 Wait State Insertion

Set the number of SRAM wait cycles in the SRAMWTSC register based on the following:

- SRAM0, SRAM1
  1 wait: 60 MHz < ICLK ≤ 120 MHz
  No wait: ICLK ≤ 60 MHz

53.4.2 Instruction Fetch from the SRAM Area

When using SRAM0, SRAM1, or the SRAMHS to operate a program, initialize the SRAM area so the CPU can correctly prefetch data. If the CPU prefetches data from an SRAM area that is not initialized, an ECC error or a parity error might occur. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

53.4.3 Store Buffer of SRAM

For fast access between SRAM and CPU, a store buffer is used. When a load instruction is executed from the same address after a store instruction to SRAM, the load instruction might read out data from the buffer instead of data from the SRAM. To read data on the SRAM correctly, use either of the following procedures:

- After writing to the SRAM (address = A), use the NOP instruction, then read the SRAM (address = A)
- After writing to the SRAM (address = A), read data from area other than SRAM (address = A), then read the SRAM (address = A).

54. Standby SRAM

54.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. Table 54.1 lists the Standby SRAM specifications.

Table 54.1 Standby SRAM specifications

Parameter	Specifications
SRAM capacity	8 KB
SRAM address	200F E000h to 200F FFFFh
Access	The number of access depends on the frequency between ICLK and PCLKB. See section 54.2.4, Access Cycle for details.
Data retention	Data can be retained in Deep Software Standby mode
Parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption

54.2 Operation

54.2.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.DEEPCUT[1:0] bits. If the DPSBYCR.DEEPCUT[1:0] bits are set to 00b, data in the Standby SRAM is retained in Deep Software Standby mode. See section 11, Low Power Modes, for details on the DPSBYCR.DEEPCUT[1:0] bits.

54.2.2 Low-Power Function

Power consumption can be reduced by setting Module Stop Control Register A (MSTPCRA) to stop supply of the clock signal to the SRAM. Setting the MSTPA7 bit in MSTPCRA to 1 stops supply of the clock signal to the Standby SRAM. The Standby SRAM is then placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset. The Standby SRAM is not accessible if it is in the module-stop state. Do not transition to the module-stop state while access to the Standby SRAM is in progress. For details on the MSTPCRA register, see section 11, Low Power Modes.

54.2.3 Parity Calculation Function

The parity calculation function for Standby SRAM is the same as for SRAM1 or SRAM0 without error correction code (ECC). The function of the OAD bit in the PARIOAD register and the flow of the SRAM parity check are shared by the Standby SRAM modules. For details, see section 53.3.5, Parity Calculation Function and section 53.3.6, SRAM Error Sources.

54.2.4 Access Cycle

Table 54.2 Standby SRAM access cycle

	Read (cycles)		Write (cycles)	
Frequency	Word access	Halfword/byte access	Word access	Halfword/byte access
Same Frequency ICLK = PCLKB	3 ICLK		2 ICLK	
Different Frequency ICLK > PCLKB	1 ICLK + 2 to 3 PCLKB		1 ICLK + 1 to 2 PCLKB	

54.3 Usage Notes

54.3.1 Instruction Fetch from the Standby SRAM area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

55. Flash Memory

55.1 Overview

The MCU provides up to 2-MB code flash memory and 64-KB data flash memory. The Flash Control Unit (FCU) controls programming and erasure of the flash memory. The Flash Application Command Interface (FACI) controls the FCU in accordance with the specified FACI commands.

Table 55.1 lists the specifications of the code flash memory and data flash memory, and Figure 55.1 shows a block diagram of the related modules. Figure 55.2 shows the configuration of the code flash memory, and Figure 55.3 shows the configuration of the data flash memory.

Table 55.1 Specifications of the code flash memory and data flash memory

Parameter	Code flash memory specifications	Data flash memory specifications
Memory capacity	• Up to 2 MB	64 KB
Read cycle	• 80 MHz < ICLK frequency ≤ 120 MHz: Cache hit: 1 cycle Cache miss: 3 cycles • 40 MHz < ICLK frequency ≤ 80 MHz: Cache hit: 1 cycle Cache miss: 2 cycles • ICLK frequency ≤ 40 MHz: Cache hit: 1 cycle Cache miss: 1 cycle	A read operation takes seven cycles of FCLK in words or bytes (FCLK frequency is up to 60 MHz)
Value after erasure	FFh	Undefined
Programming/erasing methods	• Programming and erasing of code and data flash memory handled by FACI commands specified in the FACI command issuing area (407E 0000h) • Programming by dedicated flash-memory programmer transfer through a serial interface (serial programming) • Programming of flash memory by user program (self-programming)	
Security function	Protection against illicit tampering with or reading of data in flash memory	
Protection	Protection against erroneous overwriting of flash memory	
Background operations (BGOs)	• Code flash memory can be read during code flash memory programming*1 • Code flash memory can be read during data flash memory programming • Data flash memory can be read during code flash memory programming	
Units of programming and erasure	• 128-byte units for programming in user area • Block units for erasure in user area	• 4/8/16-byte units for programming in data area • 64/128/256-byte units for erasure in data area
Other functions	Interrupts can be accepted during self-programming	
	An expansion area of flash memory (option bytes) can be set in the initial MCU settings	
On-board programming (four types)	Programming in serial programming mode (SCI boot mode): • Asynchronous serial interface (SCI9) used • Transfer rate adjusted automatically Programming in serial programming mode (USB boot mode): • USBFS used • Dedicated hardware not required, so direct connection to PC is possible Programming in On-chip debug mode: • JTAG or SWD interface used • Dedicated hardware not required Programming by a routine for code and data flash memory programming within the user program: • Allows code and data flash memory programming without resetting the system	

Note 1. Constraints apply to the combinations of ranges in which writing can proceed. See Table 55.11.

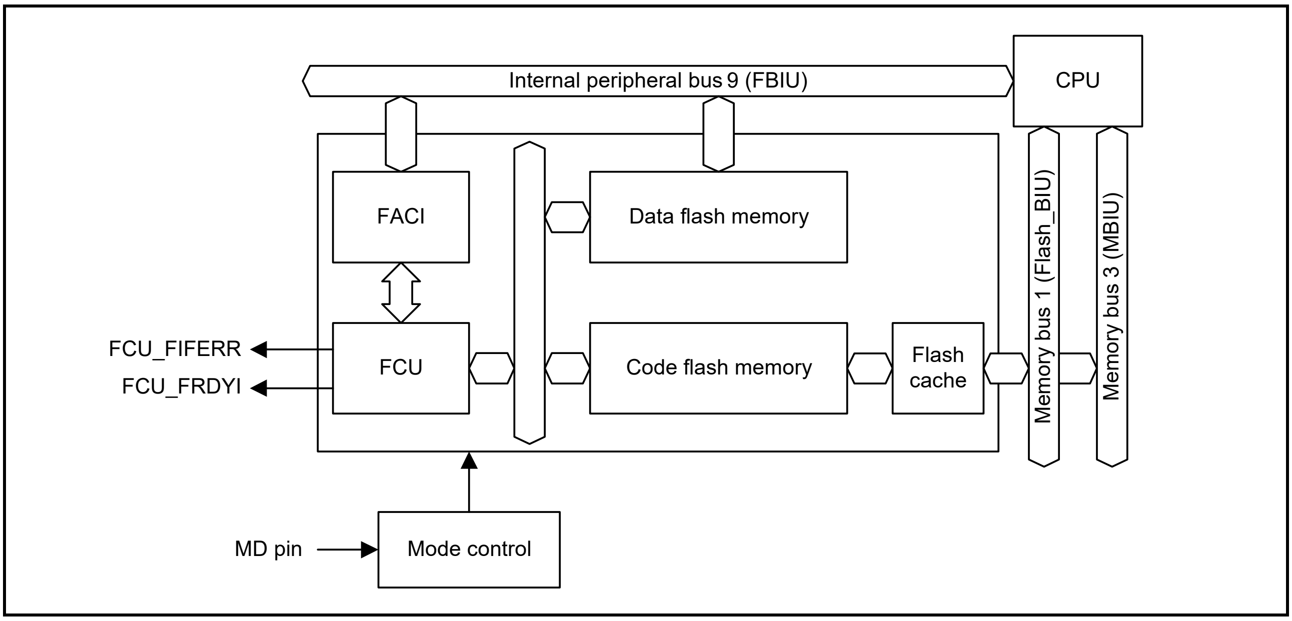

Figure 55.1 Block diagram of flash memory-related modules

55.2 Structure of Memory

Figure 55.2 shows the mapping of the code flash memory, and Table 55.2 shows the read and programming/erasure addresses by product. The user space of the code flash memory is divided into 8- and 32-KB blocks, which serve as the units of erasure. The user area is available for storing the user program.

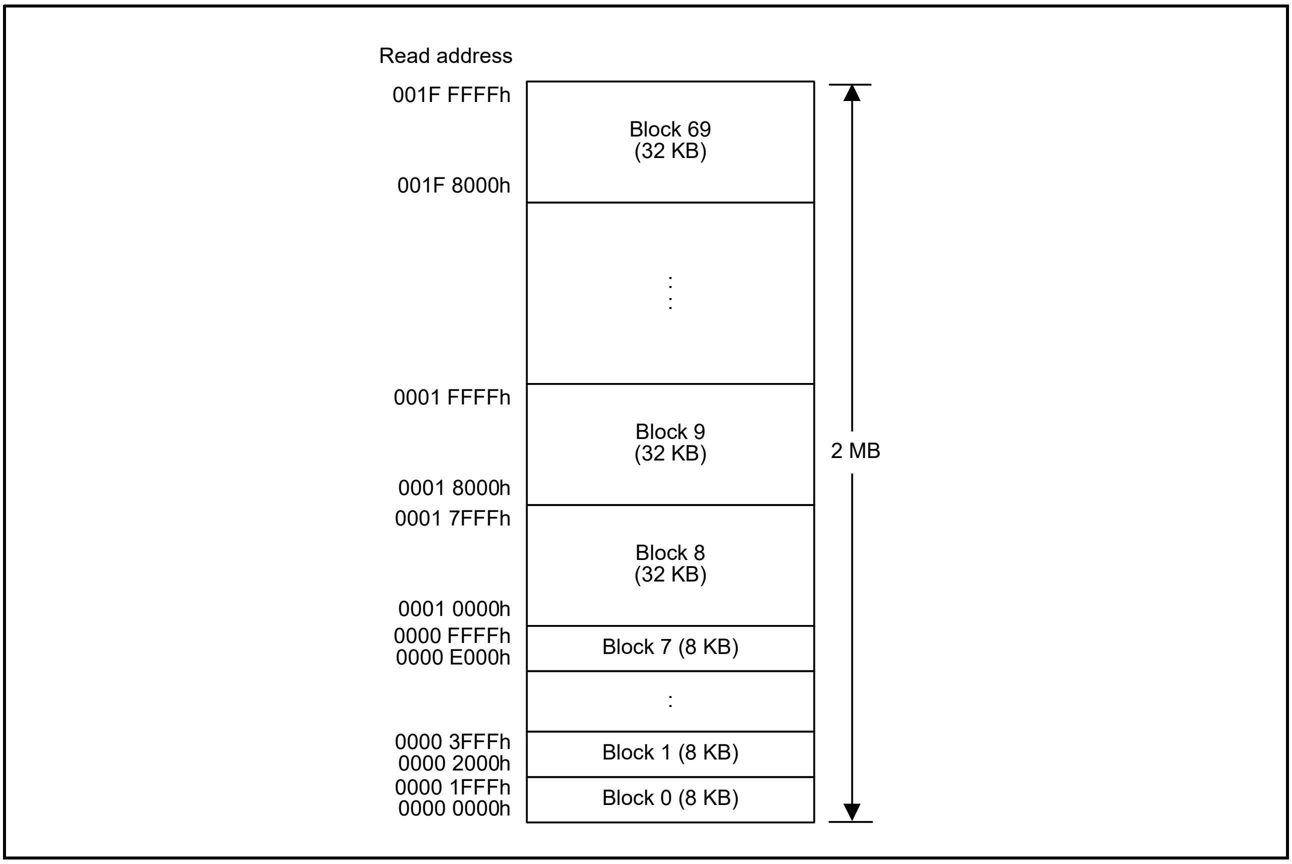

Figure 55.2 Mapping of the code flash memory

Table 55.2 Read and P/E addresses by product for the code flash memory

Product	Read address	P/E address	Number of blocks
2-MB product	0000 0000h to 001F FFFFh	0000 0000h to 001F FFFFh	0 to 69
1-MB product	0000 0000h to 000F FFFFh	0000 0000h to 000F FFFFh	0 to 37

The data area of the data flash memory is divided into 64-byte blocks, with each being a unit for erasure. Figure 55.3 shows the mapping of the data flash memory.

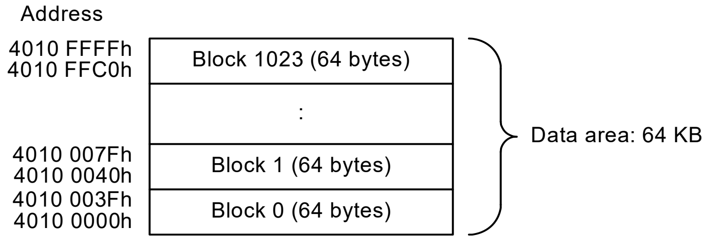

Figure 55.3 Mapping of the data flash memory

55.3 Flash Cache

55.3.1 Overview

The flash cache (FCACHE) speeds up read access from the bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and DMA
- FLPF, for the prefetch access in CPU instruction fetches.

Table 55.3 Flash cache overview

Parameter	Flash cache 1 (FCACHE1)	Flash cache 2 (FCACHE2)	Prefetch Buffer (FLPF)
Cache target region	0000 0000h - 001F FFFFh	0000 0000h - 001F FFFFh	0000 0000h - 001F FFFFh
Target bus master	CPU instruction fetch	CPU Operand Access and Access from other than CPU	FLPF
Capacity	256 bytes	16 bytes	32 bytes
Associativity	• 8-way set associative • 128 bits/entry (128-bit aligned data) • 2 entries/way	• Fully associative • 128 bits/entry (128-bit aligned data) • 1 entry for FCACHE2	• Fully associative • 128 bits/entry (128-bit aligned data) • 2 entries
Access cycles	• Cache hit: 0 waits • Cache miss: Number of waits set in Flash Wait Cycle Register	• Cache hit: 0 waits • Cache miss: Number of waits set in Flash Wait Cycle Register	• Cache hit: 0 waits • Cache miss: Number of waits set in Flash Wait Cycle Register

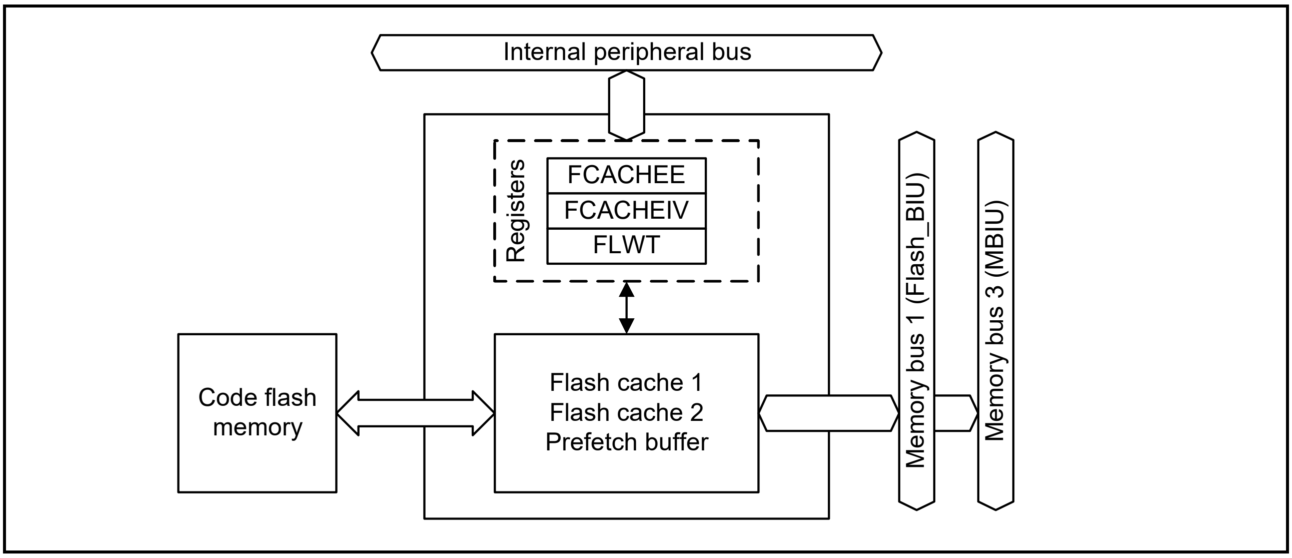

Figure 55.4 **FCACHE block diagram**

55.3.2 Register Descriptions

55.3.2.1 Flash Cache Enable Register (FCACHEE)

Address(es): FCACHE.FCACHEE 4001 C100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	FCACHEEN	FCACHE Enable	0: Disable FCACHE 1: Enable FCACHE.	R/W
b15 to b1	—	Reserved	These bits are read as 0.	R

The FCACHEE.FCACHEEN bit enables or disables the flash cache function of FCACHE1, FCACHE2, and FLPF. This bit does not affect FCACHEIV.FCACHEIV. When FCACHE is enabled, the HPROT[3] determines whether it is cacheable or non-cacheable. See section 15.8 for details on HPROT[3].

55.3.2.2 Flash Cache Invalidate Register (FCACHEIV)

Address(es): FCACHE.FCACHEIV 4001 C104h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACH EIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	FCACHEIV	FCACHE Invalidate	• Reads: 0: Do not invalidate 1: Invalidate. • Writes: When write value is 1, FCACHE is invalidated. When write value is 0, this setting is ignored.	R/W
b15 to b1	—	Reserved	These bits are read as 0.	R

When 1 is written to the FCACHEIV.FCACHEIV bit, the flash cache data in FCACHE1, FCACHE2, and FLPF is invalidated.

55.3.2.3 Flash Wait Cycle Register (FLWT)

Address(es): FCACHE.FLWT 4001 C11Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	FLWT[2:0]*1	Flash Wait Cycle	b2 b0 0 0 0: 0 waits (ICLK ≤ 40 MHz) 0 0 1: 1 wait (40 MHz < ICLK ≤ 80 MHz) 0 1 0: 2 waits (80 MHz < ICLK ≤ 120 MHz). Other settings are reserved.	R/W
b15 to b3	—	Reserved	These bits are read as 0.	R

Note 1. Settings other than 000b are prohibited in the SubOSC-speed mode.

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory. For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

55.4 Operation

Use the FCACHEE register to set up and enable flash operation.

To set up the flash cache and prepare to rewrite the flash memory:

1. Disable the flash cache by resetting FCACHEE.FCACHEEN.*1
2. Invalidate the flash cache by setting FCACHEIV.FCACHEIV.
3. Check that FCACHEIV.FCACHEIV is 0.
4. Enable the flash cache by setting FCACHEE.FCACHEEN.

Note 1. It is not necessary to disable the flash cache on the first setup after reset.

55.4.1 Notice to use Flash Cache

When using Flash cache by access from the CPU, Arm® MPU should also be set to cacheable.

See the ARMv7-M Architecture Reference Manual and the Cortex-M4 Devices Generic User Guide.

55.5 Operating Modes Associated with the Flash Memory

Figure 55.5 shows a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see section 3, Operating Modes.

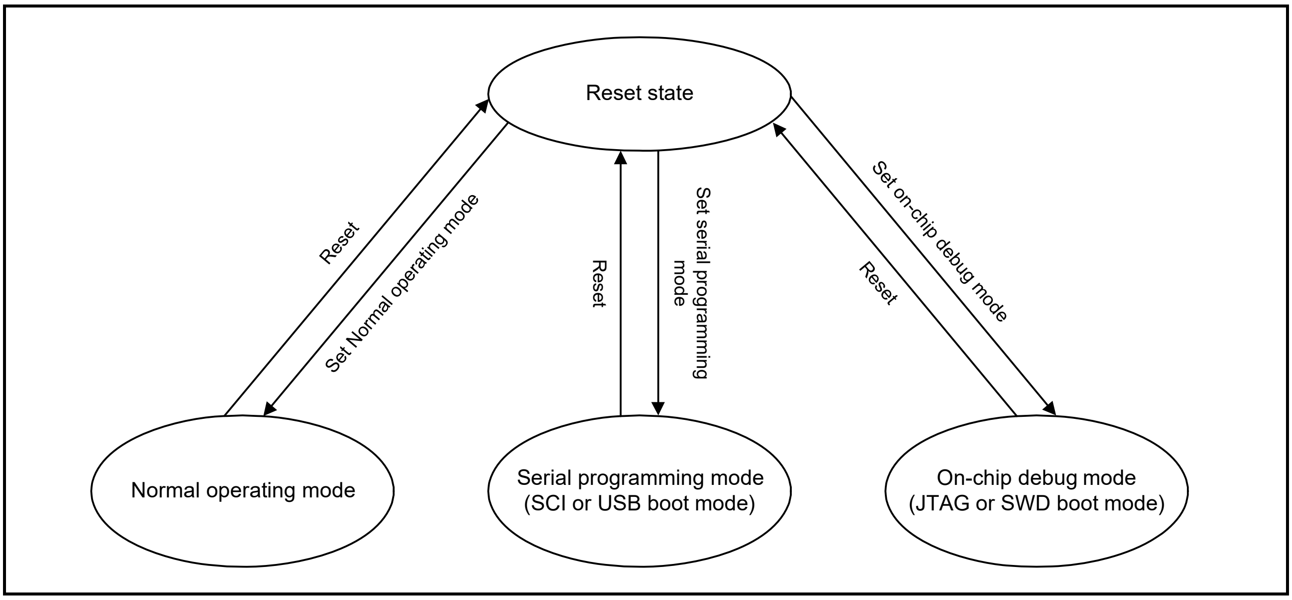

Figure 55.5 Mode transitions associated with flash memory

The flash memory area where programming and erasure are permitted and where the boot program executes after a reset differ with the mode. Table 55.4 shows the differences between the modes.

Table 55.4 Difference between modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	• Code flash memory • Data flash memory	• Code flash memory • Data flash memory	• Code flash memory • Data flash memory
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

55.5.1 ID Code Protection

This function prohibits programming and on-chip debugging. The device validates or invalidates the ID code and determines the ID code based on an ID code stored in the flash memory. When ID code protection is enabled, the ID code sent from the host is compared with the ID code in the flash memory to determine whether they match. Programming and on-chip debugging are enabled only when the two match. The ID code in flash memory consists of four 32-bit words.

ID code bits 127 and 126 determine whether ID code protection is enabled and the method of authentication to use with the host. Table 55.5 shows how the ID code determines the method of authentication.

Table 55.5 Specifications for ID code protection

Operating mode on boot up	ID code	State of protection	Operations on connection with the programmer or on-chip debugger
Serial programming mode (SCI/USB boot mode) On-chip debug mode (JTAG/SWD boot mode)	FFh, …, FFh (All bytes = FFh)	Protection disabled	ID code validation is not performed, the ID code always matches, and connection to the programmer or the on-chip debugger is permitted.
	Bit 127 = 1, Bit 126 = 1, and at least one of the 16 bytes is not FFh	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or on-chip debugger is permitted. Non-matching ID code: Additional transition to the ID code protection waiting state. When the ID code sent from the programmer or the on-chip debugger is "ALeRASE" in ASCII code (414C_6552_4153_45FF_FFFF_FFFF_FFFF_FFFFh), the content of the user flash (code and data) area and the configuration area are erased. However, forced erasure is not executed when the AWS.FSPR*1 bit is 0.
	Bit 127 = 1 and bit 126 = 0	Protection enabled	Matching ID code: Authentication ends and connection to the programmer or the on-chip debugger is permitted. Non-matching ID code: Additional transition to the ID code protection waiting state.
	Bit 127 = 0	Protection enabled	ID code validation is not performed, the ID code is always non-matching, and connection to the programmer or the on-chip debugger is prohibited.

Note 1. For details on the AWS.FSPR bit, see section 7.2.3, Access Window Setting Register (AWS).

55.6 Overview of Functions

By using a dedicated flash-memory programmer to program the on-chip flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be programmed before or after it is mounted on the target system.

Additionally, security functions to prohibit overwriting of the user program written to the on-chip flash memory are incorporated to prevent tampering by third parties.

Programming by the user program (self-programming) is available for applications that might require updating after system manufacturing or shipment. Protection features for safely overwriting the flash memory area are also provided. Additionally, interrupt processing during self-programming is supported so programming can proceed while processing external communications and other functions. Table 55.6 lists the programming methods and the corresponding operating modes.

Table 55.6 Programming methods (1 of 2)

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	

Table 55.6 Programming methods (2 of 2)

Programming method	Functional overview	Operating mode
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory can program the data flash memory. Background operation can also be used for reading from and writing to the code flash memory by itself, but only when the address ranges of the code flash memory that are the targets for programming and reading satisfy particular conditions (see Table 55.11). When those conditions are met, a program resident in one half of the code flash memory can be executed to program the other half of the code flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system.	On-chip debug mode
	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	

Table 55.7 lists the functions of the on-chip flash memory. The functions in serial programming are realized by serial programmer commands, while the functions in self-programming are realized by reading of the on-chip flash memory by a FACI command or the user program.

Table 55.7 Basic functions

		Availability	
Function	**Functional overview**	**Serial programming**	**Self-programming**
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block.	Supported	Supported
Programming	Writes to the specified address.	Supported	Supported
Read	Reads data programmed in the flash memory.	Supported	Not supported (read by user program is possible)
ID code check	Compares the ID code sent by the host with the code stored in the ROM, and if the two match, the FCU enters the wait state for programming and erasure commands from the host.	Supported	Not supported (ID authentication is not performed)
Security configuration	Configures the security function for serial programming.	Supported with conditions (only switching from enabled to disabled configuration is possible)	Supported with conditions (Only switching from enabled to disabled is possible)
Protection configuration	Configures the access window for flash area protection in the code flash memory.	Supported	Supported

The on-chip flash memory supports the ID code security function. Authentication of ID codes is a security function for use with serial programming and with JTAG or SWD programming. Table 55.8 lists the security functions supported by the on-chip flash memory, and Table 55.9 lists available operations and security settings.

Table 55.8 Security functions

Function	Description
ID authentication	Result of ID authentication can be used to control the connection of a serial programmer for serial programming.

Table 55.9 Available operations and security settings

Function	All security settings and erasure, programming, and read operations		Cautions regarding the security setting configuration
	Serial programming and on-chip debug mode	Self-programming mode	Self-programming mode
ID authentication	When ID codes do not match: • Block erasure commands: Not supported • Programming commands: Not supported • Read commands: Not supported • Security configuration commands: Not supported • Protection configuration commands: Not supported When ID codes match: • Block erasure commands: Supported • Programming commands: Supported • Read commands: Supported • Security configuration commands: Supported • Protection configuration commands: Supported	(ID authentication is not performed.) • Blank check: Supported • Block erasure: Supported • Programming: Supported • Security configuration: Supported • Protection configuration: Supported	ID authentication is not performed.

55.6.1 Configuration Area Bit Map

Figure 55.6 shows the configuration area bit map. The boot program must use these bits as hexadecimal data.

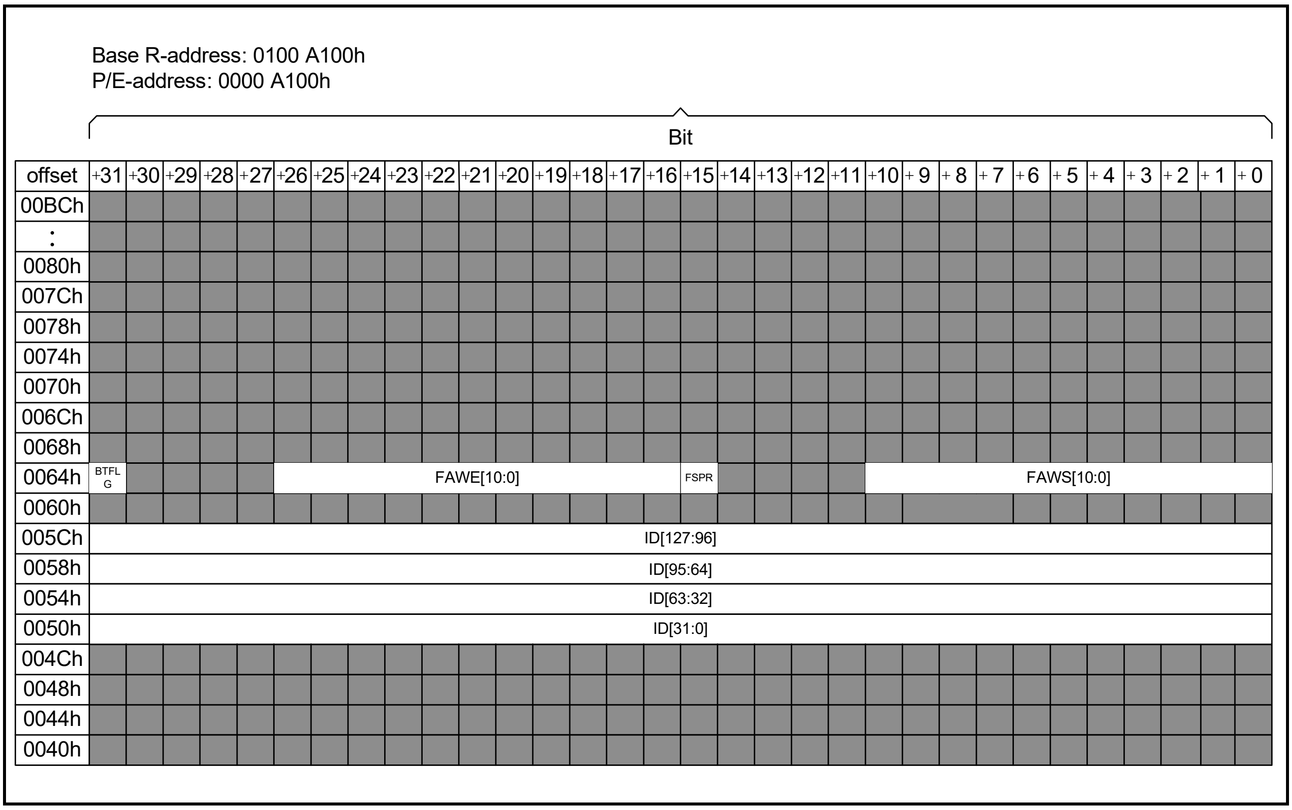

Figure 55.6 Configuration area bit map

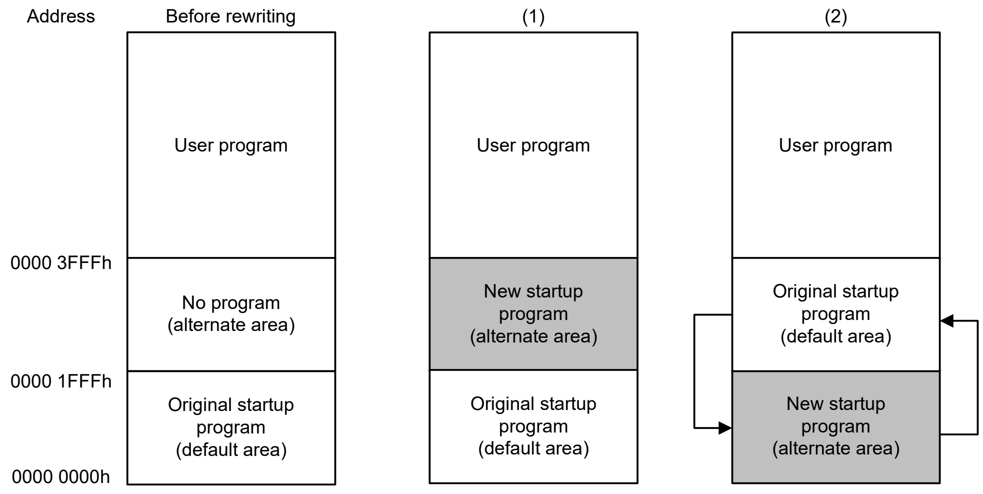
55.6.2 Startup Area Select

The startup area select function allows the boot program to be safely updated. The size of the startup area is 8 KB, and the startup area is located in the user area. FACI controls the address of the startup area based on the startup area select flag (AWS.BTFLG) that is located in the configuration area. The startup area can be locked by the AWS.FSPR[*1] bit.

Note 1. For the AWS.FSPR bit, see section 7.2.3, Access Window Setting Register (AWS).



(1) Program a new startup program in the alternate area. If the alternate area fails to be rewritten, the new startup program can be rewritten again after starting up using the default area, because the original startup program is in the default area.
(2) After the alternate area is successfully rewritten, the default and alternate areas are switched using the self-programming library. After that, the program in the alternate area starts after a reset.

Figure 55.7 Overview of startup program protection

55.6.3 Protection by Access Window

Issuing the program or block erase command to a flash memory area outside of the access window results in the command-locked state. The access window is only valid in the user area of the code flash memory. The access window provides protection in self-programming mode, serial programming mode, and on-chip debug mode.

The access window is specified in both the AWS.FAWS[10:0] and AWS.FAWE[10:0][*1] bits. The following describes how to set the FAWS and FAWE bits in different conditions:

- FAWE = FAWS: The P/E command can execute anywhere in the user area of the code flash memory
- FAWE > FAWS: The P/E command can only execute in the window from the block pointed to by the FAWS bits to one block lower than the one pointed to by the FAWE bits
- FSWE < FAWS: The P/E command cannot execute anywhere in the user area of the code flash memory.

Note 1. For information on the AWS.FAWS and AWS.FAWE bits, see section 7.2.4, OCD/Serial Programmer ID Setting Register (OSIS).

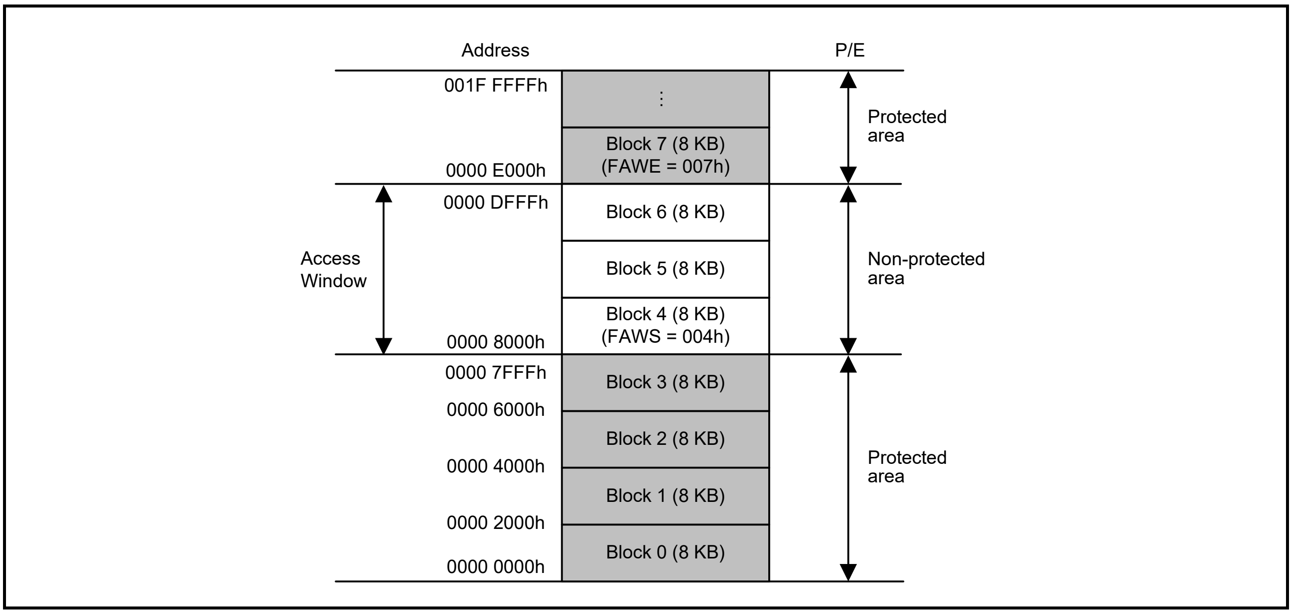


Figure 55.8 Start block address (FAWS) and end block address (FAWE) of access window when the access window only includes the 8-KB block size

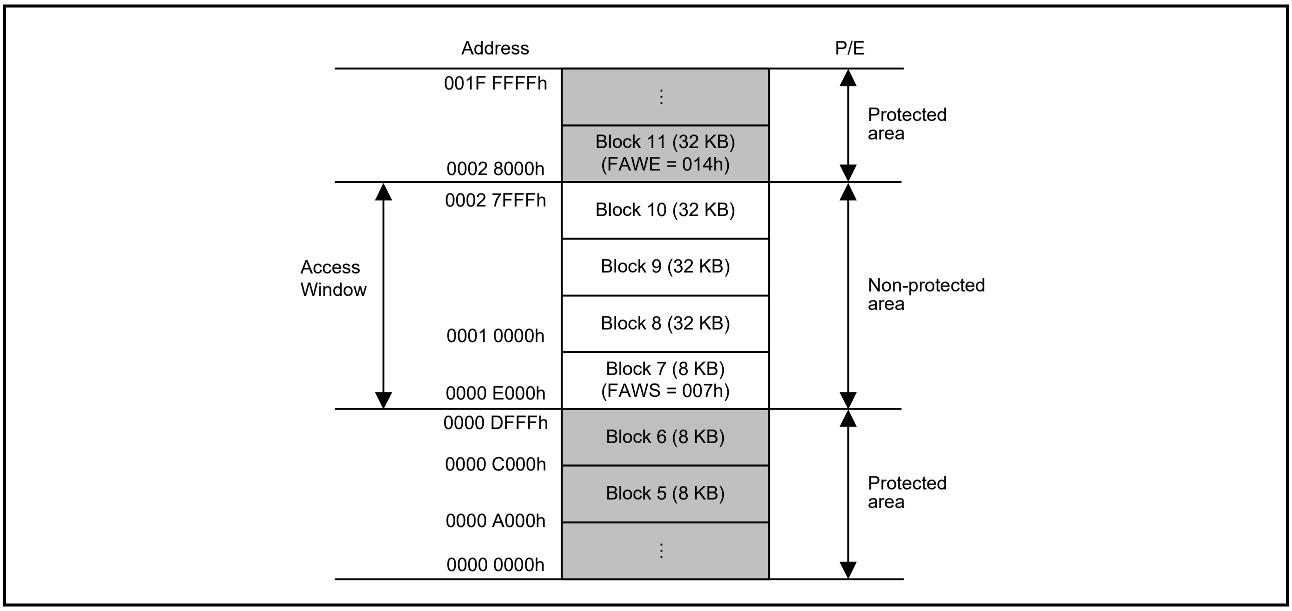

Figure 55.9 Start block address (FAWS) and end block address (FAWE) of access window when the access window includes 8-KB and 32-KB block sizes

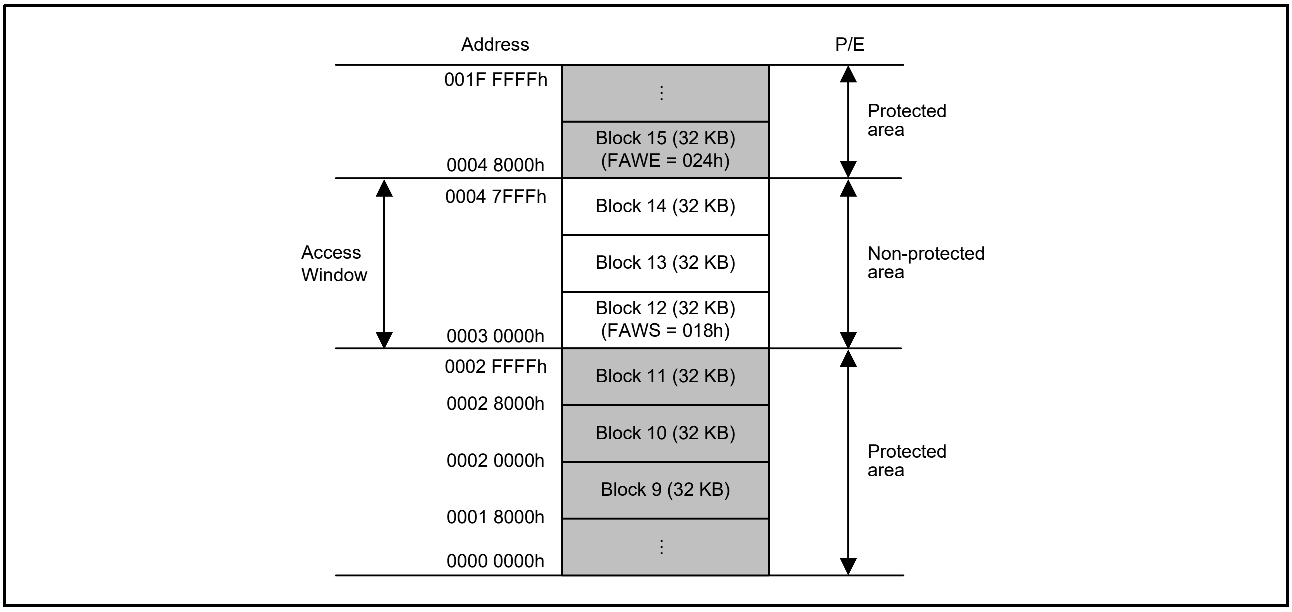

Figure 55.10 Start block address (FAWS) and end block address (FAWE) of access window when the access window only includes the 32-KB block size

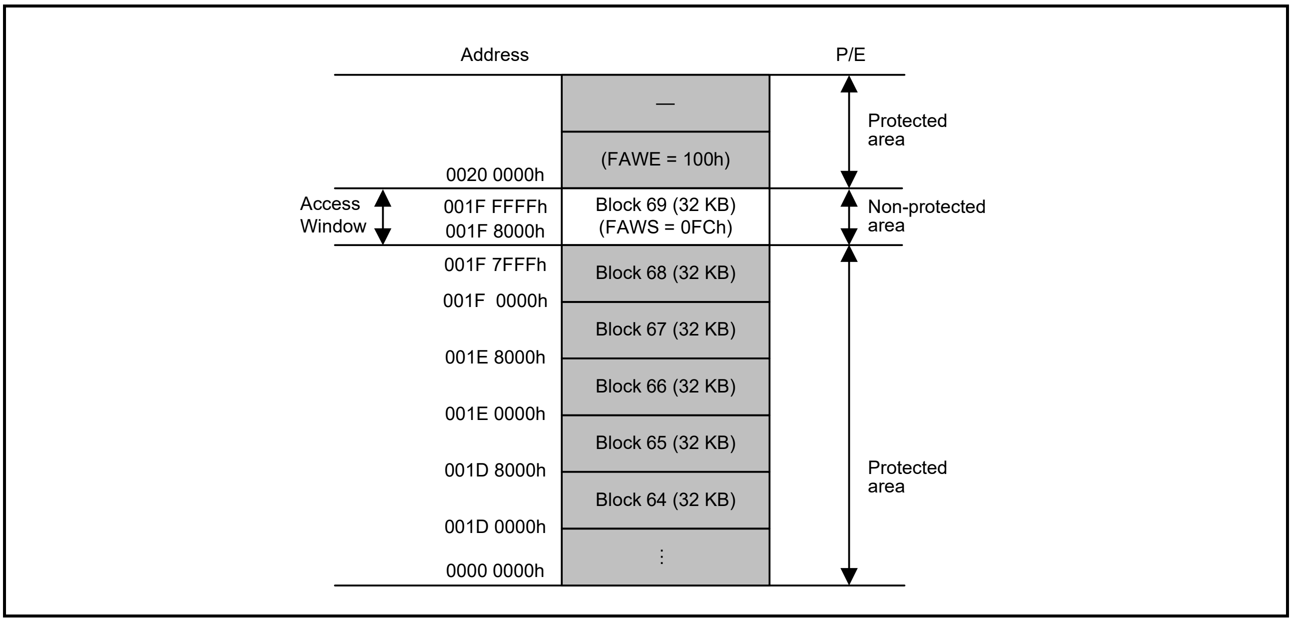

Figure 55.11 Start block address (FAWS) and end block address (FAWE) of access window when the access window only includes the final block

55.7 Programming Commands

The FACI controls the FCU in accordance with the specified FACI commands.

55.8 Suspend Operation

Reading from the code or data flash memory is not possible during programming or erasure when the address ranges do not satisfy the conditions for background operation. When a P/E suspend command is issued to suspend the programming or erasure of the code or data flash memory, reading from the memory is enabled. One suspend command mode is available for programming and two suspend command modes are available for erasure (suspension priority mode and erasure priority mode). The P/E resume command is available for resuming suspended programming or erasure.

55.9 Protection

Provided types of protection include:

- Software protection
- Error protection
- Boot program protection.

55.10 Serial Programming Mode

The serial programming modes include:

- Boot mode with SCI9
- USB boot mode with the USBFS.

Table 55.10 lists the I/O pins for the flash memory-related modules.

Table 55.10 I/O pins for flash memory-related modules

Pin name	I/O	Applicable modes	Function
MD	Input	SCI boot mode USB boot mode (Serial programming mode)	Selection of operating mode
P110/RXD9	Input	SCI boot mode	For host communication, to receive data through SCI
P109/TXD9	Output		For host communication, to transmit data through SCI
USB_DP, USB_DM	I/O	USB boot mode	USB data I/O
USB_VBUS	Input		Detection of connection and disconnection of USB cables

55.10.1 SCI Boot Mode

In boot mode, the host sends control commands and data for programming, and the code and data flash memory area are programmed or erased accordingly. An on-chip SCI handles transfer between the host and the MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When the MCU is activated in boot mode, the embedded program for serial programming is executed. This program automatically adjusts the bit rate of the SCI and controls programming and erasure by receiving control commands from the host. The USB cable must not be connected on reset release.

Figure 55.12 shows the system configuration for operations in boot mode.

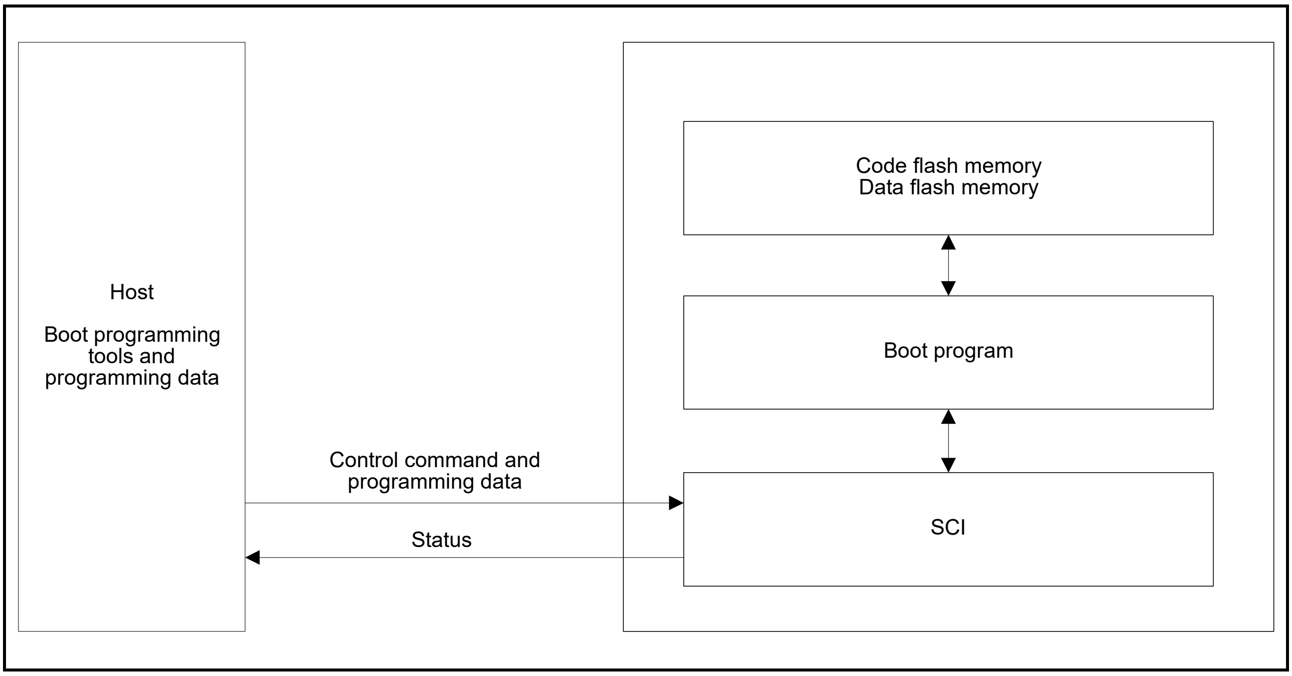

Figure 55.12 System configuration in SCI boot mode

55.10.2 USB Boot Mode

In USB boot mode, the code and data flash memory are programmed or erased by control commands and data for programming transmitted from an externally connected host through the USB interface.

Using USB boot mode requires preparation on the host side of the tools for transmitting control commands and data for programming, and of the data. Figure 55.13 shows the configuration of a system for use in USB boot mode. The USB cable must be connected on reset release.

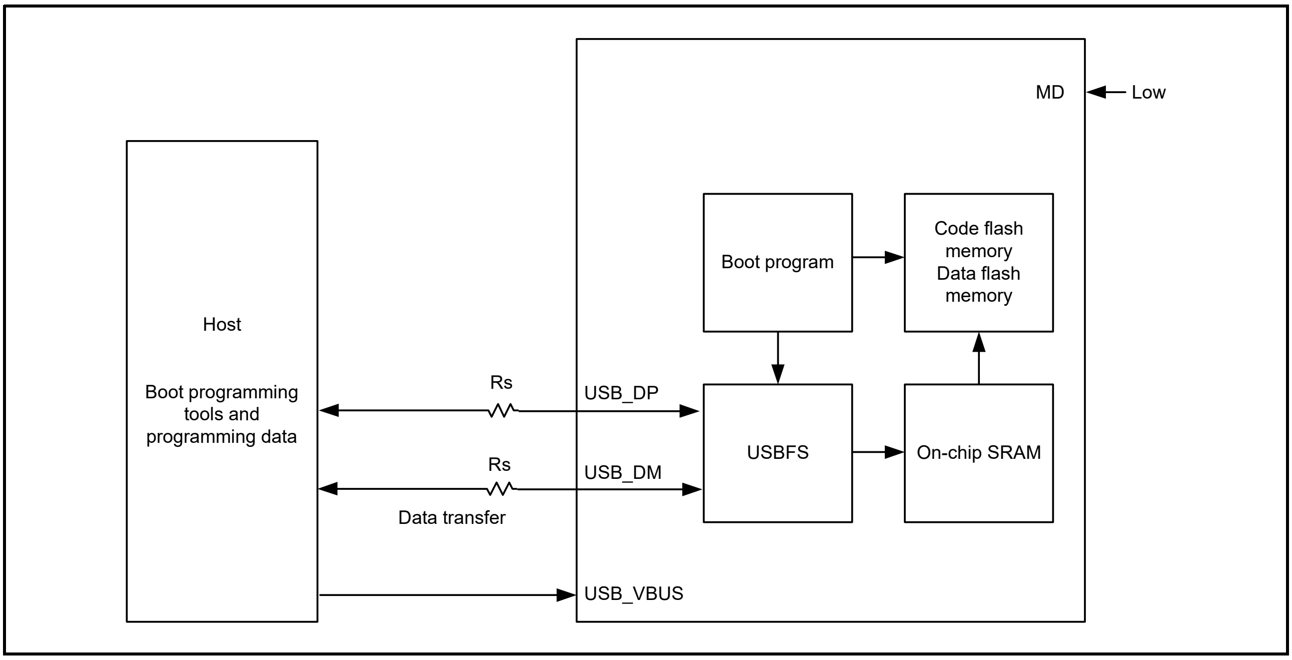

Figure 55.13 System configuration in USB boot mode

55.11 Using a Serial Programmer for Programming

A dedicated flash memory programmer can be used to program the flash memory in serial programming mode.

55.11.1 Serial Programming

The MCU is mounted on the system board for serial programming. A connector to the board allows programming by the flash memory programmer to proceed.

55.11.2 Programming Environments

Figure 55.14 shows the environments that Renesas recommends for programming the flash memory of the MCU with data.

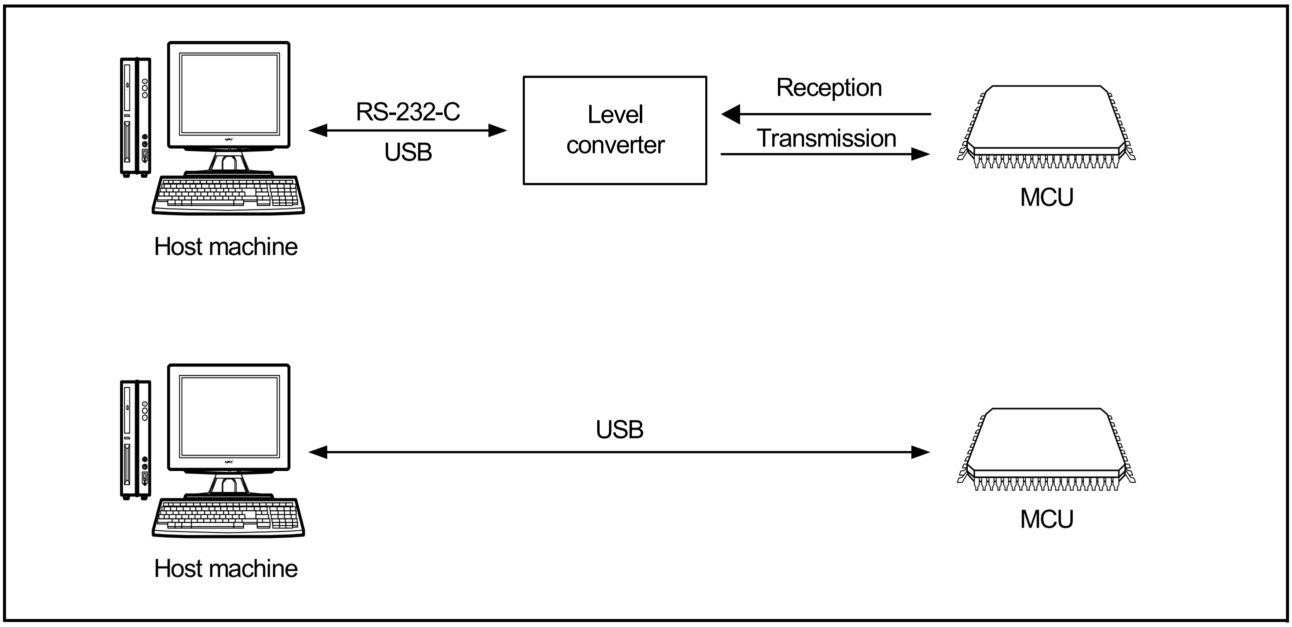

Figure 55.14 Environments for writing programs to the flash memory

55.12 Programming through Self-Programming

55.12.1 Overview

The MCU supports programming of the flash memory by the user program itself. The programming commands can be used with user programs for writing to both the code and data flash memory. This enables upgrading of user programs and overwriting of constant data fields.

For data flash memory programming, the background operation facility makes it possible to program the memory from a programming program in the code flash memory. This programming program can also be copied in advance to and executed from the internal SRAM or external memory.

For code flash memory programming, background operation is available for use when the address ranges of the code flash memory area to be programmed and the code flash memory area to be read satisfy particular conditions (see Table 55.11). For self-programming, a programming program in one half of the code flash memory can be used to program the other half of the code flash memory. This programming program can also be copied in advance to and executed from the internal SRAM or external memory. This is useful when the address ranges do not satisfy the conditions for background operation.

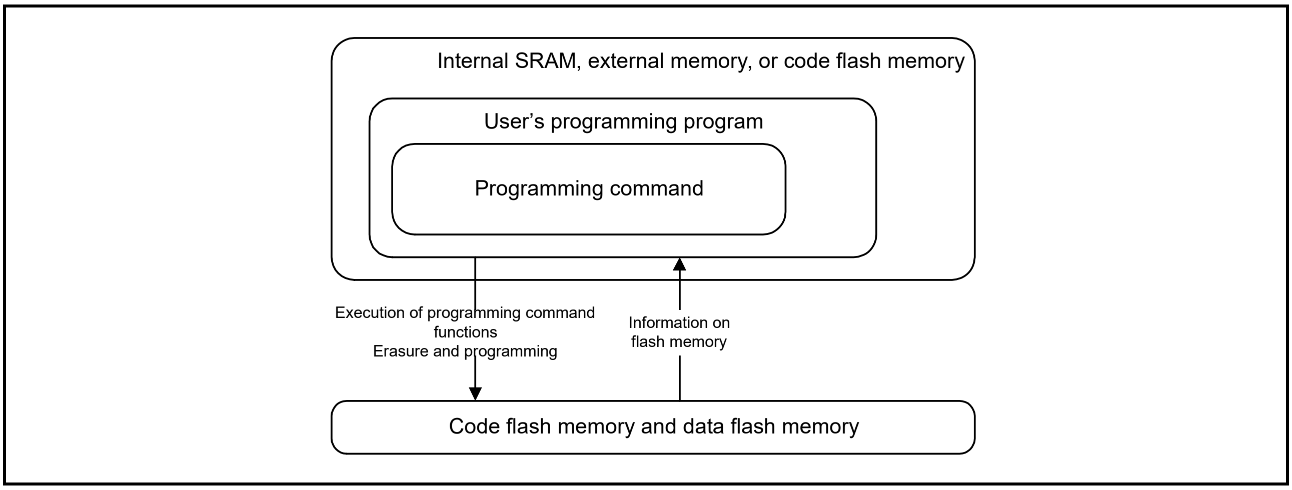

Figure 55.15 Schematic view of self-programming

55.12.2 Background Operation

Background operation can be used when a combination of the flash memory for writing and reading is any of those listed in Table 55.11.

Table 55.11 Conditions under which background operation is available

Product	Range for writing	Range for reading
All products	Data flash memory	Code flash memory
	Code flash memory	Data flash memory
2-MB products	First half (1 MB) of the user area of the code flash memory (addresses 0000 0000h to 000F FFFFh)	Second half (1 MB) of the user area of the code flash memory (addresses 0010 0000h to 001F FFFFh)
	Second half (1 MB) of the user area of the code flash memory (addresses 0010 0000h to 001F FFFFh)	First half (1 MB) of the user area of the code flash memory (addresses 0000 0000h to 000F FFFFh)
1-MB products	First half (0.5 MB) of the user area of the code flash memory (addresses 0000 0000h to 0007 FFFFh)	Second half (0.5 MB) of the user area of the code flash memory (addresses 0008 0000h to 000F FFFFh)
	Second half (0.5 MB) of the user area of the code flash memory (addresses 0008 0000h to 000F FFFFh)	First half (0.5 MB) of the user area of the code flash memory (addresses 0000 0000h to 0007 FFFFh)

55.13 Reading the Flash Memory

55.13.1 Reading the Code Flash Memory

No special settings are required to read the code flash memory in Normal mode. Data can be read through access to addresses in the code flash memory. Values read from code flash memory that was erased but not yet reprogrammed, such as code flash memory in the non-programmed state, are all read as 1s.

55.13.2 Reading the Data Flash Memory

No special settings are required to read the data flash memory in Normal mode. Data can be read through access to addresses in the data flash memory. Values read from data flash memory that was erased but not yet reprogrammed again, such as data flash memory in the non-programmed state, are undefined. Use blank checking to confirm that an area is in the non-programmed state.

55.14 Usage Notes

55.14.1 Reading Areas Where Programming or Erasure Was Interrupted

When programming or erasure of an area of flash memory is interrupted, the data stored in the area become undefined. To avoid reading undefined data, which can be a source of faulty operation, do not fetch instructions or read data from areas where programming or erasure was interrupted.

55.14.2 Constraint on Additional Writes

Other than the configuration area, no other area can be written to twice. After a write to a flash memory area is complete, erase the area before attempting to overwrite data in that area. The configuration area can be overwritten.

55.14.3 Resets during Programming and Erasure

After a reset triggered by a signal assertion on the RES pin during programming and erasure, wait for tRESW until the operating voltage is within the range stipulated in the electrical characteristics before releasing the device from the reset state. For details on tRESW, see section 60.3.3, Reset Timing.

55.14.4 Allocation of Vectors for Interrupts and Other Exceptions during Programming and Erasure

Generation of an interrupt or other exception during programming or erasure might lead to fetching of the vector from the code flash memory. If the vector allocation does not satisfy the conditions for using background operation, set the address for vector fetching to an address that is not in the code flash memory.

55.14.5 Constraints during Programming and Erasure

During programming and erasure, do not:

- Permit the operating voltage from the power supply to go beyond the allowed range
- Change the frequency of the peripheral clock.

55.14.6 Abnormal Termination of Programming and Erasure

When programming or erasure ends abnormally because of the generation of a reset by the RES pin, the programming or erasure state of the flash memory with undefined data cannot be verified or checked. For the area where programming or erasure ends abnormally, the blank check function cannot determine whether the area was erased successfully. Erase the area again to ensure that the corresponding area is completely erased before use.

56. 2D Drawing Engine (DRW)

56.1 Overview

The 2D Drawing Engine (DRW) provides flexible functions that can support almost any object geometry, rather than being bound to only a few specific geometries such as lines, triangles, or circles. The edges of every object can be independently blurred or anti-aliased.

Rasterization is executed on the bounding box of the object from left to right and top to bottom, and performed one pixel per clock. The 2D Drawing Engine can also raster from bottom to top in certain cases, to optimize the performance. In addition, optimization methods are provided to avoid rasterization of many empty pixels of the bounding box.

The distances to the edges of the object are calculated by a set of edge equations for every pixel of the bounding box. These edge equations can be combined to describe the entire object. If a pixel is inside the object, it is selected for rendering, and if it is outside it is discarded. If it is on the edge, an alpha value can be chosen proportional to the distance of the pixel to the nearest edge for anti-aliasing. Every pixel that is selected for rendering can be textured. The resulting aRGB quadruple can be modified by a general raster operation approach independently for each of the four channels. The aRGB quadruples can then be blended with one of the multiple blend modes of the module.

The 2D Drawing Engine provides two inputs (texture read and framebuffer read) and one output (framebuffer write). The internal color format is always aRGB (8888). The color formats from the inputs are converted to the internal format on read and converted back on write.

Figure 56.1 shows examples of objects that can be drawn in hardware with the 2D Drawing Engine, Figure 56.2 shows a simplified rendering pipeline setup, and Figure 56.3 shows a block diagram of the module.

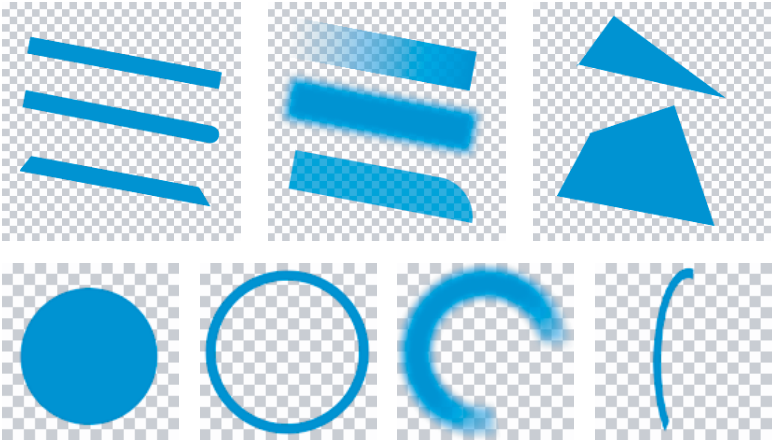

Figure 56.1 Examples of drawing objects

The 2D Drawing Engine also supports a display list mode, which makes it possible to decouple the CPU and graphics controller efficiently and perform rendering in parallel with other CPU activities.

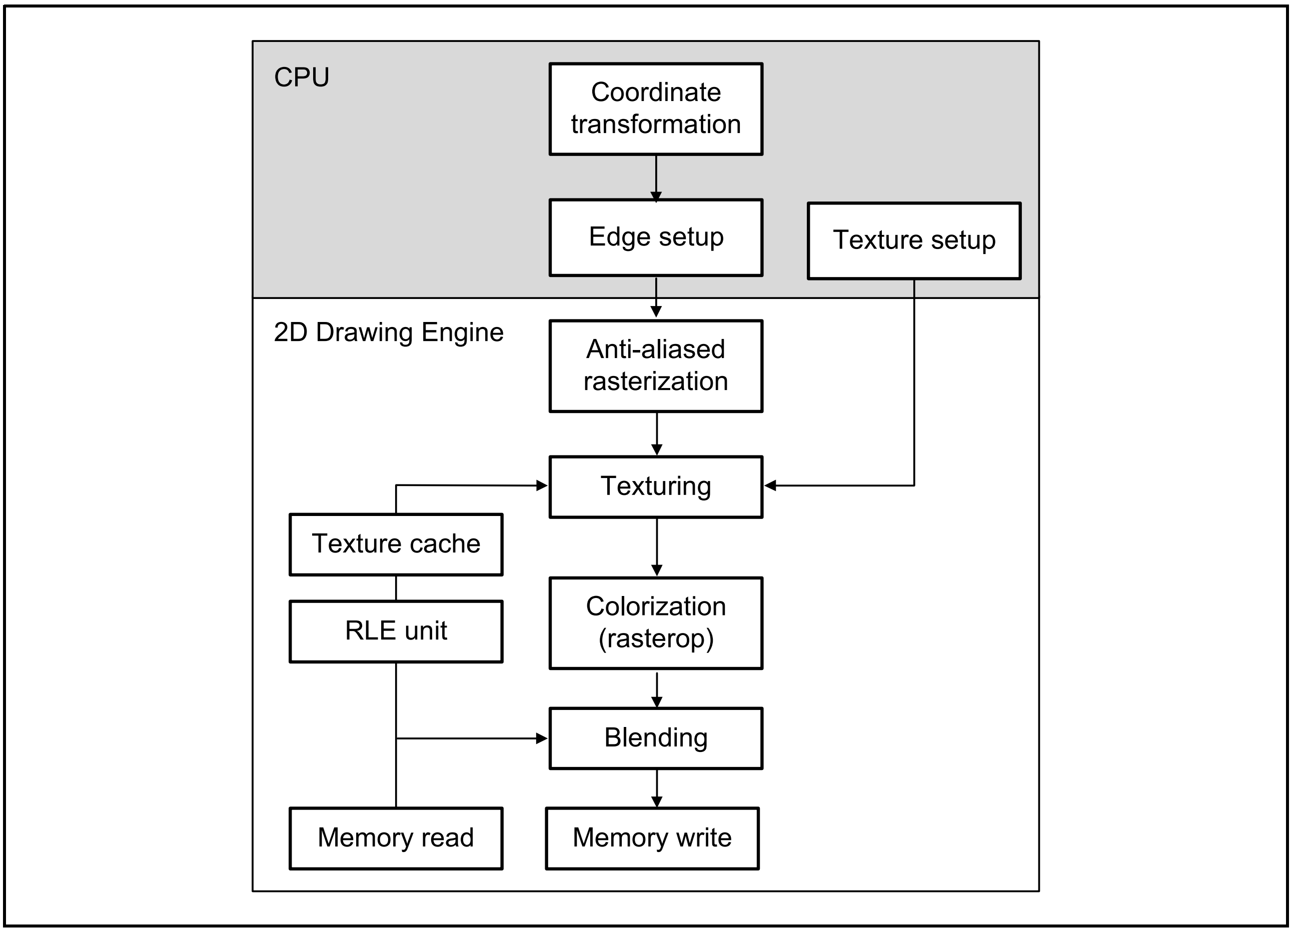

Figure 56.2 Simplified rendering pipeline setup

Note: When using the DRW, set the clock to ICLK = PCLKA.

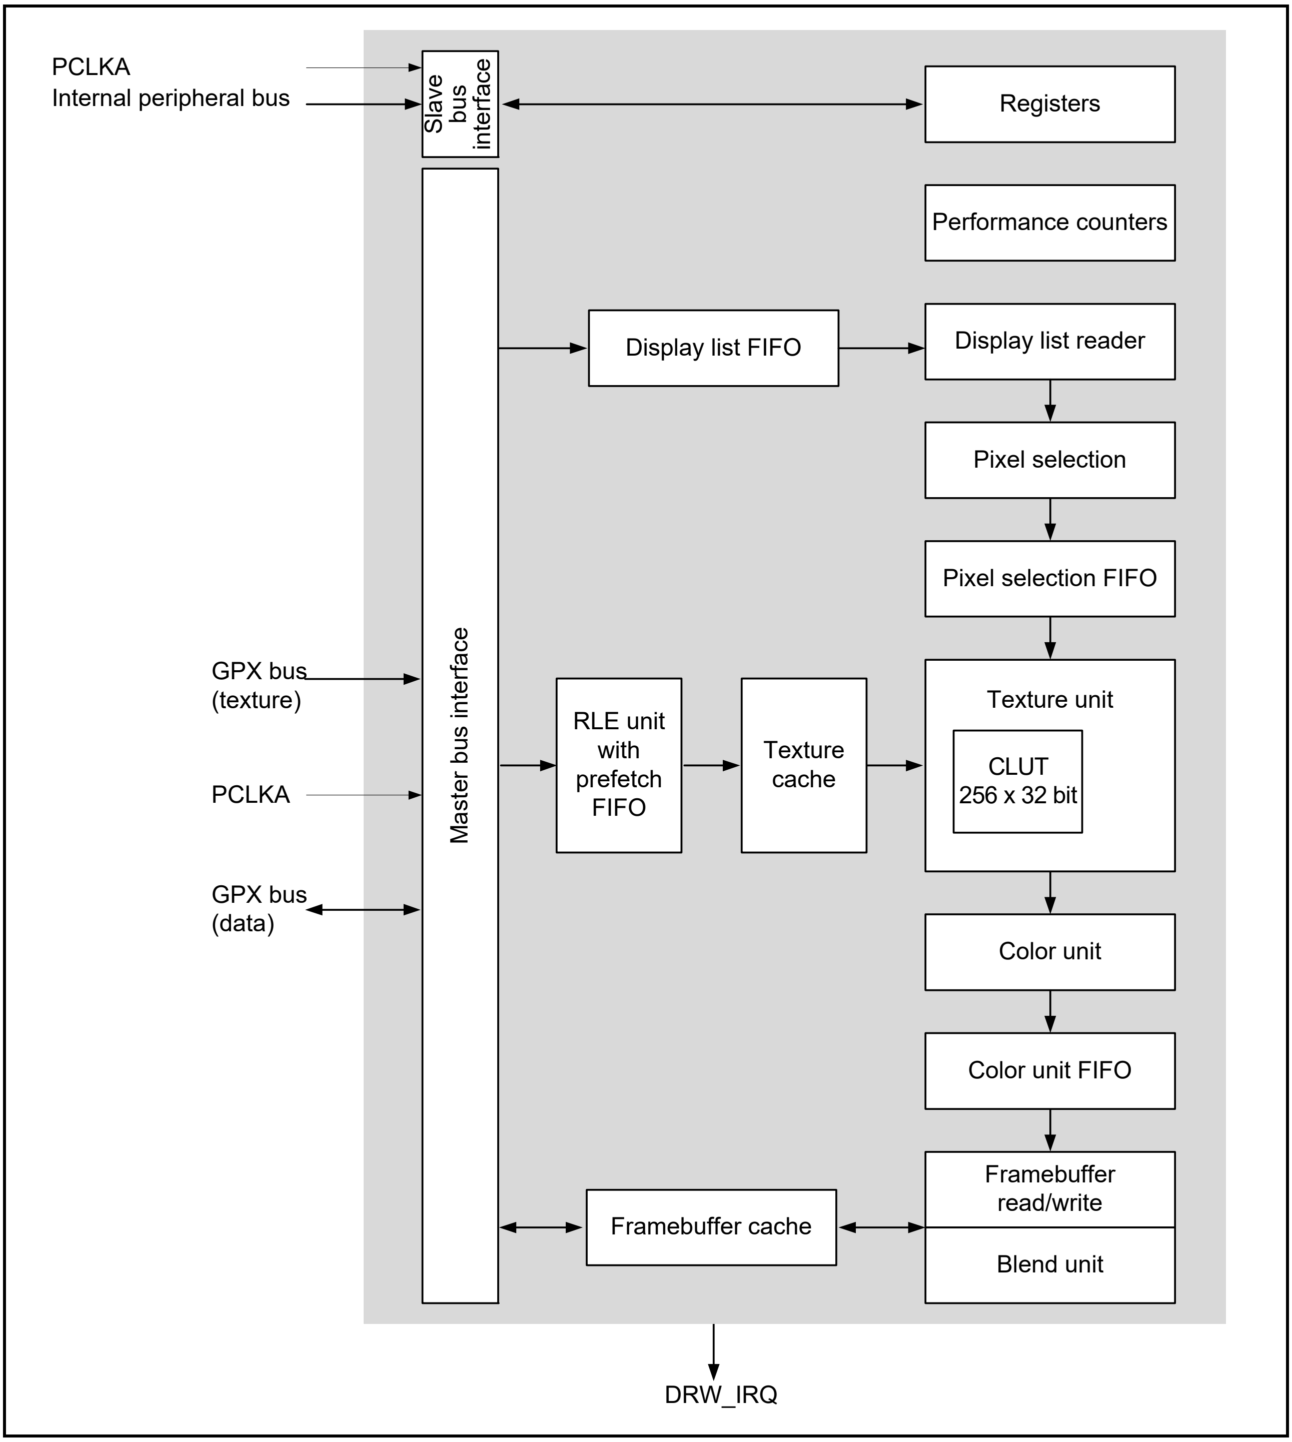

Figure 56.3 Block diagram of the 2D Drawing Engine

The 2D Drawing Engine accesses the GPX bus as bus master through separate caches for:

- Reading and writing pixel data from and to the framebuffer
- Reading textures
- Reading display lists.

The control registers are accessed through the internal peripheral bus interface.

56.2 Register Descriptions

56.2.1 Geometry Control Register (CONTROL)

.

Bit	Symbol	Bit name	Description	R/W
b0	PATTERN ENABLE	Pattern Color Enable for Pixel Source	Pixel source is a pattern color (blend of COLOR1 and COLOR2 depending on PATTERN and pattern index). 0: Disable pattern 1: Enable pattern. When patterns are used to fill a primitive an index into the pattern bit mask is generated for each pixel with the U limiter. Depending on the pattern bits the color is selected from COLOR1 and COLOR2 registers. Fractional indices can be interpolated between those two values by using TEXTUREFILTERX = 1. The pattern can be wrapped by using TEXTURECLAMPX = 0, and the mask must be set in the TEXMASK register using the mask for u.	W
b1	TEXTURE ENABLE	Texture Enable for Pixel Source	Pixel source is read from texture and used as an alpha to blend between COLOR1 and COLOR2. 0: Disable texture 1: Enable texture.	W
b2	PATTERN SOURCEL5	Limiter 5 Enable for Pattern Index	Limiter 5 is used as pattern index instead of the default U limiter. Limiter 5 can be combined with limiter 6 to form a quadratic limiter that can be used to make quadratic pattern functions to draw radial patterns.	W
b3	USEACB	Alpha Blend Mode	0: Use WRITEALPHA[1:0] mode 1: Use full alpha channel blending mode.	W

Bit	Symbol	Bit name	Description	R/W
b5, b4	READ FORMAT[3:2]	Texture Format Descriptor	Bits [3] and [2] of the texture buffer format. See the detailed description of the READFORMAT[1:0] bit in this section.	W
b6	BSFA	Blend Source Factor for Alpha Channel	Valid in alpha channel blending mode (USEACB = 1). 0: Use 1.0 as blend source factor for alpha channel 1: Use alpha as blend source factor for alpha channel.	W
b7	BDFA	Blend Destination Factor for Alpha Channel	Valid in alpha channel blending mode (USEACB = 1). 0: Use 1.0 as blend destination factor for alpha channel 1: Use alpha as blend destination factor for alpha channel.	W
b8	WRITE FORMAT2	Writeback Framebuffer Format	Bit [2] of framebuffer pixel format. See the description of WRITEFORMAT[1:0] in this section.	W
b9	BSF	Blend Source Factor	Source factor is alpha (factor is 1 per default). 0: Use 1.0 as blend source factor 1: Use alpha as blend source factor.	W
b10	BDF	Blend Destination Factor	Destination factor is alpha (factor is 1 per default). 0: Use 1.0 as blend destination factor 1: Use alpha as blend destination factor.	W
b11	BSI	Blend Source Factor Inverted	Source factor is inverted (meaning 1-a or 1-1 depending on BSF). 0: Use blend factor as specified through BSF 1: Invert blend source factor (1-x).	W
b12	BDI	Blend Destination Factor Inverted	Destination factor is inverted (meaning 1-a or 1-1 depending on BDF). 0: Use blend factor as specified through BDF 1: Invert blend destination factor (1-x).	W
b13	BC2	Blend color 2	Select of blend color 2 instead of framebuffer pixel. 0: Use pixel from framebuffer as destination (DST) 1: Use color 2 as destination (DST).	W
b14	TEXTURE CLAMPX	Calculating U Limiter Outside Used Texture	This bit describes what happens when the U limiter (x direction in texture space) calculates a u value outside of the used texture. 0: Texture wrap mode: Integer part of the calculated value from the U limiter is AND gated with TEXUMASK, resulting in a repetition of texture in the x/u direction 1: Texture clamp mode: Texture color at the border of the texture is taken, resulting in a repetition of texture border color in the x/u direction.	W
b15	TEXTURE CLAMPY	Calculating V Limiter Outside Used Texture	This bit describes what happens when the V limiter (y direction in texture space) calculates a v value outside of the used texture. 0: Texture wrap mode: Integer part of the calculated value from the V limiter is AND gated with TEXVMASK, resulting in a repetition of texture in the y/v direction. 1: Texture clamp mode: Texture color at the border of the texture is taken, resulting in a repetition of texture border color in the y/v direction.	W
b16	TEXTURE FILTERX	Linear Filtering on Texture U Axis	0: No filtering on texture U axis 1: Linear filtering on texture U axis.	W
b17	TEXTURE FILTERY	Linear Filtering on Texture V Axis	0: No filtering on texture V axis 1: Linear filtering on texture V axis.	W
b19, b18	READ FORMAT[1:0]	Texture Format Descriptor	Pixel format of the texture buffer. b5 b4 b19 b18 0 0 0 0: 8 bpp a (8) 0 0 0 1: 16 bpp RGB (565) 0 0 1 0: 32 bpp aRGB (8888) 0 0 1 1: 16 bpp aRGB (4444) 0 1 0 0: 16 bpp aRGB (1555) 0 1 0 1: 8 bpp aCLUT (44), 4 bit alpha and 4 bit indexed color 1 0 0 1: 8 bpp CLUT (8)/I (8), 8 bit indexed color/luminance 1 0 1 0: 4 bpp CLUT (4)/I (4), 4 bit indexed color/luminance 1 0 1 1: 2 bpp CLUT (2)/I (2), 2 bit indexed color/luminance 1 1 0 0: 1 bpp CLUT (1)/I (1), 1 bit indexed color/luminance. Other settings are prohibited.	W

Bit	Symbol	Bit name	Description	R/W
b21, b20	WRITE FORMAT[1:0]	Writeback Framebuffer Format	Pixel format of the framebuffer. b8 b21 b20 0 0 0: 8 bpp a (8) 0 0 1: 16 bpp RGB (565) 0 1 0: 32 bpp aRGB (8888) 0 1 1: 16 bpp aRGB (4444). Other settings are prohibited.	W
b23, b22	WRITE ALPHA[1:0]	Writeback Alpha Source for Framebuffer	• In non-alpha channel blending mode (USEACB = 0): Sets the alpha source for the framebuffer. b23 b22 0 0: Use alpha from color 2 0 1: Use source alpha (pixel coverage) 1 0: Use 0.0 as alpha 1 1: Use alpha from framebuffer. • In alpha channel blending mode (USEACB = 1): Blends alpha in color 2 instead of framebuffer alpha. 00b: BC2A = 1: Use alpha in color 2 as destination (DST_A) else: BC2A = 0: Use alpha from framebuffer as destination (DST_A).	W
b24	RLE ENABLE	RLE Enable	0: Disable RLE 1: Enable RLE.	W
b25	CLUT ENABLE	CLUT Enable	0: Disable CLUT 1: Enable CLUT. If CLUTENABLE = 0 (CLUT disabled), the index is directly put on the RGB channels.	W
b26	COLKEY ENABLE	Color Keying Enable	0: Disable color keying 1: Enable color keying.	W
b27	CLUT FORMAT	CLUT Format	0: Format CLUT as aRGB (8888) 1: Format CLUT as RGB (565).	W
b28	BSIA	Blend Source Factor Inverted in Alpha Channel	• In alpha channel blending mode (USEACB = 1): 0: Use blend factor as specified through BSFA 1: Invert blend source factor (1-x).	W
b29	BDIA	Blend Destination Factor Inverted in Alpha Channel	• In alpha channel blending mode (USEACB = 1): 0: Use blend factor as specified through BDFA 1: Invert destination blend factor (1-x).	W
b31, 30	RLE PIXEL WIDTH[1:0]	Texel Width for RLE Unit	b31 b30 0 0: 1 byte per texel 0 1: 2 bytes per texel 1 0: 3 bytes per texel 1 1: 4 bytes per texel.	W

56.2.3 Interrupt Control Register (IRQCTL)

Address(es): DRW.IRQCTL 400E 40C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	BUSIRQCLR	BUSIRQEN	DLISTIRQCLR	ENUMIRQCLR	DLISTIRQEN	ENUMIRQEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ENUMIRQEN	ENUMIRQ Interrupt Mask Enable	0: Disable (mask) ENUMIRQ enumeration interrupt 1: Enable (unmask) ENUMIRQ enumeration interrupt.	W
b1	DLISTIRQEN	DLISTIRQ Interrupt Mask Enable	0: Disable (mask) DLISTIRQ display list interrupt 1: Enable (unmask) DLISTIRQ display list interrupt.	W

Bit	Symbol	Bit name	Description	R/W
b2	ENUMIRQCLR	Clear ENUMIRQ	0: Do not clear ENUMIRQ enumeration interrupt 1: Clear ENUMIRQ enumeration interrupt.	W
b3	DLISTIRQCLR	Clear DLISTIRQ	0: Do not clear DLISTIRQ display list interrupt 1: Clear DLISTIRQ display list interrupt.	W
b4	BUSIRQEN	BUSIRQ Interrupt Mask Enable	0: Disable (mask) BUSIRQ bus error interrupt 1: Enable (unmask) BUSIRQ bus error interrupt.	W
b5	BUSIRQCLR	Clear BUSIRQ	0: Do not clear BUSIRQ bus error interrupt 1: Clear BUSIRQ bus error interrupt.	W
b31 to b6	—	Reserved	The write value should be 0.	W

56.2.4 Cache Control Register (CACHECTL)

Address(es): DRW.CACHECTL 400E 40C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CFLUSHTX	CENABLETX	CFLUSHFX	CENABLE FX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CENABLEFX	Framebuffer Cache Enable	0: Disable the framebuffer cache 1: Enable the framebuffer cache.	W
b1	CFLUSHFX	Flush Framebuffer Cache	0: Do not flush the framebuffer cache 1: Flush the framebuffer cache.	W
b2	CENABLETX	Texture Cache Enable	0: Disable the texture cache 1: Enable the texture cache.	W
b3	CFLUSHTX	Flush Texture Cache	0: Do not flush the texture cache 1: Flush the texture cache.	W
b31 to b4	—	Reserved	The write value should be 0.	W

56.2.5 Status Control Register (STATUS)

Address(es): DRW.STATUS 400E 4000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	BUSERRMDL	BUSERRMTX	BUSERRMFB	—	BUSIRQ	DLISTIRQ	ENUMIRQ	DLISTACTIVE	CACHEDIRTY	BUSYWRITE	BUSYENUM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	BUSY ENUM	Enumeration Unit Status	0: Enumeration unit idle 1: Enumeration unit is busy, new primitive cannot be started.	R

Bit	Symbol	Bit name	Description	R/W
b1	BUSY WRITE	Framebuffer Writeback Status	0: Framebuffer writeback finished 1: Framebuffer writeback busy, framebuffer type cannot be changed.	R
b2	CACHE DIRTY	Framebuffer Cache Status	0: Framebuffer cache is not dirty 1: Framebuffer cache is dirty, and frame should not be flipped.	R
b3	DLIST ACTIVE	Display List Reader Status	0: Display list reader is idle 1: Display list reader is busy, and no direct write access to registers allowed.	R
b4	ENUM IRQ	Enumeration Interrupt Triggered	0: Enumeration not finished or interrupt disabled 1: Enumeration finished interrupt triggered.	R
b5	DLIST IRQ	Display List Interrupt Triggered	0: Display list not finished or interrupt disabled 1: Display list finished interrupt triggered.	R
b6	BUS IRQ	Bus Error Interrupt Triggered	0: No bus error occurred or interrupt disabled 1: Bus error interrupt triggered.	R
b7	—	Reserved	This bit is read as 0.	R
b8	BUSERR MFB	Framebuffer Bus Error Interrupt Triggered	0: No framebuffer bus error occurred or interrupt disabled 1: Framebuffer bus error interrupt triggered.	R
b9	BUSERR MTXMRL	Texture Bus Error Interrupt Triggered*1	0: No texture bus error occurred or interrupt disabled 1: Texture bus error interrupt triggered.	R
b10	BUSERR MDL	Display List Bus Error Interrupt Triggered	0: No display list bus error occurred or interrupt disabled 1: Display list bus error interrupt triggered.	R
b31 to b11	—	Reserved	These bits are read as 0.	R

Note 1. Because the RLE unit is also reading data through the texture bus, an error during RLE data access is also reflected in this bit.

56.2.6 Hardware Version and Feature Set ID Register (HWREVISION)

Address(es): DRW.HWREVISION 400E 4004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	ACBLEND	—	COLORKEY	TEXCLUT256	RLEUNIT	—	TEXCLU	PERFCOUNT	TXCACHE	FBCACHE	DLR	—
Value after reset:	0	0	0	0	1	1	1	1	1	0	1	1	1	1	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	REV[11:0]											
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1	1

Bit	Symbol	Bit name	Description	R/W
b11 to b0	REV[11:0]	Revision Number	Revision number.	R
b16 to b12	—	Reserved	These bits are read as 0.	R
b17	DLR	Display List Reader Available	Display list reader is available.	R
b18	FBCACHE	Framebuffer Cache Available	Framebuffer cache is available.	R
b19	TX CACHE	Texture Cache Available	Texture cache is available.	R
b20	PERF COUNT	Two Performance Counter Available	Two performance counter is available.	R
b21	TEXCLUT	Texture CLUT Available	Texture CLUT is available.	R
b22	—	Reserved	This bit is read as 0.	R
b23	RLEUNIT	RLE Unit Available	RLE unit is available.	R

Bit	Symbol	Bit name	Description	R/W
b24	TEX CLUT256	Texture CLUT with 16 or 256 Entries Available	Texture CLUT with 16 or 256 entries is available.	R
b25	COLORKEY	Color Key Available	Color key is available.	R
b26	—	Reserved	This bit is read as 1.	R
b27	ACBLEND	Alpha Channel Blending Available	Alpha channel blending is available.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

56.2.7 Base Color Register (COLOR1)

Address(es): DRW.COLOR1 400E 4064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	COLOR1A[7:0]								COLOR1R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	COLOR1G[7:0]								COLOR1B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	COLOR1B[7:0]	Blue Channel of Color 1	Specifies blue channel of color 1.	W
b15 to b8	COLOR1G[7:0]	Green Channel of Color 1	Specifies green channel of color 1.	W
b23 to b16	COLOR1R[7:0]	Red Channel of Color 1	Specifies red channel of color 1.	W
b31 to b24	COLOR1A[7:0]	Alpha Channel of Color 1	Specifies alpha channel of color 1. 00h: Transparent ... FFh: Opaque.	W

56.2.8 Secondary Color Register (COLOR2)

Address(es): DRW.COLOR2 400E 4068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	COLOR2A[7:0]								COLOR2R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	COLOR2G[7:0]								COLOR2B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	COLOR2B[7:0]	Blue Channel of Color 2	Specifies blue channel of color 2.	W
b15 to b8	COLOR2G[7:0]	Green Channel of Color 2	Specifies green channel of color 2.	W
b23 to b16	COLOR2R[7:0]	Red Channel of Color 2	Specifies red channel of color 2.	W
b31 to b24	COLOR2A[7:0]	Alpha Channel of Color 2	Specifies alpha channel of color 2. 00h: Transparent ... FFh: Opaque.	W

56.2.9 Pattern Register (PATTERN)

Address(es): DRW.PATTERN 400E 4074h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	PATTERN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	PATTERN[7:0]	Bitmap of the Pattern	Specifies bitmap of the pattern.	W
b31 to b8	—	Reserved	The write value should be 0.	W

56.2.10 Limiter N Start Value Register (LnSTART)

Address(es): DRW.L1START 400E 4010h, DRW.L2START 400E 4014h, DRW.L3START 400E 4018h, DRW.L4START 400E 401Ch, DRW.L5START 400E 4020h, DRW.L6START 400E 4024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LSTART[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LSTART[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	LSTART[31:0]	Start Value of the nth Limiter	Specifies start value of the nth limiter.	W

56.2.11 Limiter N X-Axis Increment Register (LnXADD)

Address(es): DRW.L1XADD 400E 4028h, DRW.L2XADD 400E 402Ch, DRW.L3XADD 400E 4030h, DRW.L4XADD 400E 4034h, DRW.L5XADD 400E 4038h, DRW.L6XADD 400E 403Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LXADD[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LXADD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	LXADD[31:0]	X-Axis Increment	Specifies x-axis increment.	W

56.2.12 Limiter N Y-Axis Increment Register (LnYADD)

Address(es): DRW.L1YADD 400E 4040h, DRW.L2YADD 400E 4044h, DRW.L3YADD 400E 4048h, DRW.L4YADD 400E 404Ch, DRW.L5YADD 400E 4050h, DRW.L6YADD 400E 4054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LYADD[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LYADD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	LYADD[31:0]	Y-Axis Increment	Specifies y-axis increment.	W

56.2.13 Limiter M Band Width Parameter Register (LmBAND)

Address(es): DRW.L1BAND 400E 4058h, DRW.L2BAND 400E 405Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LBAND[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LBAND[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	LBAND[31:0]	Limiter m Band Width Parameter	Specifies limiter m band width parameter.	W

56.2.14 Texture Base Address Register (TEXORIGIN)

Address(es): DRW.TEXORIGIN 400E 40BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TEXORIGIN[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TEXORIGIN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	TEXORIGIN[31:0]	Texture Base Address	Specifies texture base address.	W

56.2.15 Texels Per Texture Line Register (TEXPITCH)

Address(es): DRW.TEXPITCH 400E 40B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TEXPITCH[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TEXPITCH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	TEXPITCH[31:0]	Texels Per Texture Line	Specifies texels per texture line. Valid range: 0 to 2048.	W

56.2.16 Texture Size or Texture Address Mask Register (TEXMASK)

Address(es): DRW.TEXMASK 400E 40B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TEXVMASK[20:5]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TEXVMASK[4:0]					TEXUMASK[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	TEXUMASK[10:0]	U Mask in Texture Mode	Specifies the U mask. Set to texture_width -1. • In texture wrapping mode (CONTROL2.TEXTURECLAMPX = 0): Texture_width must be a power of 2 • In texture clamping mode (CONTROL2.TEXTURECLAMPX = 1): All widths up to 2048 are allowed.	W
b31 to b11	TEXVMASK[20:0]	V Mask in Texture Mode	Specifies the V mask. Set to DRWTEXPITCH (texture_height - 1). • In texture wrapping mode (CONTROL2.TEXTURECLAMPY = 0): Texture_height must be a power of 2 • In texture clamping mode (CONTROL2.TEXTURECLAMPY = 1): All heights up to 1024 are allowed.	W

56.2.17 U Limiter Start Value Register (LUSTART)

Address(es): DRW.LUSTART 400E 4090h

	CLDATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	CLDATA[31:0]	Texture CLUT Data	Specifies texture CLUT data.	W

56.2.27 CLUT Offset Register (TEXCLOFFSET)

Address(es): DRW.TEXCLOFFSET 400E 40E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CLOFFSET[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CLOFFSET[7:0]	Texture CLUT Offset	Specifies texture CLUT offset. CLOFFSET[7:0] is OR gated with the original index.	W
b31 to b8	—	Reserved	The write value should be 0.	W

56.2.28 Color Key Register (COLKEY)

Address(es): DRW.COLKEY 400E 40E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	COLKEYR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	COLKEYG[7:0]								COLKEYB[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	COLKEYB[7:0]	Blue Channel of Color Key	Specifies blue channel of color key.	W
b15 to b8	COLKEYG[7:0]	Green Channel of Color Key	Specifies green channel of color key.	W
b23 to b16	COLKEYR[7:0]	Red Channel of Color Key	Specifies red channel of color key.	W
b31 to b24	—	Reserved	The write value should be 0.	W

56.2.29 Bounding Box Dimension Register (SIZE)

Address(es): DRW.SIZE 400E 4078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SIZEY[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SIZEX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	SIZEX[15:0]	Bounding Box Width	Specifies width of bounding box in pixels. Valid range: 0 to 1024.	W
b31 to b16	SIZEY[15:0]	Bounding Box Height	Specifies height of bounding box in pixels. Valid range: 0 to 1024.	W

56.2.30 Framebuffer Pitch And Spanstore Delay Register (PITCH)

Address(es): DRW.PITCH 400E 407Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SSD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PITCH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	PITCH[15:0]	Pitch of the Framebuffer	A negative width can be used to render bottom-up instead of top-down.	W
b31 to b16	SSD[15:0]	Spanstore Delay	Specifies number of scan lines to delay spanstore operations.	W

56.2.31 Framebuffer Base Address Register (ORIGIN)

Address(es): DRW.ORIGIN 400E 4080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ORIGIN[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ORIGIN[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	ORIGIN[31:0]	Address of the First Pixel in Framebuffer	Writing to ORIGIN triggers the start of rendering.	W

56.2.32 Display List Start Address Register (DLISTSTART)

Address(es): DRW.DLISTSTART 400E 40C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLISTSTART[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DLISTSTART[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	DLISTSTART[31:0]	Display List Start Address	Setting a new display list base address triggers execution of the new display list. Execution stops only when a new list is set or the current list terminates.	W

56.2.33 Performance Counters Control Register (PERFTRIGGER)

Address(es): DRW.PERFTRIGGER 400E 40D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PERFTRIGGER2[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PERFTRIGGER1[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	PERFTRIGGER1[15:0]	Trigger of Performance Counter 1	Selects the internal event that increments the PERFCOUNT1 register. 0: Disable performance counter 1: Select 2D Drawing Engine active cycles 2: Select framebuffer read access 3: Select framebuffer write access 4: Select texture read access 5: Select invisible pixels (enumerated but selected with alpha 0%) 6: Select invisible pixels while internal FIFO is empty (lost cycles) 7: Select display list reader active cycles 8: Select framebuffer read hits 9: Select framebuffer read misses 10: Select framebuffer write hits 11: Select framebuffer write misses 12: Select texture read hits 13: Select texture read misses 31: Select every clock cycle (for use as timer).	W
b31 to b16	PERFTRIGGER2[15:0]	Trigger of Performance Counter 2	Same as for PERFTRIGGER1, but for performance counter 2.	W

56.2.34 Performance Counter k (PERFCOUNTk) (k = 1, 2)

Address(es): DRW.PERFCOUNT1 400E 40CCh, DRW.PERFCOUNT2 400E 40D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PERFCOUNT[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PERFCOUNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	PERFCOUNT[31:0]	Performance Counter k Value	Specifies counter k value. The counter is reset by writing PERFCOUNTk = 0000_0000h.	R/W

56.3 Drawing Features

56.3.1 Drawing Features Summary

56.3.1.1 Color formats

Supported color formats are:

Framebuffer formats

- 8-bit: a (8)
- 16-bit: RGB (565), aRGB (4444)
- 32-bit: aRGB (8888).

Texture formats

- 1-bit: CLUT (1)/I (1)
- 2-bit: CLUT (2)/I (2)
- 4-bit: CLUT (4)/I (4)
- 8-bit: a (8), CLUT (8)/I (8), aCLUT (44)
- 16-bit: aRGB (4444), aRGB (1555), RGB (565)
- 24-bit: RGB (888) (run length encoded (RLE) unit)
- 32-bit: aRGB (8888).

CLUT formats use a 256-entry color lookup table.

56.3.1.2 BitBLT features

The 2D Drawing Engine supports the BitBLT features using its vector drawing function to draw a rectangle and texture it based on the selected BitBLT function. This approach results in the following BitBLT features:

- Fill
- Copy
- Stretch BitBLT
- Rotate and scale
- Alpha blending

- Bilinear filtering
- Color conversion
- Subpixel exact placement.

56.3.1.3 Vector drawing features

The vector 2D Drawing Engine uses a half-plane rendering approach, which simplifies implementation of edge anti-aliasing and blurring features without much overhead. When combining some of its functional units, the module can draw not only linear primitives such as lines or polygons, but also quadratic equation-based primitives such as circles and ellipsoids. The following primitives are supported:

- Lines
- Polygons
- Circles and ellipses
- Quadratic curves (software driver support)
- 2D texture mapping
- Bilinear filtering of the textures.

56.3.2 Vector Drawing

For a detailed explanation of the algorithms, see section 56.6, Rendering Pipeline. Supported vector drawing includes:

Lines

- Arbitrary width
- Round endpoints
- Truncated endpoints
- Alpha gradients
- Soft edges (blurring)
- Render attribute: color, pattern, or texture.

Polygons

- Triangles and quadrangles (complex polygons are tessellated by software)
- Alpha gradients
- Soft edges (blurring)
- Per edge controls for anti-aliasing
- Render attribute: color, pattern, or texture.

Circles and ellipses

- All conic sections
- Filled or with arbitrary width
- Arcs of 0° to 360°
- Soft edges
- Alpha gradients
- Render attribute: color, pattern, or texture.

Quadratic Bézier

- Approximated by circle arcs
- Arbitrary width

- Round or truncated endpoints
- Outlines, blurring
- Alpha gradients
- Render attribute: color.

Texture mapping

- 2D array of pixels that can be mapped implicitly or explicitly on all primitives provided by the 2D Drawing Engine
- Translation, rotation, and scaling/shearing
- Bilinear filtering of the textures
- 3D-like texturing accomplished with line-by-line mapping, if constant in one axis.

56.3.3 BitBLT

A dedicated BitBLT unit is not required in the 2D Drawing Engine. The rendering pipeline described for vector drawing is used as the BitBLT unit and already provides a 1 pixel/cycle throughput. For details, see section 56.6, Rendering Pipeline.

56.3.3.1 Fill

Any rectangle in the framebuffer can be filled with any value. Possible color formats are any 8-, 16-, or 32-bpp format. The driver optimizes the fill to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and fills 32 bits per clock, resulting in 2 to 4 times faster fill performance for 8- and 16-bpp formats.

56.3.3.2 Copy

Any rectangle in the framebuffer can be filled with any rectangular data from the texture input. When the texture input points to the framebuffer, copying from framebuffer to framebuffer is possible. To avoid copy problems because of overlapping source and destination areas, the copy start point can be selected from top left to bottom right. Possible color formats are any 8-, 16-, or 32-bpp format.

The driver optimizes the copy to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and copies 32 bits per clock, resulting in 2 to 4 times faster copy performance for 8- and 16-bpp formats.

56.3.3.3 Stretch BitBLT

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y directions is selectable, and filtering can be enabled independently for each axis.

56.3.3.4 Rotate and scale

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y direction and any rotation angle is selectable. The x and y directions can be rotated and scaled independently, and filtering for the scalers can be enabled independently for each axis.

56.3.3.5 Alpha blending

Alpha blending is a fundamental block in the rendering pipeline, so the full alpha blend feature set is available for any BitBLT operation. It is possible to copy an area and blend it over the destination by using any constant global alpha value (register value) or by using an alpha mask. The alpha mask is part of the texture data and can be either a per-pixel value together with a pixel color (aRGB formats) or an alpha-only format using a register color.

In addition to the color channels, the alpha channel can be blended. The formula for the alpha channel can be set independently from the formula for the color channels.

56.3.3.6 Bilinear filtering

The texture unit can be used to scale, rotate, or shear images. The texturing result can be filtered in the x and y directions independently. When selecting both filters, the result is a bilinear filtered texture. Using the unit twice with two independent textures would generate trilinear filtered bitmaps, improving the visual impression for high dynamic scale ratios.

56.3.3.7 Color conversion

Color conversion is required when using different texture formats than the framebuffer format. For saving texture memory, several formats are supported with less bpp than the framebuffer usually has. The 2D Drawing Engine always operates internally with 32-bpp aRGB (8888). All input data is converted into 32 bpp, and finally is converted back into the framebuffer format.

56.4 Input and Output Data Formats

56.4.1 Source and Destination Data

There are two possible inputs, the framebuffer and the texture or pattern input. The output is always the framebuffer.

Every drawing operation is internally rendered in 32 bpp aRGB (8888). If the input color does not provide an alpha channel, the blue channel is taken as the alpha channel. This alpha can be substituted with any alpha (for example, by an external constant) during the colorization step in the 2D Drawing Engine.

56.4.2 Framebuffer Color Formats

Table 56.1 shows the supported framebuffer color formats.

Table 56.1 Framebuffer color formats

Framebuffer memory occupation	Format	Remarks
8 bpp	a (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the color step in the 2D Drawing Engine.
16 bpp	RGB (565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	aRGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
32 bpp	aRGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The framebuffer color format is selected in the Surface Control Register bits, CONTROL2.READFORMAT[2:0].

56.4.3 Texture Color Formats

Table 56.2 shows the supported texture color formats.

Table 56.2 Texture color formats (1 of 2)

Texture memory occupation	Format	Remarks
1 bpp	CLUT (1)/I (1)	In this mode, a 1-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
2 bpp	CLUT (2)/I (2)	In this mode, a 2-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
4 bpp	CLUT (4)/I (4)	In this mode, a 4-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.

Table 56.2 Texture color formats (2 of 2)

Texture memory occupation	Format	Remarks
8 bpp	CLUT (8)/I (8)	In this mode, an 8-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
	a (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the colorization step in the 2D Drawing Engine.
	aCLUT (44)	This color format uses 1 byte per pixel. 4 bits are used as an alpha value and 4 bits are used as an index to a color palette. This approach saves space if 16 colors are sufficient to describe the image, because the next bigger alpha format would be 2-byte aRGB (4444).
16 bpp	RGB(565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	aRGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
	aRGB (1555)	This color format uses 2 bytes per pixel. Every color channel has 5 bits and the topmost single bit is taken as an alpha value. This can be used to hold an image with a transparency mask.
24 bpp	RGB (888)	This color format uses 3 bytes per pixel with 8 bits for each color channel. This format is only available as run length encoded data (RLE compression).
32 bpp	aRGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The texture color format is selected in the Surface Control Register bits, CONTROL2.WRITEFORMAT[3:0].

56.5 Texture Data Processing

Figure 56.4 shows the processing of texture data.

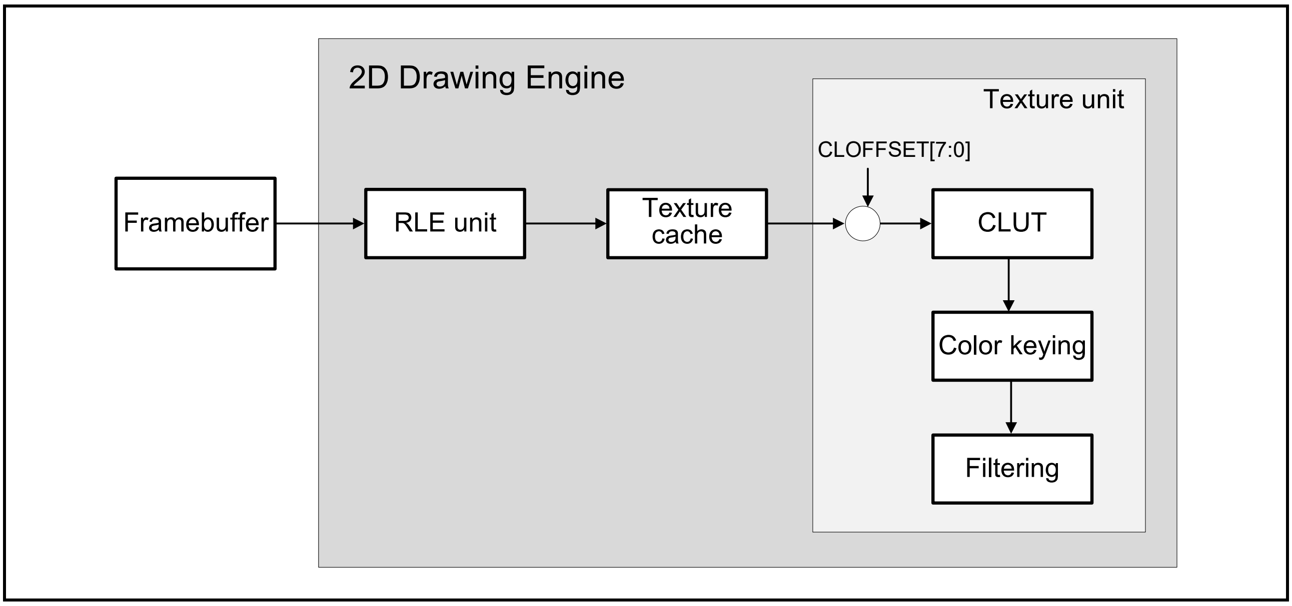

Figure 56.4 Texture data processing

56.5.1 Texture Color Format

Table 56.3 shows the supported texture data formats.

Table 56.3 Texture color formats

Texel bit width	Texel format
32 bits	aRGB (8888)
24 bits	RGB (888)
16 bits	aRGB (4444), aRGB (1555), RGB (565)
8 bits	CLUT (8)I (8), a (8), aCLUT (44)
4 bits	CLUT (4)/I (4)
2 bits	CLUT (2)/I (2)
1 bit	CLUT (1)/I (1)

56.5.2 Run Length Encoded (RLE) Unit

The RLE unit decompresses Targa-like compressed textures and hands the decompressed texel data over to the texture unit. The key features are:

- Support for Targa format
- Avoids the additional Targa limitation to scan lines
- Support for clipping of compressed images, in which the 2D Drawing Engine is allowed to copy only a portion of a larger original texture
- Control of the RLE unit in drawing list operation
- Bypassing of the RLE unit logic if uncompressed textures are fetched from the framebuffer.

Texture cache

The RLE unit feeds the texture cache. The texture cache can be disabled by setting CACHECTL.CENABLETX = 0.

Caution: A texture cache flush operation (CACHECTL.CFLUSHTX = 1) is necessary at the beginning and end of every new RLE texture.

The texture cache and the RLE unit can be bypassed by setting CONTROL2.RLEENABLE = 0.

56.5.2.1 RLE Texel formats

Table 56.4 lists the data formats supported by the RLE unit.

Table 56.4 Texel formats supported by the RLE unit (1 of 2)

Memory texel format	RLE parameters	RLE coded unit format (CONTROL2.RLEPIXELWIDTH[1:0])	Delivered format
32-bit aRGB (8888)	Included in Targa and RLE formats	32 bits (11b)	32 bits
24-bit RGB (888)		24 bits (10b)	32 bits *1
16-bit aRGB (4444), aRGB (1555), RGB (565)		16 bits (01b)	16 bits
8-bit CLUT (8)I (8), a (8), aCLUT (44)		8 bits (00b)	8 bits
4-bit CLUT (4)/I (4)	Optional for RLE *2	8 = 2 x 4 bits	4 + 4 bits

Table 56.4 Texel formats supported by the RLE unit (2 of 2)

Memory texel format	RLE parameters	RLE coded unit format (CONTROL2.RLEPIXELWIDTH[1:0])	Delivered format
2-bit CLUT (2)/I (2)	No RLE		
1-bit CLUT (1)/I (1)			

Note 1. 24-bit RGB (888) encoded texels are delivered as aRGB (8888) with Alpha set to 1.

Note 2. Encoding of textures with 4 bits per texel is not defined by the Targa specification but can be done by:
- Combining two 4-bit texels to one byte
- Padding with 4 zero bits at the end of the file, if the number of texels is odd
- Encoding as with 8-bit texels.

Texel addressing for RLE textures

The address of a texel is the byte address of the first byte of the texel. The origin of the texture is given by the register TEXORIGIN.

Note: The RLE code must begin at a word boundary of the memory.

Caution: When the FIFO is filled, there is no provision to inhibit read access beyond the end of the RLE code. To avoid memory access violations, the RLE code must be padded by 32 memory words, where every bit of each word is set to 1.

56.5.2.2 Targa RLE format

Run-length encoded (RLE) images include two types of data elements:

- Run-length packets
- Raw packets.

The first field (1 byte) of each packet is called the repetition count field. The second field is called the pixel value field (1, 2, 3. or 4 bytes). For run-length packets, the pixel value field contains a single pixel value. For raw packets, the field is a variable number of pixel values.

The highest order bit of the repetition count indicates whether the packet is a raw packet or a run-length packet, as follows:

- If bit [7] of the repetition count is set to 1, the packet is a run-length packet
- If bit [7] of the repetition count is set to zero, the packet is a raw packet.

The lower 7 bits of the repetition count specify how many pixel values are represented by the packet. For a run-length packet, this count indicates how many successive pixels have the pixel value specified in the pixel value field. For raw packets, this count specifies how many pixel values are actually contained in the next field. This 7-bit value is actually encoded as 1 less than the number of pixels in the packet (a value of 0 implies 1 pixel while a value of 7Fh implies 128 pixels).

Run-length packet

Run-length packets are composed of two parts. The first is a repetition count and the second is the pixel value to repeat.

Table 56.5 Run-length packet

Field name	Packet type (must be 1 for run-length)	Pixel count (number of pixels encoded in this packet - 1)	Pixel data (the shared pixel value to be used)
Field size	1 bit	7 bits	Pixel depth (field 5.5)

Raw packet

The raw packet always includes two fields. The first field is the repetition count and the second field is the pixel data field.

Table 56.6 Raw packet

Field name	Packet type (must be 0 for raw packet)	Pixel count (number of pixels encoded by this packet - 1)	Pixel data
Field size	1 bit	7 bits	Pixel depth x pixel count - 1

56.5.3 Color Lookup Table (CLUT)

The color lookup table receives an index that addresses one out of the 256 predefined colors.

The predefined color format can be selected as:

- CONTROL2.CLUTFORMAT = 0: aRGB (8888)
- CONTROL2.CLUTFORMAT = 1: RGB (565).

The CLUT is filled by the use of two registers:

- TEXCLDATA
  The aRGB (8888) color definition is written to this register, while the CLUT address is taken from TEXCLADDR.
- TEXCLADDR.
  This is set to the first address of the CLUT to write to and is automatically incremented after each write to TEXCLDATA.

An offset for indexed formats (CLUT (1), CLUT (2), CLUT (4), and CLUT (8)) can be set up in the TEXCLOFFSET register to allow selecting an offset part of the CLUT. The CLUT index is calculated by CLUT (x) or TEXCLOFFSET.CLOFFSET[7:0].

56.5.3.1 CLUT/I pixel data formats

The following tables explain in which order the pixels are stored within the byte. The left-most pixel is stored at the lowest bit of the memory byte.

CLUT (1)/I (1) format

The CLUT (1)/I (1) format expresses 1 pixel by using a total of 1 bit.

Memory byte	7 (MSB)	6	5	4	3	2	1	0 (LSB)
Pixel	P7	P6	P5	P4	P3	P2	P1	P0

The left-most pixel is stored at lowest bit of the memory byte.

CLUT (2)/I (2) format

The CLUT (2)/I (2) format expresses 1 pixel by using a total of 2 bits.

Memory byte	7 (MSB)	6	5	4	3	2	1	0 (LSB)
Pixel	P3		P2		P1		P0	

The left-most pixel is stored at lowest 2 bits of the memory byte.

CLUT (4)/I (4) format

The CLUT (4)/I (4) format expresses 1 pixel by using a total of 4 bits.

Memory byte	7 (MSB)	6	5	4	3	2	1	0 (LSB)

Pixel	P1	P0

The left-most pixel is stored at lowest 4 bits of the memory byte.

56.5.4 Color Keying

The 2D Drawing Engine provides a color keying unit in front of the texture unit. It operates as follows:

1. If enabled, the incoming color is compared with a transparent color, defined by COLKEY.
2. If the value matches, the alpha and color values are set to 0 to mark the color as transparent and handle it as if alpha was pre-multiplied.
3. If the value does not match, then alpha is set to 1.
4. Additional operations such as alpha_in × alpha_const are still possible.

With this approach, an object such as a round icon can be cut out from a rectangular texture and still can be faded by a constant alpha over the background.

56.6 Rendering Pipeline

56.6.1 Coordinate Transformation

Coordinate transformation such as rotation, translation, projection, and scaling must be done on the application side. This is not part of the 2D Drawing Engine hardware or driver. Because all coordinates fed into the 2D Drawing Engine are in fixed point format, these calculations can be made in fixed point format and do not require a floating point unit.

56.6.2 Rasterization

During rasterization, the vector data of the object must be converted to pixel data. To convert the data, the program sets up the edge interpolation hardware, called a limiter, for each edge of the object that calculates a decision value. The limiter determines which side of the edge the pixel is positioned on. The 2D Drawing Engine includes six internal hardware limiters. In principle, the limiter registers contain the distance between the pixel being processed and the edge.

In the linear setup, a limiter describes a half plane. The intersection of all half planes is the object. If three half planes intersect, a triangle is created as shown in Figure 56.5.

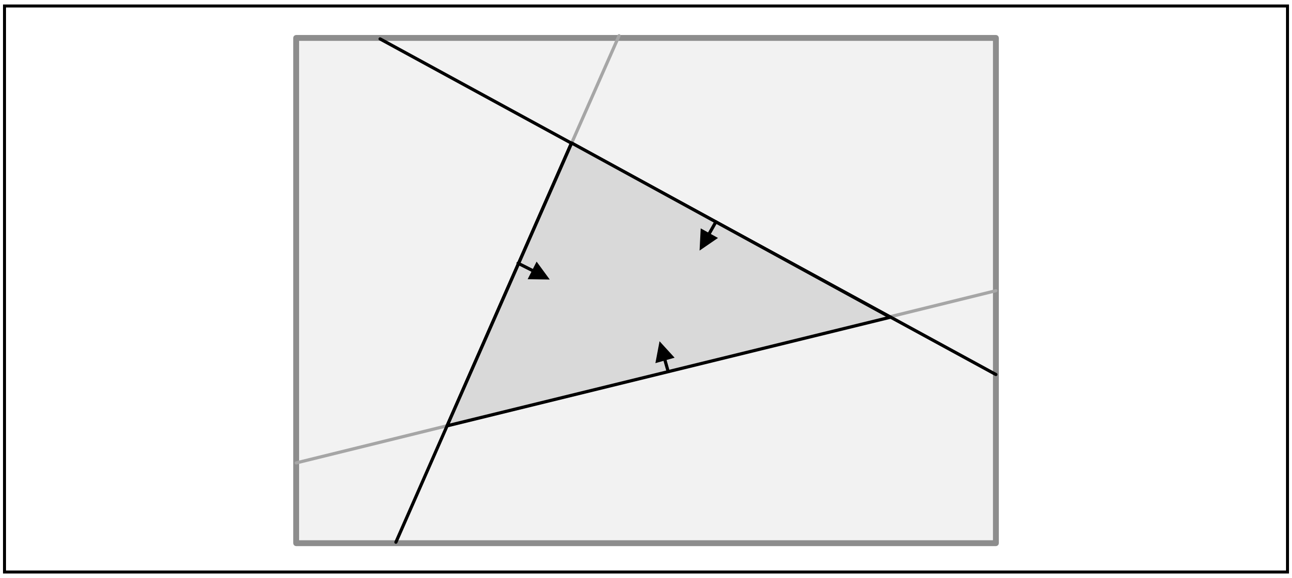

Figure 56.5 Intersection of half planes

The limiter output is clamped to an interval of [0:1]. In limiters 1 and 2 it is possible to apply a band filter before the clamping operation. In this case, the limiter is not describing a half plane but a small band. With this approach, a single limiter can describe a thick line of infinite length.

The output of the different limiters can be combined by the combiner units with a maximum or minimum operation.

Maximum operation describes the union of both half planes, and minimum operation describes the intersection of both half planes. The final output is then used as an alpha value. Edge anti-aliasing can be done with no additional effort with this hardware.

To calculate the decision value for each possible pixel with a limiter, the bounding box of the object must be calculated. Then, the decision value for the top left corner of the bounding box must be calculated for each edge. Finally, the increments for a step in the x direction and a step in the y direction must be calculated. This is done by the CPU in the driver.

With this information, the 2D Drawing Engine scans the whole bounding box and calculates the decision value for every pixel incrementally. For a block diagram of the entire rasterization unit, see section 56.1, Overview.

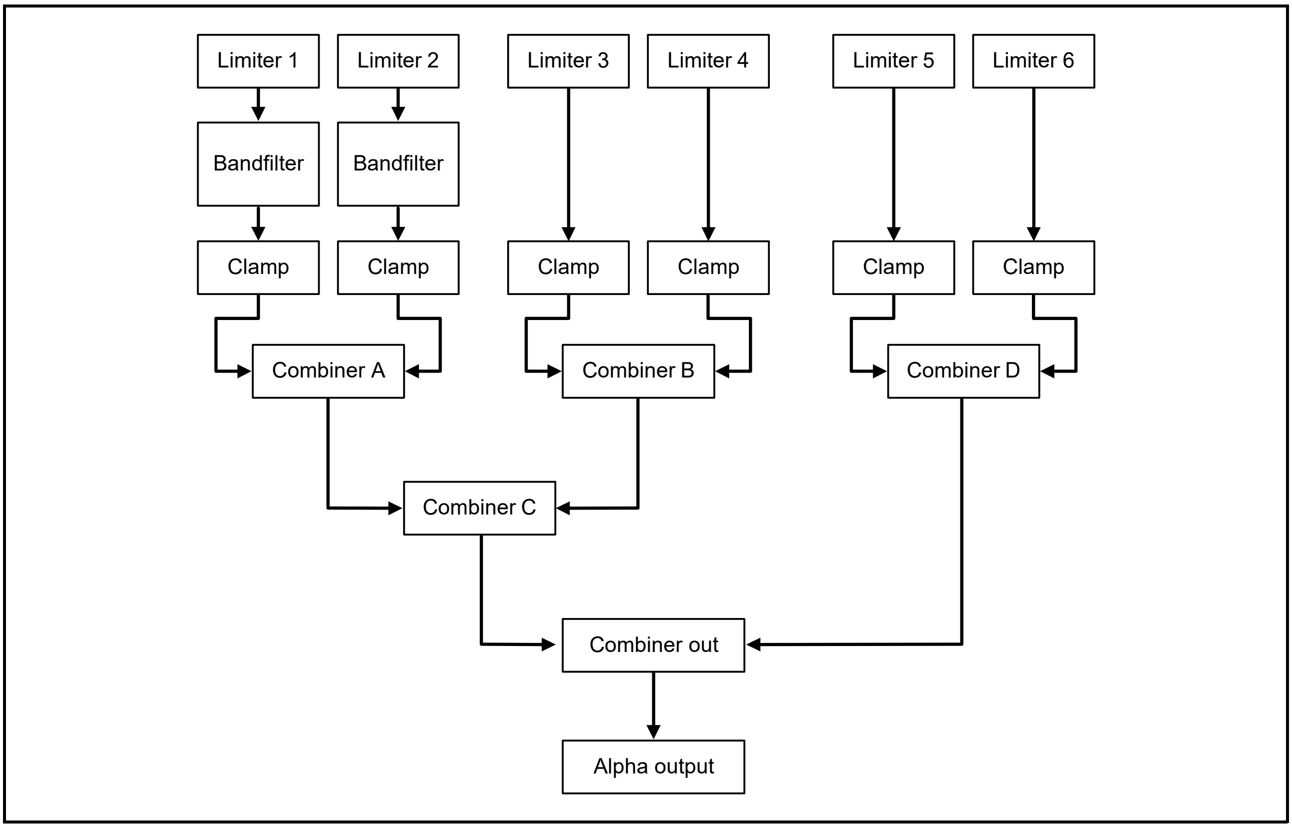

Figure 56.6 Block diagram of rasterization unit

The limiters calculate distances and the combiner units combine them to an alpha value. The combiner units define the conditions for whether or not a pixel is in the bounding box. The alpha value must be greater than 0.

Note: It is possible to have all limiters switched off.

56.6.2.1 Edge setup linear case

(1) Mathematical background

To setup a linear edge, consider the line equation in the classical form:

This can be written as:

$$y = \tilde{a}x + \tilde{b}$$

This can be rewritten as:

$$0 = f(x, y) = \tilde{a}x - y + \tilde{b} = ax + by + c$$

with $a = \tilde{a}, b = -1, c = \tilde{b}$

This is a more general form. Consider a vector form of this equation:

$$\vec{p} = \begin{pmatrix} x \\ y \end{pmatrix}, \vec{n} = \begin{pmatrix} a \\ b \end{pmatrix} \Rightarrow f(x, y) = ax + by + c = \vec{p} \cdot \vec{n} + c$$

If a point $\vec{p}_0$ is on the line:

$$0 = f(x, y) = \vec{p}_0 \cdot \vec{n} + c \Rightarrow c = -\vec{p}_0 \cdot \vec{n}$$

Rewriting the constant, the equation becomes:

$$c = -\vec{p}_0 \cdot \vec{n} \Rightarrow f(x, y) = (\vec{p} - \vec{p}_0) \cdot \vec{n}$$

The vector $\vec{n}$ is called the normal vector and is perpendicular to the line. The setup can be seen in Figure 56.7.

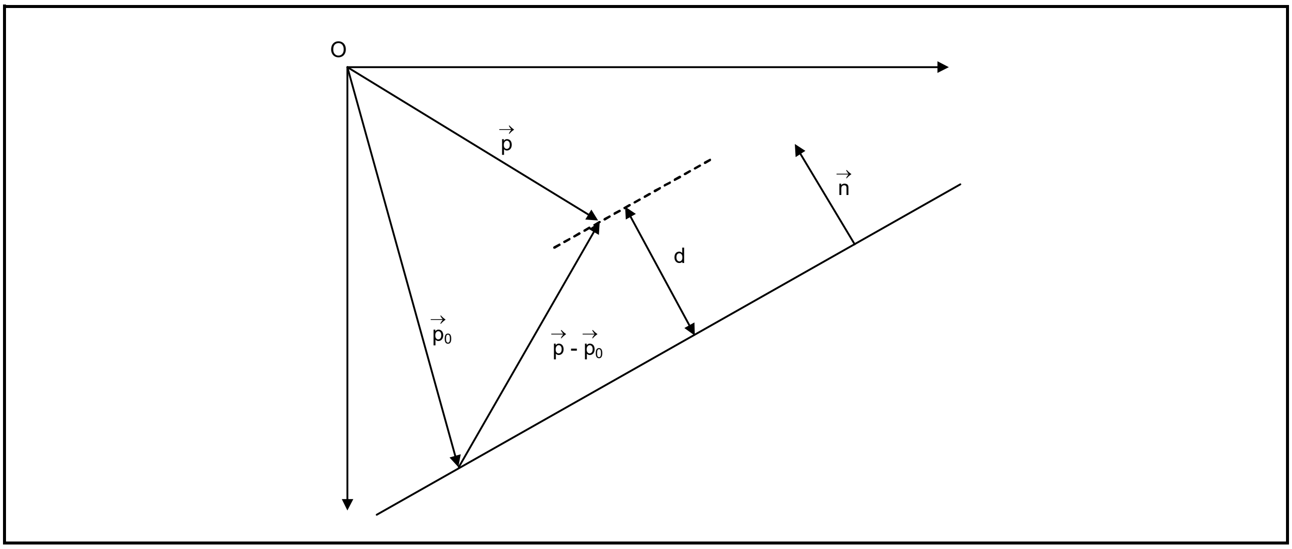

Figure 56.7 Distance of a point to a line

The projection of $\vec{p} - \vec{p}_0$ to $\vec{n}$ is the distance d of the point P to the line. In this case, f (x, y) describes the distance to the line of the pixel with coordinates (x, y).

To calculate the distance of every pixel of the bounding box incrementally, first the distance to the line at origin must be calculated:

$$f(0, 0) = -\vec{p}_0 \cdot \vec{n} = c$$

Next the increments for a step in the x direction and a step in the y direction must be calculated:

$$f(\vec{p} + \vec{e}_x) = (\vec{p} + \vec{e}_x - \vec{p}_0) \cdot \vec{n} = f(\vec{p}) + \vec{e}_x \cdot \vec{n} = f(\vec{p}) + a$$

$$f(\vec{p} + \vec{e}_y) = (\vec{p} + \vec{e}_y - \vec{p}_0) \cdot \vec{n} = f(\vec{p}) + \vec{e}_y \cdot \vec{n} = f(\vec{p}) + b$$

with $\vec{e}_x = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \vec{e}_y = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$

Consequently, the new distance can be calculated from the old distance with the increments a and b. A step in the x direction changes the distance by a, and a step in the y direction changes the distance by b. The distance of the origin to the line is c.

With this information, the entire bounding box can be scanned. If the bounding box top left corner is not at the origin, an offset must be added.

(2) Limiter operation

The 2D Drawing Engine contains six limiters. Each limiter contains three registers:

- LnSTART
- LnXADD
- LnYADD.

See Figure 56.8 for details. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not wanted.

Note: In Figure 56.8, the following abbreviations are used:
start = LnSTART
xadd = LnXADD
yadd = LnYADD

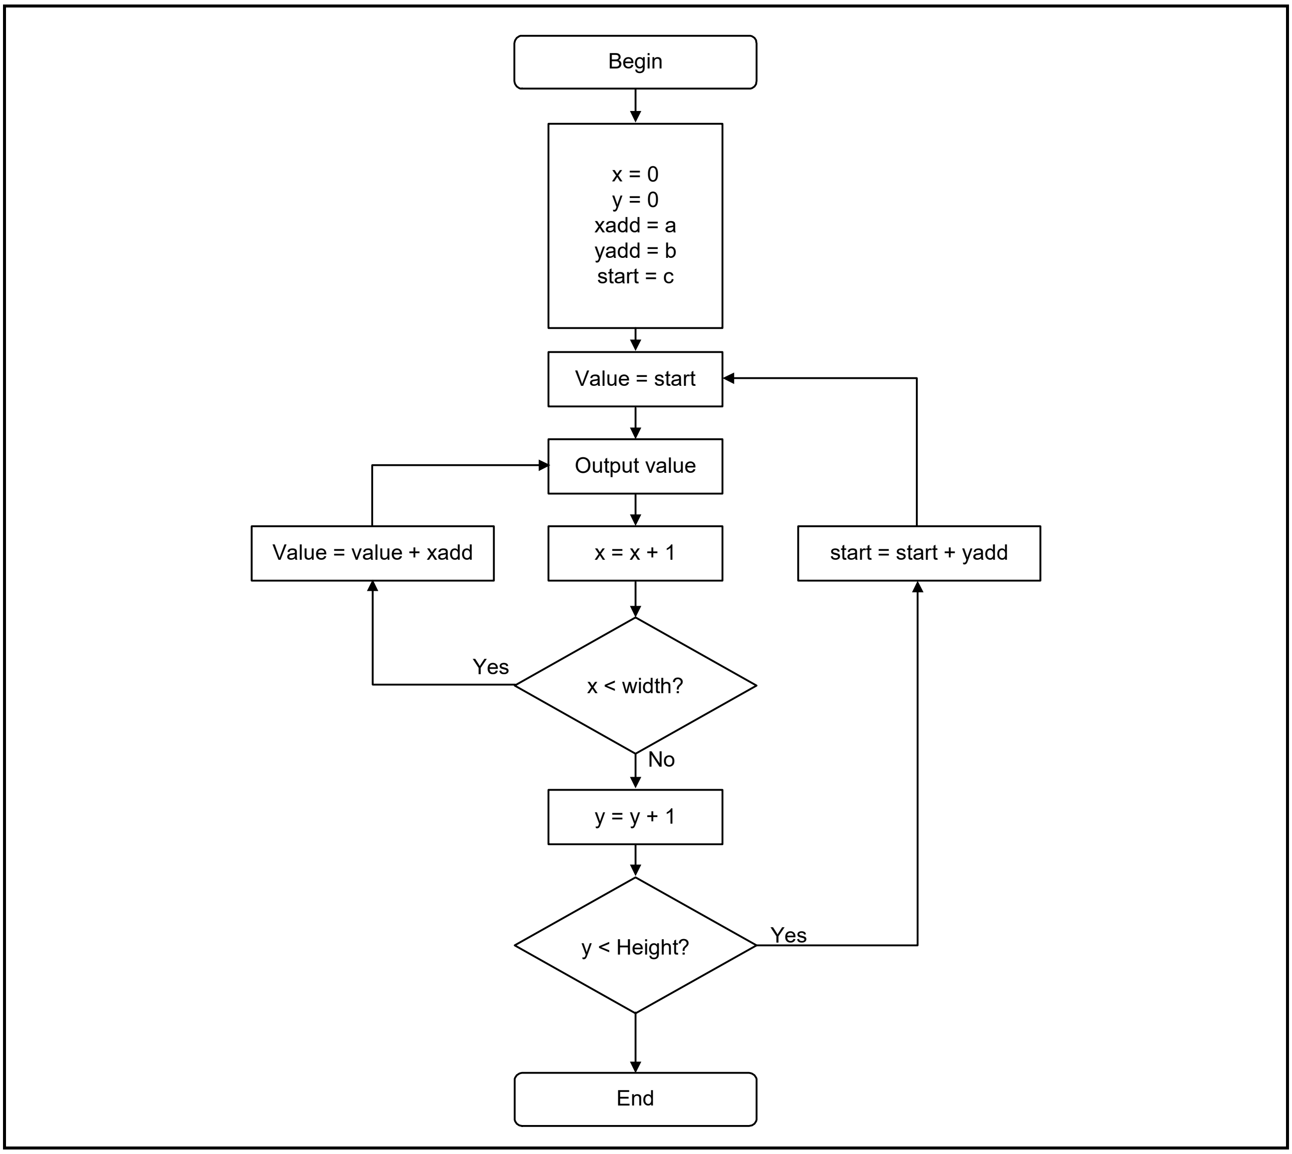

Figure 56.8 Operation flow of the linear limiter

(3) Example

If a straight line is given by the points P0 and P1, then the values are calculated as follows:

$$\Delta\vec{p} = \vec{p}_1 - \vec{p}_0 = \begin{pmatrix} x_1 - x_0 \\ y_1 - y_0 \end{pmatrix} = \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}$$

The normal vector (perpendicular but not unit size) is then:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix}$$

The not normalized distance between edge and origin is then:

$$\vec{p}_0 \cdot \vec{n} = -x_0\Delta y + y_0\Delta x$$

The limiter parameters would be:

$$\text{start} = -x_0\Delta y + y_0\Delta x$$

$$\text{xadd} = -\Delta y$$

$$\text{yadd} = \Delta x$$

In the normalized case, the normal vector is:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix} / (\sqrt{\Delta x^2 + \Delta y^2})$$

The distance between edge and origin is:

$$\vec{p}_0 \cdot \vec{n} = (-x_0 \cdot \Delta y + y_0 \cdot \Delta x) / (\sqrt{\Delta x^2 + \Delta y^2})$$

The limiter parameters would be:

$$\text{start} = (-x_0 \Delta y + y_0 \Delta x) / (\sqrt{\Delta x^2 + \Delta y^2})$$

$$\text{xadd} = -\Delta y / (\sqrt{\Delta x^2 + \Delta y^2})$$

$$\text{yadd} = \Delta x / (\sqrt{\Delta x^2 + \Delta y^2})$$

Normalization is only required if anti-aliasing is used. The driver contains an optimized inverse square root function to speed up the normalization process.

56.6.2.2 Edge setup quadratic case

(1) Mathematical background

It is also possible to set up the limiters to incrementally calculate the following equation:

$$f(x, y) = ax^2 + by^2 + cx + dy + f$$

At the origin, the value is:

$$f(0, 0) = f$$

The step in the x direction is:

$$f(x+1, y)$$

$$= a(x+1)^2 + by^2 + c(x+1) + dy + f$$

$$= ax^2 + 2ax + a + by^2 + cx + c + dy + f$$

$$= f(x, y) + 2ax + c + a$$

$$dx(x) = f(x+1, y) - f(x) = 2ax + c + a$$

The step in the y direction is:

$$f(x, y+1)$$

$$= ax^2 + b(y+1)^2 + cx + d(y+1) + f$$

$$= ax^2 + by^2 + 2by + b + cx + d(y+1) + f$$

$$= f(x, y) + 2bx + b$$

$$dy(y) = f(x+1, y) - f(x) = 2by + d + b$$

In the quadratic case, the increments dx and dy depend on x and y and are not constant. They can be calculated incrementally:

$$d^2x = dx(x+1) - dx(x) = 2a(x+1) + c + 1 - (2ax + c + 1) = 2a$$

$$d^2y = dy(y+1) - dy(y) = 2b(y+1) + d + 1 - (2by + d + 1) = 2b$$

At the origin, the increments are:

$$dx(0) = c + 1 \text{ and } dy(0) = d + 1$$

By incrementing the value by dx and dy for every step in the x and y direction and incrementing dx, dy by d^2x, and d^2y for every step in the x and y direction, the quadratic equation can be easily calculated for the whole bounding box.

(2) Limiter operation

In the quadratic case, two linear limiters are combined to operate as one quadratic limiter, called limiter 1 and limiter 2. The registers are:

- L1START, L1XADD, L1YADD
- L2START, L2XADD, L2YADD.

See Figure 56.9 for details. The gray box is an addition that performs a different operation, as in the linear setup. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not wanted.

Note: In Figure 56.9, the following abbreviations are used:

- start1 = L1START, start2 = L2START
- xadd1 = L1XADD, xadd2 = L2XADD
- yadd1 = L1YADD, yadd2 = L2YADD.

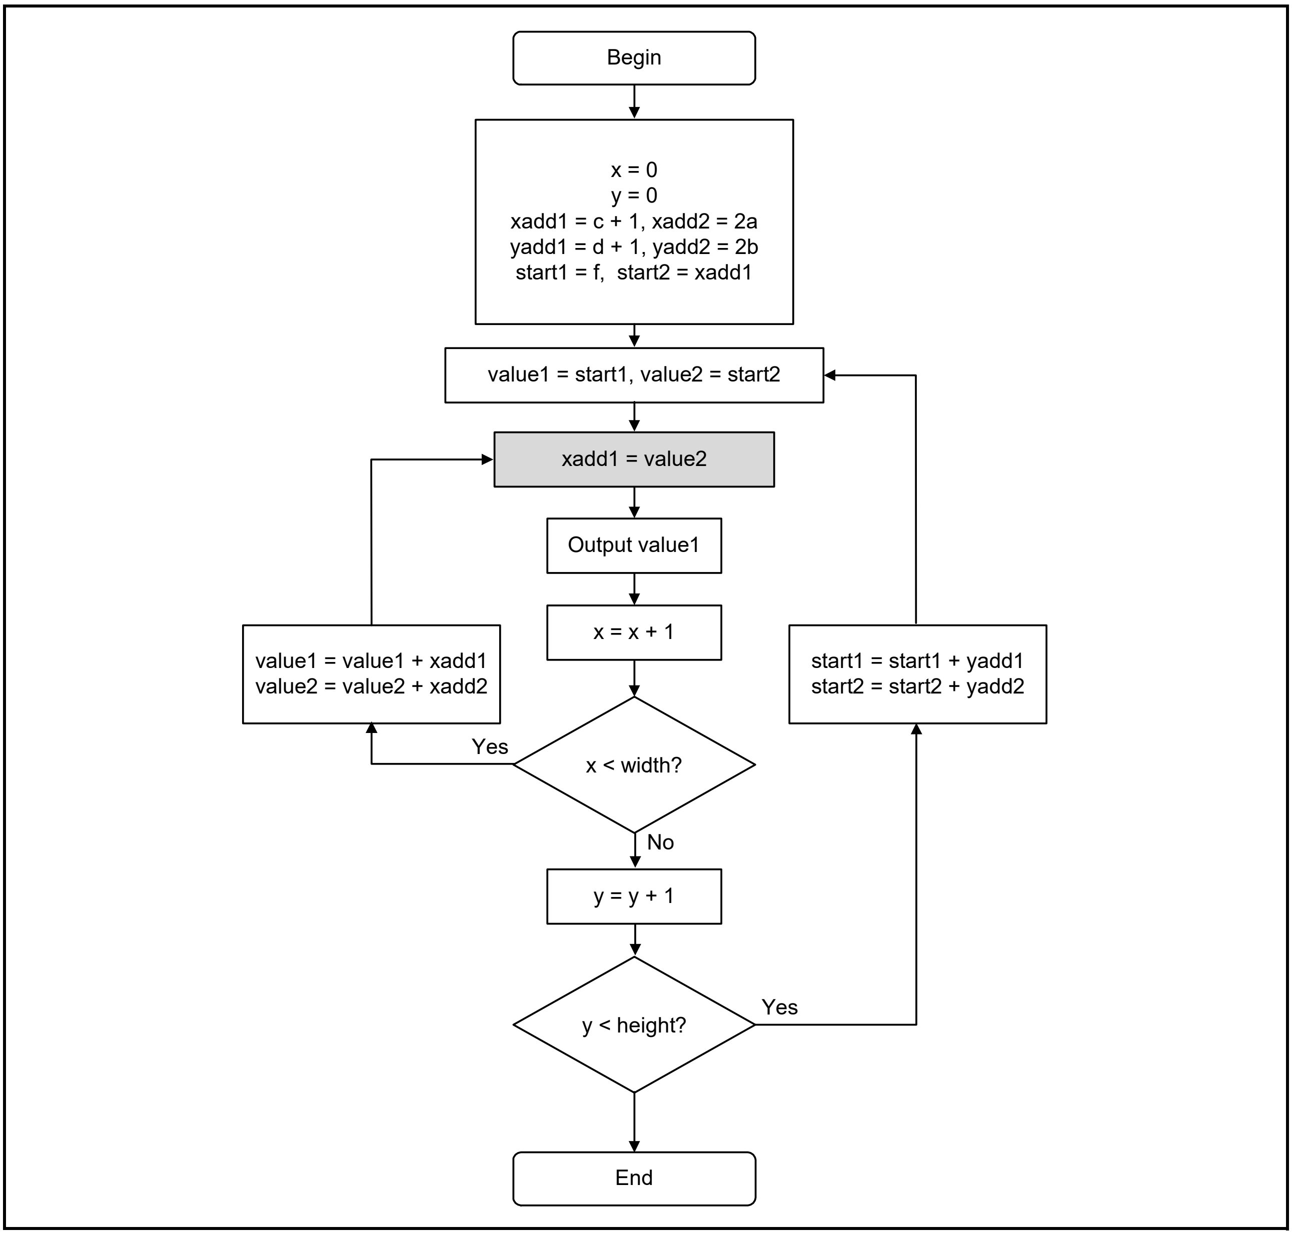

Figure 56.9 Operation flow of the quadratic limiter

(3) Example

Consider the equation for a circle with the center at $\vec{c} = \begin{pmatrix} s \\ t \end{pmatrix}$ and radius r:

$$0 = f(x, y) = (x-s)^2 + (y-t)^2 - r^2$$

This equation can be rewritten as:

$$f(x, y) = x^2 - 2xs + s^2 + y^2 - 2yt + t^2 - r^2$$

This can be sorted to fit to the original equation:

$$f(x, y) = x^2 + y^2 - 2sx - 2ty + (s^2 + t^2 - r^2)$$

With the following assignments, the circle equation can be calculated incrementally:

$a = 1$

$b = 1$

$c = -2s$

$d = -2t$

$f = s^2 + t^2 - r^2$

For the limiters with the results calculated in (1) Mathematical background, this would result in:

$\text{start1} = f = s^2 + t^2 - r^2$

$\text{xadd1} = c + 1 = -2s + 1$

$\text{yadd1} = d + 1 = -2t + 1$

$\text{start2} = \text{xadd1}$

$\text{xadd2} = 2a = 2$

$\text{yadd2} = 2b = 2$

56.6.2.3 Band filter

The output of limiter 1 and 2 can be modified to use a band filter. The band filter has a single filter parameter w.

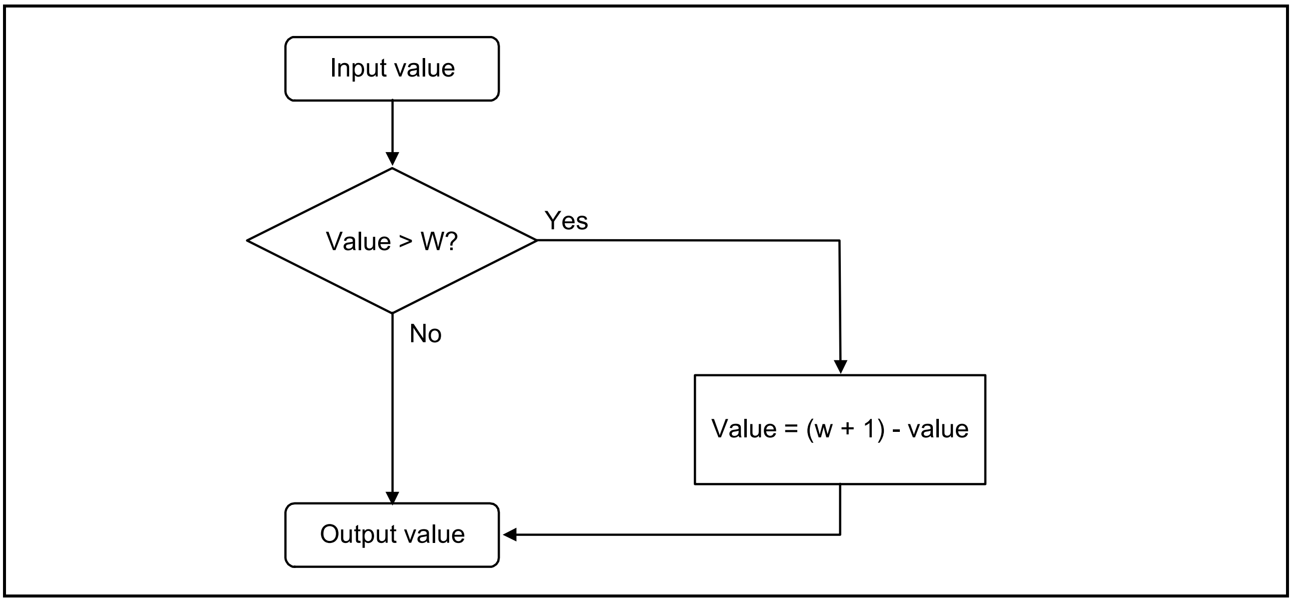

Figure 56.10 Band filter

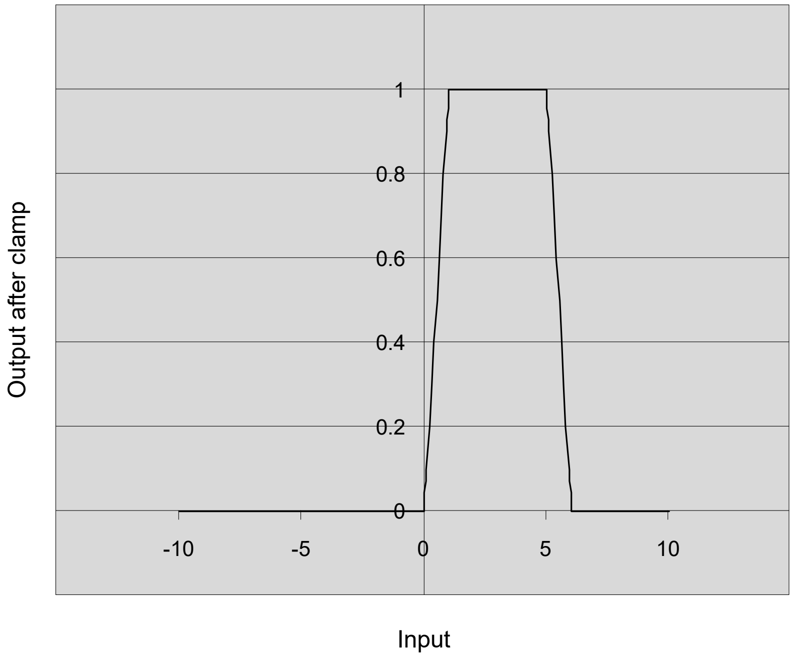

Figure 56.11 Band filter output after clamp with w = 7

56.6.2.4 Clamping unit

The clamping unit cuts the limiter output to the interval [0:1].

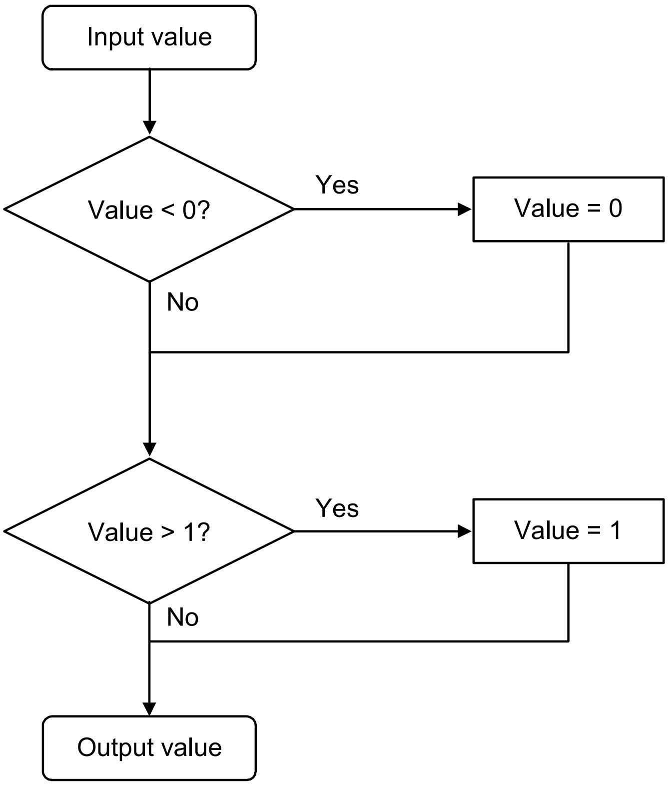

Figure 56.12 Clamping unit

The clamping unit can be put into threshold mode, in which all values greater than 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not wanted, such as for shared edges.

56.6.2.5 Combiner unit

The combiner unit can be operated in minimum mode and in maximum mode. In minimum mode the smaller value is output, and in maximum mode the larger value is output. The minimum mode represents the intersection, and the maximum mode represents the union of the two regions.

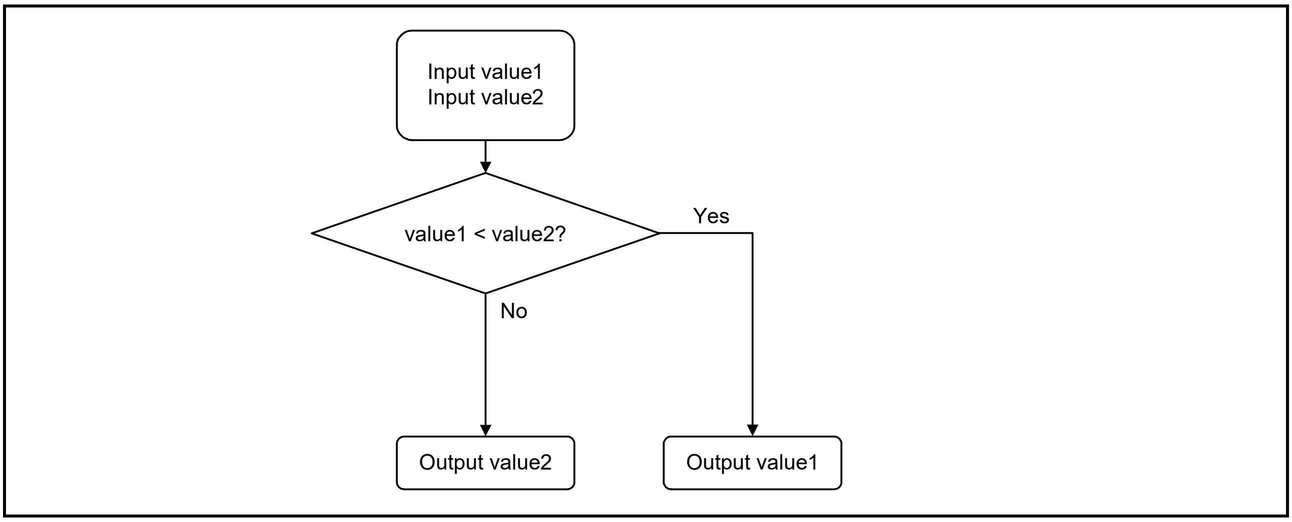

Figure 56.13 Combiner operated in minimum mode with intersection

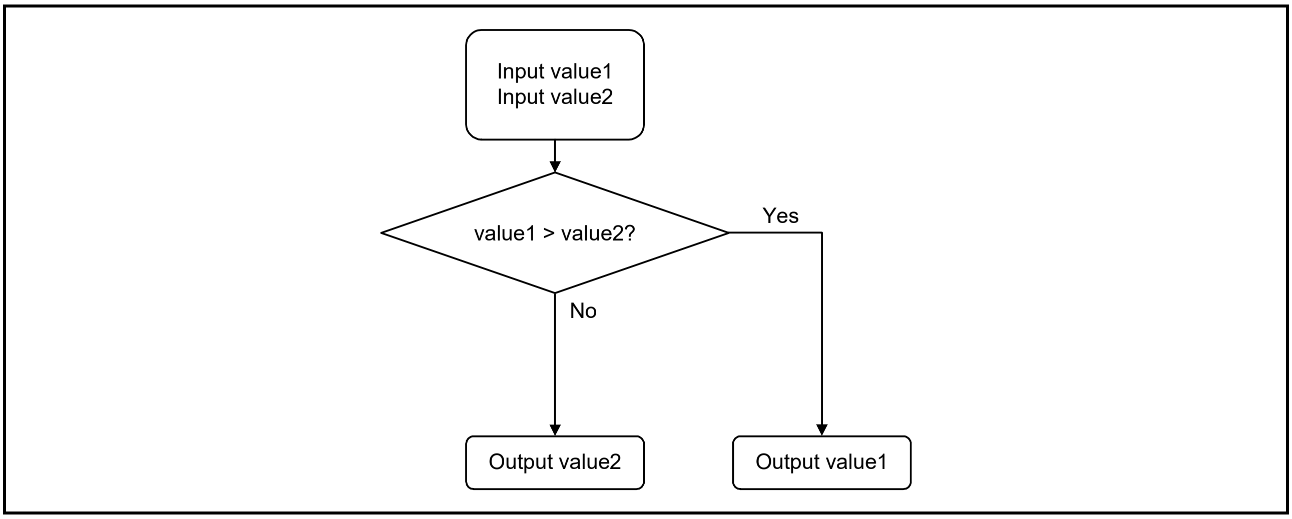

Figure 56.14 Combiner operated in maximum mode with union

56.6.2.6 Rasterization optimization

During rasterization, it is necessary to step through the whole bounding box one pixel at a time. This requirement can lead to an unnecessary number of steps for pixels that are not drawn. The 2D Drawing Engine provides optimization methods designed to reduce the number of steps required during rasterization. One optimization relies on the fact that any convex primitive can have only one span per line (a span is a contiguous horizontal line). This form of optimization detects a span start and saves the information for the next line. Another optimization is to detect a span end and stop rasterization for the current line.

(1) Spanstore

Consider the case in Figure 56.15.

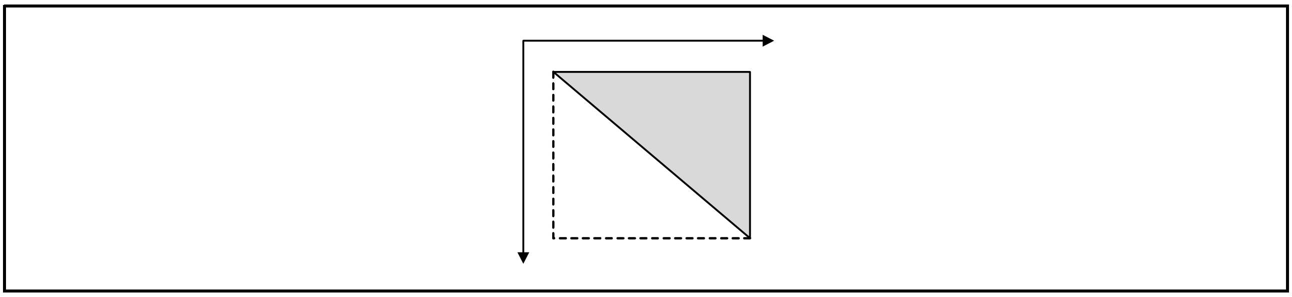

Figure 56.15 Triangle where the first edge is monotone growing

If the gray triangle must be rendered, half of the pixels processed by the rendering engine in the dotted bounding box would not be drawn. This situation can be optimized with the spanstore operation. When spanstore is activated and a span start is detected, the x position of the span start is detected.

In the next line the rendering starts with the stored x position. This only works if the edge is monotonically increasing ($y_1 > y_2 => x_1 \geq x_2$).

Consider the case in Figure 56.16.

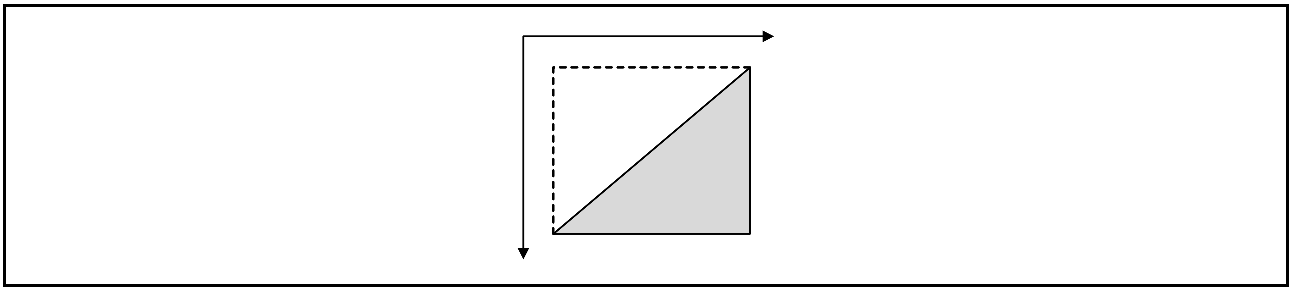

Figure 56.16 Triangle where the first edge is monotone falling

In this case, the normal spanstore operation cannot be performed. For this, the y direction of the rendering is reversed, and spanstore can operate again.

Consider the last case in Figure 56.17.

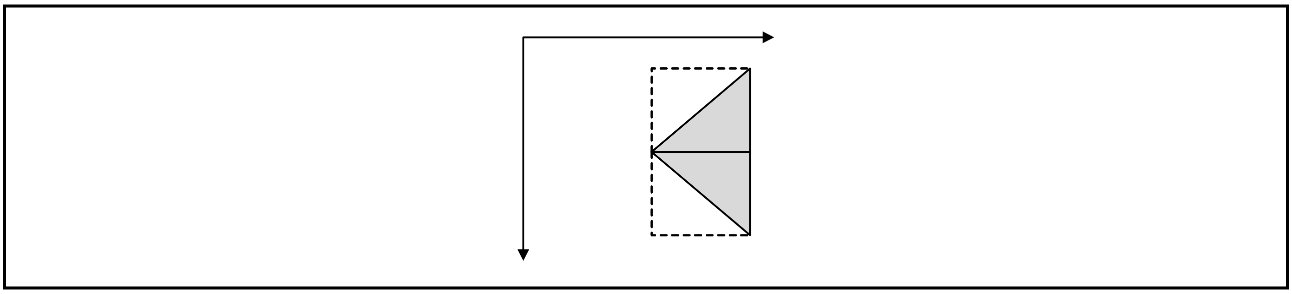

Figure 56.17 Triangle where the first edge is first monotone falling and then monotone growing

In this case, the triangle must be split and rendered as two parts for the spanstore optimization to work.

It is also possible to delay spanstore activation for a number of lines. This approach is used for rasterizing circles, as shown in Figure 56.18.

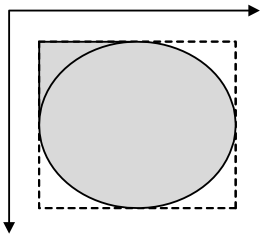

Figure 56.18 Full circle where the first edge is monotone falling for the first half and monotone growing for the second half

In this case, spanstore cannot be activated in the top left corner but can be activated in the bottom left corner. The empty corners in the top right and the bottom right cannot be rasterized because of the spanabort optimization.

(2) Spanabort

The second optimization assumes that the object that must be drawn is convex, which means there is only one span per scan line to be drawn. A non-convex object includes an object such as a triangle that is not filled and only consists of a thick border.

For a convex object, the rasterization can be stopped when the end of the first span is detected. No other constraints apply to this optimization for convex objects.

(3) Optimization efficiency

The efficiency of the optimizations can be seen for a typical case in Figure 56.19. In this case, the triangle is always rendered as single piece and is not separated into multiple triangles for higher optimizations. For this, the spanstore delay is used.

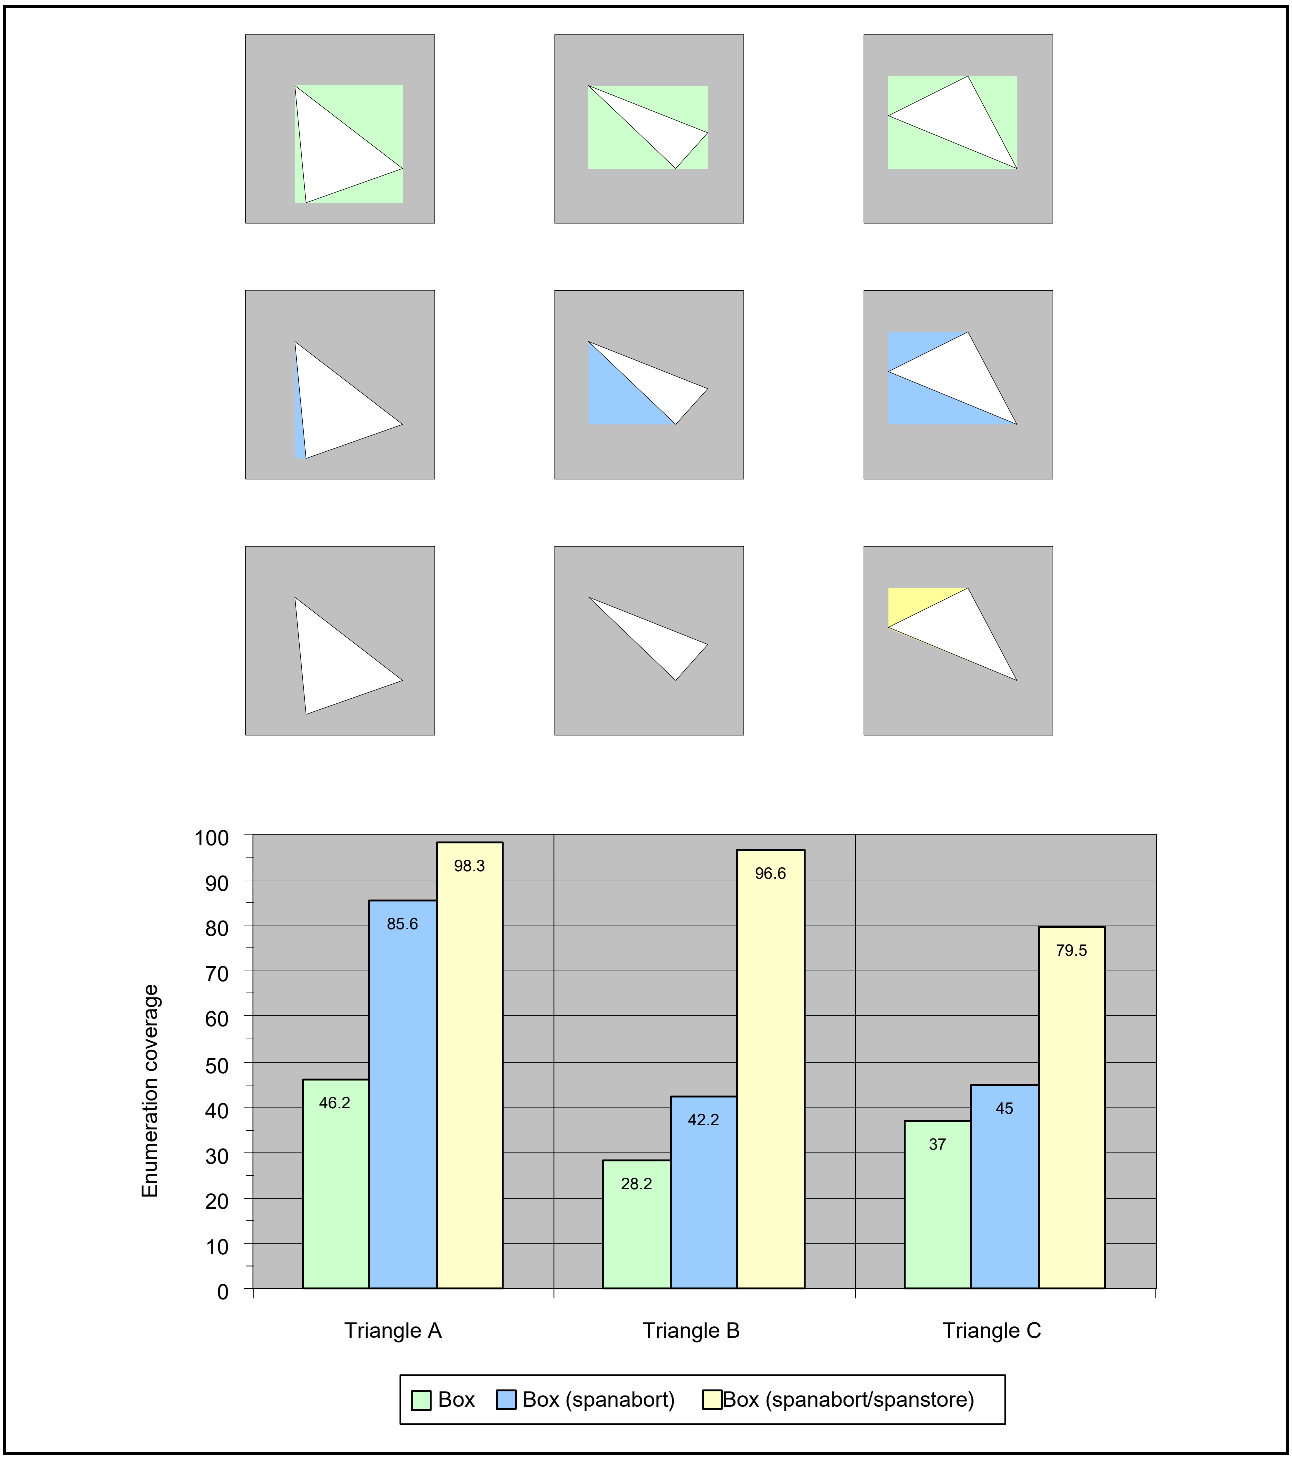

Figure 56.19 Efficiency of spanstore and spanabort optimizations with enumeration coverage equal to {pixels of primitive/pixels of bounding box}

56.6.3 Texturing

The texture unit can cover any primitive with a picture. The picture can be stretched, sheared, rotated, and translated in one step. To avoid aliasing, the result can be filtered bilinear in the u and v directions.

56.6.3.1 Mathematical background

The arbitrary mapping problem is completely determined by a mapping from 3 points in the object space (x, y) to 3 points in the texture space (u, v).

Consider the following mapping:

$$\vec{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow (\tilde{\vec{p}}_0) = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\vec{p}_1 = \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} \Rightarrow (\tilde{\vec{p}}_1) = \begin{pmatrix} u_1 \\ v_1 \end{pmatrix} = \begin{pmatrix} w \\ 0 \end{pmatrix}$$

$$\vec{p}_2 = \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} \Rightarrow (\vec{p}_2) = \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \begin{pmatrix} 0 \\ h \end{pmatrix}$$

where w is the width of the texture and h is the height of the texture.

Examine Figure 56.20 in the object space. To simplify calculations the difference vectors are taken as calculations:

$$\vec{d}_1 = \vec{p}_1 - \vec{p}_0$$

$$\vec{d}_2 = \vec{p}_2 - \vec{p}_0$$

This is equivalent to transforming from coordinate system O to coordinate system O'.

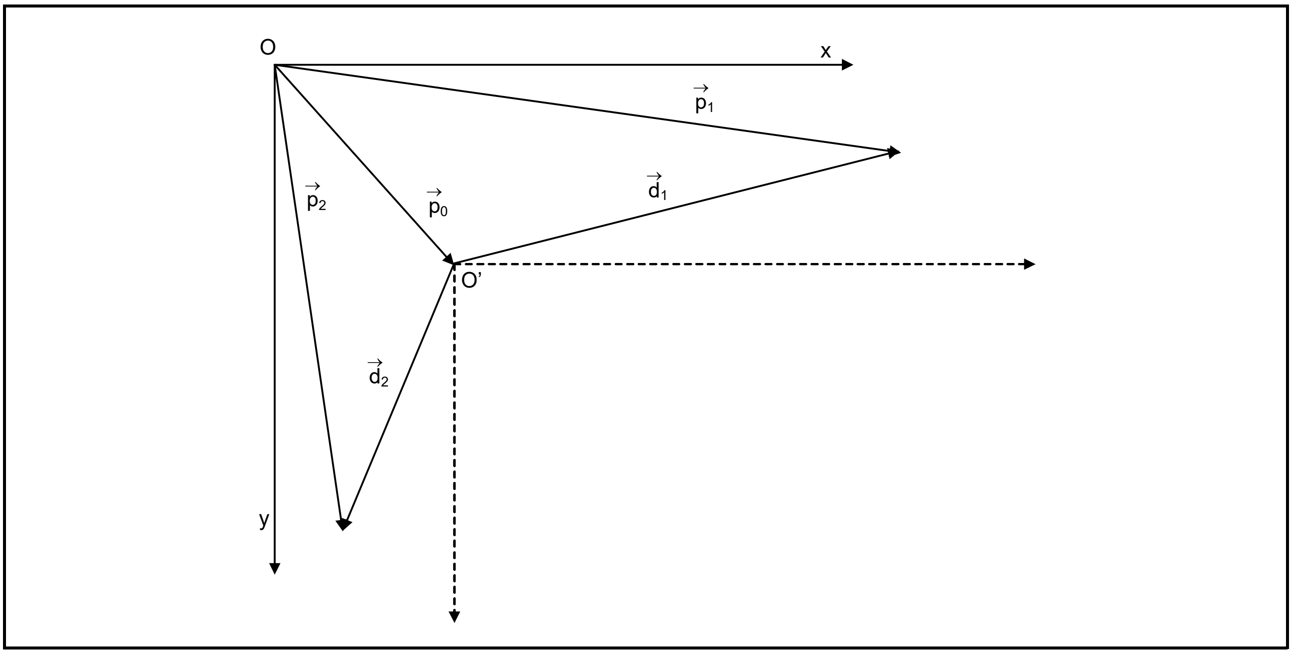

Figure 56.20 **Texture mapping, object space, and transformation from coordinate system O to O' to simplify calculations**

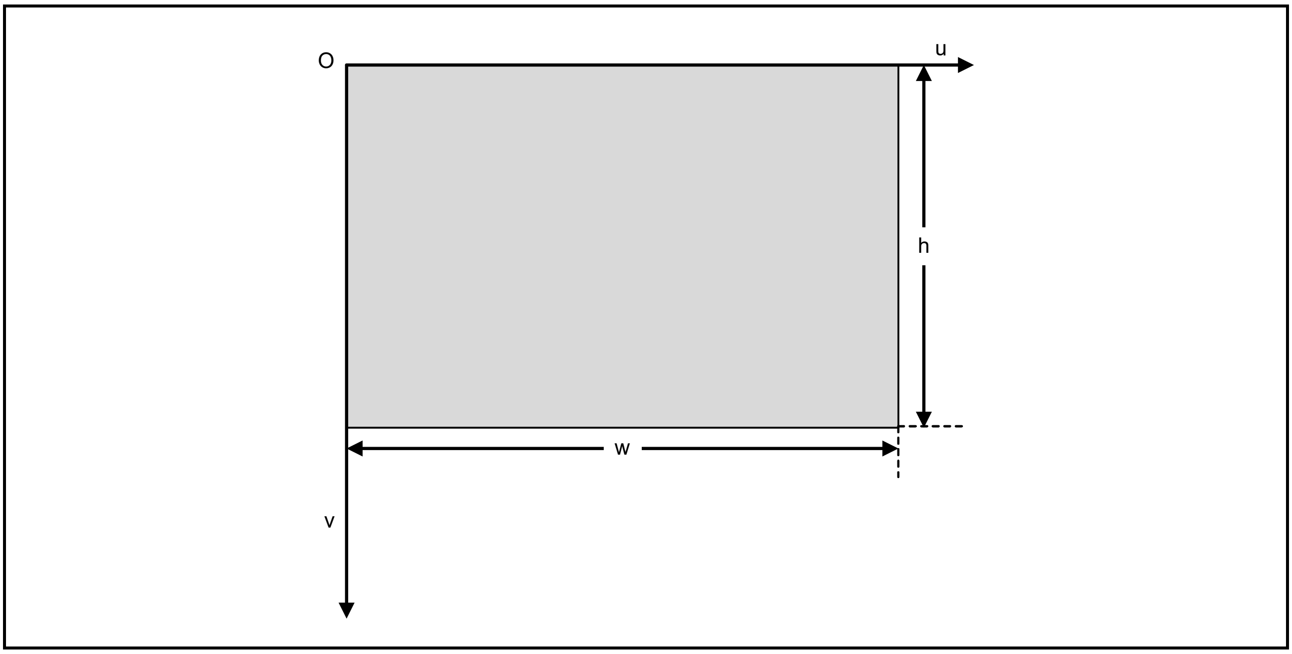

Figure 56.21 Texture mapping, texture space, and texture with width w and height h

In O’, the mapping is:

$$\vec{p}'_0 = \begin{pmatrix}0\\0\end{pmatrix} \Rightarrow (\tilde{\vec{p}}_0) = \begin{pmatrix}u_0\\v_0\end{pmatrix} = \begin{pmatrix}0\\0\end{pmatrix}$$

$$\vec{d}_1 = \begin{pmatrix}dx_1\\dy_1\end{pmatrix} \Rightarrow (\tilde{\vec{p}}_1) = \begin{pmatrix}u_1\\v_1\end{pmatrix} = \begin{pmatrix}w\\0\end{pmatrix}$$

$$\vec{d}_2 = \begin{pmatrix}dx_2\\dy_2\end{pmatrix} \Rightarrow (\tilde{\vec{p}}_2) = \begin{pmatrix}u_2\\v_2\end{pmatrix} = \begin{pmatrix}w\\h\end{pmatrix}$$

This is a linear mapping that can be described by a 2 x 2 matrix.

$$(\tilde{\vec{p}}) = M \cdot \vec{p}' = \begin{bmatrix}m_{11} & m_{12}\\m_{21} & m_{22}\end{bmatrix} \cdot \vec{p}'$$

$$\Rightarrow \begin{pmatrix}w\\0\end{pmatrix} = M \cdot \vec{d}_1 \wedge \begin{pmatrix}0\\h\end{pmatrix} = M \cdot \vec{d}_2$$

If the equations are expanded and sorted, the result is two equation systems each with two unknowns. These can be described more easily with a new matrix.

Let $A = \begin{bmatrix}dx_1 & dy_1\\dx_2 & dy_2\end{bmatrix}$ then the equation system can be rewritten as:

$$\begin{pmatrix}w\\0\end{pmatrix} = A \cdot \begin{pmatrix}m_{11}\\m_{12}\end{pmatrix} \wedge \begin{pmatrix}0\\h\end{pmatrix} = A \cdot \begin{pmatrix}m_{21}\\m_{22}\end{pmatrix}$$

This can be easily solved with determinants.

Let $c = \dfrac{1}{\det A} = \dfrac{1}{dx_1 \cdot dy_2 - dx_2 \cdot dy_1}$

The resulting constants are:

$$m_{11} = c \cdot w \cdot dy_2 = \frac{du}{dx}$$

$$m_{12} = -c \cdot w \cdot dx_2 = \frac{du}{dy}$$

$$m_{21} = c \cdot h \cdot dx_1 = \frac{dv}{dx}$$

$$m_{22} = -c \cdot h \cdot dx_2 = \frac{dv}{dy}$$

To calculate the start values for u and v at the top of the bounding box, the transformation from O' to O must be reversed. Let us and vs be the start values, then:

$$\begin{pmatrix} u_s \\ v_s \end{pmatrix} = M \cdot (-\vec{p}_0) = c \cdot \begin{pmatrix} -w \cdot (x_0 \cdot dy_2 - y_0 \cdot dx_2) \\ h \cdot (x_0 \cdot dy_1 - y_0 \cdot dx_1) \end{pmatrix}$$

Examples

U and v are in the texture space. Enter the following into any case:

- Copy case:
  dx1 = 1, dx2 = 0, dy1 = 0, dy1 = 1
- Scaling case x scaling copy case:
  dx1 = f, dx2 = 0, dy1 = 0, dy1 = 1
  with f being the scaling factor in the x direction similar for the y direction
- Rotation case:
  dx1 = cosa, dx2 = -sina, dy1 = sina, dy1 = cosa
  with the angle between d1 and the x axis in the clockwise direction.

56.6.3.2 Limiter operation

The texture limiters operate exactly the same as the spatial limiters shown in Figure 56.8, Operation flow of the linear limiter.

The register layout for the u limiter is the same:

- LUSTART = us
- LUXADD = du/dx
- LUYADD = du/dy.

The register layout for the v limiter is slightly different. TEXPITCH is multiplied to save one hardware multiplier.

- LVSTARTI = floor (vs) • TEXPITCH
  Contains the integer part of the start value.
- LVSTARTF = (vs-floor (vs)) • TEXPITCH
  Contains the fractional part of the start value.
- LVXADDI = floor (dv/dx) • TEXPITCH
  Contains the integer part of dv/dz.
- LVYADD = floor (dv/dy) • TEXPITCH
  Contains the integer part of dv/dy.
- LVYXADDF = (dv/dy - floor (dv/dy)) • TEXPITCH ((dv/dx - floor (dv/dx)) • TEXPITCH)
  Contains the fractional part of dv/dy and dv/dx combined in one register.
- TEXMASK
  Contains a mask for u and v separately to wraparound values of u and v. This is useful for staying inside the limits of the texture or repeat a texture. Wrap around textures have to have a size multiple of 2.
- TEXPITCH
  Contains the width of the texture in pixels in framebuffer memory. This information is required to calculate the new address if stepping to a new line.
- TEXORIGIN.
  Contains the base address of the texture.

56.6.4 Colorization

After a pixel is found to be part of the geometry, its color is calculated. The 2D Drawing Engine supports a very general color calculation scheme, allowing support for several color modes. This color scheme uses an interpolation between two color registers, COLOR1 and COLOR2. See Figure 56.22 for details. COLOR1 and COLOR2 are marked as A, B in the figure for clarity.

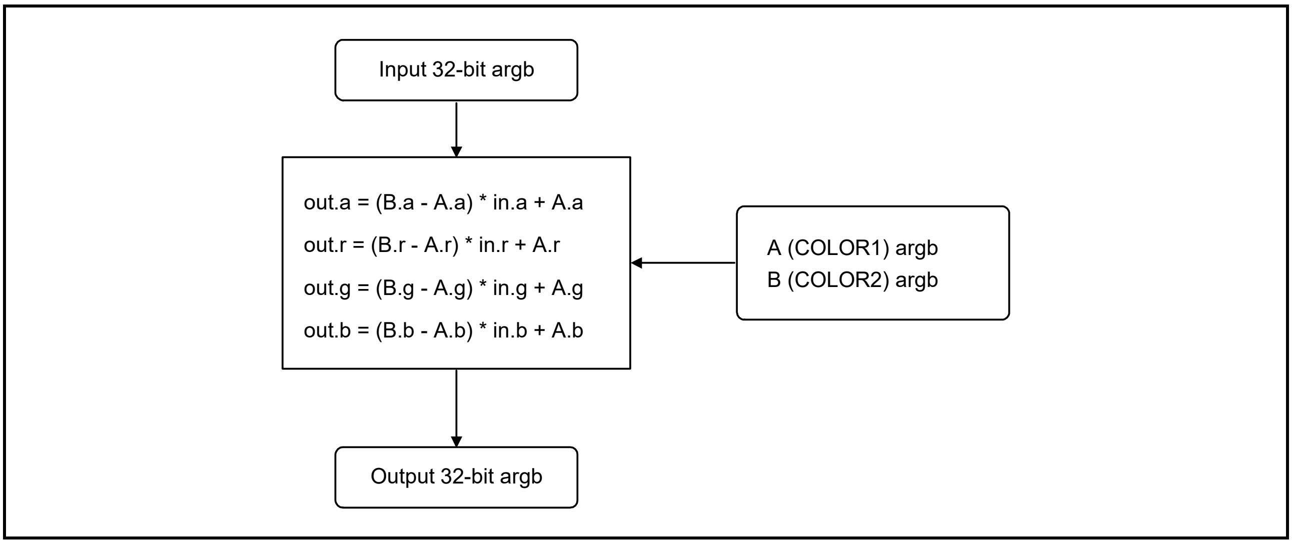

Figure 56.22 Colorization step and interpolation between the two color registers, A (COLOR1) and B (COLOR2)

This general approach can be used to support several different color modes that can be individually applied to any color or alpha channel of the input.

Table 56.7 Colorization operations

Operation	**Settings for A and B** [*1]
Copy	A = 0, B = 0xff
Replace with a constant value v	A = v, B = v
Multiply by a constant value v	A = 0, B = v
Colorize an alpha texture with the RGB value v	A.a = 0, A.r = B.r, A.g = B.g, A.b = B.b, B.a = 0xff,B.r = v.r, B.g = v.g, B.b = v.b
Invert a channel	A = 0xff, B = 0
Invert multiply with v	A = v, B = 0
Interpolate between color v and color u	A = v, B = u

Note 1. A = COLOR1, B = COLOR2

56.6.5 Blending

56.6.5.1 Color channel blending

The last step before the pixel is written to the framebuffer is to blend the pixel with the data that is already written to the framebuffer. If blending is activated, the framebuffer, referred to as DST, must be read. SRC is the output from the colorization unit.

The following color blend modes are supported:

- SRC_ZERO
- SRC_ONE
- SRC_ALPHA

- SRC_ONE_MINUS_ALPHA
- DST_ZERO
- DST_ONE
- DST_ALPHA
- DST_ONE_MINUS_ALPHA.

The selection of the color channel blend modes is performed with the following flags:

- BSF: blend source factor is alpha
- BSI: blend source factor invert
- BDF: blend destination factor is alpha
- BDI: blend destination factor invert.

The formula for the blending is:

$\mathrm{dst} = \mathrm{src} \cdot f_S + \mathrm{dst} \cdot f_D$

where:

$BSF = 0, BSI = 0 \Rightarrow f_S = 1$

$BSF = 1, BSI = 0 \Rightarrow f_S = \alpha$

$BSF = 0, BSI = 1 \Rightarrow f_S = 0$

$BSF = 1, BSI = 1 \Rightarrow f_S = 1 - \alpha$

$BDF = 0, BDI = 0 \Rightarrow f_D = 1$

$BDF = 1, BDI = 0 \Rightarrow f_D = \alpha$

$BDF = 0, BDI = 1 \Rightarrow f_D = 0$

$BDF = 1, BDI = 1 \Rightarrow f_D = 1 - \alpha$.

Table 56.8 lists all possible color channel blend modes.

Table 56.8 Color channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_ONE DST_ONE	0	0	0	0	SRC + DST
SRC_ONE	0	0	0	1	SRC
SRC_ONE DST_ALPHA	0	0	1	0	SRC + DST × ALPHA
SRC_ONE DST_ONE_MINUS_ALPHA	0	0	1	1	SRC + DST × (1 - ALPHA)
SRC_ZERO DST_ONE	0	1	0	0	DST
SRC_ZERO DST_ZERO	0	1	0	1	0
SRC_ZERO DST_ALPHA	0	1	1	0	DST × ALPHA
SRC_ZERO DST_ONE_MINUS_ALPHA	0	1	1	1	DST × (1 - ALPHA)
SRC_ALPHA DST_ONE	1	0	0	0	SRC × ALPHA + DST
SRC_ALPHA	1	0	0	1	SRC × ALPHA
SRC_ALPHA DST_ALPHA	1	0	1	0	SRC × ALPHA + DST × ALPHA
SRC_ALPHA DST_ONE_MINUS_ALPHA	1	0	1	1	SRC × ALPHA + DST × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ONE	1	1	0	0	SRC × (1 - ALPHA) + DST
SRC_ONE_MINUS_ALPHA	1	1	0	1	SRC × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ALPHA	1	1	1	0	SRC × (1 - ALPHA) + DST × ALPHA
SRC_ONE_MINUS_ALPHA DST_ONE_MINUS_ALPHA	1	1	1	1	SRC × (1 - ALPHA) + DST × (1 - ALPHA)

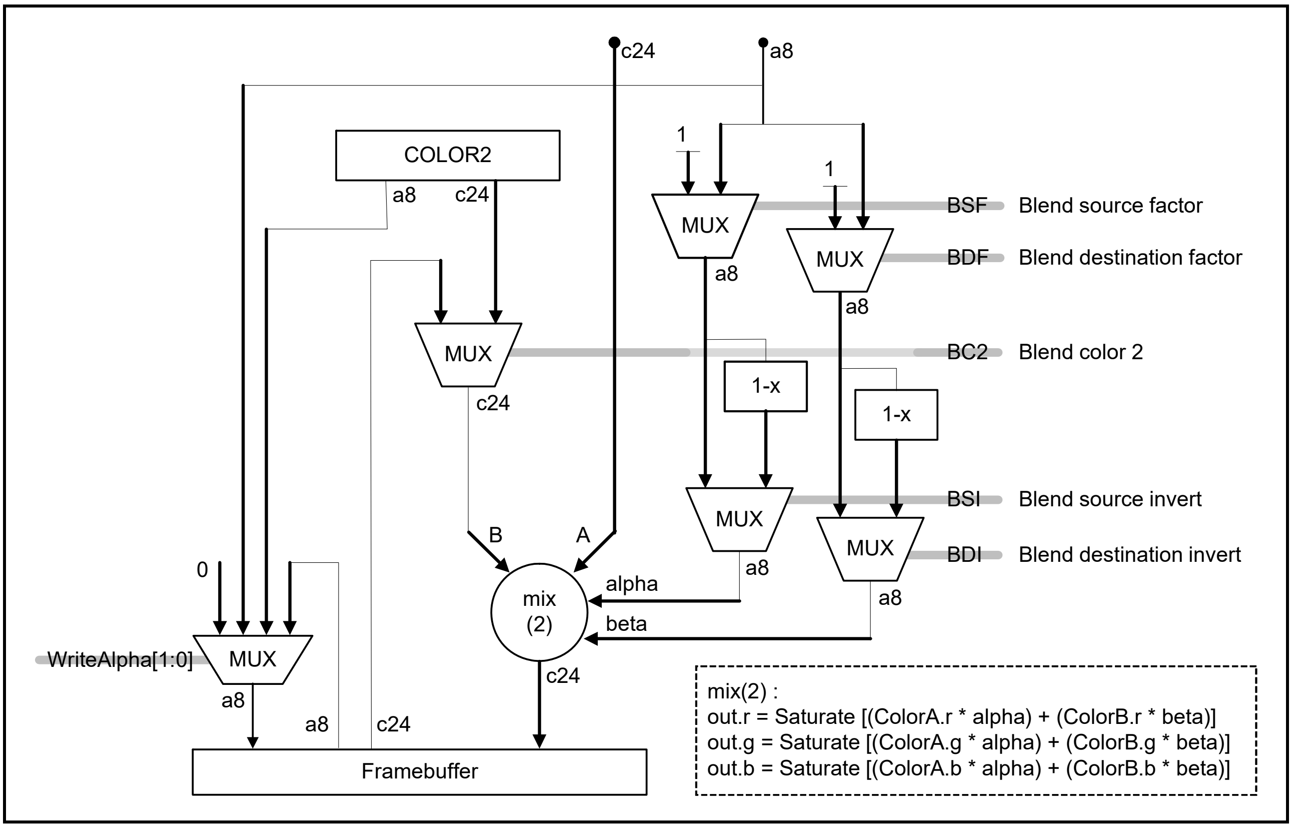

Figure 56.23 Color channel blend unit when CONTROL2.USEACB = 0

56.6.5.2 Alpha channel blending

The alpha channel can be blended in addition to the color channels. Alpha channel blending is enabled by setting CONTROL2.USEACB = 1. Alpha channel blending uses the same formulas and same blend modes as for the color channels. The alpha channel formulas can be set independently from the color channels.

The following alpha channel blend modes are supported:

- SRC_A_ZERO
- SRC_A_ONE
- SRC_A_SRC_A
- SRC_A_ONE_MINUS_SRC_A
- DST_A_ZERO
- DST_A_ONE
- DST_A_SRC_A
- DST_A_ONE_MINUS_SRC_A.

The alpha channel blend modes selected with the following flags:

- BSFA: blend source factor is SRC_A
- BSIA: blend source factor invert
- BDFA: blend destination factor is SRC_A
- BDIA: blend destination factor invert.

The formula for the blending is:

$$\text{dst\_alpha} = \text{src \_a} \cdot f_{S\_a} + \text{dst\_a} \cdot f_{D\_a}$$

where:

BSFA = 0, BSIA = 0 $\Rightarrow f_{S\_a} = 1$

BSFA = 1, BSIA = 0 $\Rightarrow f_{S\_a} = src\_a$

BSFA = 0, BSIA = 1 $\Rightarrow f_{S\_a} = 0$

BSFA = 1, BSIA = 1 $\Rightarrow f_{S\_a} = 1 - src\_a$

BDFA = 0, BDIA = 0 $\Rightarrow f_{D\_a} = 1$

BDFA = 1, BDIA = 0 $\Rightarrow f_{D\_a} = src\_a$

BDFA = 0, BDIA = 1 $\Rightarrow f_{D\_a} = 0$

BDFA = 1, BDIA = 1 $\Rightarrow f_{D\_a} = 1 - src\_a$.

Table 56.9 lists all possible alpha channel blend modes.

Table 56.9 Alpha channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_A_ONE DST_A_ONE	0	0	0	0	SRC_A + DST_A
SRC_A_ONE	0	0	0	1	SRC_A
SRC_A_ONE DST_A_SRC_A	0	0	1	0	SRC_A + DST_A × SRC_A
SRC_A_ONE DST_A_ONE_MINUS_SRC_A	0	0	1	1	SRC_A + DST_A × (1 - SRC_A)
SRC_A_ZERO DST_A_ONE	0	1	0	0	DST_A
SRC_A_ZERO DST_A_ZERO	0	1	0	1	0
SRC_A_ZERO DST_A_SRC_A	0	1	1	0	DST_A × SRC_A
SRC_A_ZERO DST_A_ONE_MINUS_SRC_A	0	1	1	1	DST_A × (1 - SRC_A)
SRC_A_SRC_A DST_A_ONE	1	0	0	0	SRC_A × SRC_A + DST_A
SRC_A_SRC_A	1	0	0	1	SRC_A × SRC_A
SRC_A_SRC_A DST_A_SRC_A	1	0	1	0	SRC_A × SRC_A + DST_A × SRC_A
SRC_A_SRC_A DST_A_ONE_MINUS_SRC_A	1	0	1	1	SRC_A × SRC_A + DST_A × (1 - SRC_A)
SRC_A_ONE_MINUS_SRC_A DST_A_ONE	1	1	0	0	SRC_A × (1 - SRC_A) + DST_A
SRC_A_ONE_MINUS_SRC_A	1	1	0	1	SRC_A × (1 - SRC_A)
SRC_A_ONE_MINUS_SRC_A DST_A_SRC_A	1	1	1	0	SRC_A × (1 - SRC_A) + DST_A × SRC_A
SRC_A_ONE_MINUS_SRC_A DST_A_ONE_MINUS_SRC_A	1	1	1	1	SRC_A × (1 - SRC_A) + DST_A × (1 - SRC_A)

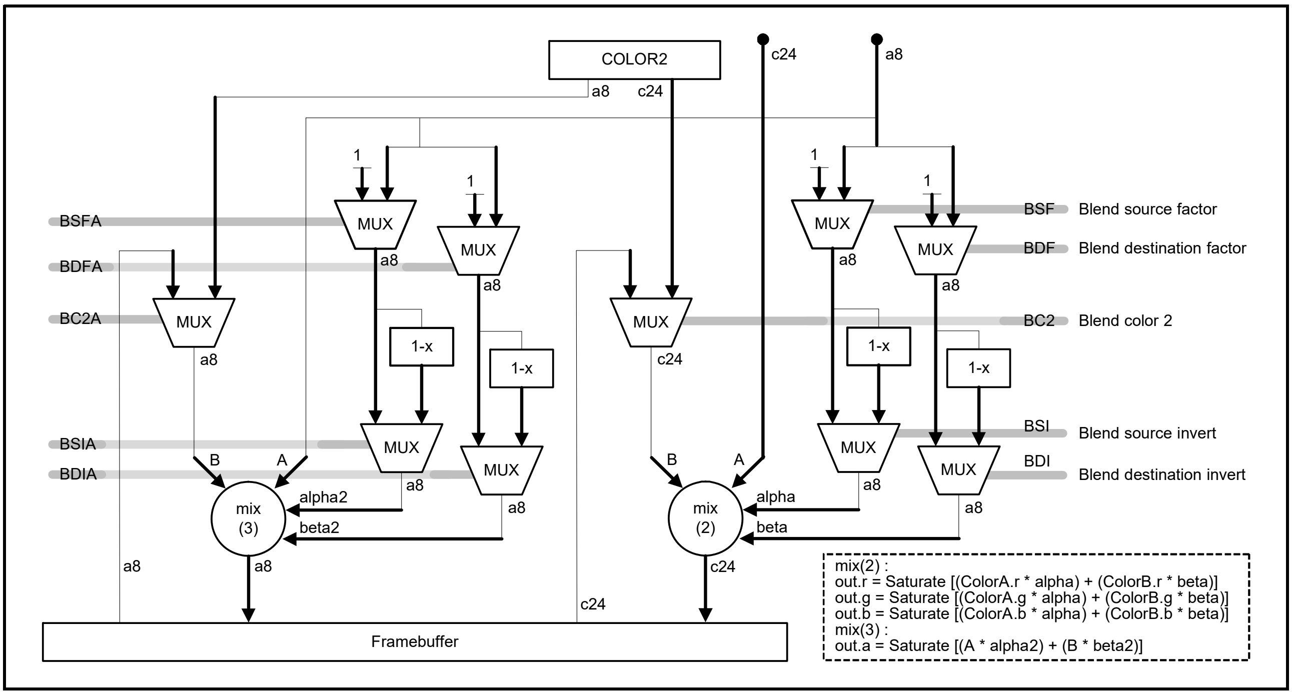

Figure 56.24 Alpha- and color-channel blend unit when CONTROL2.USEACB = 1

56.7 Rendering Modes

The rendering process can be performed in two different modes, register mode and display list mode.

56.7.1 Register Mode

In register mode, when operation is based on register settings, the host CPU configures and initiates each render process separately. To start a new render process, the host CPU must wait until the previous one is completed. In this mode, the host CPU is heavily engaged throughout the entire drawing procedure and is consequently to a large extent unavailable for other tasks.

The host CPU must set up all registers for performing a certain drawing operation before it can start the rendering process. A new register setup can only be started when the previous render process has completed. Before starting a new register setup, make sure that:

- STATUS.DLISTACTIVE = 0: Display list reader is idle
- STATUS.BUSENUM = 0: Pixel selection unit is idle.

Lastly, write the framebuffer start address to the ORIGIN register. This write triggers the 2D Drawing Engine to start rendering.

56.7.2 Display List Mode

In display list mode, the host CPU creates a display list in memory prior to starting the 2D Drawing Engine. Such a display contains a bundle of render operations. When started, the 2D Drawing Engine executes the display list autonomously in parallel with the host CPU, which is not involved with drawing operations most of the time. Use of a display list allows a fully asynchronous operation of the host CPU and the 2D Drawing Engine and offers the best possible system performance.

In this mode, the display list reader reads a memory block containing instructions on how to set the 2D Drawing Engine control registers and executes these control register writes accordingly.

Display list start

To start execution of a display list, which already resides in memory, the start address of the display list is written to the display list start address register DLISTSTART. Because rewriting DLISTSTART also stops any ongoing display list execution, make sure that the previous display list process is completed by either of the following two methods:

- Check that STATUS.DLISTACTIVE = 0, which indicates idle status of the display list reader
- Wait for the display list interrupt DRWDLISTIRQ, which indicates completion of the previous display list process.

Caution: Direct writing to 2D Drawing Engine registers while the display list mode is active (STATUS.DLISTACTIVE = 1) might lead to a 2D Drawing Engine hang-up. To prevent this, always check that the display list reader is idle ((STATUS.DLISTACTIVE = 0) before writing to any 2D Drawing Engine register.

Display list format

Display lists are stored using direct register-to-value mappings, which means that the display list contains a one byte index that addresses a certain register and the value to be written to the register. The register index is derived from the address offset of the register address and can be calculated by dividing the address offset by 4. For the index of each register, see section 56.2, Register Descriptions.

As the 2D Drawing Engine registers are always 32 bits wide, each data unit (called a data word) to be written to a register is of the same size. An address word that contains the indices of the register to be written is stored in a packed notation with up to four indices stored in one 32-bit address word.

A display list command always starts with an address word, followed by up to four data words, one for each register. The indices are read and interpreted from LSB to MSB, so the register of the low byte index is written first.

Example

In the following example:

DWORD 201A 1930h	// start of list address word
DWORD 0000 0013h	// data word 1 (for register 30h)
DWORD FFFF FFAAh	// data word 2 (for register 19h)
DWORD 4033 6480h	// data word 3 (for register 1Ah)
DWORD 0001 0000h	// data word 4 (for register 20h)
DWORD...	// next address word.

This stream of dwords updates the DRW registers as follows:

- Write 0000_0013h to register 30h = 48, which is IRQCTL
- Write FFFF_FFAAh to register 19h = 25, which is COLOR1
- Write 4033_6480h to register 1Ah = 26, which is COLOR2
- Write 0001_0000h to register 20h = 32, which is ORIGIN.

Address word indices

Besides referencing a register, the indices of an address word can also have other meanings, depending on their value.

Table 56.10 Address indices function (1 of 2)

Index	Function	
00h to 7Fh	Register indices Two register indices trigger additional actions:	
	- 20h = 32:	A write to ORIGIN to set a new frame buffer address is delayed until the ongoing frame buffer write-back is complete, when STATUS.BUSYWRITE = 0.
	- 32h = 50:	A write to DLISTSTART sets a new display list start address stops the current display list and starts the new one.
80h	Gap index, which is used to fill unused bytes of an address word. For example, if fewer than four indices are required, the remaining bytes are filled with 80h. In this case, the number of the subsequent data words must be reduced accordingly.	

Table 56.10 Address indices function (2 of 2)

Index	Function	
FFh	If the first index of an address word contains the special index FFh, the subsequent (second) index is interpreted as follows:	
	- Bit [0] set:	Display list end.
	- Bit [1] set:	Issue a full pipeline flush and wait (necessary before flip).
	- Bit [2] set:	Wait for writeback complete (necessary before framebuffer format change).
	- Bits [3:7]	Set all to 0s.
	Bit [1] and [2] settings are mutually exclusive. All indices after the special index FFh are ignored, and the next address word is read, if no display list end (bit [0] = 1) was set.	
	The remaining two indices must be set to 00h.	

Caution: Gap indices 80h must not be placed between other indices, for example as "index1 - 80h - index3 - index4". Always fill all indices after 80h with the gap index.

Caution: If any of the special indices 80h and FFh are used, no register index can follow after them in the same address word.

Table 56.11 2D Drawing Engine registers overview (1 of 2)

Register function	Symbol	Index
Control registers:		
Geometry control 0	CONTROL	0
Surface control	CONTROL2	1
Interrupt control	IRQCTL	48
Cache control	CACHECTL	49
Status control	STATUS	n.a.*1
Hardware version and feature set ID	HWREVISION	n.a.*1
Color registers:		
Base color	COLOR1	25
Secondary color	COLOR2	26
Pattern	PATTERN	29
Limiter registers:		
Limiter 1 start value	L1START	4
Limiter 2 start value	L2START	5
Limiter 3 start value	L3START	6
Limiter 4 start value	L4START	7
Limiter 5 start value	L5START	8
Limiter 6 start value	L6START	9
Limiter 1 x-axis increment	L1XADD	10
Limiter 2 x-axis increment	L2XADD	11
Limiter 3 x-axis increment	L3XADD	12
Limiter 4 x-axis increment	L4XADD	13
Limiter 5 x-axis increment	L5XADD	14

Limiter 3 y-axis increment	L3YADD	18
Limiter 4 y-axis increment	L4YADD	19
Limiter 5 y-axis increment	L5YADD	20
Limiter 6 y-axis increment	L6YADD	21
Limiter 1 band width parameter	L1BAND	22

Table 56.11 2D Drawing Engine registers overview (2 of 2)

Register function	Symbol	Index
Limiter 2 band width parameter	L2BAND	23
Texture registers:		
Texture base address	TEXORIGIN	47
Texels per texture line	TEXPITCH	45
Texture size or texture address mask	TEXMASK	46
U limiter start value	LUSTART	36
U limiter x-axis increment	LUXADD	37
U limiter y-axis increment	LUYADD	38
V limiter start value integer part	LVSTARTI	39
V limiter start value fractional part	LVSTARTF	40
V limiter x-axis increment integer part	LVXADDI	41
V limiter y-axis increment integer part	LVYADDI	42
V limiter increment fractional parts	LVYXADDF	43
Color lookup table start address	TEXCLADDR	55
Write Data to DRWTEXCLADDR; after each data write, DRWTEXCLADDR is incremented by 1.	TEXCLDATA	56
Offset to the index for the indexed texture formats i8, i4, i2, and i1	TEXCLOFFSET	57
Compare value for R,G, B components of internal texel color representation.	COLKEY	58
Miscellaneous registers:		
Bounding box dimension	SIZE	30
Framebuffer pitch and spanstore delay	PITCH	31
Address of the first pixel in framebuffer	ORIGIN	32
Display list start address	DLISTSTART	50
Performance counters control	PERFTRIGGER	53
Performance counter 1	PERFCOUNT1	51
Performance counter 2	PERFCOUNT2	52

Note 1. These registers are read-only and cannot be accessed in display list mode, and they therefore have no index.

56.7.3 Stopping the Render Process

Stopping an ongoing render process requires a specific procedure, which is described in section 56.10, Stopping the 2D Drawing Engine Render Process.

56.8 Interrupts

The 2D Drawing Engine generates three interrupts:

- DRWBUSIRQ
- DRWENUMIRQ
- DRWDLISTIRQ.

56.8.1 Interrupt sources

DRWBUSIRQ

This is the 2D Drawing Engine bus error interrupt. It occurs when the 2D Drawing Engine attempts to access an undefined address range through the following:

- Framebuffer Base Address Register ORIGIN
- Texture Base Address Register TEXORIGIN

- Display List Start Address Register (DLISTSTART).

The bus error interrupt DRWBUSIRQ is then generated. The bus error interrupt only serves for debugging purposes. The interrupt source can be determined by the BUSERRMFB, BUSERRMTXMRL, and BUSERRMDL bits of the STATUS register.

Note: After a DRWBUSIRQ occurrence, you must apply a system reset.

DRWENUMIRQ

This is the current render process finished interrupt.

DRWDLISTIRQ

This is the display list interrupt. It is asserted on completion of a display list process. DRWDLISTIRQ is activated if one of the following is true:

- The entire display list is complete
- The display list processing stops because a new display list start is triggered by a write to the Display List Start Address Register (DLISTSTART).

56.8.2 Interrupt Control

The three 2D Drawing Engine interrupts are combined into a single shared interrupt, DRW_IRQ, to the CPU. Each interrupt can be masked (disabled), or unmasked (enabled) by setting its associated enable bit in the Interrupt Control Register (IRQCTL).

The occurrence of an enabled interrupt (one with its mask bit set to 1 in IRQCTL) is monitored in the Status Control Register (STATUS) with its associated interrupt status bit is set to 1. The shared 2D Drawing Engine interrupt DRW_IRQ is then generated.

To clear the interrupt, the host CPU must write 1 to the interrupt clear bit in IRQCTL. The interrupt clear bit returns to 0 automatically.

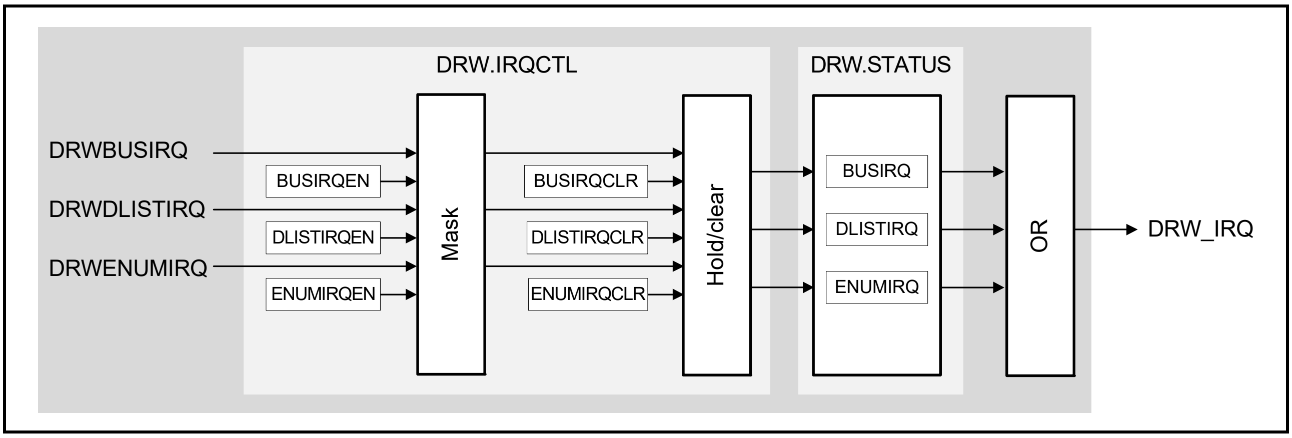

Figure 56.25 Interrupt Controller Unit (ICU)

56.9 Performance Counters

The 2D Drawing Engine features two independent 32-bit performance counter registers (PERFCOUNTk (k = 1, 2)) to count the number of occurrences of a certain event. The events to be counted can be set up independently for each performance counter register with the Performance Counter Control Registers, PERFTRIGGER.PERFTRIGGER2 for PERFCOUNT2 and PERFTRIGGER.PERFTRIGGER1 for PERFCOUNT1.

Table 56.12 lists the performance counter trigger events that can be selected.

Table 56.12 Performance counter trigger events

PERFTRIGGER.PERFTRIGGERk	Event
0	Disable performance counter
1	2D Drawing Engine active cycles
2	Framebuffer read access
3	Framebuffer write access
4	Texture read access
5	Invisible pixels (enumerated but selected with alpha 0%)
6	Invisible pixels while internal FIFO is empty (lost cycles)
7	Display list reader active cycles
8	Framebuffer read hits
9	Framebuffer read misses
10	Framebuffer write hits
11	Framebuffer write misses
12	Texture read hits
13	Texture read misses
31	Every clock cycle (for use as timer)

56.10 Stopping the 2D Drawing Engine Render Process

If a render process has started either in register or display list mode, the 2D Drawing Engine processes the data autonomously until the render process is finished. Depending on the rendering, this process might take several milliseconds.

If the 2D Drawing Engine is to be disabled because, for example, the MCU enters a low power mode, proceed as follows to stop the ongoing rendering:

1. Set the following registers as follows:

   SIZE = 0001 0001h
      Set bounding box dimensions to 1 pixel x 1 line.
   CONTROL2 = 0000 0000h
      Color format a (8), no texture, CLUT.
   ORIGIN = UnmappedAddress
      The UnmappedAddress is an address that is not available for 2D Drawing Engine access.
      The recommended UnmappedAddress is given here under the key word “UnmappedAddress”.
   Alternatively do the same in display list mode:

   ```
   DWORD 8020 011Eh             // start of “address word” list
   DWORD 0001 0001h             // SIZE = 0001 0001h
   DWORD 0000 0000h             // CONTROL2 = 0000 0000h
   DWORD UnmappedAddress        // ORIGIN = UnmappedAddress
   ```
2. Wait for the Bus Error corresponding to the unmapped address violation, which indicates access to an unmapped address and the stop of the render process.
   UnmappedAddress = FFFF FFF0h
3. Disable the 2D Drawing Engine, if wanted.

57. JPEG Codec (JPEG)

57.1 Overview

The JPEG Codec conforms to the JPEG baseline compression and decompression standard to provide high-speed compression of image data and high-speed decoding of JPEG data. Table 57.1 lists the JPEG Codec specifications and Figure 57.1 shows a block diagram.

Table 57.1 JPEG Codec specifications

Parameter	Specifications
Compliant standard	Complies with JPEG Baseline standard within the range described in this document. The JPEG Codec does not support the following features: • Scanning with two elements • Non-interleave scanning with multiple elements
Operational precision	Conforms to JPEG Part 2, ISO-IEC10918-2
Image input/output system	Block interleave method
Pixel format	• Compression: YCbCr422 (H = 2:1:1, V = 1:1:1) • Decompression: YCbCr444 (H = 1:1:1, V = 1:1:1), YCbCr422 (H = 2:1:1, V = 1:1:1), YCbCr411 (H = 4:1:1, V = 1:1:1), YCbCr420 (H = 2:1:1, V = 2:1:1) • Output pixel format to the buffer: ARGB8888, RGB565
Quantization table	• Four tables provided
Huffman table	• Four tables provided (two tables for AC coefficients and two tables for DC coefficients)
Markers supported	SOI (start of image), SOF0 (start of frame type 0), SOS (start of scan), DQT (define quantization tables), DHT (define Huffman tables), DRI (define restart interval), RSTm (restart marks), and EOI (end of image)
Processing unit	8-byte address boundary units can be set
Image sizes that can be processed	Sizes divisible by the minimum coded unit (MCU): 8 lines by 8 pixels in YCbCr444, 8 lines by 16 pixels in YCbCr422, 8 lines by 32 pixels in YCbCr411, 16 lines by 16 pixels in YCbCr420

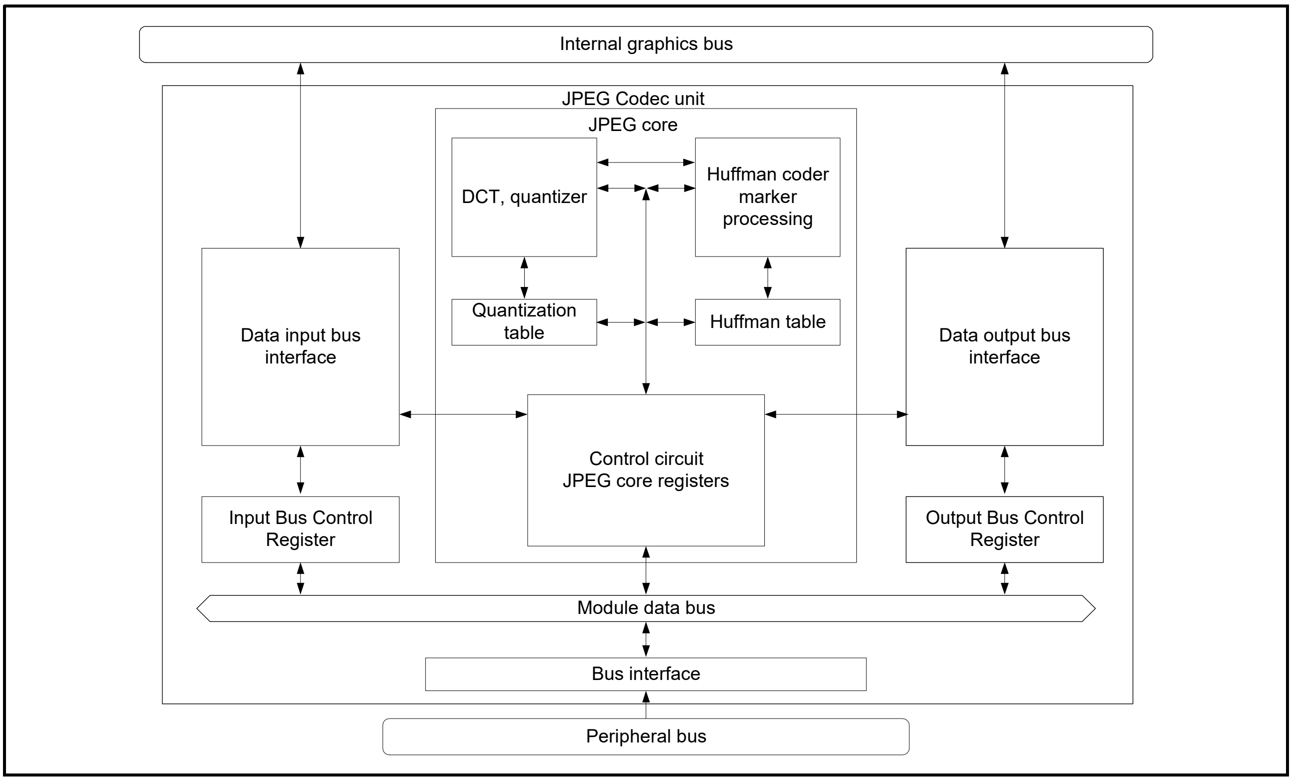

Figure 57.1 JPEG Codec block diagram

Note: When using the JPEG, set the clock to ICLK = PCLKA.

57.2 Register Descriptions

57.2.1 JPEG Code Mode Register (JCMOD)

Address(es): JPEG.JCMOD 400E 6000h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	DSP	REDU[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	REDU[2:0]	Pixel Format	- With compression b2 b0 0 0 1: YCbCr422. Other settings are prohibited. - With decompression b2 b0 0 0 0: YCbCr444 0 0 1: YCbCr422 1 1 0: YCbCr411 0 1 0: YCbCr420. Other settings result in an error. The JPEG Codec cannot process them normally.	R/W*2
b3	DSP	Compression/Decompression Set*1	0: Select compression process 1: Select decompression process.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When changing between processing for compression and decompression, you must reset the JPEG Codec in advance by setting the BRST bit in JPEG Code Command Register (JCCMD).

Note 2. In decompression mode, these bits are read-only.

57.2.2 JPEG Code Command Register (JCCMD)

Address(es): JPEG.JCCMD 400E 6001h

	b7	b6	b5	b4	b3	b2	b1	b0
	BRST	—	—	—	—	JEND	JRST	JSRT
Value after reset:	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b0	JSRT	JPEG Core Process Start Command	Set this bit to 1 to start JPEG core processing. Do not write this bit to 1 again while the JPEG Codec is in operation.	W
b1	JRST	JPEG Core Process Stop Clear Command	Set this bit to 1 to clear the process-stopped state caused by requests to read the image size and pixel format (enabled in the INT3 bit in JINTE0).	W*1
b2	JEND	Interrupt Request Clear Command	Set this bit to 1 to clear an interrupt request. This bit is only valid for the interrupt sources associated with the INS6, INS5, and INS3 bits in JINTS0.	W

Bit	Symbol	Bit name	Description	R/W
b6 to b3	—	Reserved	The write value should be 0.	W
b7	BRST	Bus Reset	Set this bit to 1 to reset the JCDTCU, JCDTCM, JCDTCD, JCDERR and JCRST registers. Do not set this bit to 1 while the JPEG Codec is in operation (from setting the JPEG core process start command to writing the last output code and image data). For the bus reset processing, see section 57.5, Bus Reset Processing.	W

Note: Clearing the bits in this register to 0 after setting a command is not required. Multiple commands must not be set simultaneously.

Note 1. In compression mode, this bit is invalid.

57.2.3 JPEG Code Quantization Table Number Register (JCQTN)

Address(es): JPEG.JCQTN 400E 6003h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	QT3[1:0]		QT2[1:0]		QT1[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b1, b0	QT1[1:0]	Quantization Table Number for the First Color Component	b1 b0 0 0: Quantization table 0 (JCQTBL0) 0 1: Quantization table 1 (JCQTBL1) 1 0: Quantization table 2 (JCQTBL2) 1 1: Quantization table 3 (JCQTBL3).	R/W*1
b3, b2	QT2[1:0]	Quantization Table Number for the Second Color Component	b3 b2 0 0: Quantization table 0 (JCQTBL0) 0 1: Quantization table 1 (JCQTBL1) 1 0: Quantization table 2 (JCQTBL2) 1 1: Quantization table 3 (JCQTBL3).	R/W*1
b5, b4	QT3[1:0]	Quantization Table Number for the Third Color Component	b5 b4 0 0: Quantization table 0 (JCQTBL0) 0 1: Quantization table 1 (JCQTBL1) 1 0: Quantization table 2 (JCQTBL2) 1 1: Quantization table 3 (JCQTBL3).	R/W*1
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In decompression mode, these bits are read-only.

57.2.4 JPEG Code Huffman Table Number Register (JCHTN)

Address(es): JPEG.JCHTN 400E 6004h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	HTA3	HTD3	HTA2	HTD2	HTA1	HTD1
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	HTD1	Huffman Table Number (DC) for the First Color Component	b1 b0 0 0: DC/AC Huffman table 0 (JCHTBD0 and JCHTBA0) 1 1: DC/AC Huffman table 1 (JCHTBD1 and JCHTBA1). Other settings are prohibited.	R/W*1
b1	HTA1	Huffman Table Number (AC) for the First Color Component		R/W*1
b2	HTD2	Huffman Table Number (DC) for the Second Color Component	b3 b2 0 0: DC/AC Huffman table 0 (JCHTBD0 and JCHTBA0) 1 1: DC/AC Huffman table 1 (JCHTBD1 and JCHTBA1). Other settings are prohibited.	R/W*1
b3	HTA2	Huffman Table Number (AC) for the Second Color Component		R/W*1
b4	HTD3	Huffman Table Number (DC) for the Third Color Component	b5 b4 0 0: DC/AC Huffman table 0 (JCHTBD0 and JCHTBA0) 1 1: DC/AC Huffman table 1 (JCHTBD1 and JCHTBA1). Other settings are prohibited.	R/W*1
b5	HTA3	Huffman Table Number (AC) for the Third Color Component		R/W*1
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In decompression mode, these bits are read-only.

57.2.5 JPEG Code DRI Upper Register (JCDRIU)

Address(es): JPEG.JCDRIU 400E 6005h

	b7	b6	b5	b4	b3	b2	b1	b0
	DRIU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	DRIU[7:0]	Upper Bytes of MCUs Preceding RST Marker	Valid settings: 00h to FFh (0 to 255).*1	R/W*2

Note 1. When both JCDRIU = 00h and JCDRID = 00h, neither the DRI nor the RST marker is placed.
Note 2. In decompression mode, these bits are invalid.

57.2.6 JPEG Code DRI Lower Register (JCDRID)

Address(es): JPEG.JCDRID 400E 6006h

	b7	b6	b5	b4	b3	b2	b1	b0
	DRIU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	DRIU[7:0]	Lower Bytes of MCUs Preceding RST Marker	Valid settings: 00h to FFh (0 to 255).*1	R/W*2

Note 1. When both JCDRIU = 00h and JCDRID = 00h, neither the DRI nor the RST marker is placed.
Note 2. In decompression mode, these bits are invalid.

57.2.7 JPEG Code Vertical Size Upper Register (JCVSZU)

Address(es): JPEG.JCVSZU 400E 6007h

	b7	b6	b5	b4	b3	b2	b1	b0
	VSZU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	VSZU[7:0]	Upper Bytes of Vertical Image Size	Valid settings: 00h to FFh (0 to 255).*2	R/W*1

Note 1. In decompression mode, these bits are read-only.
Note 2. In the decompression process, a downloaded value from the JPEG coded data is set.

57.2.8 JPEG Code Vertical Size Lower Register (JCVSZD)

Address(es): JPEG.JCVSZD 400E 6008h

	b7	b6	b5	b4	b3	b2	b1	b0
	VSZD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	VSZD[7:0]	Lower Bytes of Vertical Image Size	Valid settings: 00h to FFh (0 to 255).*2	R/W*1

Note 1. In decompression mode, these bits are read-only.
Note 2. In the decompression process, a downloaded value from the JPEG coded data is set.

57.2.9 JPEG Code Horizontal Size Upper Register (JCHSZU)

Address(es): JPEG.JCHSZU 400E 6009h

	b7	b6	b5	b4	b3	b2	b1	b0
	HSZU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	HSZU[7:0]	Upper Bytes of Horizontal Image Size	Valid settings: 00h to FFh (0 to 255).*2	R/W*1

Note 1. In decompression mode, these bits are read-only.
Note 2. In the decompression process, a downloaded value from the JPEG coded data is set.

57.2.10 JPEG Coded Horizontal Size Lower Register (JCHSZD)

Address(es): JPEG.JCHSZD 400E 600Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	HSZD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	HSZD[7:0]	Lower Bytes of Horizontal Image Size	Valid settings: 00h to FFh (0 to 255).*2	R/W*1

Note 1. In decompression mode, these bits are read-only.
Note 2. In the decompression process, a downloaded value from the JPEG coded data is set.

57.2.11 JPEG Code Data Count Upper Register (JCDTCU)

Address(es): JPEG.JCDTCU 400E 600Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	DCU[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	DCU[7:0]	Upper Bytes of Counted Amount of Data to Be Compressed	Valid settings: 00h to FFh (0 to 255).	R*2

Note 1. The values in this register are reset before compression starts.
Note 2. In decompression mode, these bits are invalid.

57.2.12 JPEG Code Data Count Middle Register (JCDTCM)

Address(es): JPEG.JCDTCM 400E 600Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	DCM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	DCM[7:0]	Middle Bytes of Counted Amount of Data to Be Compressed	Valid settings: 00h to FFh (0 to 255).	R*2

Note 1. The values in this register are reset before compression starts.
Note 2. In decompression mode, these bits are invalid.

57.2.13 JPEG Code Data Count Lower Register (JCDTCD)

Address(es): JPEG.JCDTCD 400E 600Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	DCD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	DCD[7:0]	Lower Bytes of Counted Amount of Data to Be Compressed	Valid settings: 00h to FFh (0 to 255).	R*2

Note 1. The values in this register are reset before compression starts.
Note 2. In decompression mode, these bits are invalid.

57.2.14 JPEG Interrupt Enable Register 0 (JINTE0)

Address(es): JPEG.JINTE0 400E 600Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	INT7	INT6	INT5	—	INT3	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	INT3	Interrupt Request Signal INS3 Enable Control	Enables interrupt generation when determined that image size and pixel format of compressed data can be read by analyzing the data.	R/W*2
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	INT5	Interrupt Request Last MCU Data Number Error Enable Control	Enables interrupt generation when final number of MCU data units in Huffman-coding segment is not correct in decompression. When this bit is not set to enable, no error code is returned.	R/W*2
b6	INT6	Interrupt Request Total Number Error Enable Control	Enables interrupt generation when total number of data units in Huffman-coding segment is not correct in decompression. When this bit is not set to enable, no error code is returned.	R/W*2

Bit	Symbol	Bit name	Description	R/W
b7	INT7	Interrupt Request Restart Interval Data Number Error Enable Control	Enables interrupt generation when number of data units in restart interval of Huffman-coding segment is not correct in decompression. When this bit is not set to enable, no error code is returned.	R/W*2

Note 1. When any of the bits from INT7 to INT5 sets to 1, the INS5 bit in the JINTS0 register indicates 1 as the error status on occurrence of the compression data error, and the ERR[3:0] bits in the JCDERR register indicate the specific error code.
Note 2. In compression mode, these bits are invalid.

57.2.15 JPEG Interrupt Status Register 0 (JINTS0)

Address(es): JPEG.JINTS0 400E 600Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	INS6	INS5	—	INS3	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	INS3	Request for Reading the Image Size and Pixel Format	This bit sets to 1 when image size and pixel format can be read. When an interrupt occurs, the JPEG Codec stops processing and the state is indicated in the JCRST register. To resume module processing, set the JPEG Core Process Stop Clear Command Bit (JRST) in JCCMD.	R/W*2, *3
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	INS5	JPEG Decompression Error Occurrence	This bit sets to 1 when a compressed data error occurs.	R/W*2, *3
b6	INS6	JPEG Decompression Process End	This bit sets to 1 when the JPEG Codec completes compression process normally.	R/W*2
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The interrupt sources in this register should be cleared by clearing the associated interrupt status bits to 0 and setting the relevant bit in JCCMD appropriately.
Note 2. Clear this bit by writing 0 to it. Do not write 1 to this bit.
Note 3. In compression mode, these bits are invalid.

57.2.16 JPEG Code Decode Error Register (JCDERR)

Address(es): JPEG.JCDERR 400E 6010h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ERR[3:0]			
Value after reset:	0	0	0	0	1	0	1	0

Bit	Symbol	Bit name	Description	R/W
b3 to b0	ERR[3:0]	Error Code	See Table 57.3 and Table 57.4. for error codes.	R/W*2
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The values in this register are reset before the JPEG Codec starts decompression.
Note 2. In compression mode, these bits are invalid.

57.2.17 JPEG Code Reset Register (JCRST)

Address(es): JPEG.JCRST 400E 6011h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	RST	Operating State	0: All other states 1: Suspended state caused by JINTE0 interrupt sources.	R*2
b7 to b1	—	Reserved	These bits are read as 0.	R

Note 1. To resume processing, set the JPEG core process stop clear command bit (JRST) in JCCMD.
Note 2. In compression mode, this bit is invalid.

57.2.18 JPEG Interface Compression Control Register (JIFECNT)

Address(es): JPEG.JIFECNT 400E 6040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	JOUTSWAP[2:0]			—	DINRINI	DINRCMD	DINLC	—	DINSWAP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	DINSWAP[2:0]	Byte/Halfword/Word Swap	Swaps input image data in compression. b2 b0 0 0 0: (1) (2) (3) (4) (5) (6) (7) (8) 0 0 1: (2) (1) (4) (3) (6) (5) (8) (7) [Byte swap] 0 1 0: (3) (4) (1) (2) (7) (8) (5) (6) [Halfword swap] 0 1 1: (4) (3) (2) (1) (8) (7) (6) (5) [Halfword - byte swap] 1 0 0: (5) (6) (7) (8) (1) (2) (3) (4) [Word swap] 1 0 1: (6) (5) (8) (7) (2) (1) (4) (3) [Word - byte swap] 1 1 0: (7) (8) (5) (6) (3) (4) (1) (2) [Word - halfword swap] 1 1 1: (8) (7) (6) (5) (4) (3) (2) (1) [Word - halfword - byte swap].	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	DINLC	Count Mode Setting for Stopping Input Image Data Lines	0: Turn off count mode for stopping input of image data lines 1: Turn on count mode for stopping input of image data lines.	R/W*1
b5	DINRCMD	Input Image Data Lines Resume Command	Set this bit to 1 to resume reading of input image data. This bit is only valid when the count mode for stopping input of image data lines is on. This bit is always read as 0.	W*1
b6	DINRINI	Address Initialization when Resuming Input of Image Data Lines	This bit is only valid when the count mode for stopping input of image data lines is on. Set this bit before writing 1 to the data-line resume command bit. 0: Do not initialize transfer address when input of image data lines restarts 1: Initialize transfer address when input of image data lines restarts.	R/W*1
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Bit name	Description	R/W
b10 to b8	JOUTSWAP[2:0]	Byte/Halfword/Word Swap	Swaps output coded data in compression. b10 b8 0 0 0: (1) (2) (3) (4) (5) (6) (7) (8) 0 0 1: (2) (1) (4) (3) (6) (5) (8) (7) [Byte swap] 0 1 0: (3) (4) (1) (2) (7) (8) (5) (6) [Halfword swap] 0 1 1: (4) (3) (2) (1) (8) (7) (6) (5) [Halfword - byte swap] 1 0 0: (5) (6) (7) (8) (1) (2) (3) (4) [Word swap] 1 0 1: (6) (5) (8) (7) (2) (1) (4) (3) [Word - byte swap] 1 1 0: (7) (8) (5) (6) (3) (4) (1) (2) [Word - halfword swap] 1 1 1: (8) (7) (6) (5) (4) (3) (2) (1) [Word - halfword - byte swap].	R/W*1
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In decompression mode, these bits are invalid.

57.2.19 JPEG Interface Compression Source Address Register (JIFESA)

Address(es): JPEG.JIFESA 400E 6044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ESA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ESA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	ESA[2:0]	Input Image Data Source Address	The lower three bits should be set to 0. These bits are read as 0.	R/W
b31 to b3	ESA[31:3]		Input image data source address in 8-byte units.	R/W*2

Note 1. This register must be set in 8-byte units.

Note 2. In decompression mode, these bits are invalid.

57.2.20 JPEG Interface Compression Line Offset Register (JIFESOFST)

Address(es): JPEG.JIFESOFST 400E 6048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	ESMW[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	ESMW[2:0]	Input Image Data Lines Offset	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b14 to b3	ESMW[14:3]		Input image data lines offset in 8-byte units.	R/W*2
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This register must be set in 8-byte units.

Note 2. In decompression mode, these bits are invalid.

57.2.21 JPEG Interface Compression Destination Address Register (JIFEDA)

Address(es): JPEG.JIFEDA 400E 604Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	EDA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EDA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	EDA[2:0]	Output Coded Data Destination Address	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b31 to b3	EDA[31:3]		Output coded data destination address in 8-byte units.	R/W*2

Note 1. This register must be set in 8-byte units.

Note 2. In decompression mode, these bits are invalid.

57.2.22 JPEG Interface Compression Source Line Count Register (JIFESLC)

Address(es): JPEG.JIFESLC 400E 6050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LINES[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	LINES[2:0]	Number of Input Image Data Lines to Be Read	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b15 to b3	LINES[15:3]		Number of input image data lines to be read, in 8-line units.	R/W*2
b18 to b16	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b31 to b19	—	Reserved	These bits are read as undefined. The write value should be 1	R

Note 1. This register must be set in 8-byte units.

Note 2. In decompression mode, these bits are invalid.

57.2.23 JPEG Interface Decompression Control Register (JIFDCNT)

Address(es): JPEG.JIFDCNT 400E 6058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	VINTER[1:0]		HINTER[1:0]		OPF[1:0]		—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	JINRINI	JINRCMD	JINC	—	JINSWAP[2:0]			—	DOUTRINI	DOUTRCMD	DOUTLC	—	DOUTSWAP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	DOUTSWAP[2:0]	Byte/Halfword/Word Swap	Swaps output image data in decompression. b2 b0 0 0 0: (1) (2) (3) (4) (5) (6) (7) (8) 0 0 1: (2) (1) (4) (3) (6) (5) (8) (7) [Byte swap] 0 1 0: (3) (4) (1) (2) (7) (8) (5) (6) [Halfword swap] 0 1 1: (4) (3) (2) (1) (8) (7) (6) (5) [Halfword - byte swap] 1 0 0: (5) (6) (7) (8) (1) (2) (3) (4) [Word swap] 1 0 1: (6) (5) (8) (7) (2) (1) (4) (3) [Word - byte swap] 1 1 0: (7) (8) (5) (6) (3) (4) (1) (2) [Word - halfword swap] 1 1 1: (8) (7) (6) (5) (4) (3) (2) (1) [Word - halfword - byte swap].	R/W*1
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	DOUTLC	Count Mode for Stopping Output Image Data Lines	0: Turn off count mode for stopping output of image data lines 1: Turn on count mode for stopping output of image data lines.	R/W*1
b5	DOUTRCMD	Output Image Data Lines Resume Command	Set this bit to 1 to resume writing of image data. This bit is only valid when the count mode for stopping output of image data lines is on. This bit is always read as 0.	W*1
b6	DOUTRINI	Address Initialization When Resuming Output of Image Data Lines	This bit is only valid when the count mode for stopping output of image data lines is on. Set this bit before writing 1 to the data-line resume command bit. 0: Do not initialize transfer address when output of image data lines restarts 1: Initialize transfer address when output of image data lines restarts.	R/W*1
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10 to b8	JINSWAP[2:0]	Byte/Halfword/Word Swap	Swaps input coded data in decompression. b10 b8 0 0 0: (1) (2) (3) (4) (5) (6) (7) (8) 0 0 1: (2) (1) (4) (3) (6) (5) (8) (7) [Byte swap] 0 1 0: (3) (4) (1) (2) (7) (8) (5) (6) [Halfword swap] 0 1 1: (4) (3) (2) (1) (8) (7) (6) (5) [Halfword - byte swap] 1 0 0: (5) (6) (7) (8) (1) (2) (3) (4) [Word swap] 1 0 1: (6) (5) (8) (7) (2) (1) (4) (3) [Word - byte swap] 1 1 0: (7) (8) (5) (6) (3) (4) (1) (2) [Word - halfword swap] 1 1 1: (8) (7) (6) (5) (4) (3) (2) (1) [Word - halfword - byte swap].	R/W*1
b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	JINC	Count Mode Setting for Stopping Input Coded Data	0: Turn off count mode for stopping input of coded data 1: Turn on count mode for stopping input of coded data.	R/W*1
b13	JINRCMD	Input Coded Data Resume Command	Set this bit to 1 to resume reading of input coded data. This bit is only valid when the count mode for stopping input of coded data is on. This bit is always read as 0.	W*1

Bit	Symbol	Bit name	Description	R/W
b14	JINRINI	Address Initialization When Input Coded Data is Resumed	This bit is only valid when the count mode for stopping input of coded data is on. Set this bit before writing 1 to the data resume command bit. 0: Do not initialize transfer address when input of coded data restarts 1: Initialize transfer address when input of coded data restarts.	R/W*1
b23 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	OPF[1:0]	Specifies Output Image Data Pixel Format*2	b25 b24 0 0: Setting prohibited 0 1: ARGB8888 1 0: RGB565 1 1: Setting prohibited.	R/W*1
b27, b26	HINTER[1:0]	Horizontal Subsampling	Subsamples horizontal output image data. b27 b26 0 0: No subsampling 0 1: Subsample output data into 1/2 1 0: Subsample output data into 1/4 1 1: Subsample output data into 1/8.	R/W*1
b29, b28	VINTER[1:0]	Vertical Subsampling	Subsamples vertical output image data. b29 b28 0 0: No subsampling 0 1: Subsample output data into 1/2 1 0: Subsample output data into 1/4 1 1: Subsample output data into 1/8.	R/W*1
b31 to b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In compression mode, these bits are invalid.
Note 2. Operation with the initial value is prohibited. Set these bits to 01b or 10b before starting operation.

57.2.24 JPEG Interface Decompression Source Address Register (JIFDSA)

Address(es): JPEG.JIFDSA 400E 605Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DSA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DSA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	DSA[2:0]	Input Coded Data Source Address	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b31 to b3	DSA[31:3]		Input coded data source address in 8-byte units.	R/W*2

Note 1. This register must be set in 8-byte units.
Note 2. In compression mode, these bits are invalid.

57.2.25 JPEG Interface Decompression Line Offset Register (JIFDDOFST)

Address(es): JPEG.JIFDDOFST 400E 6060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	DDMW[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	DDMW[2:0]	Output Image Data Lines Offset	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b14 to b3	DDMW[14:3]		Output image data lines offset in 8-byte units.	R/W*2
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This register must be set in 8-byte units.
Note 2. In compression mode, these bits are invalid.

57.2.26 JPEG Interface Decompression Destination Address Register (JIFDDA)

Address(es): JPEG.JIFDDA 400E 6064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DDA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DDA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	DDA[2:0]	Output Image Data Destination Address	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b31 to b3	DDA[31:3]		Output image data destination address in 8-byte units.	R/W*2

Note 1. This register must be set in 8-byte units.
Note 2. In compression mode, these bits are invalid.

57.2.27 JPEG Interface Decompression Source Data Count Register (JIFDSDC)

Address(es): JPEG.JIFDSDC 400E 6068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	JDATAS[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	JDATAS[2:0]	Amount of Input Coded Data to Be Read	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b15 to b3	JDATAS[15:3]		Amount of input coded data to be read, in 8-byte units.	R/W*2
b18 to b16	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b31 to b19	—	Reserved	These bits are read as undefined. The write value should be 1.	R

Note 1. This register must be set in 8-byte units.
Note 2. In compression mode, these bits are invalid.

57.2.28 JPEG Interface Decompression Destination Line Count Register (JIFDDLC)

Address(es): JPEG.JIFDDLC 400E 606Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LINES[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	LINES[2:0]	Number of Output Image Data Lines to Be Written	The lower three bits should be set to 0. These bits are read as 0.	R/W*2
b15 to b3	LINES[15:3]		Specifies number of lines of output image data to be written. Set the value so that the output image data line count matches the MCU unit. For YCbCr444, YCbCr422, and YCbCr411 output, the setting value × 1 is equal to the output image data line count. For YCbCr420 output, the setting value × 2 is equal to the output image data line count.	R/W*2
b18 to b16	—	Reserved	These bits are read as undefined. The write value should be 0.	R/W
b31 to b19	—	Reserved	These bits are read as undefined. The write value should be 1.	R

Note 1. Set this register so that the output image data line count matches the MCU unit.
Note 2. In compression mode, these bits are invalid.

57.2.29 JPEG Interface Decompression alpha Set Register (JIFDADT)

Address(es): JPEG.JIFDADT 400E 6070h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ALPHA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	ALPHA[7:0]	Alpha Value for Adding to ARGB8888 Format	Alpha value setting for output in ARGB8888 format.	R/W*1
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In compression mode, these bits are invalid.

57.2.30 JPEG Interrupt Enable Register 1 (JINTE1)

Address(es): JPEG.JINTE1 400E 608Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CBTEN	DINLEN	—	—	DBTEN	JINEN	DOUTLEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	DOUTLEN	Interrupt Request Bit DOUTLF Enable Control	Enables or disables a data transfer processing interrupt request (JPEG_JDTI) when the DOUTLF bit in JINTS1 sets to 1. 0: Disable interrupt request 1: Enable interrupt request.	R/W*1
b1	JINEN	Interrupt Request Bit JINF Enable Control	Enables or disables a data transfer processing interrupt request (JPEG_JDTI) when the JINF bit in JINTS1 sets to 1. 0: Disable interrupt request 1: Enable interrupt request.	R/W*1
b2	DBTEN	Interrupt Request Bit DBTF Enable Control	Enables or disables a data transfer processing interrupt request (JPEG_JDTI) when the DBTF bit in JINTS1 sets to 1. 0: Disable interrupt request 1: Enable interrupt request.	R/W*1
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	DINLEN	Interrupt Request Bit DINLF Enable Control	Enables or disables a data transfer processing interrupt request (JPEG_JDTI) when the DINLF bit in JINTS1 sets to 1. 0: Disable interrupt request 1: Enable interrupt request.	R/W*2

Bit	Symbol	Bit name	Description	R/W
b6	CBTEN	Interrupt Request Bit CBTF Enable Control	Enables or disables a data transfer processing interrupt request (JPEG_JDTI) when the CBTF bit in JINTS1 sets to 1. 0: Disable interrupt request 1: Enable interrupt request.	R/W*2
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. In compression mode, these bits are invalid.
Note 2. In decompression mode, these bits are invalid.

57.2.31 JPEG Interrupt Status Register 1 (JINTS1)

Address(es): JPEG.JINTS1 400E 6090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CBTF	DINLF	—	—	DBTF	JINF	DOUTLF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	DOUTLF	Request for Decompressed Data Output Line Finish	In decompression, this bit sets to 1 when the number of lines of output image data indicated in JIFDDLC is written. This bit is only valid when the DOUTLC bit in JIFDCNT is set to 1.	R/W*1,*2,*3
b1	JINF	Request for JPEG Input Finish	This bit sets to 1 when the amount of input coded data indicated in JIFDSDC is read in decompression. This bit is only valid when the JINC bit in JIFDCNT is set to 1.	R/W*1,*2,*3
b2	DBTF	Request for Decompressed Data Bottom Finish	This bit sets to 1 when the last output image data is written in decompression.	R/W*1,*2,*3
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	DINLF	Request for Data Input Line Finish	This bit sets to 1 when the number of input image data lines indicated in JIFESLC is read in compression. This bit is only valid when the DINLC bit in JIFECNT is set to 1.	R/W*1,*2,*4
b6	CBTF	Request for Compressed Data Bottom Finish	This bit sets to 1 when the last output coded data is written in compression.	R/W*1,*2,*4
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Clear the interrupt sources of this register by writing 0s to this register.
Note 2. When the bit is read as 1, write 0 to clear it. When the bit is read as 0, write 1 to set it.
Note 3. In compression mode, these bits are invalid.
Note 4. In decompression mode, these bits are invalid.

57.3 Operation

57.3.1 Compression

This section describes the compression process flows.

(1) Processing overview

The compression process overview is as follows:

1. The JPEG core is activated. A marker is output, after which, image data can be input. Approximately 30,000 cycles are required (for generating the SOI to SOS markers).

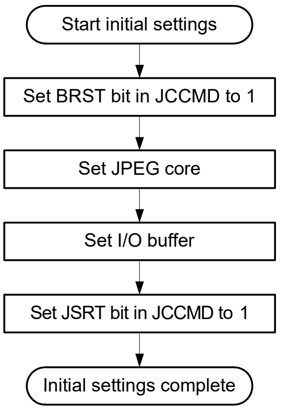
2. Image data is transferred in MCUs from the external buffer to the JPEG Codec.
    - If the count mode for stopping the input of image data lines is on, reading stops each time the number of lines set in JIFESLC is read. To resume reading, set the DINRCMD bit in JIFECNT to 1.
    - When the DINRINI bit in JIFECNT is 0, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
    - When the DINRINI bit is 1, the address set in JIFESA is used on resumption.
    - Reading is also stopped when one frame of image data is completely transferred.
    - If the count mode for stopping the input of image data lines is off, reading continues until one frame of image data is completely transferred.
3. Image data is input to the JPEG core. The input data is processed in MCUs at any time in the JPEG core.
4. Coded data is transferred from the JPEG Codec to the external buffer.
5. Compression is complete after one frame of data is processed completely.

(2) Compression flow

(a) Initial settings

To set the initial settings for compression:

After completing the JPEG core settings and input/output buffer settings and transferring image data to the external buffer, activate the JPEG Codec by setting the JSRT bit in JCCMD to 1. After the JPEG Codec is activated, the JPEG markers (SOI to SOS) are generated and output. Generating the markers takes approximately 30,000 cycles.



JPEG core settings	
Pixel format setting:	REDU bits in JCMOD
Compression setting:	DSP bit in JCMOD
Quantization table number setting:	JCQTN
Huffman table number setting:	JCHTN
DRI setting:	JCDRIU, JCDRID
Vertical image size setting:	JCVSZU, JCVSZD
Horizontal image size setting:	JCHSZU, JCHSZD
Quantization table setting:	JCQTBL0 to JCQTBL3
Huffman table setting:	JCHTBD0, JCHTBD1, JCHTBA0, JCHTBA1
I/O buffer settings	
Byte/halfword/word swap setting:	JOUTSWAP[2:0], DINSWAP[2:0] bits in JIFECNT
Input data line stop count mode setting:	DINLC bit in JIFECNT
Address initialization setting for resumption of input image data:	DINRINI bit in JIFECNT
Source address setting:	JIFESA
Line offset setting:	JIFESOFST
Destination address setting:	JIFEDA
Source line count setting:	JIFESLC
Interrupt settings:	CBTEN, DINLEN bits in JINTE1

Figure 57.2 Flow of compression initial settings

(b) Compression process

The compression process flow is as follows:

1. When JPEG compression process is completed, the INS6 bit in JINTS0 sets to 1. However, the JPEG Codec continues processing, because the coded data remains to be transferred. The CBTF bit in JINTS1 sets to 1 when the last coded data is transferred. The interrupt source is cleared by a 0 write to the INS6 bit. However, the interrupt request asserted by this interrupt source cannot be cleared by a 0 write to the INS6 bit. Set an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request.
2. When the JPEG Codec has completed compression and all coded data is transferred, the CBTF flag in JINTS1 sets to 1. When the CBTEN bit in JINTE1 is 1 here, an interrupt is generated. The interrupt source is cleared by a 0 write to the CBTF flag.

3. If the count mode for stopping image data lines is on, when the specified number of image data lines set in JIFESLC is read, the DINLF flag in JINTS1 sets to 1, and reading stops. When the DINLEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by a 0 write to the DINLEN bit. Setting the DINRCMD bit in JIFECNT to 1 resumes reading.
    - When the DINRINI bit in JIFECNT is 0, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
    - When the DINRINI bit is 1, the address set in JIFESA is used on resumption.

(c) Data correction

After the output coded data is divided by 8, if the remainder is 1 to 6 bytes, transfer of bytes 1 to 6 of the remainder might not complete successfully. If the transfer is unsuccessful, bytes 1 to 6 of the remainder are written to the address specified in the JPEG interface compression destination address register (JIFEDA), overwriting the existing data.*1

For this reason, it is necessary to check whether the output coded data was transferred successfully and, if not, to perform data correction.

Note 1. The JPEG Codec handles the output of coded data in 16-bit units. For this reason, if the coded data has an odd code length, the final code output is D9FFh. (FFh is appended.) When the remainder is 1, 3, or 5 bytes, the remainder data (1, 3, or 5 bytes) + FFh is written to the address specified in JIFEDA, overwriting the existing data.

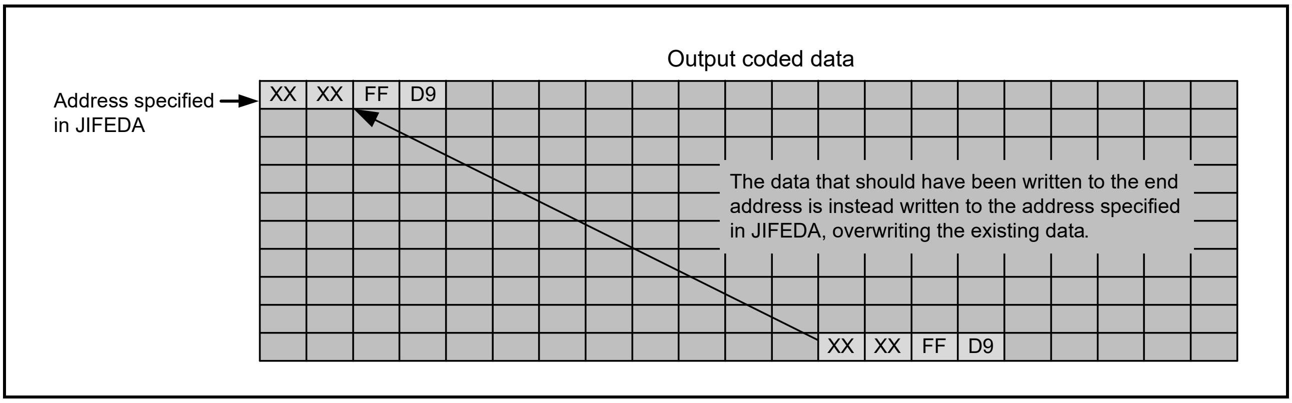


Figure 57.3 Conceptual diagram of abnormal transfer of output coded data

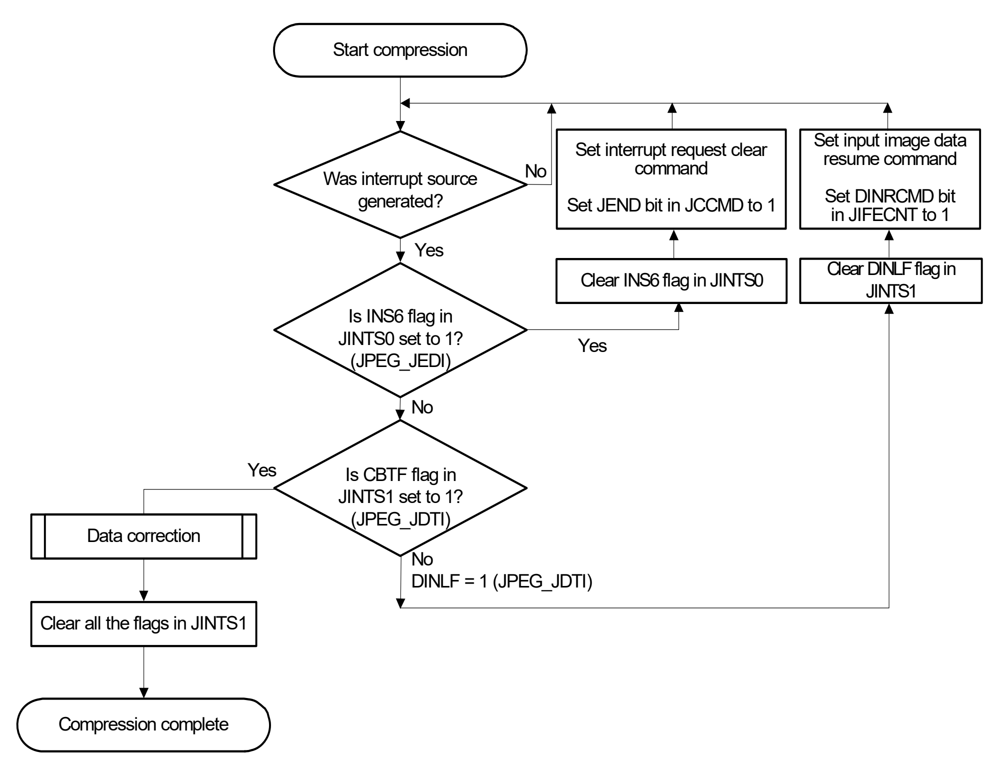

Figure 57.4 Compression process flow

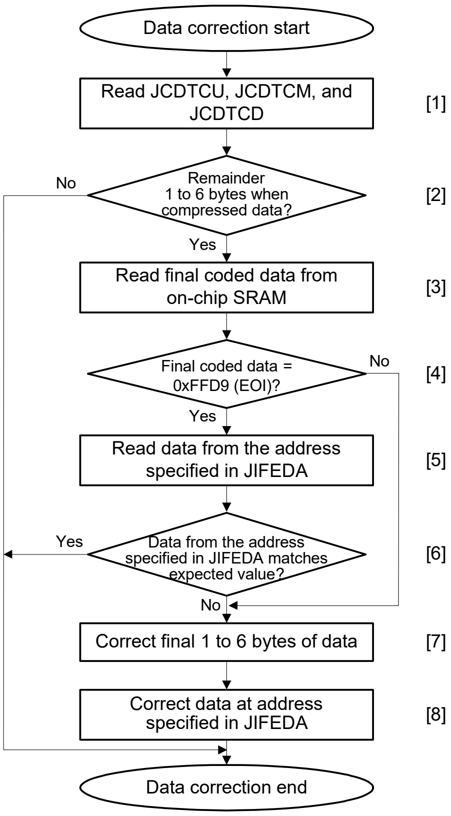

[1] Read the compressed data volume from JCDTCU, JCDTCM, and JCDTCD.

[2] After dividing the compressed data volume by 8, determine whether the remainder is 1 to 6 bytes.

[3] Based on the compressed data volume read in [1], read the data from the address to which the final coded data (0xFFD9) was written.

[4] Determine if the final coded data EOI (0xFFD9) was written.

[5] Read from the address specified in JIFEDA the number of remainder data bytes calculated in [2].

[6] Determine whether the data read from the address specified in JIFEDA matches the expected value. This is the beginning of the JPEG data, so the expected value is 0xFFD8 (SOI), 0xFFDB (DQT), 0x00XX (XX: 0x84 for quantization table 2, 0xC5 for quantization table 3).

[7] If the transfer did not complete successfully, write the 1 to 6 bytes read in [6] to the end address.

[8] Some data is overwritten, so correct the data at the address specified in JIFEDA.

Note 1. If the coded data has an odd code length, the final code output is D9FFh. (FFh is appended.) Therefore, when the remainder is 1, 3, or 5 bytes, this should be corrected to 2, 4, or 6 bytes of data, respectively.

Figure 57.5 Data correction flow

(3) JPEG coded data format

Figure 57.6 shows the data output stream in compression. The amount of coded data from SOI to EOI is indicated in JCDTCU, JCDTCM, and JCDTCD. When both JCDRIU and JCDRID are set to 0000_0000h, the following markers are not output:

- DRI marker
- RST marker (in compressed image data).

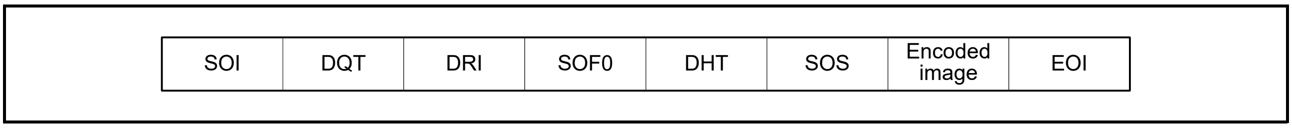

Figure 57.6 JPEG coded data format

- DQT: Not output for unused table
- DHT: Output in the order DC0, AC0, DC1, and AC1. Not output for unused tables
- SOF0: Component identifiers are C1 = first color component, C2 = second color component, and C3 = third color component
- SOS: Scan component selectors are CS1 = first color component, CS2 = second color component, and CS3 = third color component.

Header volume (reference)

- SOI: 2 bytes (FFD8)
- DQT: 134 bytes when two quantization tables are used, 199 bytes when three quantization tables are used (±65 bytes/table increase or decrease)
- DRI: 6 bytes
- SOF0: 19 bytes (4:2:2)
- DHT: 420 bytes (two tables are used)
- SOS: 14 bytes (4:2:2)
- EOI: 2 bytes (FFD9).

(4) Table setting

(a) Quantization table specification

The order of addresses shown in 8 × 8 blocks corresponds to that of the register addresses. Do not access this table while the JPEG Codec is processing.

Table 57.2 Quantization table

00	01	02	03	04	05	06	07
08	09	0A	0B	0C	0D	0E	0F

JCQTBL3 (400E 61C0h) = C0h
JCQTBL3 (400E 61C1h) = C1h
JCQTBL3 (400E 61C2h) = C2h
JCQTBL3 (400E 61C3h) = C3h
:
JCQTBL3 (400E 61FFh) = FFh

(b) Huffman table specification

This section provides examples of the Huffman table specification given in the ITU-T T81 Annex K.3.3 recommended by JPEG. In compression, the following settings must be specified for all the codes so that Huffman codes can be generated for all the group numbers.

- DC Huffman table: The number of codes for each code length is 12, and the group numbers in the order of frequency of occurrence are 12.
- AC Huffman table: The number of codes for each code length is 162, and the zero run length/group numbers in the order of frequency of occurrence are 162.

Do not access the following tables while the JPEG Codec is processing. In particular, read access is prohibited.

- Table K.3/T81

JCHTBD0 (400E 6200h) = 00h
JCHTBD0 (400E 6201h) = 01h
JCHTBD0 (400E 6202h) = 05h
JCHTBD0 (400E 6203h) = 01h
:
JCHTBD0 (400E 621Bh) = 0Bh

JCHTBA1 (400E 6323h) = 02h
:
JCHTBA1 (400E 63D1h) = FAh

(5) Input pixel format

Image data in the YCbCr422 format can be input to the JPEG Codec. Allocation of data in the YCbCr422 format can be changed by the DINSWAP[2:0] bits in JIFECNT as shown in the following diagrams.

- When the DINSWAP[2:0] bits = 000b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Y0 8 bits	Cb0 8 bits	Y1 8 bits	Cr0 8 bits	Y2 8 bits	Cb1 8 bits	Y3 8 bits	Cr1 8 bits

- When the DINSWAP[2:0] bits = 001b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Cb0 8 bits	Y0 8 bits	Cr0 8 bits	Y1 8 bits	Cb1 8 bits	Y2 8 bits	Cr1 8 bits	Y3 8 bits

- When the DINSWAP[2:0] bits = 010b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Y1 8 bits	Cr0 8 bits	Y0 8 bits	Cb0 8 bits	Y3 8 bits	Cr1 8 bits	Y2 8 bits	Cb1 8 bits

- When the DINSWAP[2:0] bits = 100b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Y2 8 bits	Cb1 8 bits	Y3 8 bits	Cr1 8 bits	Y0 8 bits	Cb0 8 bits	Y1 8 bits	Cr0 8 bits

- When the DINSWAP[2:0] bits = 101b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Cb1 8 bits	Y2 8 bits	Cr1 8 bits	Y3 8 bits	Cb0 8 bits	Y0 8 bits	Cr0 8 bits	Y1 8 bits

- When the DINSWAP[2:0] bits = 110b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Y3 8 bits	Cr1 8 bits	Y2 8 bits	Cb1 8 bits	Y1 8 bits	Cr0 8 bits	Y0 8 bits	Cb0 8 bits

- When the DINSWAP[2:0] bits = 111b

b63 b56	b55 b48	b47 b40	b39 b32	b31 b24	b23 b16	b15 b8	b7 b0
Cr1 8 bits	Y3 8 bits	Cb1 8 bits	Y2 8 bits	Cr0 8 bits	Y1 8 bits	Cb0 8 bits	Y0 8 bits

(6) Output coded data

For compression, coded data is output. The JPEG Codec handles the output of coded data in 16-bit units. For this reason, if the coded data has an odd code length such as fractional, the final code for output is D9FFh.

The JOUTSWAP[2:0] bits in JIFECNT can be used to alter the arrangement of coded data in output.

57.3.2 Decompression

This section describes the decompression process flows.

(1) Processing overview

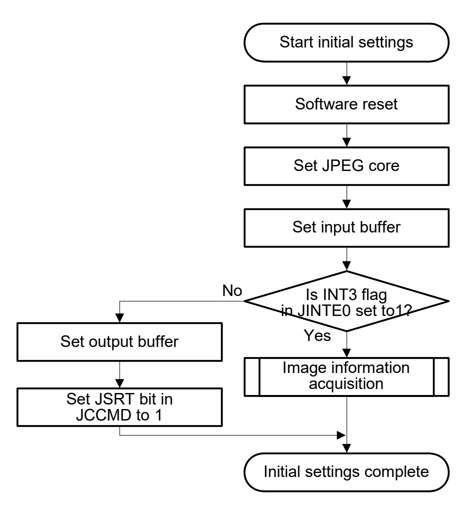
The decompression process overview is as follows:

1. The JPEG core is activated.
2. Coded data is transferred from the external buffer to the JPEG Codec.
    - If the count mode for stopping the input of coded data is on, reading stops each time the amount of coded data set in JIFDSLC is read. To resume reading, set the JINRCMD bit in JIFDCNT to 1.
    - When the JINRINI bit in JIFDCNT is 0, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
    - When the JINRINI bit is 1, the address set in JIFDSA is used on resumption.
    - Reading stops when the end of the coded data is detected.
    - If the count mode for stopping the input of coded data is off, reading continues until the end of code is detected. With this JPEG Codec, more coded data can be read than the coded data size because coded data reading continues until the end of code is detected.
3. Coded data is input to the JPEG core. The input data is processed in MCUs at any time in the JPEG core.
4. Image data is transferred in MCUs from the JPEG Codec to the external buffer.
    - If the count mode for stopping the output of image data lines is on, writing stops each time the number of image data lines set in JIFDDLC is written. To resume writing, set the DOUTRCMD bit in JIFDCNT to 1.
    - When the DOUTRINI bit in JIFDCNT is 0, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
    - When the DOUTRINI bit is 1, the address set in JIFDDA is used on resumption.
    - Writing stops when one frame of image data is completely transferred.
    - If the count mode for stopping the output of image data lines is off, writing continues until one frame of image data is completely transferred.
5. Decompression is complete after one frame of data is processed completely.

(a) Initial settings

To set the initial settings for decompression:

1. When the INT3 bit in JINTE0 is 0:
   After completing the JPEG core settings and input/output buffer settings and transferring coded data to the external buffer, activate the JPEG Codec by setting the JSRT bit in JCCMD to 1.
2. When the INT3 bit in JINTE0 is 1:
    a. After completing the JPEG core settings and input buffer settings and transferring coded data to the external buffer, activate the JPEG Codec by setting the JSRT bit in JCCMD to 1.
    b. When the image size and pixel format become readable after the coded data is decompressed, the INS3 bit in JINTS0 is set. At this time, decompression stops temporarily.
    c. After the image size and pixel format are read, set the output buffer.
    d. After interrupt handling, set the JRST bit in JCCMD to 1 to resume decompression.



Software reset
Reset the JPEG Codec in advance by setting the BRST bit in the JCCMD register.

JPEG core settings

Decompression setting:	DSP bit in JCMOD
Interrupt setting:	INT7 to INT5 and INT3 flags in JINTE0

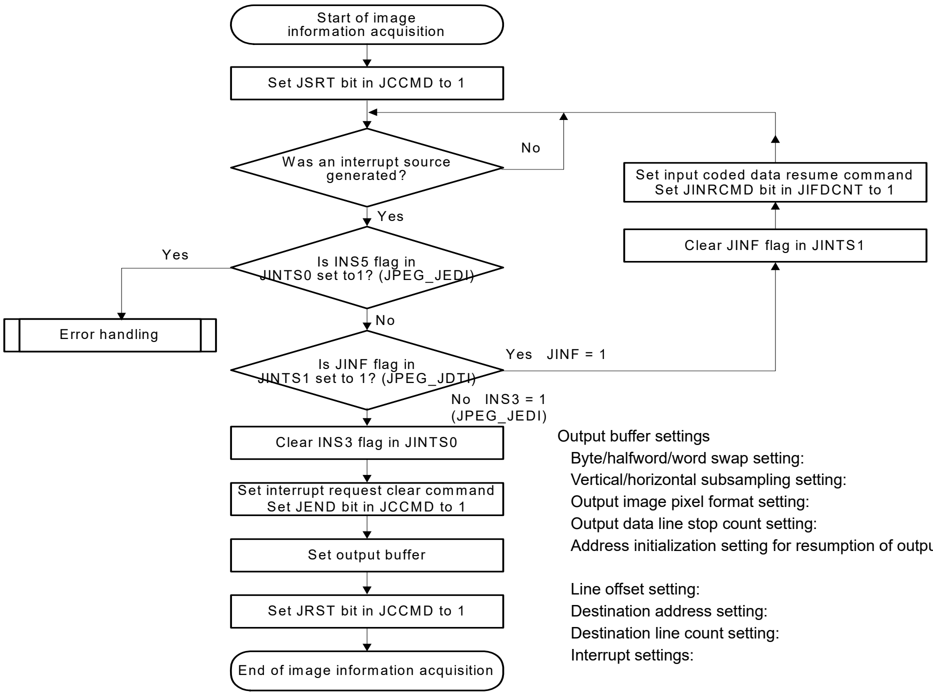
Input buffer settings

Byte/halfword/word swap setting:	JINSWAP bit in JIFDCNT
Input coded data stop count setting:	JINC bit in JIFDCNT
Address initialization setting for resumption of input coded data:	JINRINI bit in JIFDCNT
Source address setting:	JIFDSA
Source count setting:	JIFDSDC
Interrupt setting:	JINEN bit in JINTE0

Output buffer settings

Byte/halfword/word swap setting:	DOUTSWAP bit in JIFDCNT
Vertical/horizontal subsampling setting:	VINTER and HINTER bits in JIFDCNT
Output image pixel format setting:	OPF bits in JIFDCNT
Output data line stop count setting:	DOUTLC bit in JIFDCNT
Address initialization setting for resumption of output image data:	DOUTRINI bit in JIFDCNT
Line offset setting:	JIFDDOFST
Destination address setting:	JIFDDA
Destination line count setting:	JIFDDLC
Interrupt setting:	DBTEN, DOUTLEN bits in JINTE1

Figure 57.7 Flow of decompression initial settings



Output buffer settings

Byte/halfword/word swap setting:	DOUTSWAP bit in JIFDCNT
Vertical/horizontal subsampling setting:	VINTER and HINTER bits in JIFDCNT
Output image pixel format setting:	OPF bits in JIFDCNT
Output data line stop count setting:	DOUTLC bit in JIFDCNT
Address initialization setting for resumption of output image data:	DOUTRINI bit in JIFDCNT
Line offset setting:	JIFDDOST
Destination address setting:	JIFDDA
Destination line count setting:	JIFDDLC
Interrupt settings:	DBTEN, DOUTLEN bits in JINTE1

Figure 57.8 Flow of image information acquisition

(b) Decompression process

The decompression process flow is as follows:

1. When JPEG decompression process is completed, the INS6 bit in JINTS0 sets to 1. However, the JPEG Codec continues processing, because the image data remains to be transferred. The DBTF bit in JINTS1 sets to 1 when the last image data is transferred. The interrupt source is cleared by a 0 write to the INS6 bit. However, the interrupt request asserted by this interrupt source cannot be cleared by a 0 write to the INS6 bit. Set an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request.
2. When the JPEG Codec has completed decompression and all image data is transferred, the DBTF flag in JINTS1 sets to 1. When the DBTEN bit in JINTE1 is 1 here, an interrupt is generated. The interrupt source is cleared by a 0

write to the DBTF flag.

3. If the count mode for stopping input coded data is on, when the specified amount of coded data set in JIFDSDC is read, the JINF flag in JINTS1 sets to 1, and reading stops. When the JINEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by a 0 write to the JINF bit. Setting the JINRCMD bit in JIFDCNT to 1 resumes reading.
   - When the JINRINI bit in JIFDCNT is 0, the addresses for reading on resumption are continued from the addresses in the previous round of transfer.
   - When the JINRINI bit is 1, the address set in JIFDSA is used on resumption.
4. If the count mode for stopping the output image data is on, when the specified number of image data lines set in JIFDDLC is written, the DOUTLF flag in JINT1 sets to 1 and writing stops. When the DOUTLEN bit in JINTE1 is 1 here, an interrupt is generated. An interrupt source is cleared by a 0 write to the DOUTLF bit. Setting the DOUTRCMD bit in JIFDCNT to 1 resumes writing.
   - When the DOUTRINI bit in JIFDCNT is 0, the addresses for writing on resumption are continued from the addresses in the previous round of transfer.
   - When the DOUTRINI bit is 1, the address set in JIFDDA is used on resumption.

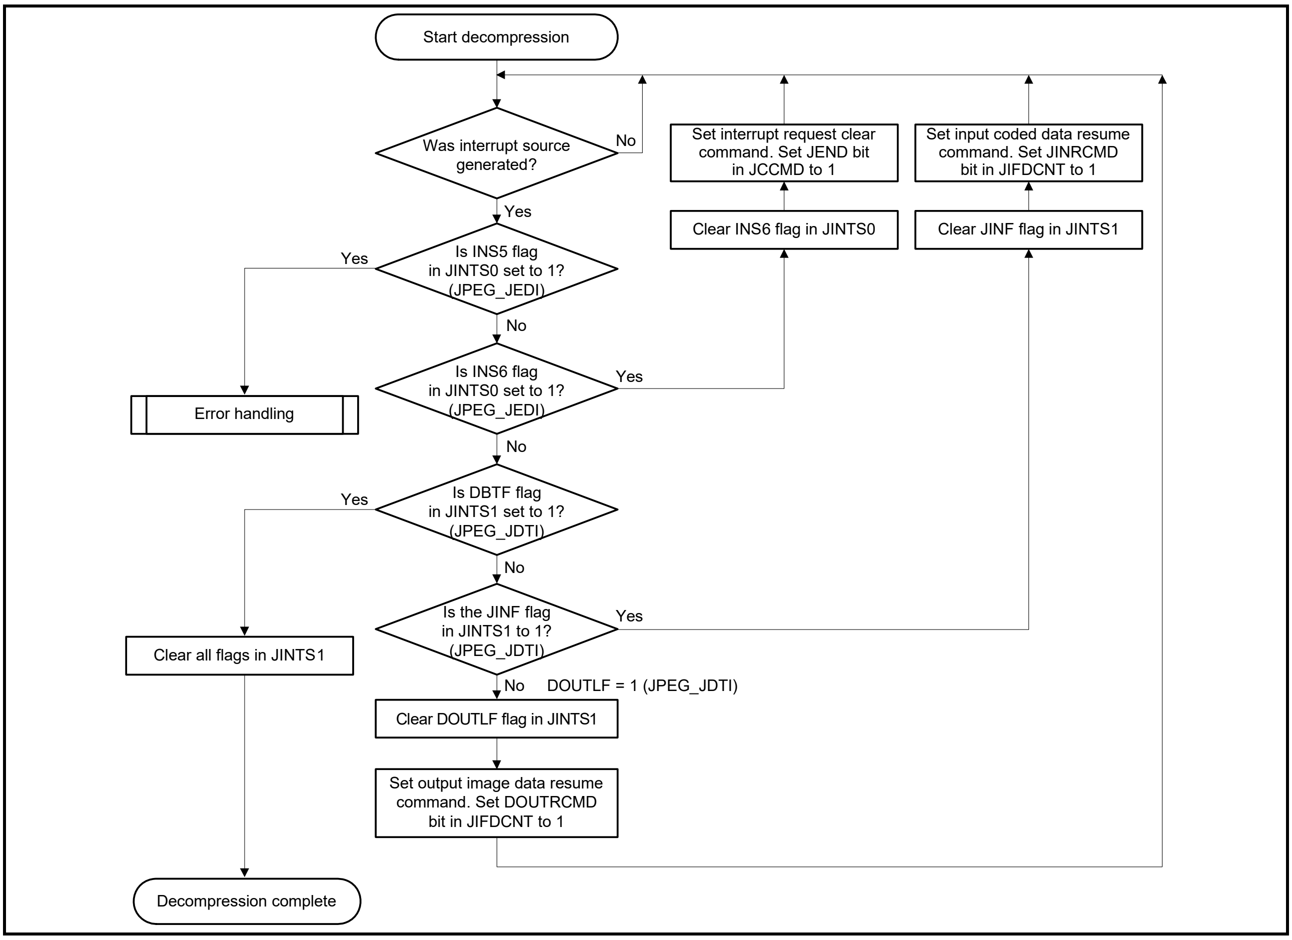


Figure 57.9 Decompression process flow

(c) Error handling

If the INS5 bit in JINTS0 is 1, it indicates that there is an error in the input JPEG coded data and that the decompression process by the JPEG Codec has ended. Read the ERR[3:0] bits in JCDERR to determine the cause of the error. Interrupt signals asserted because of the interrupt source indicated in the INS5 bit cannot be negated by clearing the interrupt status with a 0 write. To clear the interrupt request, you must set the interrupt request clear command (by setting the JEND bit in JCCMD to 1). To perform decompression or compression processing after error handling finishes, start the processing from the initial settings.

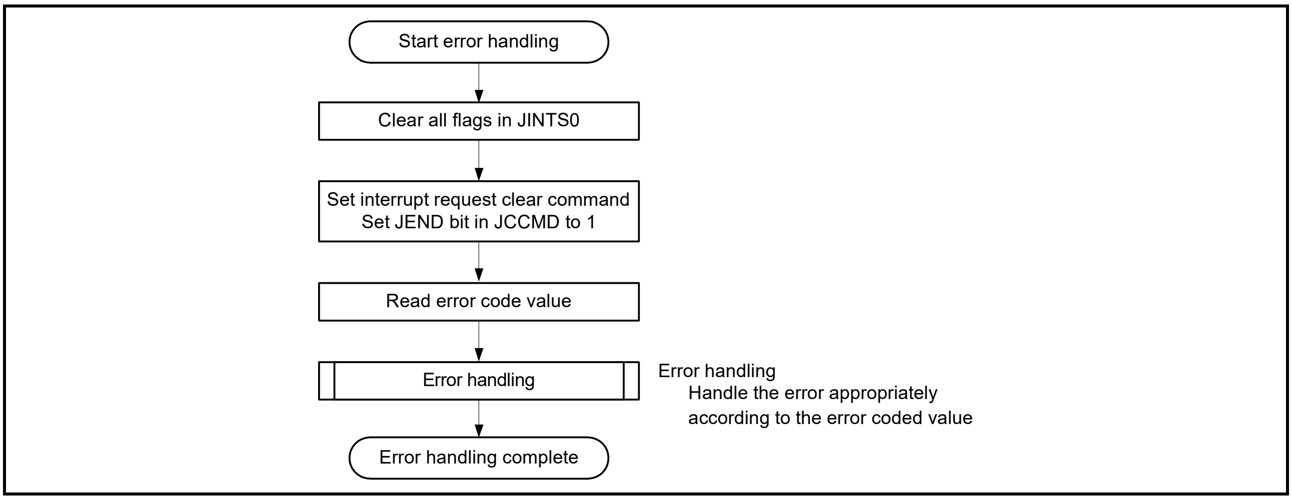

Figure 57.10 Error handling flow

(2) Input JPEG coded data

The markers to be processed in decompression are SOI, SOF0, SOS, DQT, DHT, DRI, RSTm, and EOI. Except for the error markers shown in Table 57.3, other markers are ignored even if they are read.

The JINSWAP[2:0] bits in JIFDCNT can be used to alter the arrangement for the input of coded data.

(3) JPEG decompression errors

(a) Error markers

If a marker error is found during analysis of compressed data for decompression, the code to identify the error type (shown in Table 57.3) is set to the ERR[3:0] bits in JCDERR. When an error is detected, the JPEG Codec generates an interrupt signal and terminates decoding. The stored code value is set to 1010b (default value) at the start of processing of the next frame or after a bus reset.

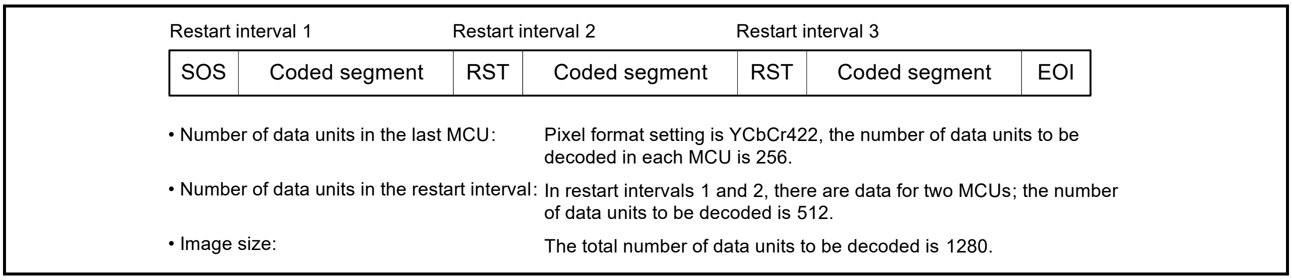
Table 57.3 Decompression error codes

Code	Description
0000b	Normal
0001b	SOI not detected: SOI not detected until EOI detected
0010b	SOF1 to SOFF detected
0011b	Unprovided pixel format detected
0100b	SOF accuracy error: Value other than 8 detected
0101b	DQT accuracy error: Value other than 0 detected
0110b	Component error 1: Number of SOF0 header components detected is value other than 1, 3, or 4
0111b	Component error 2: Number of components differs between SOF0 header and SOS
1000b	SOF0, DQT, and DHT not detected when SOS detected
1001b	SOS not detected: SOS not detected until EOI detected
1010b	EOI not detected (default)
1011b	Restart interval data number error detected
1100b	Image size error detected
1101b	Last MCU data number error detected
1110b	Block data number error detected

(b) Huffman coded segment error

During the compression data analysis in decompression operation, if there is an increase or decrease in the decoded data count because of an error resulting from bit reversal or missing data in the Huffman-coded segment, determine the error type, and set the error code in the ERR[3:0] bits in JCDERR. Table Table 57.4 lists the segment error codes. The error code is set, an interrupt signal is issued, and the process ends only if the INT7 to INT5 bit in JINTE0 associated with the detected error is set to 1. The set code value returns to the default value (1010h) at the start of processing of the next frame or after a bus reset. However, in this error detection if an error in the Huffman-coded segment does not result in an alteration in the decoded data count, the error is undetected.

Figure 57.11 shows an example of the number of data units in a Huffman coded segment with pixel format setting YCbCr422, DRI = 2, X = 80 pixels, and Y = 8 pixels.



- Number of data units in the last MCU: Pixel format setting is YCbCr422, the number of data units to be decoded in each MCU is 256.
- Number of data units in the restart interval: In restart intervals 1 and 2, there are data for two MCUs; the number of data units to be decoded is 512.
- Image size: The total number of data units to be decoded is 1280.

Figure 57.11 Huffman coded segment

Table 57.4 Segment error codes

Code	Description
0000h	Normal
1011h	Restart interval data number error: The number of data units in each interval is compared with the number of data units specified by the DRI marker. If an interval has more or less data than is specified by the DRI marker, the decompression error code (1011) is set. The last interval which is shorter than the restart interval is not compared. If the DRI marker segment is not placed or the specified number is 00, an error is not detected even if the RSTm marker is placed. Also, an m indicating the order of RSTm marker modulo 8 (m = 0 to 7) is exempt from the error detection analysis. When the INT7 bit in JINTE0 sets to 0, this error is not detected.
1100h	Image size error: The number of data units in an image that is calculated from the number of lines specified by the frame parameter and the number of samples per line is compared with the total number of data units from SOS to EOI (in pixel units). If the numbers of data units do not match, the decompression error code (1100) is set. When the INT6 bit in JINTE0 sets to 0, this error is not detected. The number of data units in an image is shown in MCUs. As a result, the number of lines and the number of samples per line for calculation must be shown in MCUs.
1101h	Last MCU data number error: Whether the number of data units in MCUs on EOI detection is shown in MCU units is checked and fractions are detected. If error (1100) occurs simultaneously with another error, error (1100) has priority. When the INT5 bit in JINTE0 sets to 0, this error is not detected.
1110h	Block data number error: Whether a block is an 8 × 8 array is checked and fractions are detected. When the INT7 to INT5 bits in JINTE0 are all set to 0, this error is not detected.

57.3.3 Output Pixel Format in Decompression

The JPEG Codec is capable of decompressing JPEG encoded data created in the YCbCr444, YCbCr422, YCbCr411, and YCbCr420 formats. The pixel format of the output image is ARGB8888 or RGB565. Figure 57.12 shows the flow of converting decompressed data to the given output pixel format.

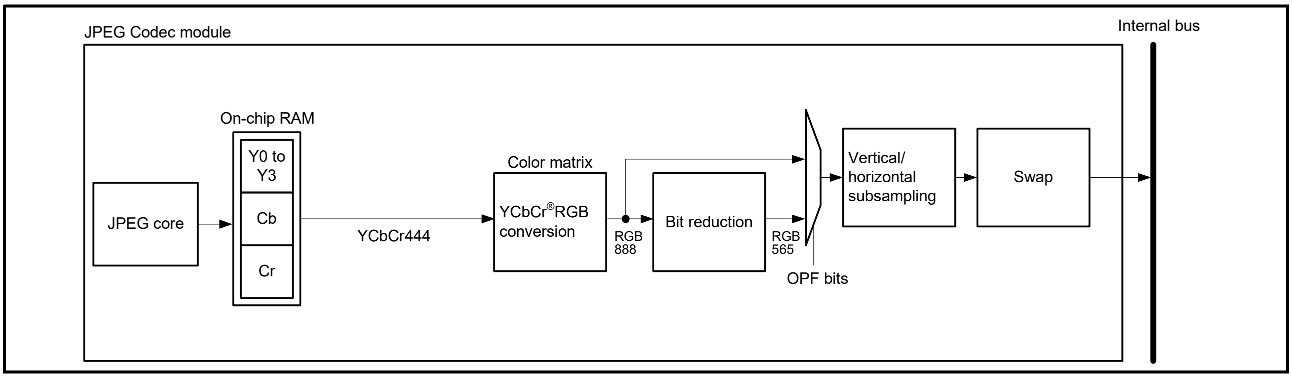


Figure 57.12 Output pixel format conversion in decompression block diagram

(1) On-chip SRAM

Data decoded by the JPEG core is stored in MCUs on SRAM in the JPEG Codec.

(2) YCbCr → RGB conversion

Data in the YCbCr444 format is converted to the RGB888 format. The following formulas are used:

$$R = 1.000Y + 1.402Cr$$
$$G = 1.000Y - 0.344Cb - 0.714Cr$$
$$B = 1.000Y + 1.772Cb$$

(3) Bit reduction

RGB888 data is reduced to RGB565 data. The lower three bits of red and blue, and lower two bits of green are removed.

(4) Output pixel format selection

The pixel format to be output is selected in the OPF[1:0] bits in JIFDCNT. When the DOUTSWAP[2:0] bits in JIFDCNT = 000b, allocation of data in the pixel format is as follows:

- ARGB8888 (32 bits/pixel)

b31 b24	b23 b16	b15 b8	b7 b0
*1	Red 8 bits	Green 8 bits	Blue 8 bits

Note 1. This value is determined by the ALPHA[7:0] bits in JIFDADT.

- RGB565 (16 bits/pixel)

b15 b11	b10 b5	b4 b0
Red 5 bits	Green 6 bits	Blue 5 bits

(5) Vertical and horizontal subsampling

The output data can be horizontally and vertically subsampled based on the VINTER[1:0] and HINTER[1:0] settings in JIFDCNT. Figure 57.13 to Figure 57.15 show the line subsampling modes. In the figures, for the ARGB8888 and RGB565 output formats, one cell represents one pixel. Because sub-sampling is carried out in minimum coded units (MCUs), the numbers of the horizontal and vertical block units vary based on the decompressed pixel format.

Table 57.5 and Table 57.6 show the values of n and m in the figures.

Horizontal

Table 57.5 Number of horizontal blocks (1 of 2)

Compression format	Output format	n
YCbCr444	ARGB8888, RGB565	1
YCbCr422	ARGB8888, RGB565	2

Table 57.5 Number of horizontal blocks (2 of 2)

Compression format	Output format	n
YCbCr411	ARGB8888, RGB565	4
YCbCr420	ARGB8888, RGB565	2

Vertical

Table 57.6 Number of vertical blocks

Compression format	Output format	m
YCbCr444	ARGB8888, RGB565	1
YCbCr422	ARGB8888, RGB565	1
YCbCr411	ARGB8888, RGB565	1
YCbCr420	ARGB8888, RGB565	2

- Sub-sampling into 1/2

  Even lines are skipped by sub-sampling.

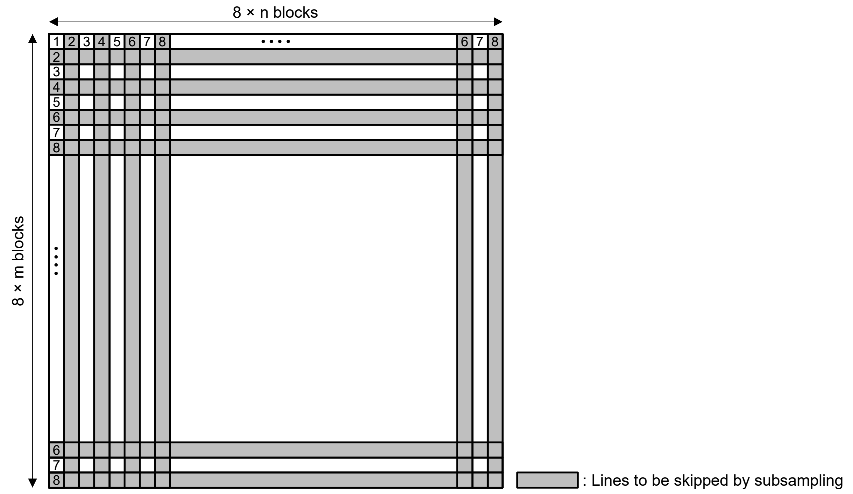

Figure 57.13 MCU when sub-sampling into 1/2 is selected

- Sub-sampling into 1/4

  The second, third, and fourth lines are skipped by sub-sampling.

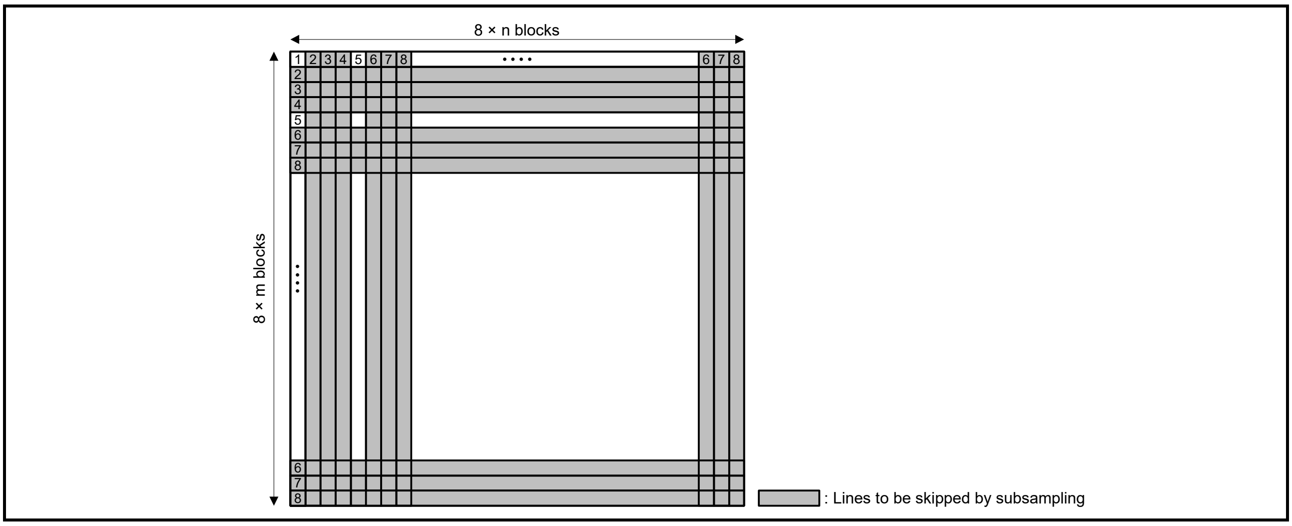

Figure 57.14 MCU when sub-sampling into 1/4 is selected

- Sub-sampling into 1/8

  The second, third, fourth, fifth, sixth, seventh, and eighth lines are skipped by sub-sampling.

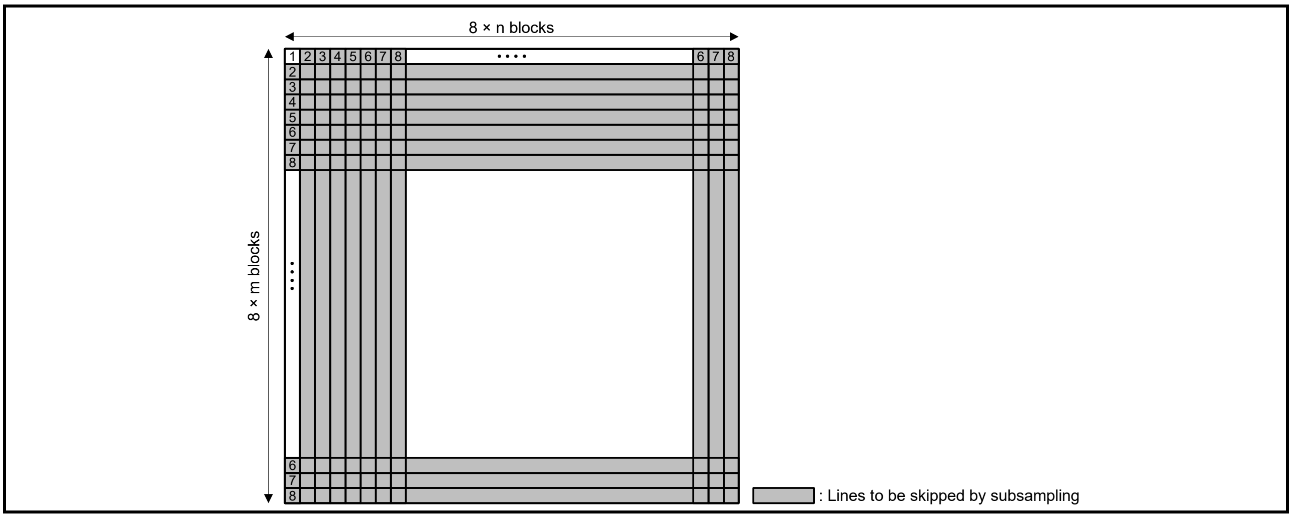

Figure 57.15 MCU when sub-sampling into 1/8 is selected

(6) Swap

Allocation of data can be changed using the DOUTSWAP[2:0] bits in JIFDCNT.

57.3.4 Storing Image Data

Figure 57.16 shows the buffer area for storing the image data.

- Start address
  - Compression: JIFESA
  - Decompression: JIFDDA
- Horizontal size
  - Compression, decompression: JCHSZU, JCHSZD
- Vertical size
  - Compression, decompression: JCVSAU, JCVSZD

- Offset
    - Compression: JIFESOFST
    - Decompression: JIFDDOFST

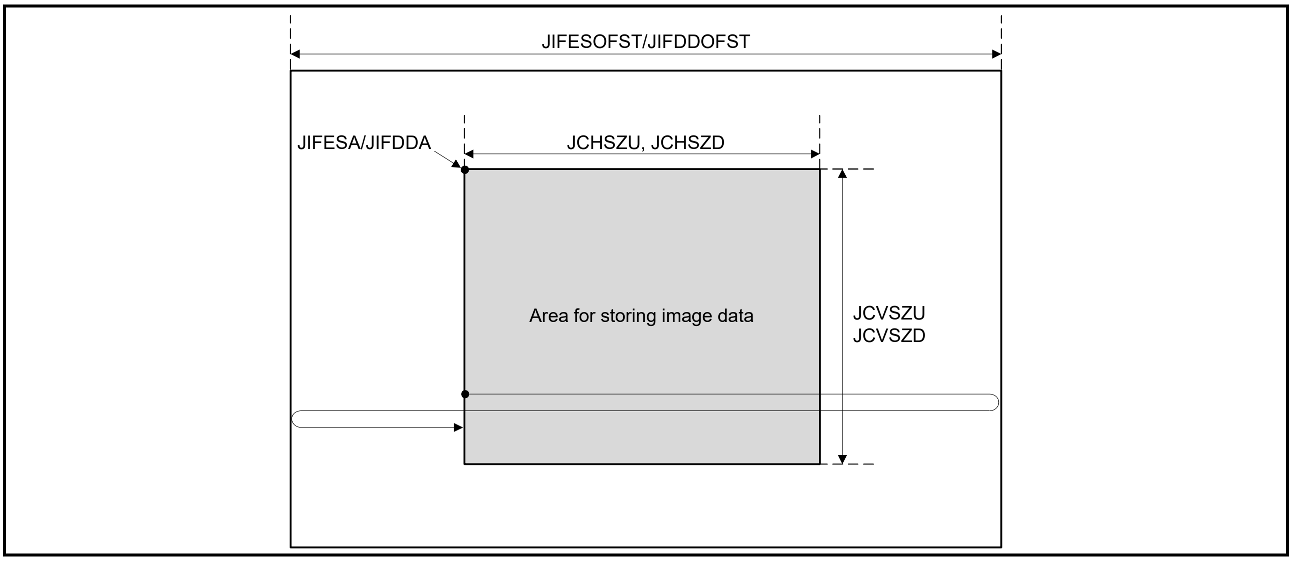

Figure 57.16 Conceptual diagram of image data storing

57.4 Interrupts

Two types of interrupt requests, compression/decompression process interrupt requests (JPEG_JEDI) and data transfer interrupt requests (JPEG_JDTI), are available in the JPEG Codec. The two types of interrupt requests are each related to multiple sources. The interrupt request cancellation methods differ depending on the source of the interrupt request.

57.4.1 Compression/Decompression Process Interrupt Request (JPEG_JEDI)

The flags in JINTS0 indicate compression and decompression-related sources. The interrupt requests asserted by these interrupt sources cannot be negated by clearing the associated interrupt status bits to 0. Issue an interrupt request clear command (by setting the JEND bit in JCCMD to 1) to clear the interrupt request. When a flag in JINTS0 sets to 1, a compression/decompression process interrupt request is sent to the Interrupt Controller Unit (ICU).

(1) Compression

- JPEG compression process end

  When the INS6 bit in JINTS0 is 1, the JPEG compression process completed successfully. After all of the coded data is transferred, the JPEG Codec completes compression.

(2) Decompression

- JPEG decompression process end

  When the INS6 bit in JINTS0 is 1, the JPEG decompression process completed successfully. After all of the image data is transferred, the JPEG Codec completes decompression.
- JPEG decompression error occurrence

  When the INS5 bit in JINTS0 is 1, the input JPEG coded data has an error and the JPEG Codec has stopped the decompression process. Read the error code (ERR[3:0] bits in JCDERR) and identify the error source. This interrupt occurs when any of the INT7 to INT5 bits in JINTE0 is 1.
- Request for reading the image size and pixel format

  When the INS3 bit in JINTS0 is 1, JPEG coded data is input, and information regarding the image size and pixel format can be read. Because the JPEG decompression process is suspended, resume the JPEG decompression process by setting the process stop clear command after accessing the required registers. This interrupt occurs when the INT3 bit in JINTE0 is 1.

57.4.2 Data Transfer Interrupt Request (JPEG_JDTI)

The flags in JINTS1 are the interrupt sources for transferring the image data and coded data. The interrupt requests asserted by these interrupt sources can be negated by clearing the associated interrupt status bits to 0.

(1) Compression

- Interrupt request generated after the specified number of input image data lines is read

  When the DINLF bit in JINTS1 is 1, the number of image data lines specified in JIFESLC is transferred. Transfer the rest of the image data to the external buffer and resume transferring the data from the external buffer. A data transfer interrupt request is sent when the DINLEN bit in JINTE1 is 1.
- Interrupt request generated after all processes are complete

  When the CBTF bit in JINTS1 is 1, the JPEG Codec has completed compression and transferred all of the coded data. The data transfer interrupt request is sent when the CBTEN bit in JINTE1 is set to 1.

(2) Decompression

- Interrupt request generated after the specified number of output image data lines is written to

  When the DOUTLF bit in the JINTS1 is 1, the number of image data lines specified in JIFDDLC is transferred. Secure a space for the next coded data in the external buffer and resume the transfer process. A data transfer interrupt request is sent when the DOUTLEN bit in JINTE1 is 1.
- Interrupt request generated after the specified amount of input coded data is read

  The JINF bit in JINTS1 sets to 1 when the amount of coded data specified in JIFDSDC is transferred. Secure the next coded data in the external buffer and resume the transfer process. A data transfer interrupt is also sent at this time if the JINEN bit in JINTE1 is 1.
- Interrupt request generated after all processes are completed

  The DBTF bit in JINTS1 sets to 1 when the JPEG Codec has completed decompression and transferred all of the coded data. A data transfer interrupt request is also sent at this time if the DBTEN bit in JINTE1 is set to 1.

57.5 Bus Reset Processing

Issuing the bus reset command (setting the BRST bit in JCCMD to 1) causes a bus reset. Do not issue the bus reset command while the JPEG Codec is operating. The following registers are initialized by a bus reset:

- JPEG Code Data Count Upper Register (JCDTCU)
- JPEG Code Data Count Middle Register (JCDTCM)
- JPEG Code Data Count Lower Register (JCDTCD)
- JPEG Interrupt Status Register 0 (JINTS0)
- JPEG Code Decode Error Register (JCDERR)
- JPEG Code Reset Register (JCRST).

57.6 Usage Notes

57.6.1 Notes on the Decompression Process

Renesas recommends that a timeout detection mechanism be implemented through software or through the operating system to prevent locking of the module in case invalid JPEG code data is detected. This timeout detection mechanism is recommended especially when setting JIFDCNT.JINC bit to 1 because the decompression process might not be complete depending on the timing of the JPEG code data input. If a timeout error occurs while decoding the image, reset the JPEG Codec by setting the BRST bit in the JCCMD register first, then follow the flow for decompression initial settings as shown in Figure 57.7.

58. Graphics LCD Controller (GLCDC)

The multifunctional Graphics LCD Controller (GLCDC) supports multiple data formats and panels. Key GLCDC features include:

- GPX bus master function for accessing graphics data
- Superimposition of three planes (single color background plane, graphics 1 plane, and graphics 2 plane)
- Supports many types of 32- and 16-bit/pixel graphics data and 8-, 4-, and 1-bit LUT data formats
- Digital interface signal output supporting the video image size of WVGA.

Figure 58.1 shows a block diagram of the GLCDC.

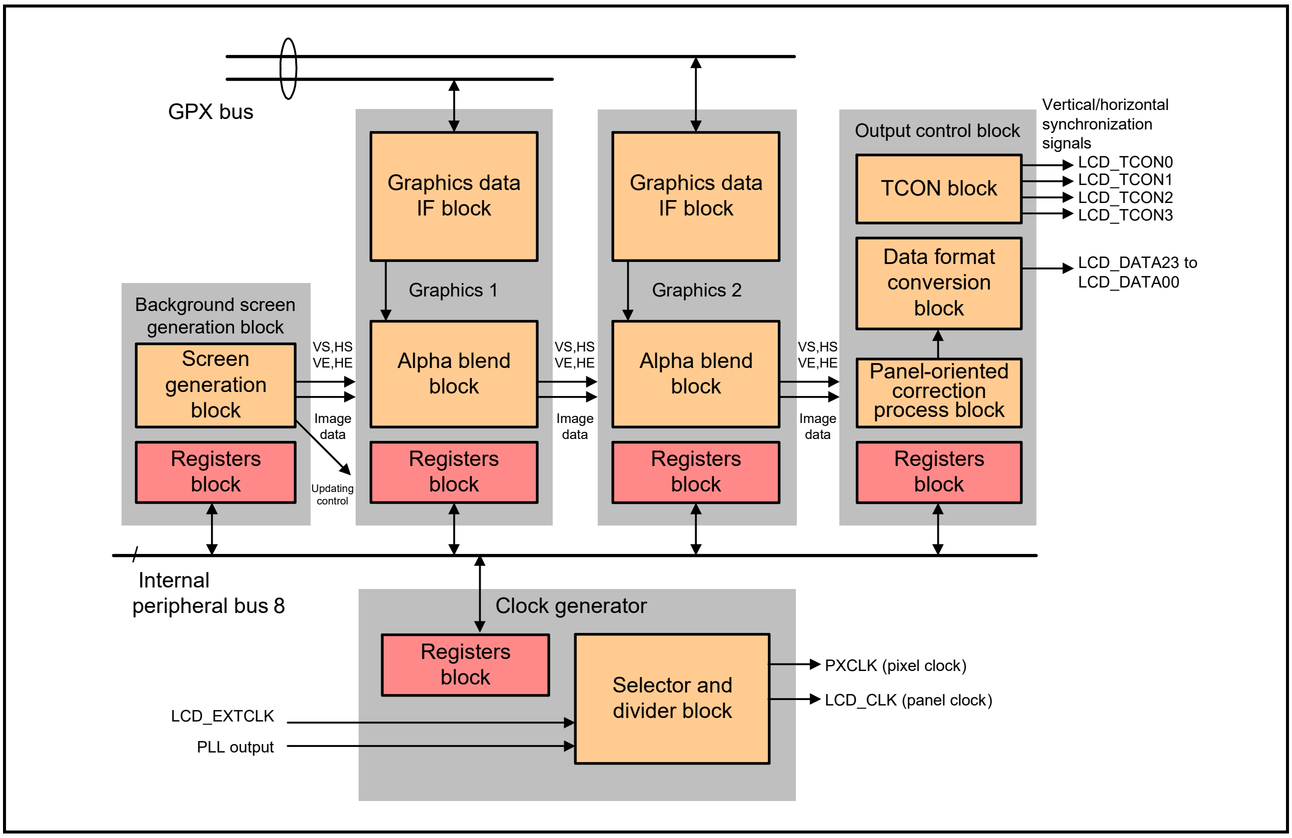

Figure 58.1 GLCDC block diagram

Note: When using the GLCDC, set the clock to ICLK = PCLKA.

Table 58.1 GLCDC I/O pins (1 of 2)

Pin name	I/O	Function
LCD_EXTCLK	Input	Panel clock source input pin
LCD_CLK	Output	Panel clock output pin
LCD_DATA23 to LCD_DATA00	Output	LCD signal output pins RGB888 signal R/G/B: 8 bits each (unsigned) RGB666 signal R/G/B: 6 bits each (unsigned) RGB565 signal R/B: 5 bits each (unsigned) G: 6 bits (unsigned) Serial RGB signal R/G/B/-: 8 bits (unsigned)
LCD_TCON3	Output	LCD_TCON3 output signal pin
LCD_TCON2	Output	LCD_TCON2 output signal pin
LCD_TCON1	Output	LCD_TCON1 output signal pin

58.1 Functional Overview

Table 58.2 provides a functional overview of GLCDC.

Table 58.2 Functional overview of GLCDC (1 of 2)

Parameter		Function
Graphics	Graphics planes	• Single color background (lowest layer) and two graphics planes • Graphics planes can be alpha-blended with the lower-layer plane
	Pixel format	• RGB-888 progressive format (-: 8 bits, R: 8 bits, G: 8 bits, B: 8 bits; 32 bits in total) • ARGB8888 progressive format (A: 8 bits, R: 8 bits, G: 8 bits, B: 8 bits; 32 bits in total) • RGB565 progressive format (A: None, R: 5 bits, G: 6 bits, B: 5 bits; 16 bits in total) • ARGB1555 progressive format (CLUT: 1 bit, R: 5 bits, G: 5 bits, B: 5 bits; 16 bits in total) • ARGB4444 progressive format (A: 4 bits, R: 4 bits, G: 4 bits, B: 4 bits; 16 bits in total) • CLUT8 progressive format (color palette address: 8 bits) • CLUT4 progressive format (color palette address: 4 bits) • CLUT1 progressive format (color palette address: 1 bit) • CLUT memory: 512 words × 32 bits per graphics plane (ARGB8888)
	Frame buffer control	The following parameters can be set for the frame buffer: • Base address: Start address of the frame buffer, aligned with a 64-byte boundary (burst transfer size) • Macro line offset: Offset address from the start address to the next macro line, aligned with a 64-byte boundary (burst transfer size) • Frame offset: Offset address from the start address to the next frame, aligned with a 64-byte boundary (burst transfer size) • Number of data transfers: Number of data transfers of a macro line • Number of macro lines: Number of macro lines in a single frame
	Alpha blending	• Alpha blending in rectangular area (blending ratio: 256 gradation levels) • Alpha blending in pixel units (blending ratio: 256 gradation levels) • RGB-index chroma key (replaced with the specified color when the object color agrees with the preset value)
Internal video image format		• Total number of vertical lines: Up to 1024 lines • Number of valid vertical lines: 16 to 1020 lines (resolution: 1 line) • Vertical front porch: 2 lines (minimum) • Vertical back porch: 1 line (minimum) • Vertical synchronization (VS) pulse width: 1 line (fixed) • Total number of horizontal pixels: Up to 1024 pixels • Number of valid horizontal pixels: 16 to 1016 pixels (resolution: 2 pixels) • Horizontal front porch: 3 pixels (minimum) • Horizontal back porch: 1 pixel (minimum) • Horizontal synchronization (HS) pulse width: 4 pixels
Data format conversion	Output video image size	• From 16 lines × 16 pixels to 1020 lines × 1016 pixels
	Data format	• RGB888 (parallel 24 bits) • RGB666 (parallel 18 bits) • RGB565 (parallel 16 bits) • RGB888 (serial 8 bits); clock cycle is four times the pixel clock • Bit endian order change and B/R signal swap
	Dither processing	• Reduces 10-bit signals (output after panel-oriented correction) to 8-, 6-, or 5-bit signals (output data format) • Supports the following modes: - Truncate mode - Round-off mode - 2×2 pattern dither mode

Table 58.2 Functional overview of GLCDC (2 of 2)

Parameter		Function
Timing control signal	Signal generation	5 timing signals (STVA, STVB, STHA, STHB, and DE) can be generated from HS / VS: • Vertical synchronization signal (variable) • Horizontal synchronization signal (variable) • Data enable signal
	Signal select	• Signals generated by the signal generation circuit can be output from LCD_TCONn pins (n = 0 to 3)
Output control panel-oriented correction processing	Brightness and contrast	• 10-bit internal processing; the sequence of this processing and gamma correction can be swapped. • Brightness: DC value adjustment range: from -512[LSB] to +512[LSB] • Contrast: gain value adjustment range: from 0 to 2 times (from 0/128 to 255/128)
	Gamma correction	• Sixteen areas; input/output: 10 bits • Gain value adjustment range in the area: From 0 to 2 times (from 0/1024 to 2047/1024)
Interrupts		• Number of specified lines interrupt (GLCDC_VPOS) • Graphics 1 buffer underflow interrupt (GLCDC_L1UNDF) • Graphics 2 buffer underflow interrupt (GLCDC_L2UNDF)

58.1.1 GLCDC Configuration

Figure 58.2 shows the configuration of the GLCDC.

The GLCDC includes the following blocks:

- Background screen generation block: Generates the background screen (including the blanking interval), selects the background color, and generates the synchronization signals for controlling the screens.
- Graphics data interface blocks (2 blocks): Convert the graphics data/CLUT data read through the GPX bus into ARGB (8888) data for internal processing, and transfer the clocks (PCLKA → PXCLK).
- Alpha blending blocks (2 blocks): Superimpose graphics data on the lower-layer screen and perform alpha blending based on the register settings and the alpha blending values for the current screen graphics data.
- TCON block: Generates the vertical and horizontal synchronization and enable signals suited for the specifications of the connected panel, from the internal vertical and horizontal synchronization signals.
- Data format conversion block: Processes data into the specific internal RGB888 format into the data of the specific format suited for the specifications of the panel with dither correction for output image data length.
- Panel-oriented correction processing block: Corrects brightness and contrast, and performs gamma correction suited for the characteristics of the connected panel, allowing either brightness and contrast correction or gamma correction to be performed first.
- Clock generator block: Generates the pixel and the panel clocks on a specific frequency from either LCD_EXTCLK or PLL output.

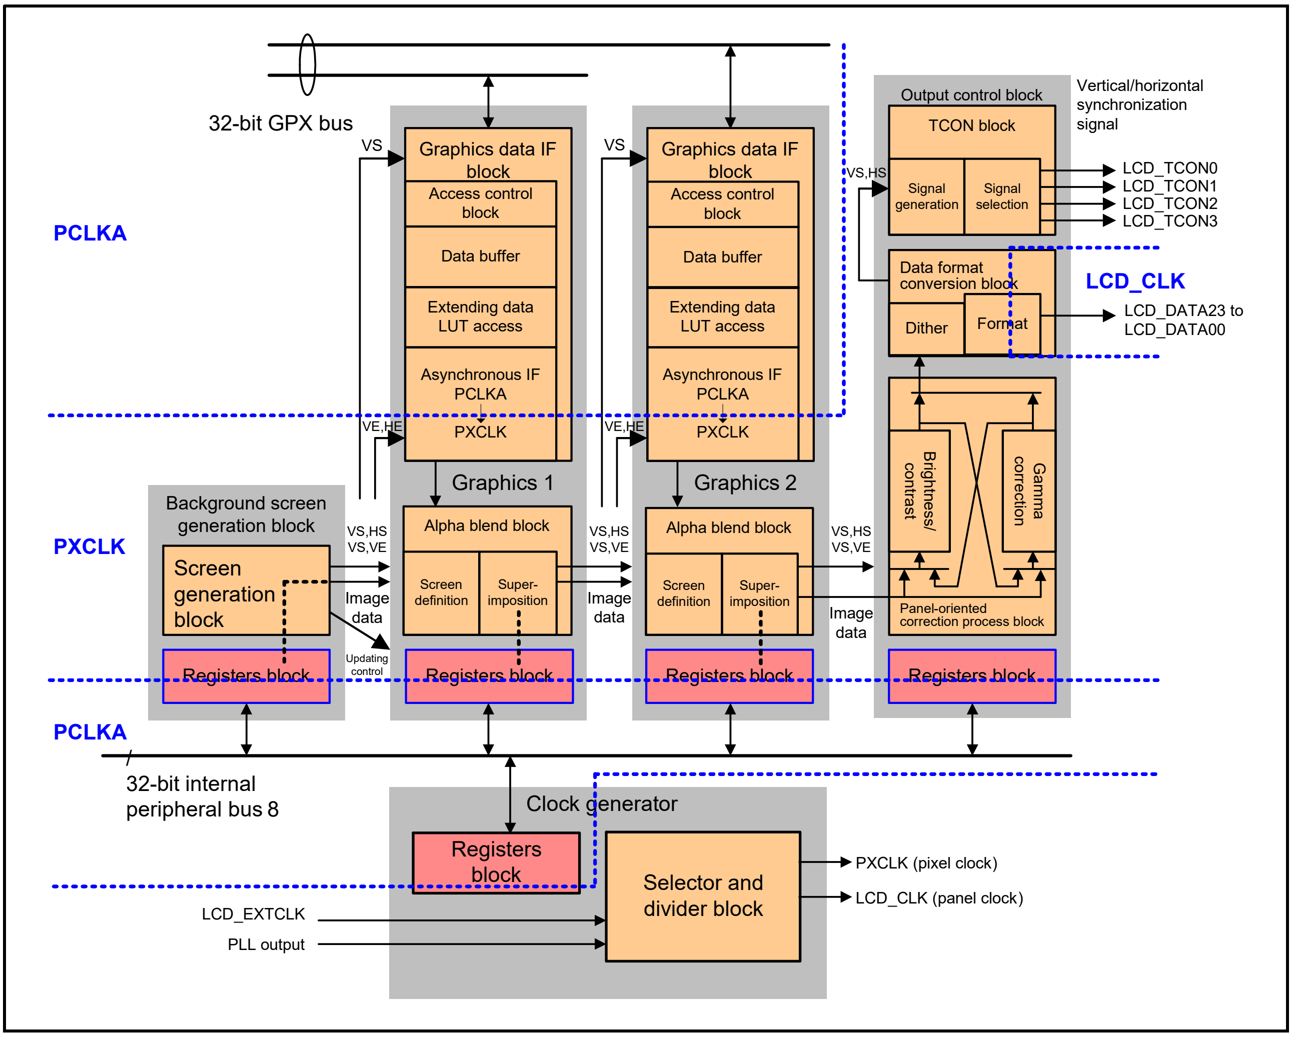

Figure 58.2 GLCDC configuration

58.1.2 Screen Format

Figure 58.3 shows the screen format overview of the GLCDC.

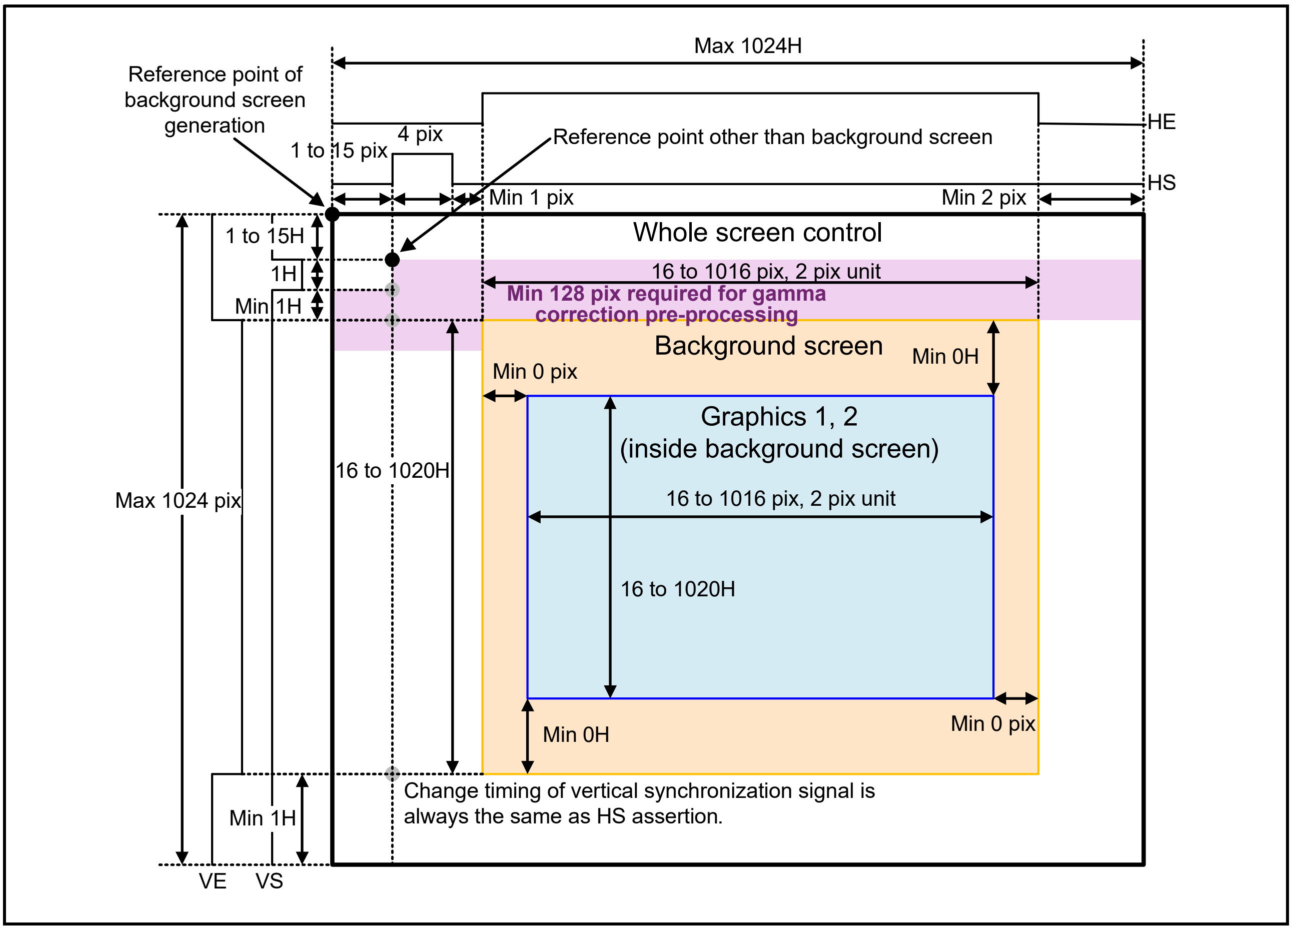

Figure 58.3 Internal screen format

The background screen generation block generates the essential timing signals for operations in the module as a whole. The graphics data interface blocks, alpha blending blocks, gamma correction block, output control block, and TCON block operate based on the synchronization and enable signals, which are sequentially transferred from the background screen generation block.

58.1.3 Graphics and Color Palette (CLUT) Data Formats

The GLCDC handles three display screens, one of which is a background screen. For the background screen, frame data is RGB888 graphics data stored in the registers, and for the other two screens, frame data is stored in the memory connected to the GPX bus as 32- or 16-bit/pixel graphics data or 8-, 4-, or 1-bit/pixel color palette (CLUT) data. The frame data of the relevant screen is read by the graphics data interface block, read into the GLCDC, and extended (converted) into ARGB8888 data for superimposition and blending. Figure 58.4 shows the frame data formats.

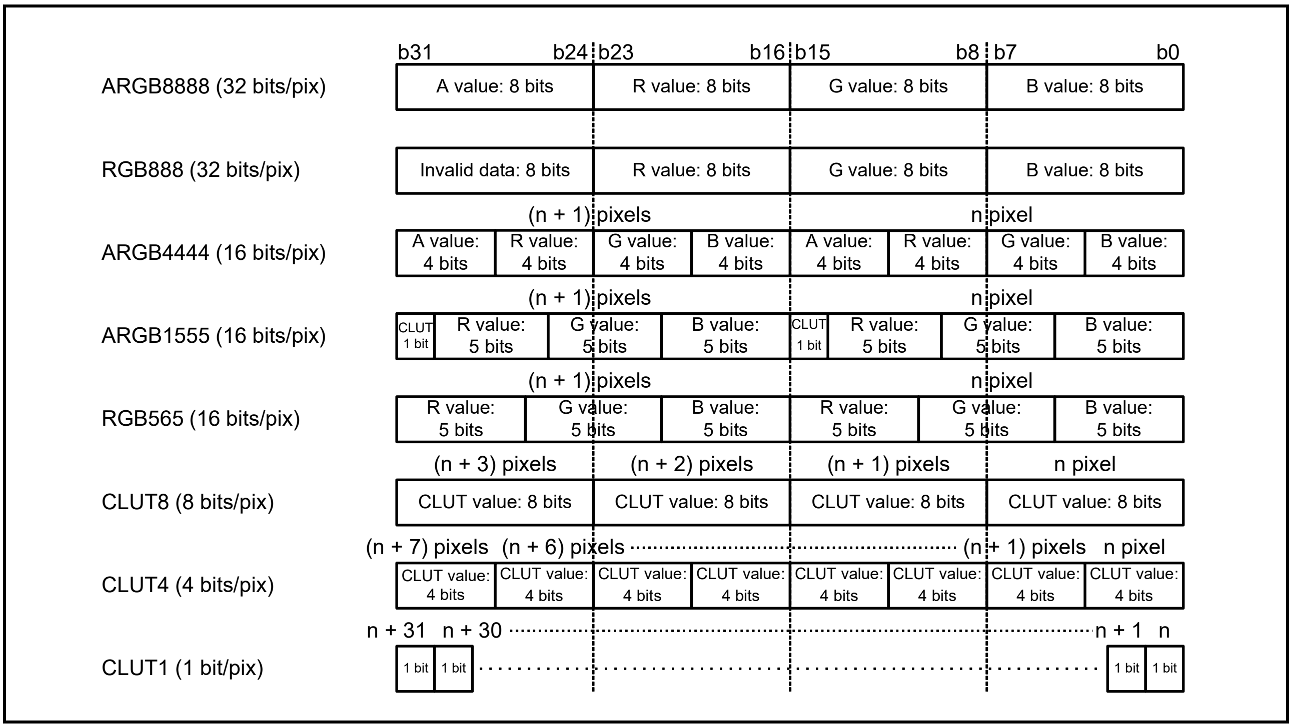

Figure 58.4 Frame data format

The A value (alpha blending value) represents the blending ratio of pixel data for displaying the lower-layer and current graphics screens after superimposition. The blending process is performed in accordance with the equations given in section 58.1.7, Graphics Data Interface. The CLUT value represents the color palette memory address (plane 0 or 1 is selected in the registers), and the data in the color palette is ARGB8888 (32 bits/pixel) graphics data. Addresses 01h/00h are accessed with CLUT1, 0Fh to 00h with CLUT4, and FFh to 00h with CLUT8. Addresses 80h/00h are accessed with ARGB1555 data.

58.1.4 Output Control for Data Format

The GLCDC can output data in accordance with the following formats and register settings:

- Data formats
  - Parallel: RGB888, RGB666, and RGB565
  - Serial: RGB888
  - Lower bits are processed in one of the following modes when 10-bit signals are reduced to 8-, 6-, and 5- bit signals:

    — Truncate mode

    — Round-off mode

    — 2×2 pattern dither processing + truncate mode.
- Pixel arrangement
  - RGB
  - BGR.
- Scan direction select for serial RGB888
  - Forward scan
  - Reverse scan.
- Data output delay of serial RGB888

  - 0 to 3 clock cycles.
- Pin assignment.
  - Little endian
  - Big endian.

For details on dither processing, see section 58.2.48, Output Control Block Panel Dither Correction Register (OUT_PDTHA).

Bit assignment of LCD signals for parallel RGB888 format

Table 58.3 shows RGB signal inputs assigned to the LCD signal outputs for the parallel RGB888 output format.

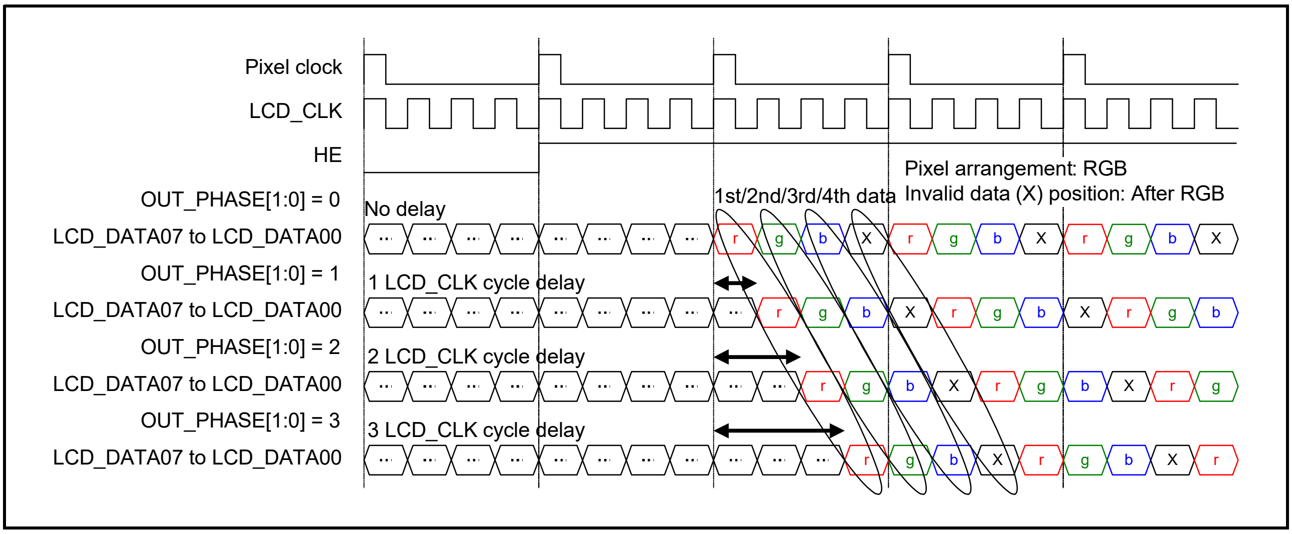

Figure 58.5 Serial RGB888 (4x speed) output timing

58.1.5 Output Control for Panel-Oriented Correction Process

The following panel-oriented correction processes are provided:

- Brightness correction
- Contrast correction
- RGB gamma correction.

Brightness correction always precedes contrast correction, but RGB gamma correction can either precede or follow brightness and contrast correction, based on the register settings. In panel-oriented correction, 10-bit RGB data obtained by extending 8-bit RGB data output from graphics 2 is used, and 10-bit RGB data is also output to the output control (data format conversion) block. Figure 58.6 shows the configuration of the panel-oriented correction circuit.

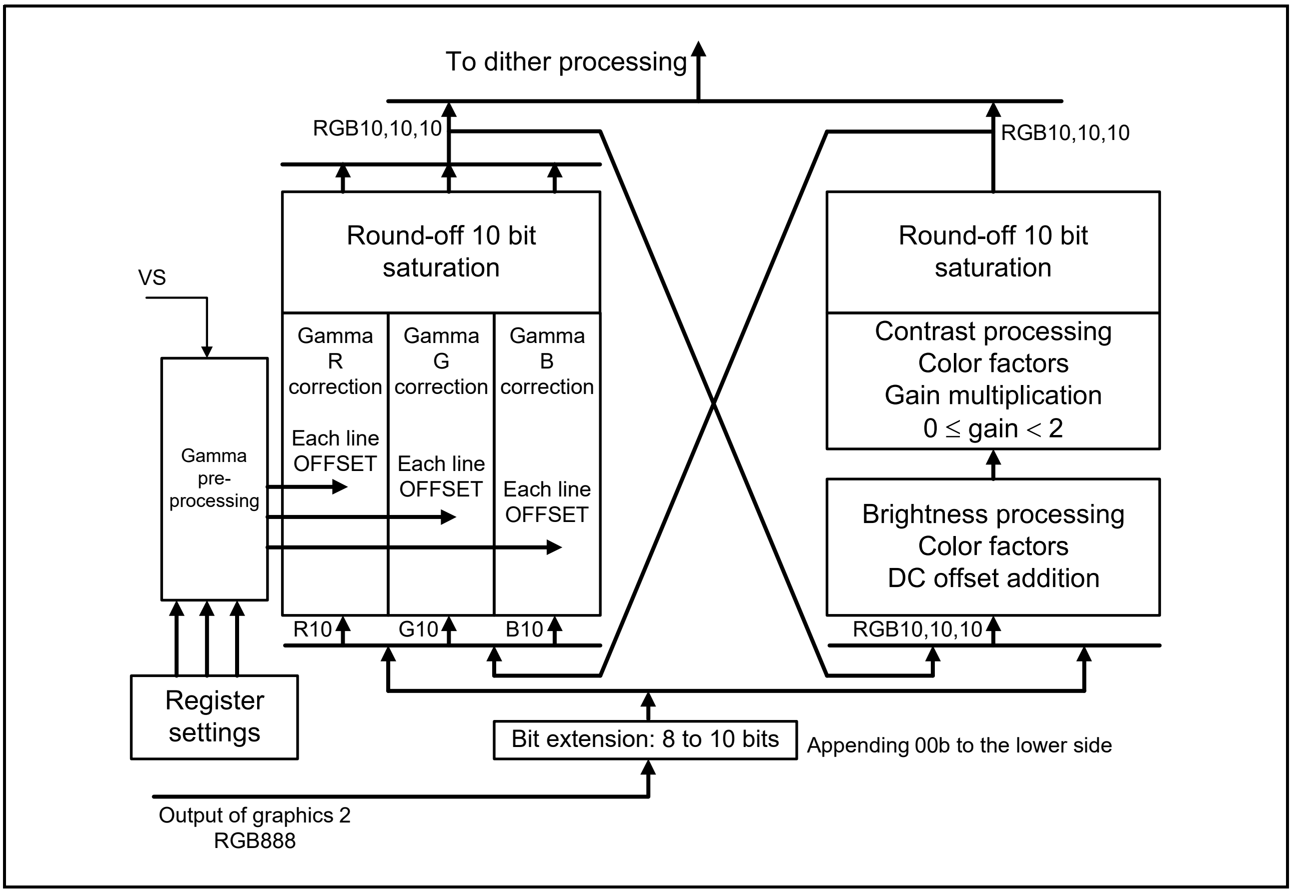

Figure 58.6 Configuration of panel-oriented correction circuit

58.1.6 Output Control for TCON

Any of the four signals generated from the internal vertical and horizontal synchronization signals (STVA, STVB, STHA, and STHB) that have passed through the data format conversion block can be selected for output on four pins, LCD_TCON0, LCD_TCON1, LCD_TCON2, and LCD_TCON3. The generated signals are completely independent of the image data. They are not affected by the output image format or any internal data process, and no register settings for signal generation affect the output image format or any internal data process. The data enable signal DE, which is to be generated by the TCON block, is the logical AND of the two signals STVB and STHB, which were previously generated by the TCON block. Consequently, three signals in total can actually be generated if DE is to be output.

58.1.7 Graphics Data Interface

Two circuit systems are provided for reading graphics data (graphics 1 and 2), each of which incorporates an access control block, data buffer, CLUT memory, data extension block, and asynchronous interface block.

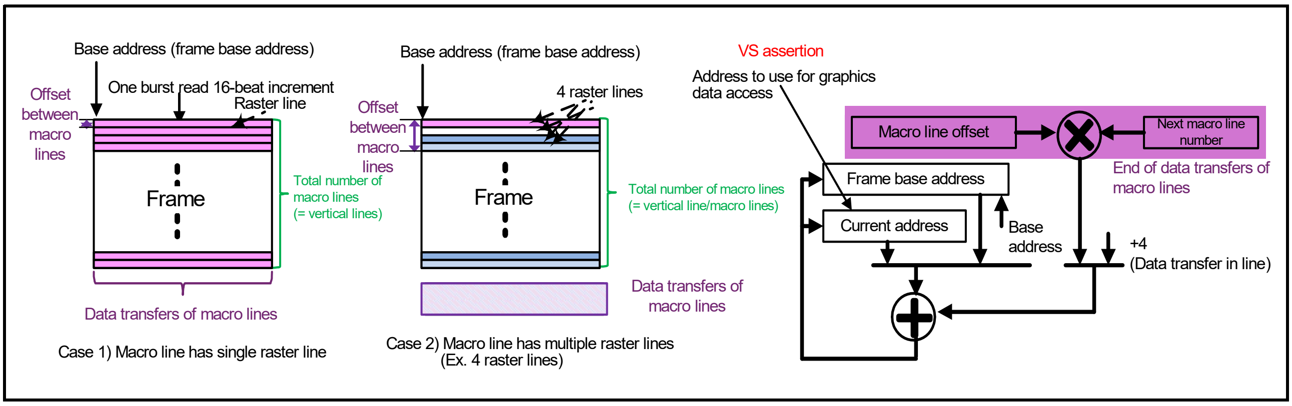

Figure 58.7 Calculation of graphics data access address

Graphics (or CLUT) data is accessed and output to the pixel operation block as ARGB8888 data (32 bits/pixel).

The GPX bus is accessed in word (32-bit) units in 16-beat increment burst reads, in accordance with the preset parameters in the two-dimensional addressing mode, in which the macro line structure is accounted for as shown in Figure 58.7, and data is stored in the data buffer. Even if invalid data is at the macro line end, all the data is stored in the data buffer, and the invalid data is skipped when data is read internally. Regardless of the format of the graphics data, data is extended to ARGB8888 data before being output to the alpha blending blocks.

58.1.8 Blending

The following processes are performed for the graphics areas specified in the registers. The lower-layer graphics plane is output without any processing to the display area outside the graphics area.

- Display plane selection
- RGB-index chroma-key
- Alpha blending.

Figure 58.8 shows the relationship between the graphics display selection and rectangular alpha blending area.

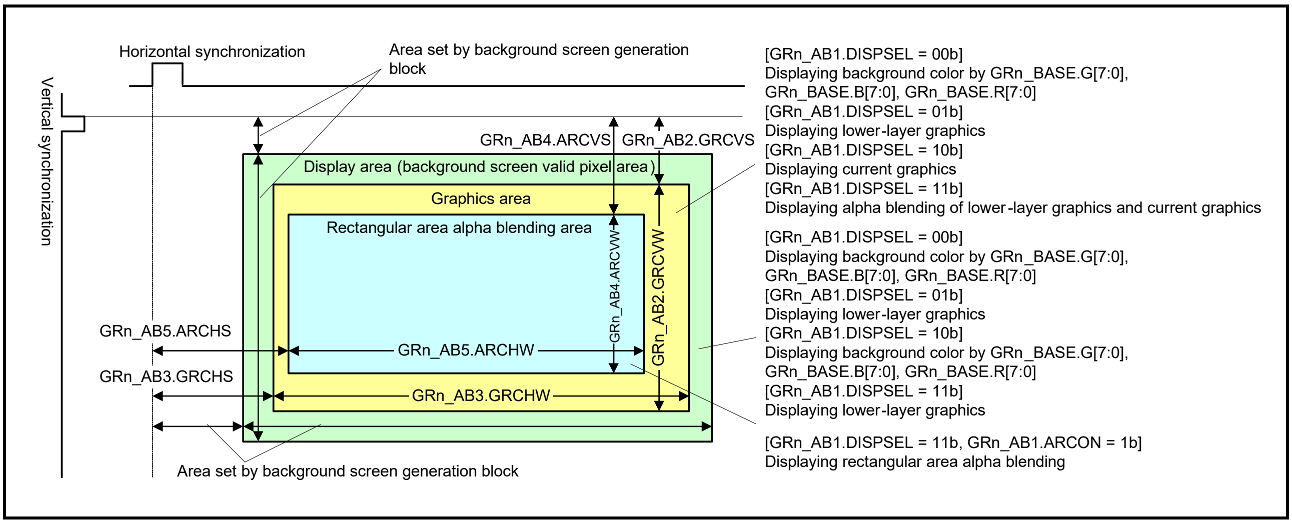

Figure 58.8 Graphics display selection

(1) Display plane selection

Based on the register settings, the following data is output to the graphics area:

- Background color:
  - RGB data specified in the registers.

- Lower-layer graphics:
  - RGB data input from the previous module
  - Output from the background screen generation block for graphics 1
  - Output from graphics 1 for graphics 2.
- Current graphics:
  - RGB data obtained by the graphics data interface block extending the graphics data read by the graphics 1 or 2 module through the GPX bus or CLUT data to ARGB8888 format data.
- Blending:
  - RGB data obtained by blending the lower-layer graphics data and current graphics data obtained by the graphics data interface block extension to ARGB8888 format data, based on the alpha blending values or the register settings.

It is possible to modify the register values related to these functions while display operation is in progress, and to allow reflection of the updates to the internal operations when the VS (vertical synchronization signal) is asserted, if reflection of the register settings to the internal operations on vertical synchronization is enabled.

(2) RGB-index chroma-key

If the RGB value of the ARGB8888 data input from the graphics data interface block agrees with the value set in the GRn_AB8 register, the ARGB8888 data is entirely replaced with the value preset in the GRn_AB9 register. All the ARGB8888 data input from the graphics data interface block is subject to this process. If your application excludes CLUT memory output from this process, you must disable the corresponding process in GRn_AB7.CKON.

(3) Alpha blending

If blending is selected in the selected display plane, lower-layer graphics and current graphics are alpha-blended based on the register settings using either of the following two functions.

(a) Alpha-blending in a rectangular area

The following process is performed for the rectangular area (in the graphics area) preset in the registers:

1. Lower-layer graphics and current graphics planes are blended in accordance with the A value set in the registers.
2. After the number of frames set in the registers passes, the A value is updated to the A value + Δ (register setting).
3. The lower-layer graphics and current graphics planes are blended in accordance with this updated A value.
4. The process of updating the A value after the number of frames set in the registers passes is repeated (A value: min/max value saturation).

(b) Alpha-blending in pixel units

The lower-layer graphics and current graphics planes are blended in accordance with the A value of the ARGB8888 data input from the graphics data interface block.

Figure 58.9 shows the update of the alpha blending value in the rectangular alpha blending area.

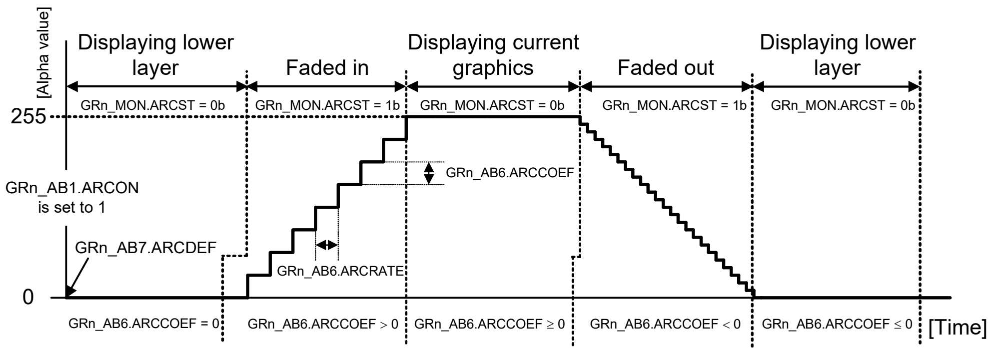

Figure 58.9 Updating of alpha blending value

Alpha blending is based on the following formulas:

When A value = 255
Rout/Gout/Bout = current graphics data
When A value $\neq$ 255
$\mathrm{Rout} = (\mathrm{Rin1} \times A + \mathrm{Rin0} \times (256 - A))/256$
$\mathrm{Gout} = (\mathrm{Gin1} \times A + \mathrm{Gin0} \times (256 - A))/256$
$\mathrm{Bout} = (\mathrm{Bin1} \times A + \mathrm{Bin0} \times (256 - A))/256$

where,

A: alpha blending value
Rin1/Gin1/Bin1: current graphics data
Rin0/Gin0/Bin0: lower-layer graphics data

58.2 Register Descriptions

58.2.1 Color Palette (CLUT)

- Color Palette 0 Plane for Graphics 1 Plane 0 to Color Palette 0 Plane for Graphics 1 Plane 255 (GR1_CLUT0[0] to GR1_CLUT0[255])
  Address(es): GLCDC.GR1_CLUT0[0] 400E 0000h to GLCDC.GR1_CLUT0[255] 400E 03FCh
- Color Palette 1 Plane for Graphics 1 Plane 0 to Color Palette 1 Plane for Graphics 1 Plane 255 (GR1_CLUT1[0] to GR1_CLUT1[255])
  Address(es): GLCDC.GR1_CLUT1[0] 400E 0400h to GLCDC.GR1_CLUT1[255] 400E 07FCh
- Color Palette 0 Plane for Graphics 2 Plane 0 to Color Palette 0 Plane for Graphics 2 Plane 255 (GR2_CLUT0[0] to GR2_CLUT0[255])
  Address(es): GLCDC.GR2_CLUT0[0] 400E 0800h to GLCDC.GR2_CLUT0[255] 400E 0BFCh
- Color Palette 1 Plane for Graphics 2 Plane 0 to Color Palette 1 Plane for Graphics 2 Plane 255 (GR2_CLUT1[0] to GR2_CLUT1[255])
  Address(es): GLCDC.GR2_CLUT1[0] 400E 0C00h to GLCDC.GR2_CLUT1[255] 400E 0FFCh

x: Undefined

Bit	Symbol	Bit name	Description	R/W
b7 to b0	B[7:0]	B Value of Color Palette n Plane for Graphics m Plane	B value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

Bit	Symbol	Bit name	Description	R/W
b15 to b8	G[7:0]	G Value of Color Palette n Plane for Graphics m Plane	G value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
b23 to b16	R[7:0]	R Value of Color Palette n Plane for Graphics m Plane	R value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
b31 to b24	A[7:0]	Alpha Blending Value of Color Palette n Plane for Graphics m Plane	Alpha blending value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

B[7:0] bits (B Value of Color Palette n Plane for Graphics m Plane)

The B[7:0] bits set the B value when this color palette is used.

G[7:0] bits (G Value of Color Palette n Plane for Graphics m Plane)

The G[7:0] bits set the G value when this color palette is used.

R[7:0] bits (R Value of Color Palette n Plane for Graphics m Plane)

The R[7:0] bits set the R value when this color palette is used.

A[7:0] bits (Alpha Blending Value of Color Palette n Plane for Graphics m Plane)

The A[7:0] bits set the alpha blending value when this color palette is used.

All the planes can always be accessed through the register access bus (internal peripheral bus 8), regardless of the plane specified to be used by the graphics data access block. The updates are reflected to the internal operations directly, not in synchronization with the vertical synchronization signal. To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for internal operations, and then modify the GRn_CLUTINT.SEL bit for controlling the plane that is to be used.

58.2.2 Background Plane Setting Operation Control Register (BG_EN)

Address(es): GLCDC.BG_EN 400E 1000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	VEN	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	EN	Background Plane Operation Enable	0: Disable background plane operation 1: Enable background plane operation.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	VEN	Control of GLCDC Internal Register Value Reflection to Internal Operations	0: Disable GLCDC register values from being reflected in internal operations at start of screen generation 1: Enable GLCDC register values to be reflected in internal operations at start of screen generation. This bit is cleared to 0 by an internal source.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SWRST	Software Reset Control	0: Place entire module in software reset state 1: Release entire module from software reset state.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

EN bit (Background Plane Operation Enable)

The EN bit enables or disables the operation of the background plane generation module. When the operation is stopped (this bit is cleared to 0) after the operation is enabled (set to 1), the operation is stopped at the end of screen generation, unlike when a software reset occurs.

When setting this bit to 1, set the BG_EN.VEN bit to 1 simultaneously to enable register value reflection to internal operations. When clearing this bit to 0, also clear the BG_EN.VEN bit to 0 simultaneously. Before clearing this bit to 0, confirm that the BG_MON.VEN bit is cleared to 0, to make sure that the signal for controlling reflection of the register values to internal operations is negated. Operation is not guaranteed if this bit and the BG_EN.VEN bit are set to 1, or if the settings in other registers are modified before the BG_MON.EN bit is cleared to 0.

VEN bit (Control of GLCDC Internal Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the GLCDC internal register to the GLCDC internal operation on assertion of the vertical synchronization signal (input). When this bit is set to 1, the signal of GLCDC internal register values reflection control is set to 1 at the immediate start of the screen, and are automatically cleared to 0 at the end of the vertical valid pixel of the same screen. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, while this bit is 1, do not modify any register whose value is reflected to the internal operations at the start of the screen in the GLCDC or on assertion of the vertical synchronization signal (input). Otherwise, operation is not guaranteed.

SWRST bit (Software Reset Control)

The SWRST bit controls a software reset of the entire GLCDC, not only the background plane generation module. When this bit is cleared to 0, the GLCDC enters the reset state from any operation state. This bit must be set to 1 before the registers are set or operation enabled. Although the registers (except the CLUT memory and the some of the operation control registers) can be set while this bit is set to 1 (immediately after), before accessing the CLUT memory, enabling operation, or reflecting the register values to the internal operation by the vertical synchronization signal, confirm that PXCLK/LCD_CLK and PCLKA are supplied and that the BG_MON.SWRST bit, which monitors the entire module software reset state, is set to 1. Operation is not guaranteed if the software accesses CLUT memory, enables operation, or reflects the register vales to the internal operation on the vertical synchronization signal while PXCLK/LCD_CLK and PCLKA are not supplied or the BG_MON.SWRST bit is not set to 1. The peripheral bus clock (PCLKA) must be supplied to the GLCDC when this bit is used to apply or cancel a software reset. If PCLKA is not supplied, writing to this bit is impossible.

The bits in this register control the GLCDC states. The internal states can be read from the associated bits in the status monitor registers and BG_EN.VEN (this register). Because the GLCDC, which operates on multiple clock signals, requires a certain period for state transition, you must confirm that the internal state has stabilized (state transition is complete) when settings are modified. Operation is not guaranteed if settings are modified again before the internal state stabilizes (state transition is complete). However, clearing a software reset to 0 immediately makes the whole GLCDC reset, setting it to 1 releases the reset state. These operations do not require the clock supply of PXCLK.

58.2.3 Background Plane Setting Free-Running Period Register (BG_PERI)

Address(es): GLCDC.BG_PERI 400E 1004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	FV[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FH[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1

Bit	Symbol	Bit name	Description	R/W
b10 to b0	FH[10:0]	Background Plane Horizontal Synchronization Signal Period	Period based on pixel clocks (PXCLK). 017h: 24 cycles (pixels) 3FFh: 1024 cycles (pixels). Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	FV[10:0]	Background Plane Vertical Synchronization Signal Period	Period based on lines. 013h: 20 lines 3FFh: 1024 lines. Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

FH[10:0] bits (Background Plane Horizontal Synchronization Signal Period)

The FH[10:0] bits set the horizontal synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 017h to 3FFh. Operation is not guaranteed if a value outside the valid range is set.

FV[10:0] bits (Background Plane Vertical Synchronization Signal Period)

The FV[10:0] bits set the vertical synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 013h to 3FFh. Operation is not guaranteed if a value outside the valid range is set.

58.2.4 Background Plane Setting Synchronization Position Register (BG_SYNC)

Address(es): GLCDC.BG_SYNC 400E 1008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	VP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	HP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit name	Description	R/W
b3 to b0	HP[3:0]	Background Plane Horizontal Synchronization Signal Assertion Position	Position based on pixel clocks (PXCLK). 0h: Setting prohibited 1h: 1st cycle (pixel) : Fh: 15th cycle (pixel).	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	VP[3:0]	Background Plane Vertical Synchronization Assertion Position	Position based on lines. 0h: Setting prohibited 1h: 1st line : Fh: 15th line.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HP[3:0] bits (Background Plane Horizontal Synchronization Signal Assertion Position)

The HP[3:0] bits set the horizontal synchronization signal assertion position of the background plane. The signal is held asserted for a 4-pixel clock width.

VP[3:0] bits (Background Plane Vertical Synchronization Assertion Position)

The VP[3:0] bits set the vertical synchronization signal assertion position of the background plane. The signal is held asserted for a 1H width, and the assertion timing within a single horizontal line is specified in BG_SYNC.HP[3:0].

58.2.5 Background Plane Setting Full Image Vertical Size Register (BG_VSIZE)

Address(es): GLCDC.BG_VSIZE 400E 100Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	VW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	VW[10:0]	Background Plane Vertical Valid Pixel Width	Width based on lines. 010h: 16 lines : 3FCh: 1020 lines. Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	VP[10:0]	Background Plane Vertical Valid Pixel Start Position	Position based on of lines. 003h: 3rd line : 3EFh: 1007th lines Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

VW[10:0] bits (Background Plane Vertical Valid Pixel Width)

The VW[10:0] bits set the vertical valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 010h to 3FCh. Operation is not guaranteed if a value outside the valid range is set.

VP[10:0] bits (Background Plane Vertical Valid Pixel Start Position)

The VP[10:0] bits set the vertical valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 003h to 3EFh. Operation is not guaranteed if a value outside the valid range is set.

Specify the vertical valid pixel area between the assertion position of the vertical synchronization signal + 2 and the (background plane end - 1)th line. Operation is not guaranteed if the area is specified outside this range.

58.2.6 Background Plane Setting Full Image Horizontal Size Register (BG_HSIZE)

Address(es): GLCDC.BG_HSIZE 400E 1010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	HP[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	HW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	HW[10:0]	Background Plane Horizontal Valid Pixel Width	Width based on pixel clocks (PXCLK). 010h: 16 cycles : 3F8h: 1016 cycles. Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	HP[10:0]	Background Plane Horizontal Valid Pixel Start Position	Position based on pixel clocks (PXCLK). 006h: 6th cycle (pixel) : 3EEh: 1006th cycle (pixel). Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HW[10:0] bits (Background Plane Horizontal Valid Pixel Width)

The HW[10:0] bits set the horizontal valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 010h to 3F8h. Operation is not guaranteed if a value outside the valid range is set. When serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to these bits.

HP[10:0] bits (Background Plane Horizontal Valid Pixel Start Position)

The HP[10:0] bits set the horizontal valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 000h to 7FFh. However, the valid range is 006h to 3EEh. Operation is not guaranteed if a value outside the valid range is set.

Specify the horizontal valid pixel area between the assertion position of the horizontal synchronization signal + 5 and pixel number (line end - 2). Operation is not guaranteed if the area is specified outside this range.

The background plane generation module outputs the values that are specified in the Background Color Register (BG_BGC) for the area defined by the Full Image Vertical Size Register (BG_VSIZE) and Full Image Horizontal Size Register (BG_HSIZE), and it outputs 00h as the RGB values for the blanking interval area.

58.2.7 Background Plane Setting Background Color Register (BG_BGC)

Address(es): GLCDC.BG_BGC 400E 1014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit name	Description	R/W
b0	EN	Background Plane Operation Monitor	0: Operation is stopped 1: Operation is in progress.	R
b7 to b1	—	Reserved	These bits are read as 0.	R

Bit	Symbol	Bit name	Description	R/W
b8	VEN	Entire Module Internal Operation Reflection Control Signal Monitor	0: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is negated 1: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is asserted.	R
b15 to b9	—	Reserved	These bits are read as 0.	R
b16	SWRST	Entire Module SW Reset State Monitor	0: Entire module is in software reset state 1: Entire module is released from software reset state.	R
b31 to b17	—	Reserved	These bits are read as 0.	R

EN bit (Background Plane Operation Monitor)

The EN bit indicates whether the background plane generation module is operating or not. To stop the operation of the background plane generation module by clearing BG_EN.EN to 0, read this bit to confirm that the operation of the background plane is complete. Clearing BG_EN.EN to 0 does not stop the operation until completion of the background plane, unlike when BG_EN.SWRST is cleared to 0.

VEN bit (Entire Module Internal Operation Reflection Control Signal Monitor)

The VEN bit indicates the value of the signal for controlling reflection of the GLCDC internal register values to the internal operations. This signal is asserted at the start of a screen immediately after setting BG_EN.VEN to 1 and negated at the VE negate timing output from the background screen generation block.

SWRST bit (Entire Module SW Reset State Monitor)

The SWRST bit indicates the software reset state of the entire module when PXCLK is supplied. This bit value indicates the result of the peripheral module clock A (PCLKA) resampling the result of the pixel clock (PXCLK) sampling the BG_EN.SWRST bit. Even if PXCLK is not supplied, clearing the BG_EN.SWRST to 0 clears this bit to 0.

58.2.9 Graphics 1 Register Update Control Register (GR1_VEN)
Graphics 2 Register Update Control Register (GR2_VEN)

Address(es): GLCDC.GR1_VEN 400E 1100h, GLCDC.GR2_VEN 400E 1200h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PVEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	PVEN	Control of Graphics n Register Value Reflection to Internal Pixel Operations	0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS). This bit is cleared to 0 by an internal source.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PVEN bit (Control of Graphics n Register Value Reflection to Internal Pixel Operations)

The PVEN bit enables or disables reflection of the register values to the internal operations of the pixel operation circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and are automatically cleared to 0. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, if the signal output is asserted from the background plane generation module that controls reflection of the register values to the internal operations of all the modules, the register values are always reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in this block. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

58.2.10 Graphics 1 Frame Buffer Read Control Register (GR1_FLMRD)
Graphics 2 Frame Buffer Read Control Register (GR2_FLMRD)

Address(es): GLCDC.GR1_FLMRD 400E 1104h, GLCDC.GR2_FLMRD 400E 1204h

Bit	Symbol	Bit name	Description	R/W
b0	RENB	Graphics Data Read Enable	0: Disable reading 1: Enable reading. Graphics data is the frame buffer data.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

RENB bit (Graphics Data Read Enable)

The RENB bit enables or disables reading of the graphics data (frame buffer data in memory connected through the GPX bus). If the current graphics data is required, data read must be enabled (GRn_FLMRD.RENB = 1) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

If the current graphics data is not required, data read must be disabled (GRn_FLMRD.RENB = 0) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

58.2.11 Graphics 1 Frame Buffer Control Register 1 (GR1_FLM1) Graphics 2 Frame Buffer Control Register 1 (GR2_FLM1)

Bit	Symbol	Bit name	Description	R/W
b1, b0	BSTMD[1:0]	Burst Transfer Control for Graphics Data Access	b1 b0 0 0: Setting prohibited 0 1: Setting prohibited 1 0: Setting prohibited 1 1: 16-beat increment burst transfer (64-byte boundary). Graphics data is the frame buffer data.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BSTMD[1:0] bits (Burst Transfer Control for Graphics Data Access)

The BSTMD[1:0] bits control burst transfers for accessing the graphics data (frame buffer data in memory connected to memory through the GPX bus). In this GLCDC, these bits are fixed to 11b. Operation is not guaranteed if these bits are set to any other value.

58.2.12 Graphics 1 Frame Buffer Control Register 2 (GR1_FLM2) Graphics 2 Frame Buffer Control Register 2 (GR2_FLM2)

	BASE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b31 to b0	BASE[31:0]	Base Address for Accessing Graphics Data	Start address in the frame buffer where graphics data is to be stored. Fix GRn_FLM2.BASE[5:0] to 0 during 64-byte burst transfer.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BASE[31:0] bits (Base Address for Accessing Graphics Data)

The BASE[31:0] bits specify the base address (start address in the first frame buffer) for graphics data access. Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM2.BASE[5:0]) must be fixed to 0.

58.2.13 Graphics 1 Frame Buffer Control Register 3 (GR1_FLM3) Graphics 2 Frame Buffer Control Register 3 (GR2_FLM3)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	LNOFF[15:0]	Macro Line Offset Address for Accessing Graphics Data	Macro line offset address for accessing graphics data (frame buffer data). Signed, 16-bit integer.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LNOFF[15:0] bits (Macro Line Offset Address for Accessing Graphics Data)

The LNOFF[15:0] bits specify the macro line offset address for accessing graphics data (offset to be added to the current address at the macro line end for calculating the start address of the next macro line). Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM3.LNOFF[5:0]) must be fixed to 0.

58.2.14 Graphics 1 Frame Buffer Control Register 5 (GR1_FLM5)
Graphics 2 Frame Buffer Control Register 5 (GR2_FLM5)

Address(es): GLCDC.GR1_FLM5 400E 1118h, GLCDC.GR2_FLM5 400E 1218h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	LNNUM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DATANUM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b15 to b0	DATANUM[15:0]	Number of Data Transfer Times Per Line for Accessing Graphics Data	Number of data transfers per macro line for accessing graphics data (frame buffer data), where one transfer is defined as 16-beat burst access (64-byte boundary). 0000h: Once : FFFFh: 65536 times.	R/W
b26 to b16	LNNUM[10:0]	Number of Lines Per Frame for Accessing Graphics Data	Number of macro lines per frame for accessing graphics data (frame buffer data). 000h: 1 macro line : 3FBh: 1020 macro lines. Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DATANUM[15:0] bits (Number of Data Transfer Times Per Line for Accessing Graphics Data)

The DATANUM[15:0] bits specify the number of data transfers per macro line for accessing graphics data, where one transfer is defined as a 16-beat burst access through the GPX bus. For all the data transfers, at least 2 bytes of valid pixel data are required (16 pixels in LUT1 format and 16 pixels or more in the other formats). If the number of bytes per macro line cannot be divided by 64 (4 bytes × 16-beat), DATANUM is obtained by rounding up to the whole number.

LNNUM[10:0] bits (Number of Lines Per Frame for Accessing Graphics Data)

The LNNUM[10:0] bits specify the number of lines per frame for accessing graphics data. When graphics data for the number of lines set to these bits is read, it signals the end of the frame and the base address is loaded.

The following are two use cases for macro lines. In these use cases, the frame size is 480 pixels × 272 lines and the pixel format is RGB565 (16 bpp).

Case 1) One macro line is configured to be equivalent to the frame raster width. The number of macro lines is equivalent to the number of vertical lines.

DATANUM: 000Eh (15 times = 16 × 480 / 512)
LNNUM: 10Fh (272 macro lines = 272 / 1)

Case 2) One macro line is configured to be repeated during the display frame. The number of macro lines is not equivalent to the number of vertical lines. In the example, one macro line has 16 times the raster width.

DATANUM: 00EFh (240 times = 16 × 480 / 512 × 16)
LNNUM: 010h (17 macro lines = 272 / 16)

58.2.15 Graphics 1 Frame Buffer Control Register 6 (GR1_FLM6) Graphics 2 Frame Buffer Control Register 6 (GR2_FLM6)

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b27 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b30 to b28	FORMAT[2:0]	Data Format for Accessing Graphics Data	Data format for accessing graphics data (frame buffer data). b30 b28 0 0 0: RGB565 (16 bits/pixel) 0 0 1: RGB888 (32 bits/pixel, 8 bits on the MSB side are invalid) 0 1 0: ARGB1555 (16 bits/pixel, 1 bit of A is LUT data) 0 1 1: ARGB4444 (16 bits/pixel) 1 0 0: ARGB8888 (32 bits/pixel) 1 0 1: CLUT8 (8 bits/pixel) 1 1 0: CLUT4 (4 bits/pixel) 1 1 1: CLUT1 (1 bit/pixel).	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

FORMAT[2:0] bits (Data Format for Accessing Graphics Data)

The FORMAT[2:0] bits specify the data format for accessing graphics data. CLUT1, CLUT4, CLUT8 contain the addresses 01h or 00h, 0Fh to 00h, and FFh to 00h, respectively, for accessing the color palette. ARGB1555 contains the address for accessing the color palette (80h or 00h) in the MSB and RGB data in the other bits. ARGB8888 and ARGB4444 contain the upper 8-bit or 4-bit alpha blending values and RGB data. RGB888 and RGB565 contain RGB data only.

58.2.16 Graphics 1 Alpha Blending Control Register 1 (GR1_AB1) Graphics 2 Alpha Blending Control Register 1 (GR2_AB1)

Bit	Symbol	Bit name	Description	R/W
b1, b0	DISPSEL[1:0]	Graphics Display Plane Control	b1 b0 0 0: Background color display (value set in the GRn_BASE register) 0 1: Lower-layer graphics display 1 0: Current graphics display 1 1: Blended display of lower-layer graphics (input image from the previous stage) and current graphics (data read from the GPX bus).	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	GRCDISPON	Graphics Image Area Border Display Control	0: Turn display off 1: Turn display on.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	ARCDISPON	Image Area Border Display Control for Rectangular Area Alpha Blending	0: Turn display off 1: Turn display on.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	ARCON	Rectangular Area Alpha Blending Control	0: Turn blending off 1: Turn blending on.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DISPSEL[1:0] bits (Graphics Display Plane Control)

The DISPSEL[1:0] bits control the graphics display plane. When the plane is selected as the lower-layer graphics, the image input from the previous stage is displayed (the background plane for GR1, and output from GR1 for GR2); as the background color, the background color specified in the GLCDC registers is displayed; and as the current graphics, the ARGB8888 data obtained by expanding the graphics data read by the GLCDC from the GPX bus is displayed. When the current graphics display is selected (these bits are set to 10b), RGB888 data is displayed, regardless of the alpha blending value in the pixel. Table 58.8 and Figure 58.10 show the relationship between the register setting and display area.

GRCDISPON bit (Graphics Image Area Border Display Control)

The GRCDISPON bit turns on or off the border display for the graphics image area. When the display is turned on (this bit is set to 1), the graphics image area is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area with the display data set as FFh for each RGB color.

ARCDISPON bit (Image Area Border Display Control for Rectangular Area Alpha Blending)

The ARCDISPON bit turns on or off the border display for the image area where rectangular area alpha blending is performed. When the display is turned on (this bit is set to 1), the image area for the rectangular alpha blending is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area and the display data set as FFh for each RGB color.

ARCON bit (Rectangular Area Alpha Blending Control)

The ARCON bit turns on or off alpha blending in a rectangular area. When alpha blending is turned on (this bit is set to 1), pixels are processed in accordance with the alpha blending control specified in the relevant registers for the specified rectangular area, not in accordance with the alpha value input from the graphics data interface for each pixel. In the areas outside the rectangular area in the graphics area, pixels are processed in accordance with the alpha value input from the graphics data interface for each pixel.

Table 58.8 Display selections

GRn_AB1. DISPSEL[1:0] (display plane)	GRn_AB1. ARCON (rectangular)	GRn_AB7. CKON (chroma key)	Within rectangular alpha blending area	Outside rectangular alpha blending area within graphics area	Outside graphics area within display area	Outside display area
00b	0	0	-	Background color	Background color	Lower layer R = G = B = 00h
01b	0	0	-	Lower layer	Lower layer	Lower layer R = G = B = 00h
10b	0	0	-	Current	Background color	Lower layer R = G = B = 00h
11b	0	0	-	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 00h
11b	0	1	-	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 00h
11b	1	0	Current + rectangular alpha blending	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 00h
11b	1	1	Current + rectangular alpha blending	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 00h

Note: Operation is not guaranteed when any other value is set.

b26 to b16	GRCVS[10:0]	Vertical Start Position of Graphics Image Area	Position in lines. 002h: 2nd line : 3EEh: 1006th line. Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GRCVW[10:0] bits (Vertical Width of Graphics Image Area)

The GRCVW[10:0] bits specify the vertical width of the graphics image area.

GRCVS[10:0] bits (Vertical Start Position of Graphics Image Area)

The GRCVS[10:0] bits specify the vertical start position of the graphics image area, in reference to assertion of the vertical synchronization signal (VS). For the relationship with the graphics display plane, see Figure 58.10.

58.2.18 Graphics 1 Alpha Blending Control Register 3 (GR1_AB3) Graphics 2 Alpha Blending Control Register 3 (GR2_AB3)

Bit	Symbol	Bit name	Description	R/W
b7 to b0	ARCRATE[7:0]	Frame Rate for Alpha Blending in Rectangular Area	00h: 1 frame : FFh: 256 frames.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24 to b16	ARCCOEF[8:0]	Alpha Coefficient for Alpha Blending in Rectangular Area	Valid settings: -255 to 255. Bit [8]: Sign 0: Add 1: Subtract. Bits [7:0]: Variation, as an absolute value.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCRATE[7:0] bits (Frame Rate for Alpha Blending in Rectangular Area)

The ARCRATE[7:0] bits specify the frame rate for alpha blending in a rectangular area.

ARCCOEF[8:0] bits (Alpha Coefficient for Alpha Blending in Rectangular Area)

The ARCCOEF[8:0] bits specify the alpha coefficient for alpha blending in a rectangular area.

In alpha blending in a rectangular area, current graphics are faded in or out with the GRn_AB7.ARCDEF[7:0], GRn_AB6.ARCCOEF[8:0], and GRn_AB6.ARCRATE[7:0] settings. If the alpha value is set in the GR_ARC_DEF[7:0] bits, the GR_ARC_DEF[7:0] bits and the alpha blending in a rectangular area are turned on. Each time the vertical synchronization signal (VS) rises the number of times set in the GR_ARC_RATE[7:0] bits, the value in GR_ARC_COEF[8:0] is added to or subtracted from the alpha value. Figure 58.11 shows change in the alpha value.

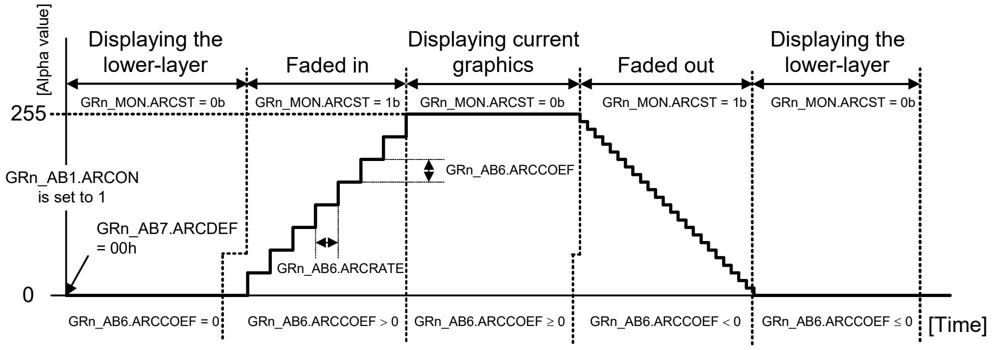

Figure 58.11 Changes in alpha value

58.2.22 Graphics 1 Alpha Blending Control Register 7 (GR1_AB7) Graphics 2 Alpha Blending Control Register 7 (GR2_AB7)

Address(es): GLCDC.GR1_AB7 400E 1138h, GLCDC.GR2_AB7 400E 1238h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	CKON	RGB-Index Chroma-Key Processing Control	0: Disable chroma-key processing 1: Enable chroma-key processing.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	ARCDEF[7:0]	Initial Alpha Value for Alpha Blending in Rectangular Area	Initial alpha value for alpha blending in rectangular area.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CKON bit (RGB-Index Chroma-Key Processing Control)

The CKON bit turns RGB-index chroma-key processing on or off. This function is enabled only if this bit is 1 when the graphics display plane is the blended display (GRn_AB1.DISPSEL[1:0] = 11b). And it is reflected to the graphics area except alpha blending in a rectangular area. For details, see Table 58.8.

ARCDEF[7:0] bits (Initial Alpha Value for Alpha Blending in Rectangular Area)

The ARCDEF[7:0] bits specify the initial alpha value for alpha blending in a rectangular area. For changes in the alpha value during fade-in or fade-out of the current graphics using this bit, see Figure 58.11.

58.2.23 Graphics 1 Alpha Blending Control Register 8 (GR1_AB8) Graphics 2 Alpha Blending Control Register 8 (GR2_AB8)

Address(es): GLCDC.GR1_AB8 400E 113Ch, GLCDC.GR2_AB8 400E 123Ch

	CKKB[7:0]								CKKR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CKKR[7:0]	R Signal for RGB-Index Chroma-Key Processing	R signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
b15 to b8	CKKB[7:0]	B Signal for RGB-Index Chroma-Key Processing	B signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
b23 to b16	CKKG[7:0]	G Signal for RGB-Index Chroma-Key Processing	G signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If RGB-index chroma-key processing is enabled when the RGB values of the current bit graphics agree with the values of the associated chroma-key bits, the image data of the current graphics (ARGB8888, including the alpha blending values) is replaced by the values in the GRn_AB9 register. In alpha blending in pixel units at later stages, the latest alpha values are used.

CKKR[7:0] bits (R Signal for RGB-Index Chroma-Key Processing)

The CKKR[7:0] bits specify the value to be compared with the R value of the current graphics in the RGB-index chroma-key processing.

CKKB[7:0] bits (B Signal for RGB-Index Chroma-Key Processing)

The CKKB[7:0] bits specify the value to be compared with the B value of the current graphics in the RGB-index chroma-key processing.

CKKG[7:0] bits (G Signal for RGB-Index Chroma-Key Processing)

The CKKG[7:0] bits specify the value to be compared with the G value of the current graphics in the RGB-index chroma-key processing.

58.2.24 Graphics 1 Alpha Blending Control Register 9 (GR1_AB9)
Graphics 2 Alpha Blending Control Register 9 (GR2_AB9)

Address(es): GLCDC.GR1_AB9 400E 1140h, GLCDC.GR2_AB9 400E 1240h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CKA[7:0]								CKG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	CKB[7:0]								CKR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CKR[7:0]	R Value after RGB-Index Chroma-Key Processing Replacement	R value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
b15 to b8	CKB[7:0]	B Value after RGB-Index Chroma-Key Processing Replacement	B value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
b23 to b16	CKG[7:0]	G Value after RGB-Index Chroma-Key Processing Replacement	G value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
b31 to b24	CKA[7:0]	A Value after RGB-Index Chroma-Key Processing Replacement	A value after RGB-index chroma-key processing replacement.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If the RGB-index chroma-key processing is enabled and the pixel data is to be replaced (the RGB values of the current graphics agree with the GRn_AB8 values), alpha blending in pixel units is performed in later stages in accordance with this image data.

CKR[7:0] bits (R Value after RGB-Index Chroma-Key Processing Replacement)

The CKR[7:0] bits specify the R value after RGB-index chroma-key processing replacement.

CKB[7:0] bits (B Value after RGB-Index Chroma-Key Processing Replacement)

The CKB[7:0] bits specify the B value after RGB-index chroma-key processing replacement.

CKG[7:0] bits (G Value after RGB-Index Chroma-Key Processing Replacement)

The CKG[7:0] bits specify the G value after RGB-index chroma-key processing replacement.

CKA[7:0] bits (A Value after RGB-Index Chroma-Key Processing Replacement)

The CKA[7:0] bits specify the A value after RGB-index chroma-key processing replacement.

58.2.25 Graphics 1 Background Color Control Register (GR1_BASE) Graphics 2 Background Color Control Register (GR2_BASE)

Address(es): GLCDC.GR1_BASE 400E 114Ch, GLCDC.GR2_BASE 400E 124Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	G[7:0]

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	B[7:0]								R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	R[7:0]	Background Color R Value	Background color R value. Unsigned 8-bit value.	R/W
b15 to b8	B[7:0]	Background Color B Value	Background color B value. Unsigned 8-bit value.	R/W
b23 to b16	G[7:0]	Background Color G Value	Background color G value. Unsigned 8-bit value.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

When the background color is selected in the display selection (GRn_AB1.DISPSEL[1:0] = 00b), this RGB data is output to the entire display image area. When the current graphics setting is selected (GRn_AB1.DISPSEL[1:0] = 10b), the RGB data is output to the outside of the graphics image area within the display image area.

R[7:0] bits (Background Color R Value)

The R[7:0] bits specify the background color R value.

B[7:0] bits (Background Color B Value)

The B[7:0] bits specify the background color B value.

G[7:0] bits (Background Color G Value)

The G[7:0] bits specify the background color G value.

58.2.26 Graphics 1 CLUT Table Interrupt Control Register (GR1_CLUTINT) Graphics 2 CLUT Table Interrupt Control Register (GR2_CLUTINT)

	—	—	—	—	—	LINE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	LINE[10:0]	Number of Detection Lines	000h: 1 line : 3FFh: 1024 lines. Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SEL	CLUT Table Control	0: Select CLUT table 0 1: Select CLUT table 1.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LINE[10:0] bits (Number of Detection Lines)

The LINE[10:0] bits specify the number of lines to be detected. When the number of lines specified in this bit are detected, the event is recognized outside the module on the HS assertion. To retain the status of the recognized event and assert the GLCDC interrupt request signal, set the prescribed value to the State Detection Control Register (SYSCNT_DTCTEN) and Interrupt Request Enable Control Register (SYSCNT_INTEN), which are system control registers. Although this function is provided to both graphics 1 and 2, it is only enabled in graphics 2 in this GLCDC.

SEL bit (CLUT Table Control)

The SEL bit controls the CLUT plane to be used for internal operations. Access to the color palette (CLUT) through the register access bus is always valid for both planes 0 and 1, regardless of the setting in this bit, and the written value is immediately reflected to the internal operations (not in synchronization with the vertical synchronization signal).

To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for the internal operations, and then modify the bits intended for controlling the plane that is to be used for the internal operations.

58.2.27 Graphics 1 Status Monitor Register (GR1_MON) Graphics 2 Status Monitor Register (GR2_MON)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	ARCST	Status Monitor for Alpha Blending in Rectangular Area	0: Fade-in/fade-out not in progress 1: Fade-in/fade-out in progress.	R
b15 to b1	—	Reserved	These bits are read as 0.	R
b16	UNDFLST	Underflow Status Monitor	0: No underflow occurred in internal operations 1: Underflow occurred in internal operations.	R
b31 to b17	—	Reserved	These bits are read as 0.	R

ARCST bit (Status Monitor for Alpha Blending in Rectangular Area)

The ARCST bit indicates whether or not alpha blending (fade-in/fade-out) in a rectangular area is in progress. When alpha blending in a rectangular area is turned on (GRn_AB1.ARCON is set to 1) and the register value is to be reflected to the internal operations on assertion of the vertical synchronization signal (VS), this bit sets to 1 immediately on assertion of the vertical synchronization signal. When alpha blending in a rectangular area is turned off (GRn_AB1.ARCON cleared to 0) or when the alpha blending (fade-in/fade-out) in a rectangular area is complete (alpha blended value reaches the minimum or maximum value), this bit clears to 0. If the alpha coefficient for the alpha blending in a rectangular area (GRn_AB6.ARCCOEF[8:0]) is set to 000h and the initial alpha value for alpha blending in a rectangular area (GRn_AB7.ARCDEF[7:0]) is set to any value other than FFh or 00h, the alpha blending value does not reach the minimum or maximum value, and this bit remains 1 (no timeout processing is performed).

UNDFLST bit (Underflow Status Monitor)

The UNDFLST bit indicates whether or not an underflow has occurred in the internal operations. The underflow interrupt request flag sets when an underflow occurs, and retains its value until it is cleared by software. However, this bit monitors the internal status, and so the flag automatically clears to 0 when the graphics data bus interface initializes on assertion of the vertical synchronization signal. Even when the current graphics data is not required (GRn_AB1.DISPSEL[1:0] = 0xb), this bit sets to 1 during the period from the graphics image valid area start to the next frame vertical synchronization signal (VS) assertion timing set in the registers.

58.2.28 Gamma G Register Update Control Register (GAMG_LATCH)
Gamma B Register Update Control Register (GAMB_LATCH)
Gamma R Register Update Control Register (GAMR_LATCH)

Bit	Symbol	Bit name	Description	R/W
b0	VEN	Control of Gamma Correction x Module Register Value Reflection to Internal Operations	0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS).	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

VEN bit (Control of Gamma Correction x Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the gamma correction circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the background plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

Although there are three VEN bits, one for each G, R, and B color, only the GAMG_LATCH.VEN bit controls the gamma correction with the reflection of the GAM_SW.GAMON bit. To enable gamma correction, set the GAMG_LATCH.VEN bit once after setting the GAM_SW.GAMON bit.

The VEN bit is set to 1 by writing 1, and automatically clears to 0 immediately on assertion of the vertical synchronization signal.

58.2.29 Gamma Correction Block Function Switch Register (GAM_SW)

Address(es): GLCDC.GAM_SW 400E 1304h

	—	—	—	—	—	GAIN01[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	GAIN01[10:0]	Gain Value of Area 1	Unsigned 11-bit fixed point value. 000h: 0.000 (0/1024) : 400h: 1.000 (1024/1024) : 7FFh: 1.999 (2047/1024).	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	GAIN00[10:0]	Gain Value of Area 0	Unsigned 11-bit fixed point value. 000h: 0.000 (0/1024) : 400h: 1.000 (1024/1024) : 7FFh: 1.999 (2047/1024).	R/W

Bit	Symbol	Bit name	Description	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Gamma correction for each color is carried out as follows:

- Din (input signal): 10 bits. To correct the output of graphics 2, 00b is appended as the lower 2 bits for extension
- Dout (output signal): 10 bits
- TH (threshold): 10 bits (register setting); up to 15 can be set
- GAIN (gain): 0/1024 to 2047/1024 for each area (register setting), can be set for up to 16 areas
- OFFSET (offset value): 21 bits (result of internal calculation; calculation of up to 15 points)

The following is automatically calculated from the assertion of the vertical synchronization signal (VS) to the start of valid pixel data internally:

- $\mathrm{Dout} = ((\mathrm{Din} - \mathrm{TH}(n)) \times \mathrm{GAIN}(n) + \mathrm{OFFSET}(n))$
- $\mathrm{OFFSET}(n) = \mathrm{OFFSET}(n - 1) + (\mathrm{TH}(n) - \mathrm{TH}(n - 1)) \times \mathrm{GAIN}(n - 1)$, where $\mathrm{OFFSET}(0) = 0$

Note: Because the gain is a positive number (≥ 0), the correction line shows a monotonic increase.

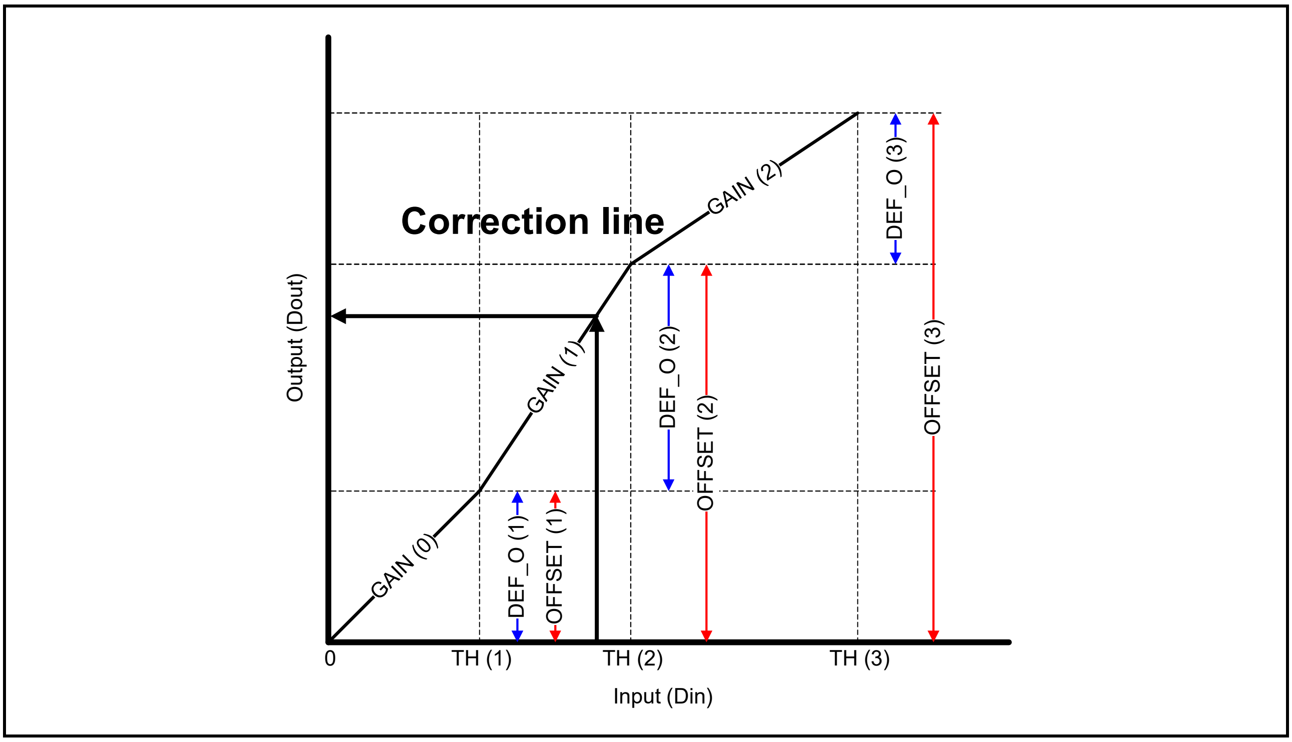

Figure 58.12 Calculation of gamma correction value

GAIN01[10:0] bits (Gain Value of Area 1)

The GAIN01[10:0] bits specify the gain value of area 1 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN00[10:0] bits (Gain Value of Area 0)

The GAIN00[10:0] bits specify the gain value of area 0 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

58.2.31 Gamma G Correction Block Table Setting Register 2 (GAMG_LUT2) Gamma B Correction Block Table Setting Register 2 (GAMB_LUT2) Gamma R Correction Block Table Setting Register 2 (GAMR_LUT2)

Address(es): GLCDC.GAMG_LUT2 400E 130Ch, GLCDC.GAMB_LUT2 400E 134Ch, GLCDC.GAMR_LUT2 400E 138Ch

b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	GAIN12[10:0]	Gain Value of Area 12	Unsigned 11-bit fixed point value. 000h: 0.000 (0/1024) : 400h: 1.000 (1024/1024) : 7FFh: 1.999 (2047/1024).	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN13[10:0] bits (Gain Value of Area 13)

The GAIN13[10:0] bits specify the gain value of area 13 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN12[10:0] bits (Gain Value of Area 12)

The GAIN12[10:0] bits specify the gain value of area 12 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

b9 to b0	TH03[9:0]	Start Threshold of Area 3	Start threshold of area 3. Unsigned 10-bit integer.	R/W
b19 to b10	TH02[9:0]	Start Threshold of Area 2	Start threshold of area 2. Unsigned 10-bit integer.	R/W
b29 to b20	TH01[9:0]	Start Threshold of Area 1	Start threshold of area 1. Unsigned 10-bit integer.	R/W
b31 to b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Set the start threshold TH(n) of area n (n = 0 to 15) to satisfy the following conditions. Otherwise, operation is not guaranteed.

TH (n) < TH (n + 1)
n = 0 to 15 and TH (0) = 000h, TH (16) = 3FFh
TH (n) = TH (n + 1) is valid only if TH (n) = 3FFh.

For details on calculation of the gamma correction value, see section 58.2.30, Gamma G Correction Block Table Setting Register 1 (GAMG_LUT1) Gamma B Correction Block Table Setting Register 1 (GAMB_LUT1) Gamma R Correction Block Table Setting Register 1 (GAMR_LUT1), and Figure 58.12.

TH03[9:0] bits (Start Threshold of Area 3)

The TH03[9:0] bits specify the start threshold of area 3 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH02[9:0] bits (Start Threshold of Area 2)

The TH02[9:0] bits specify the start threshold of area 2 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH01[9:0] bits (Start Threshold of Area 1)

The TH01[9:0] bits specify the start threshold of area 1 to be used for gamma correction in terms of an unsigned 10-bit integer.

Bit	Symbol	Bit name	Description	R/W
b0	VEN	Control of Output Control Module Register Value Reflection to Internal Operations	0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of vertical synchronization signal (VS).	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

VEN bit (Control of Output Control Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the output control circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the ground plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

58.2.44 Output Control Block Output Interface Register (OUT_SET)

Address(es): GLCDC.OUT_SET 400E 13C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Select dither output format in OUT_PDTHA.FORM[1:0].	R/W
b23 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	SWAPON	Pixel Order Control	0: RGB order 1: BGR order.	R/W
b27 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	ENDIANON	Bit Endian Control	0: Descending order (little endian) 1: Ascending order (big endian).	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the settings before operation is enabled. Operation is not guaranteed if the bit is rewritten during operation.

For details on assignment of pixel data to the output pins (LCD_DATA23 to LCD_DATA00) by setting these bits (except for OUT_SET.FRQSEL[1:0]), see Figure 58.3 to Figure 58.6.

PHASE[1:0] bits (Data Output Delay Control in Serial RGB Format)

The PHASE[1:0] bits control data output delay in serial RGB format. When the delay is 0 cycles (these bits are 00b), pixel data (R, B, or invalid data, depending on the setting in this register) is output one pixel clock (PXCLK) cycle after the horizontal data enable signal (HE). When any value other than 00b is set to OUT_SET.PHASE[1:0], pixel data output is delayed for a preset number of LCD_CLK cycles.

DIRSEL bit (**Scan Direction Select of Serial RGB Format**)

The DIRSEL bit controls the data arrangement of the serial RGB format. When this bit is set to 1, the serial RGB data is arranged in reverse direction, and when it is 0, the serial RGB is arranged in forward direction.

FRQSEL[1:0] bits (**Clock Frequency Division Control**)

The FRQSEL[1:0] bits control clock frequency division of LCD_CLK (panel output clock) and PXCLK (pixel clock for internal operations). Set these bits to 10b only for the serial RGB format (OUT_SET.FORMAT[1:0] = 11b), so that PXCLK has a quarter frequency of the LCD_CLK frequency and synchronizes with LCD_CLK. Set these bits to 00b for the parallel RGB format (OUT_SET.FORMAT[1:0] = 10b, 01b, or 00b), so that PXCLK has the same frequency as the LCD_CLK frequency and synchronizes with LCD_CLK. Otherwise, operation is not guaranteed.

FORMAT[1:0] bits (**Output Format Select**)

The FORMAT[1:0] bits select the output format of RGB data. Set these bits in accordance with the output format select bits in the Panel Dither Correction Register (OUT_PDTHA.FORM[1:0]). For serial RGB format (these bits are 11b), set OUT_PDTHA.FORM[1:0] to 00b. Otherwise, operation is not guaranteed.

SWAPON bit (**Pixel Order Control**)

The SWAPON bit controls the pixel order of RGB data output. When this bit is set to 1, internally processed data is assigned to the output pins in BGR order, and when this bit is 0, data is assigned in the RGB order. Data is assigned to the output pins (LCD_DATA23 to LCD_DATA00) with the MSB first for the RGB parallel format, and serially for the RGB serial format.

ENDIANON bit (**Bit Endian Control**)

The ENDIANON bit controls the bit order of RGB data output. When this bit is set to 1, internally processed data is assigned to the output pins in ascending order (big endian), and when this bit is 0, data is assigned in descending order (little endian).

58.2.45 Output Control Block Brightness Correction Register 1 (OUT_BRIGHT1)

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b9 to b0	BRTG[9:0]	Brightness Adjustment of G Signal	Brightness (DC) adjustment of G signal. Unsigned 10-bit integer; +512 with offset.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BRTG[9:0] bits (**Brightness Adjustment of G Signal**)

The BRTG[9:0] bits specify the brightness (DC) adjustment of the G signal.

Brightness correction of the G signal is performed as follows:

- Gout: Output of brightness correction (input of contrast correction); unsigned; 10 bits

- Gin: Input of brightness correction; unsigned; 10 bits
- BRTG: Setting in this bit
- Gout = Gin + BRTG - 512.

58.2.46 Output Control Block Brightness Correction Register 2 (OUT_BRIGHT2)

Address(es): GLCDC.OUT_BRIGHT2 400E 13CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit name	Description	R/W
b9 to b0	BRTR[9:0]	Brightness Adjustment of R Signal	Brightness (DC) adjustment of R signal. Unsigned 10-bit integer; +512 with offset.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	BRTB[9:0]	Brightness Adjustment of B Signal	Brightness (DC) adjustment of B signal. Unsigned 10-bit integer; +512 with offset.	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BRTR[9:0] bits (Brightness Adjustment of R Signal)

The BRTR[9:0] bits specify the brightness (DC) adjustment of the R signal.

Brightness correction of the R signal is performed as follows:

- Rout: Output of brightness correction (input of contrast correction); unsigned; 10 bits
- Rin: Input of brightness correction; unsigned; 10 bits
- BRTR: Setting in this bit
- Rout = Rin + BRTR - 512.

BRTB[9:0] bits (Brightness Adjustment of B Signal)

The BRTB[9:0] bits specify the brightness (DC) adjustment of the B signal.

Brightness correction of the B signal is performed as follows:

- Bout: Output of brightness correction (input of contrast correction); unsigned; 10 bits
- Bin: Input of brightness correction; unsigned; 10 bits
- BRTB: Setting in this bit
- Bout = Bin + BRTB - 512.

58.2.47 Output Control Block Contrast Correction Register (OUT_CONTRAST)

Address(es): GLCDC.OUT_CONTRAST 400E 13D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	CONTB[7:0]								CONTR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b7 to b0	CONTR[7:0]	Contrast Adjustment of R Signal	Unsigned 8-bit fixed point value adjusting GAIN on R signal. 00h: 0/128 = 0.000 : 80h: 128/128 = 1.000 : FFh: 255/128 = 1.992.	R/W
b15 to b8	CONTB[7:0]	Contrast Adjustment of B Signal	Unsigned 8-bit fixed point value adjusting GAIN on B signal. 00h: 0/128 = 0.000 : 80h: 128/128 = 1.000 : FFh: 255/128 = 1.992.	R/W
b23 to b16	CONTG[7:0]	Contrast Adjustment of G Signal	Unsigned 8-bit fixed point value adjusting GAIN on G signal. 00h: 0/128 = 0.000 : 80h: 128/128 = 1.000 : FFh: 255/128 = 1.992.	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CONTR[7:0] bits (Contrast Adjustment of R Signal)

The CONTR[7:0] bits specify the contrast (GAIN) adjustment of R signal. The location of the decimal point is between bit [7] and [6].

CONTB[7:0] bits (Contrast Adjustment of B Signal)

The CONTB[7:0] bits specify the contrast (GAIN) adjustment of B signal. The location of the decimal point is between bit [7] and [6].

CONTG[7:0] bits (Contrast Adjustment of G Signal)

The CONTG[7:0] bits specify the contrast (GAIN) adjustment of G signal. The location of the decimal point is between bit [7] and [6].

Contrast correction of each pixel is performed as follows (x = R, G, B):

- Dxout: Output of contrast correction; unsigned; 10 bits
- Dxin: Input of contrast correction (output of brightness correction); unsigned; 10 bits
- CONTx: Setting in this bit

- Dxout = Dxin × CONTx.

58.2.48 Output Control Block Panel Dither Correction Register (OUT_PDTHA)

Address(es): GLCDC.OUT_PDTHA 400E 13D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit name	Description	R/W
b1, b0	PD[1:0]	Pattern Value (D) of 2×2 Pattern Dither	Pattern value (D) of 2×2 pattern dither. Unsigned 2-bit integer.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	PC[1:0]	Pattern Value (C) of 2×2 Pattern Dither	Pattern value (C) of 2×2 pattern dither. Unsigned 2-bit integer.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	PB[1:0]	Pattern Value (B) of 2×2 Pattern Dither	Pattern value (B) of 2×2 pattern dither. Unsigned 2-bit integer.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13, b12	PA[1:0]	Pattern Value (A) of 2×2 Pattern Dither	Pattern value (A) of 2×2 pattern dither. Unsigned 2-bit integer.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	FORM[1:0]	Output Format Select	b17 b16 0 0: RGB888; select RGB888 or serial RGB as output interface format 0 1: RGB666; select RGB666 as output interface format 1 0: RGB565; select RGB565 as output interface format 1 1: Setting prohibited. Select output interface format in OUT_SET.FORMAT[1:0].	R/W
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b21, b20	SEL[1:0]	Operation Mode	b21 b20 0 0: Truncate 0 1: Round-off 1 0: 2×2 pattern dither 1 1: Setting prohibited.	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

PA[1:0], PB[1:0], PC[1:0], PD[1:0] bits (Pattern Value (A, B, C, D) of 2×2 Pattern Dither)

The PA[1:0], PB[1:0], PC[1:0], and PD[1:0] bits specify the pattern value A, B, C, and D of 2×2 pattern dither. Figure 58.13 shows the configuration of the dither correction block.

FORM[1:0] bits (Output Format Select)

The FORM[1:0] bits specify the output format of the dither process. These bits must be set in accordance with the OUT_SET.FORMAT[1:0] bits of the Output Interface Register. For serial RGB (OUT_SET.FORMAT[1:0] = 11b), set these bits to 00b. Otherwise, operation is not guaranteed.

SEL[1:0] bits (Operation Mode)

The SEL[1:0] bits specify the dither operation mode. The dither process is performed for the bits equal to or shorter than the pixel data length selected in the output format select bits (OUT_PDTHA.FORM[1:0]). OUT_PDTHA.PA[1:0], PB[1:0], PC[1:0], and PD[1:0] are used for 2×2 pattern dither.

Figure 58.13 shows the configuration of the dither correction block.

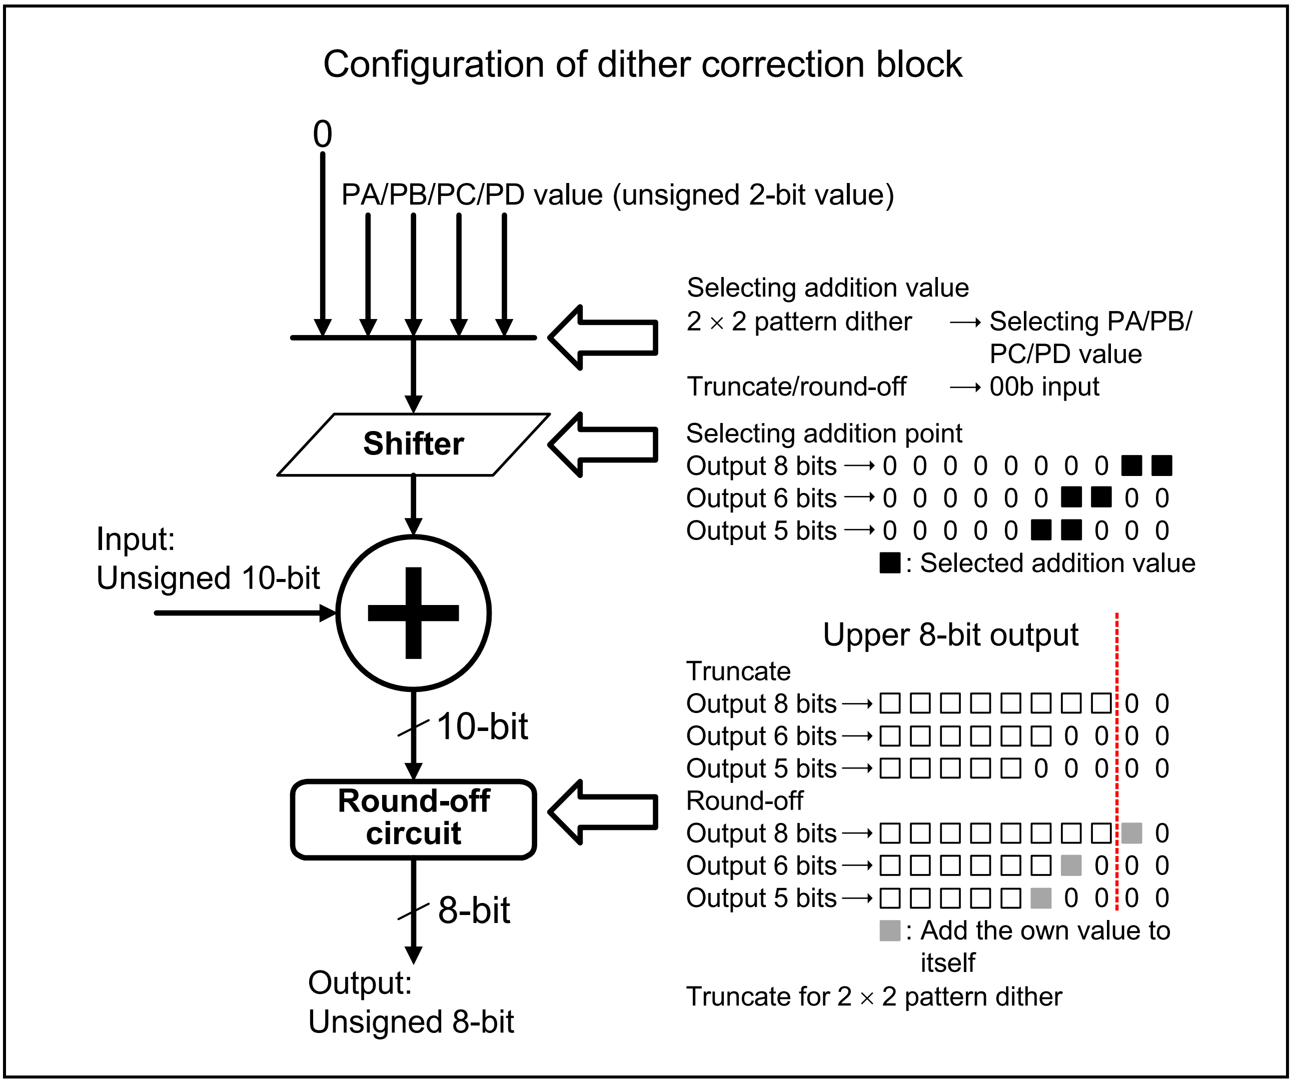

Figure 58.13 Configuration of dither correction block

Figure 58.14 shows the addition value selection method for 2×2 pattern dither.

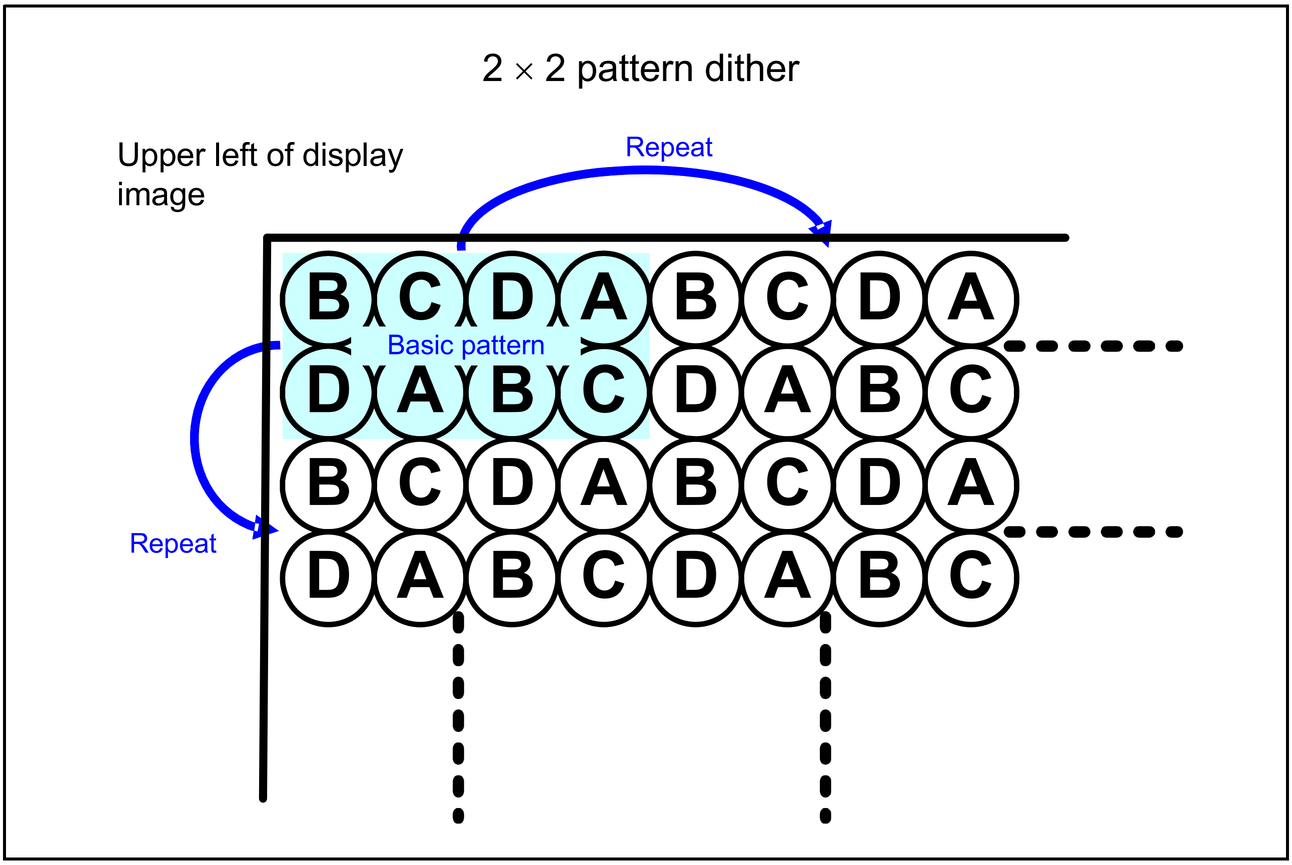

Figure 58.14 Addition value selection method for 2×2 pattern dither

A basic pattern is repeated as follows. Four frames constitute 1 cycle.

BCDA →	CDAB →	DABC →	ABCD	Shift to the left by one pixel
DABC →	ABCD →	BCDA →	CDAB	Shift to the left by one pixel
1st Frame	2nd Frame	3rd Frame	4th Frame	

- A: Value obtained after OUT_PDTHA.PA[1:0] bit value is shifted in accordance with the output format
- B: Value obtained after OUT_PDTHA.PB[1:0] bit value is shifted in accordance with the output format
- C: Value obtained after OUT_PDTHA.PC[1:0] bit value is shifted in accordance with the output format
- D: Value obtained after OUT_PDTHA.PD[1:0] bit value is shifted in accordance with the output format

Renesas recommends setting the bits as follows: PA[1:0] = 11b, PB[1:0] = 00b, PC[1:0] = 10b, PD[1:0] = 01b

When 2×2 pattern dither (OUT_PDTHA.SEL[1:0] = 10b) is to be set, the valid pixel area of the background plane must be an integer multiple of the basic pattern. If serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to the background plane horizontal valid pixel width bits (BG_HSIZE.HW[10:0]).

58.2.49 Output Control Block Output Phase Control Register (OUT_CLKPHASE)

Address(es): GLCDC.OUT_CLKPHASE 400E 13E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	FRONTGAM	—	—	—	LCDEDGE	—	TCON0EDGE	TCON1EDGE	TCON2EDGE	TCON3EDGE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	TCON3EDGE	LCD_TCON3 Output Phase Control	0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK.	R/W
b4	TCON2EDGE	LCD_TCON2 Output Phase Control	0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK.	R/W
b5	TCON1EDGE	LCD_TCON1 Output Phase Control	0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK.	R/W
b6	TCON0EDGE	LCD_TCON0 Output Phase Control	0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	LCDEDGE	LCD_DATA Output Phase Control	0: Synchronize output with rising edge of LCD_CLK 1: Synchronize output with falling edge of LCD_CLK.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	FRONTGAM	Correction Control	0: Process brightness/contrast correction followed by gamma correction 1: Process gamma correction followed by brightness/contrast correction.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TCON3EDGE bit (LCD_TCON3 Output Phase Control)

The TCON3EDGE bit controls the output phase of LCD_TCON3. When this bit is set to 1, LCD_TCON3 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON3 is output in synchronization with the rising edge.

TCON2EDGE bit (LCD_TCON2 Output Phase Control)

The TCON2EDGE bit controls the output phase of LCD_TCON2. When this bit is set to 1, LCD_TCON2 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON2 is output in synchronization with the rising edge.

TCON1EDGE bit (LCD_TCON1 Output Phase Control)

The TCON1EDGE bit controls the output phase of LCD_TCON1. When this bit is set to 1, LCD_TCON1 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON1 is output in synchronization with the rising edge.

TCON0EDGE bit (LCD_TCON0 Output Phase Control)

The TCON0EDGE bit controls the output phase of LCD_TCON0. When this bit is set to 1, LCD_ TCON0 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON0 is output in synchronization with the rising edge.

LCDEDGE bit (LCD_DATA Output Phase Control)

The LCDEDGE bit controls the output phase of the LCD_DATA pins (LCD_DATA23 to LCD_DATA00). When this bit is set to 1, the LCD_DATA pins are output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, the LCD_DATA pins are output in synchronization with the rising edge.

FRONTGAM bit (Correction Control)

The FRONTGAM bit controls the correction sequence. When this bit is set to 1, gamma correction is followed by brightness and contrast correction, and when it is cleared to 0, gamma correction follows brightness and contrast correction. In both cases, each RGB data output from the graphics 2 module is extended from 8 bits to 10 bits (with 00b appended to the lower side), and is input to the preceding stage of the correction circuit. The output is rounded to 10 bits and is input to the dither correction circuit. Although the sequence of RGB gamma correction and brightness/contrast correction can be reversed using this bit, brightness correction always precedes contrast correction.

58.2.50 TCON Reference Timing Setting Register (TCON_TIM)

Address(es): GLCDC.TCON_TIM 400E 1404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OFFSET[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	OFFSET[10:0]	Horizontal Synchronization Signal Generation Reference Timing	Offset from the assertion of the internal horizontal synchronization signal in pixels. 000h: 1 pixel : 3FFh: 1024 pixels. Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	HALF[10:0]	Vertical Synchronization Signal Generation Change Timing	Delay from the assertion of the internal horizontal synchronization signal in pixels. 000h: 1 pixel (no delay) : 3FFh: 1024 pixels. Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

OFFSET[10:0] bits (Horizontal Synchronization Signal Generation Reference Timing)

The OFFSET[10:0] bits specify the reference timing to be used when the horizontal synchronization signal is generated in the TCON. Set the offset from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. Figure 58.15 shows the horizontal synchronization signal generation reference timing in the TCON.

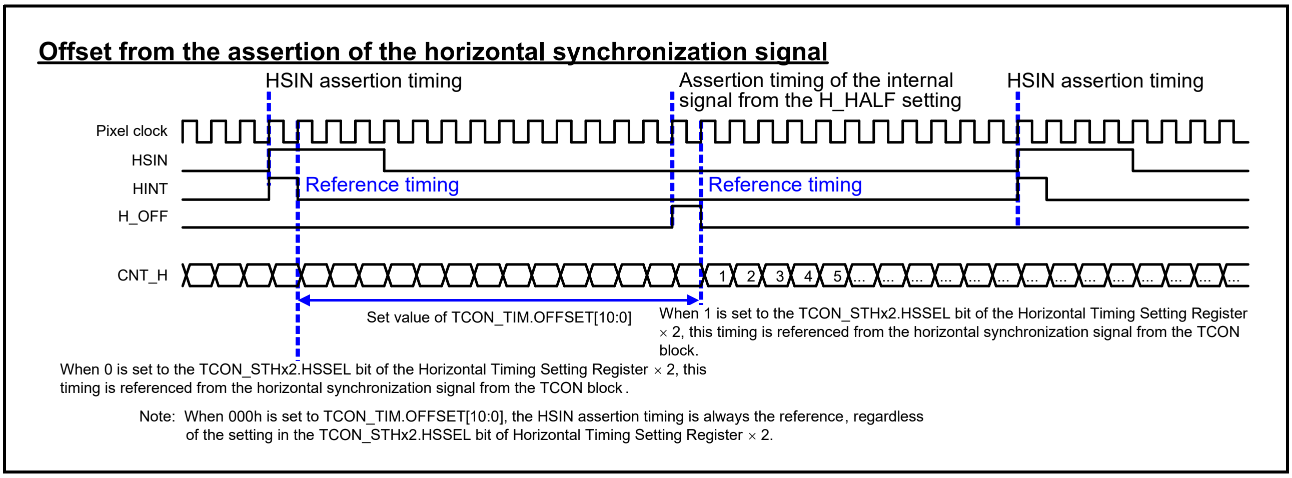

Figure 58.15 Reference timing in the TCON for horizontal synchronization signal generation

HALF[10:0] bits (Vertical Synchronization Signal Generation Change Timing)

The HALF[10:0] bits specify the vertical synchronization signal change timing when the signal is generated in the TCON. Set the change timing as a delay from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. Figure 58.16 shows the vertical synchronization signal change timing in the TCON.

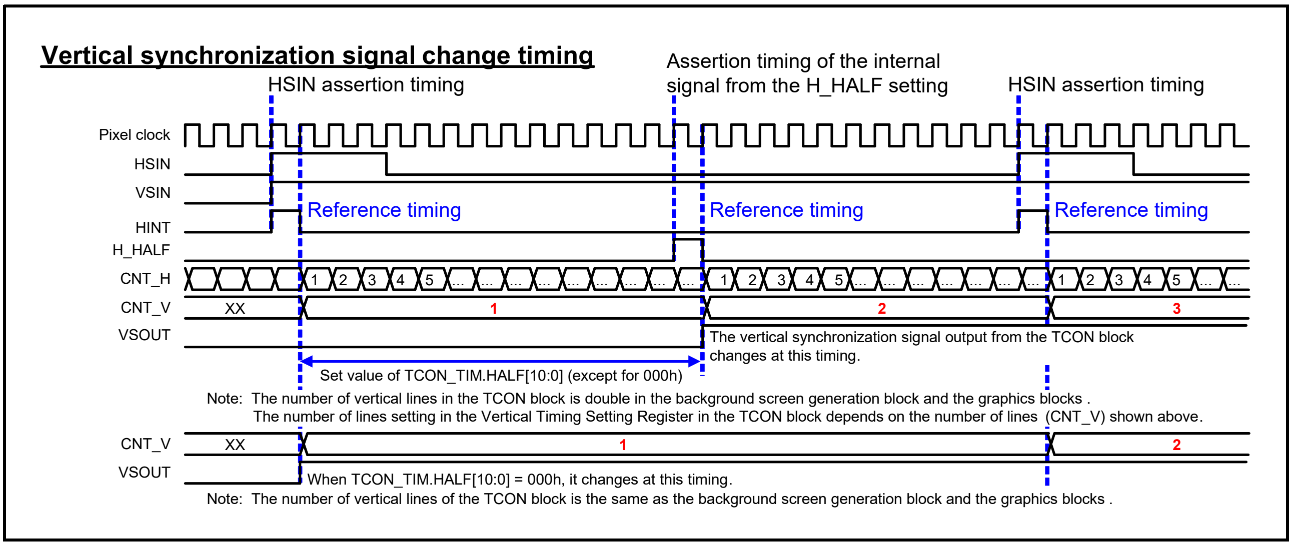

Figure 58.16 Timing in the TCON for vertical synchronization signal change

It is possible to change the vertical synchronization signal at any time within a horizontal line by setting this bit to the appropriate value.

Also, Figure 58.17 shows the relationship between the TCON block and the output format block in the output control block. These blocks are based on shared control signals (same timing) and image data, and the internal delay is the same. The delay difference specified in the register settings is the source of the timing differences on the external pins.

- TCON block: 3 cycles delay of the pixel clock (PXCLK)
- Data Format Block:
  - Parallel RGB: 3 cycles delay of the pixel clock (PXCLK)
  - Serial RGB: 3 cycles delay of the pixel clock (PXCLK)

    - The delay of the pixel head data including invalid data

    - No delay of the serial RGB data.

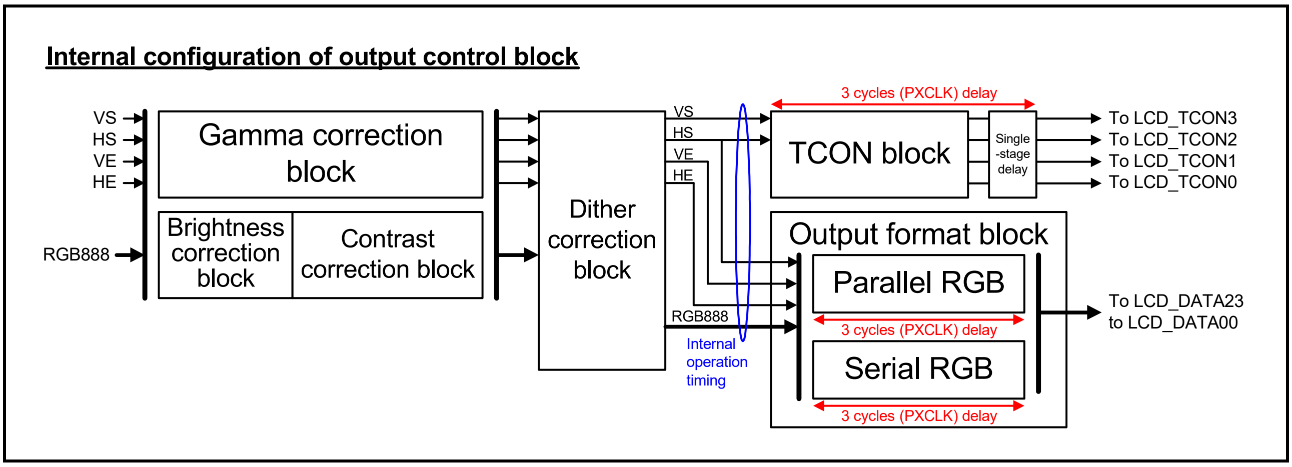

Figure 58.17 Internal configuration of output control block

58.2.51 TCON Vertical Timing Setting Register A1 (TCON_STVA1) TCON Vertical Timing Setting Register B1 (TCON_STVB1)

	—	—	—	—	—	VW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	VW[10:0]	Vertical Synchronization Signal STVx1 Second Change Timing	Signal assertion width in lines. 000h: 0 line (no vertical synchronization signal assertion) : 7FFh: 2047 lines.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	VS[10:0]	Vertical Synchronization Signal STVx1 First Change Timing	Signal delay in lines. 000h: 0 line (no delay) : 7FFh: 2047 lines.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The vertical timing setting registers (TCON_STVA1/TCON_STVB1 and TCON_STVA2/TCON_STVB2) have the same configuration, and x is either A or B in the descriptions.

VW[10:0] bits (Vertical Synchronization Signal STVx1 Second Change Timing)

The VW[10:0] bits specify the second change (negation) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the second change timing as a delay from the first change point in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing.

VS[10:0] bits (Vertical Synchronization Signal STVx1 First Change Timing)

The VS[10:0] bits specify the first change (assertion) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the change timing as a delay from the input vertical synchronization signal (VSIN) in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing.

Figure 58.18 shows the change timing of vertical synchronization signal to be generated.

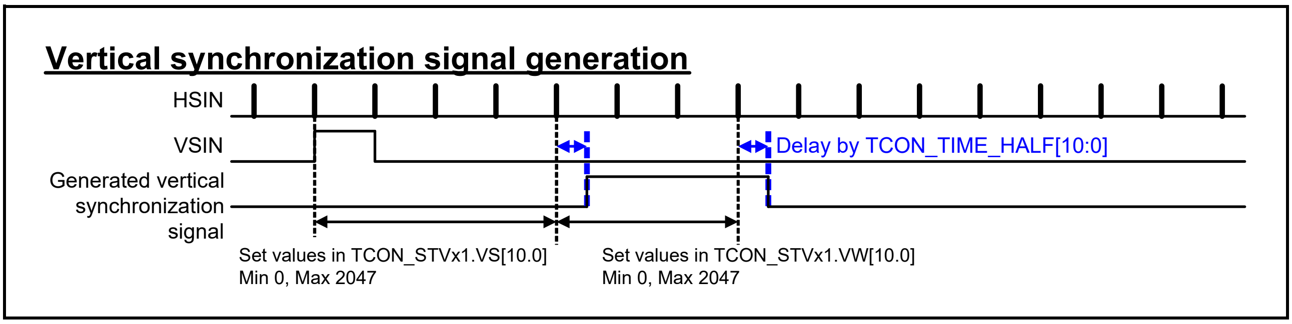

Figure 58.18 Generation of vertical synchronization signal

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The vertical timing setting registers (TCON_STVA1/TCON_STVB1 and TCON_STVA2/TCON_STVB2) have the same configuration, and x is either A or B in the descriptions.

SEL[2:0] bits (Output Signal Select Control for VSOUT/VEOUT Pin)

The SEL[2:0] bits control output signal select for the LCD_TCON0/LCD_TCON1 pin. Figure 58.19 shows the configuration of the inversion control and output signal select.

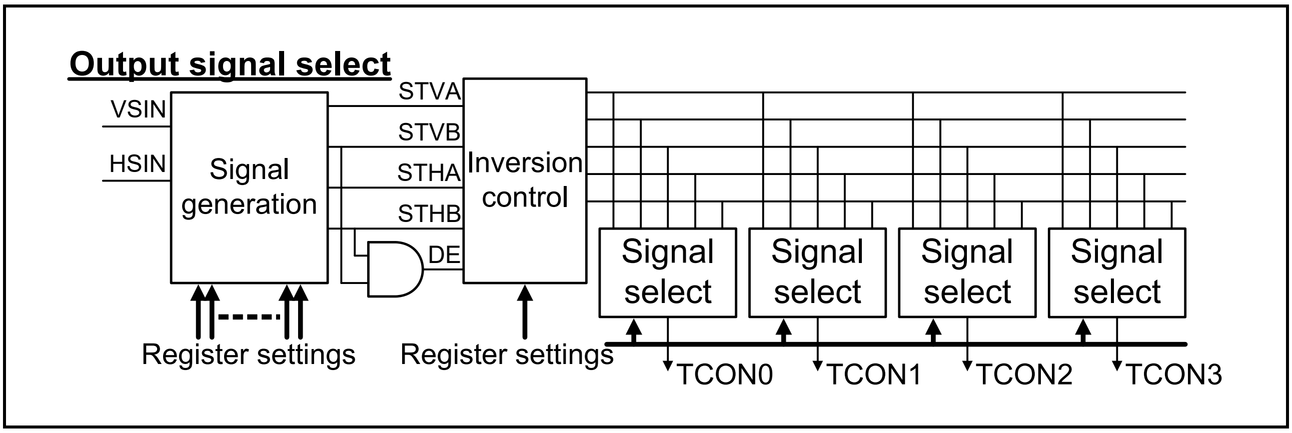

Figure 58.19 Configuration of inversion control and output signal selects

INV bit (Vertical Synchronization Signal STVx Polarity Inversion Control)

The INV bit controls polarity inversion of the vertical synchronization signal (STVx).

	—	—	—	—	—	HW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b10 to b0	HW[10:0]	Horizontal Synchronization Signal STHx1 Second Change Timing	Signal assertion width in pixels. 000h: 0 pixel (no horizontal synchronization signal assertion) : 3FFh: 1023 pixels. Other settings are prohibited.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	HS[10:0]	Horizontal Synchronization Signal STHx1 First Change Timing	Signal delay in pixels. 000h: 0 pixel (no delay) : 3FFh: 1023 pixels. Other settings are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

HW[10:0] bits (Horizontal Synchronization Signal STHx1 Second Change Timing)

The HW[10:0] bits specify the second change (negation) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the second change timing as a distance from the first change point in terms of pixels.

HS[10:0] bits (Horizontal Synchronization Signal STHx1 First Change Timing)

The HS[10:0] bits specify the first change (assertion) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the change timing as a distance from the input horizontal synchronization signal (HSIN) or the reference timing based on the offset specified in the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization signal generation reference timing) in terms of pixels.

Figure 58.20 shows the horizontal synchronization signal generation timing if the input horizontal synchronization signal (HSIN) is based on the negated edge reference of the HINT signal. Figure 58.21 shows the horizontal synchronization signal generation timing after offset. By setting the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization generation reference timing) and these horizontal synchronization bits appropriately, it is possible to generate a signal that is asserted before HSIN and negated after HSIN, where HSIN is the horizontal synchronization signal input to the TCON.

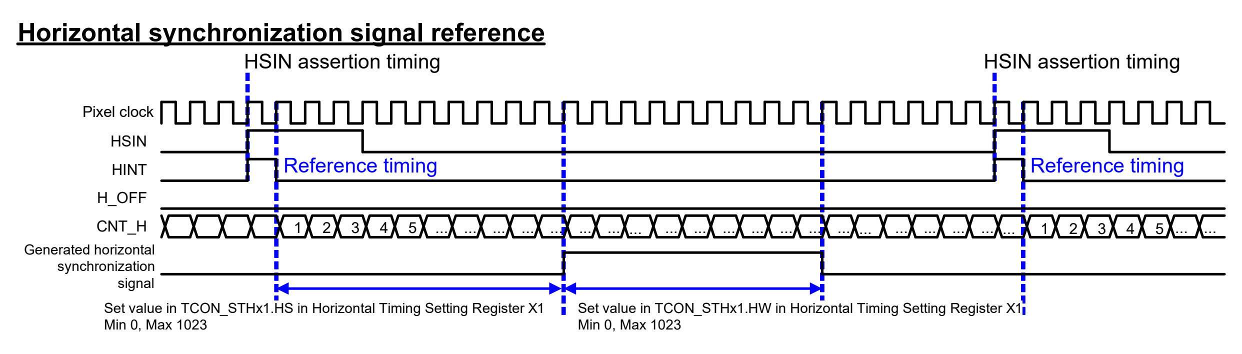

Figure 58.20 Signal generation based on input horizontal synchronization signal (HSIN)

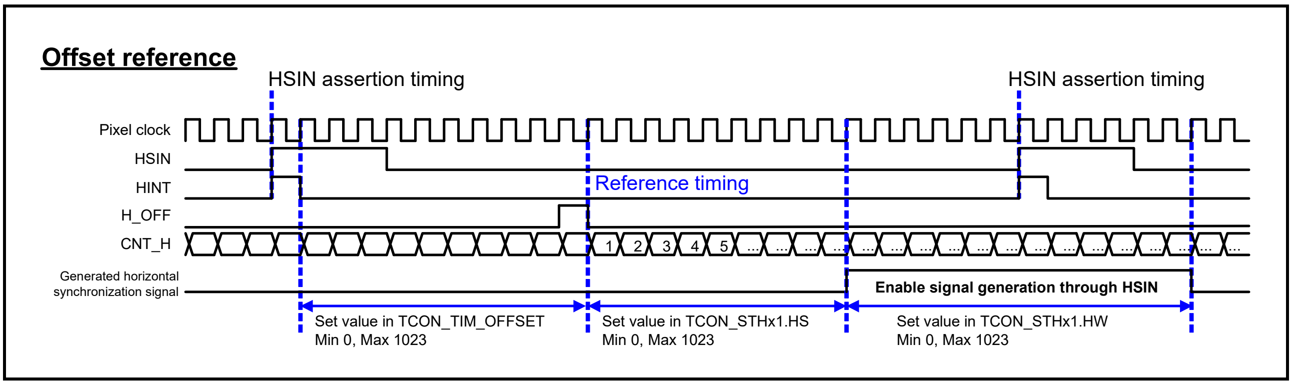

Figure 58.21 Horizontal synchronization signal generation based on offset

When generating the signal across HSIN on the offset reference, the horizontal synchronization signal of the last line of the frame spans the first line of the next frame. Even if the BG_EN.EN bit is cleared to 0 and the GLCDC operation is stopped, the horizontal synchronization signal across HSIN is not cleared at the frame end and retains the predetermined value until the second change timing set in the registers. If BG_EN.SWRST is cleared to 0, the signal returns to the initial state immediately.

58.2.54 TCON Horizontal Timing Setting Register STHA2 (TCON_STHA2)
TCON Horizontal Timing Setting Register STHB2 (TCON_STHB2)

Address(es): GLCDC.TCON_STHA2 400E 141Ch, GLCDC.TCON_STHB2 400E 1424h

R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

SEL[2:0] bits (Output Signal Select Control for LCD_TCON2/LCD_TCON3 Pin)

The SEL[2:0] bits control the output signal select for the LCD_TCON2/LCD_TCON3 pins.

INV bit (Horizontal Synchronization Signal STHx Polarity Inversion Control)

The INV bit controls polarity inversion of the horizontal synchronization signal (STHx).

HSSEL bit (Horizontal Synchronization Signal STHx Reference Timing Control)

The HSSEL bit selects the reference timing for generating the horizontal synchronization signal STHx. For details on the signal to be generated, see Figure 58.20 and Figure 58.21. For the configuration of the inversion control and output signal select, see Figure 58.19.

58.2.55 TCON Data Enable Polarity Setting Register (TCON_DE)

Address(es): GLCDC.TCON_DE 400E 1428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	INV	Data Enable Signal DE Polarity Inversion Control	0: Do not invert 1: Invert.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

INV bit (Data Enable Signal DE Polarity Inversion Control)

The INV bit controls polarity inversion of the data enable signal DE. The data enable signal DE generated in the TCON is the logical AND of the STVB and STHB signals.

58.2.56 System Control Block State Detection Control Register (SYSCNT_DTCTEN)

Address(es): GLCDC.SYSCNT_DTCTEN 400E 1440h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFDTC	L1UNDFDTC	VPOSDTC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	VPOSDTC	Specified Line Detection Control	0: Disable detection of specified line 1: Enable detection of specified line*1.	R/W
b1	L1UNDFDTC	Graphics 1 Underflow Detection Control	0: Disable detection of graphics 1 underflow 1: Enable detection of graphics 1 underflow*2.	R/W
b2	L2UNDFDTC	Graphics 2 Underflow Detection Control	0: Disable detection of graphics 2 underflow 1: Enable detection of graphics 2 underflow*2.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Set the VPOSDTC bit to 1 after setting the BG_EN.EN bit to 1.

Note 2. When setting the LnUNDFDTC (n = 1, 2) bit to 1 and when the BG_SYNC.VP[3:0] bits are set to a value greater than 5h, an unexpected GLCDC_LnUNDF (n = 1, 2) interrupt is generated after the GLCDC starts.Therefore, set the SYSCNT_STCLR.LnUNDFCLR (n = 1, 2) bit to 1, then set the SYSCNT_STMON.LnUNDF (n = 1, 2) bit to 0 to clear the unexpected GLCDC_LnUNDF (n = 1, 2) interrupt.

VPOSDTC bit (Specified Line Detection Control)

The VPOSDTC bit enables or disables detection of the specified line. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 on event notification from graphics 2. When it is cleared to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even on event notification from graphics 2.

L1UNDFDTC bit (Graphics 1 Underflow Detection Control)

The L1UNDFDTC bit enables or disables detection of the graphics 1 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 1. When it is cleared to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 1. The underflow state in graphics 1 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

L2UNDFDTC bit (Graphics 2 Underflow Detection Control)

The L2UNDFDTC bit enables or disables detection of the graphics 2 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 2. When it is cleared to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 2. The underflow state in graphics 2 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

58.2.57 System Control Block Interrupt Request Enable Control Register (SYSCNT_INTEN)

Address(es): GLCDC.SYSCNT_INTEN 400E 1444h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFINTEN	L1UNDFINTEN	VPOSINTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	VPOSINTEN	Interrupt Request Signal GLCDC_VPOS Enable Control	0: Disable GLCDC_VPOS output 1: Enable GLCDC_VPOS output.	R/W
b1	L1UNDFINTEN	Interrupt Request Signal GLCDC_L1UNDF Enable Control	0: Disable GLCDC_L1UNDF output 1: Enable GLCDC_L1UNDF output.	R/W
b2	L2UNDFINTEN	Interrupt Request Signal GLCDC_L2UNDF Enable Control	0: Disable GLCDC_L2UNDF output 1: Enable GLCDC_L2UNDF output.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

VPOSINTEN bit (Interrupt Request Signal GLCDC_VPOS Enable Control)

The VPOSINTEN bit enables or disables the interrupt request signal GLCDC_VPOS. When this bit is set to 1, the interrupt request signal GLCDC_VPOS is asserted when the associated status monitor flag SYSCNT_STMON[0] sets. When it is cleared to 0, the interrupt request signal GLCDC_VPOS is not asserted even when the associated status monitor flag SYSCNT_STMON[0] sets. If this bit is cleared during GLCDC_VPOS assertion, the associated status monitor flag SYSCNT_STMON[0] does not change, but the interrupt request signal GLCDC_VPOS is negated.

L1UNDFINTEN bit (Interrupt Request Signal GLCDC_L1UNDF Enable Control)

The L1UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L1UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L1UNDF is asserted when the associated status monitor flag SYSCNT_STMON[1] sets. When it is cleared to 0, the interrupt request signal GLCDC_L1UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[1] sets. If this bit is cleared during GLCDC_L1UNDF assertion, the associated status monitor flag SYSCNT_STMON[1] does not change, but the interrupt request signal GLCDC_L1UNDF is negated.

L2UNDFINTEN bit (Interrupt Request Signal GLCDC_L2UNDF Enable Control)

The L2UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L2UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L2UNDF is asserted when the associated status monitor flag SYSCNT_STMON[2] sets. When it is cleared to 0, the interrupt request signal GLCDC_L2UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[2] sets. If this bit is cleared during GLCDC_L2UNDF assertion, the associated status monitor flag SYSCNT_STMON[2] does not change, but the interrupt request signal GLCDC_L2UNDF is negated.

58.2.58 System Control Block Status Clear Register (SYSCNT_STCLR)

Address(es): GLCDC.SYSCNT_STCLR 400E 1448h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFCLR	L1UNDFCLR	VPOSCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	VPOSCLR	Graphics 2 Specified Line Detection Flag Clear	0: No operation 1: Clear the graphics 2 specified line detection flag.	R/W*1
b1	L1UNDFCLR	Graphics 1 Underflow Detection Flag Clear	0: No operation 1: Clear the graphics 1 underflow detection flag.	R/W*1
b2	L2UNDFCLR	Graphics 2 Underflow Detection Flag Clear	0: No operation 1: Clears the graphics 2 underflow detection flag.	R/W*1
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits are read as 0.

VPOSCLR bit (Graphics 2 Specified Line Detection Flag Clear)

Writing 1 to the VPOSCLR bit clears the graphics 2 specified line detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L1UNDFCLR bit (Graphics 1 Underflow Detection Flag Clear)

Writing 1 to the L1UNDFCLR bit clears the graphics 1 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L2UNDFCLR bit (Graphics 2 Underflow Detection Flag Clear)

Writing 1 to the L2UNDFCLR bit clears the graphics 2 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

58.2.59 System Control Block Status Monitor Register (SYSCNT_STMON)

Address(es): GLCDC.SYSCNT_STMON 400E 144Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDF	L1UNDF	VPOS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b0	VPOS	Graphics 2 Specified Line Detection Flag	0: Specified line notification not detected in graphics 2 1: Specified line notification detected in graphics 2.	R
b1	L1UNDF	Graphics 1 Underflow Detection Flag	0: No underflow detected in graphics 1 1: Underflow detected in graphics 1.	R
b2	L2UNDF	Graphics 2 Underflow Detection Flag	0: No underflow detected in graphics 2 1: Underflow detected in graphics 2.	R
b31 to b3	—	Reserved	These bits are read as 0.	R

VPOS flag (Graphics 2 Specified Line Detection Flag)

The VPOS flag indicates that the specified line notification was detected in graphics 2. When this flag is 1, it indicates that the specified line notification was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently processing the specified line. When this flag is 0, it indicates that no specified line notification was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_VPOS is negated, but this does not affect the state of graphics 2.

L1UNDF flag (Graphics 1 Underflow Detection Flag)

The L1UNDF flag indicates that an underflow was detected in graphics 1. When this flag is 1, it indicates that an underflow was detected in graphics 1 at some time in the past. It does not necessarily mean that graphics 1 is currently in the underflow state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L1UNDF is negated, but this does not affect the state of graphics 1.

Even if the current graphics data is not required (GR1_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L1UNDFDTC flag (graphics 1 underflow detection control) is 1 and detection is enabled, this flag sets to 1 at the start of the graphics image valid area. To avoid unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, clear the SYSCNT_DTCTEN.L1UNDFDTC flag and the SYSCNT_INTEN.L1UNDFINTEN bit (interrupt request signal GLCDC_L1UNDF enable control) to 0.

L2UNDF flag (Graphics 2 Underflow Detection Flag)

The L2UNDF flag indicates that an underflow was detected in graphics 2. When this flag is 1, it indicates that an underflow was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently in the underflow state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L2UNDF is negated, but this does not affect the state of graphics 2.

Even if the current graphics data is not required (GR2_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L2UNDFDTC flag (graphics 2 underflow detection control) is 1 and detection is enabled, this flag sets to 1 at the start of the graphics image valid area. To avoid the unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, clear the SYSCNT_DTCTEN.L2UNDFDTC flag and the SYSCNT_INTEN.L2UNDFINTEN bit (interrupt request signal

GLCDC_L2UNDF enable control) to 0.

58.2.60 System Control Block Version and Panel Clock Control Register (SYSCNT_PANEL_CLK)

Address(es): GLCDC.SYSCNT_PANEL_CLK 400E 1450h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit name	Description	R/W
b5 to b0	DCDR[5:0]	Clock Division Ratio Setting Control	See Table 58.9 for details on these settings.	R/W
b6	CLKEN	Panel Clock Output Enable Control	0: Disable panel clock output 1: Enable panel clock output. Before changing the PIXSEL, CLKSEL, or DCDR bit, this bit must be set to 0.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	CLKSEL	Panel Clock Supply Source Control	0: Select external clock (LCD_EXTCLK) 1: Select PLL output.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	PIXSEL	Pixel Clock Select Control	0: Select no frequency division, parallel RGB 1: Select quarter frequency, serial RGB. This setting must have the same value as OUT_SET.FRQSEL[1].	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	VER[15:0]	Version Information	Version information of the GLCDC.	R

The configuration of the pixel and panel clock generator circuits are shown in Figure 9.1, Clock generation circuit block diagram.

DCDR[5:0] bits (Clock Division Ratio Setting Control)

The DCDR[5:0] bits control the setting of the panel clock division ratio. The division ratio bit can only be set to the values listed in Table 58.9. Operation is not guaranteed for values not listed.

Table 58.9 Input clock division (1 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK(≤ 60 MHz)	CLKSEL = 1, PLL output (120 to 240 MHz)
000000b	1/2	LCD_EXTCLK/2	PLL output/2*1
000001b	1/1	LCD_EXTCLK*1	PLL output*1
000010b	1/2	LCD_EXTCLK/2	PLL output/2*1
000011b	1/3	LCD_EXTCLK/3	PLL output/3*1
000100b	1/4	LCD_EXTCLK/4	PLL output/4*1
000101b	1/5	LCD_EXTCLK/5	PLL output/5
000110b	1/6	LCD_EXTCLK/6	PLL output/6
000111b	1/7	LCD_EXTCLK/7	PLL output/7
001000b	1/8	LCD_EXTCLK/8	PLL output/8

Table 58.9 Input clock division (2 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK(≤ 60 MHz)	CLKSEL = 1, PLL output (120 to 240 MHz)
001001b	1/9	LCD_EXTCLK/9	PLL output/9
001100b	1/12	LCD_EXTCLK/12	PLL output/12
010000b	1/16	LCD_EXTCLK/16	PLL output/16
011000b	1/24	LCD_EXTCLK/24	PLL output/24
100000b	1/32	LCD_EXTCLK/32	PLL output/32

Note 1. The panel clock is output as the LCD_CLK output clock. This setting may be prohibited because LCD_EXTCLK and LCD_CLK have limited frequencies. See section 60, Electrical Characteristics.

To set the panel clock:

1. After setting the input source of the panel clock in the CLKSEL bit, set the division ratio in the DCDR[5:0] bits and the pixel clock selection.
2. Set the CLKEN bit to 1.

CLKEN bit (Panel Clock Output Enable Control)

The CLKEN bit enables or disables the panel clock output. When enabling the panel clock output and operating the panel clock block, set this bit to 1. When changing the PIXSEL, CLKSEL, or DCDR bit, you must set this bit to 0 once and stop the panel clock output. Operation is not guaranteed if any setting is changed while the panel clock is being output.

CLKSEL bit (Panel Clock Supply Source Control)

The CLKSEL bit controls the selection of the panel clock supply source from either the external clock pin (LCD_EXTCLK) or PLL output. When the external clock is selected, set this bit to 0. When PLL output is selected, set this bit to 1.

PIXSEL bit (Pixel Clock Select Control)

The PIXSEL bit controls the selection of the pixel clock output. When selecting parallel RGB, set this bit to 0 to output the same frequency as the panel clock (no frequency division). When selecting serial RGB, set this bit to 1 to output the quarter frequency of the panel clock as the pixel clock.

This bit must be synchronized with the OUT_SET.FRQSEL[1:0] setting. You must set the same value as in FRQSEL[1]. Otherwise, operation is not guaranteed.

VER[15:0] bits (Version Information)

The VER[15:0] bits provide GLCDC version information.

58.3 Operation

58.3.1 Overall Control

The GLCDC consists of six modules as shown in Figure 58.22, each of which functions independently. The four modules handling image data are interconnected by the vertical and horizontal synchronization signals VS, HS, VE, and HE, and image data (RGB888), as shown in Figure 58.23. The processing of image data is carried out with the pixel clock (PXCLK). LCD_CLK synchronizes with PXCLK (also in phase with each other), and has the same or quadruple frequency (for serial RGB888 output). The registers controlling operation and setting parameters are connected with the internal peripheral bus 8 and operate on PCLKA. The circuits, including the data buffer and the CLUT memory, operate on PCLKA to read graphics data from the GPX bus, access the color palette (CLUT) memory, and expand graphics data into the ARGB8888 format.

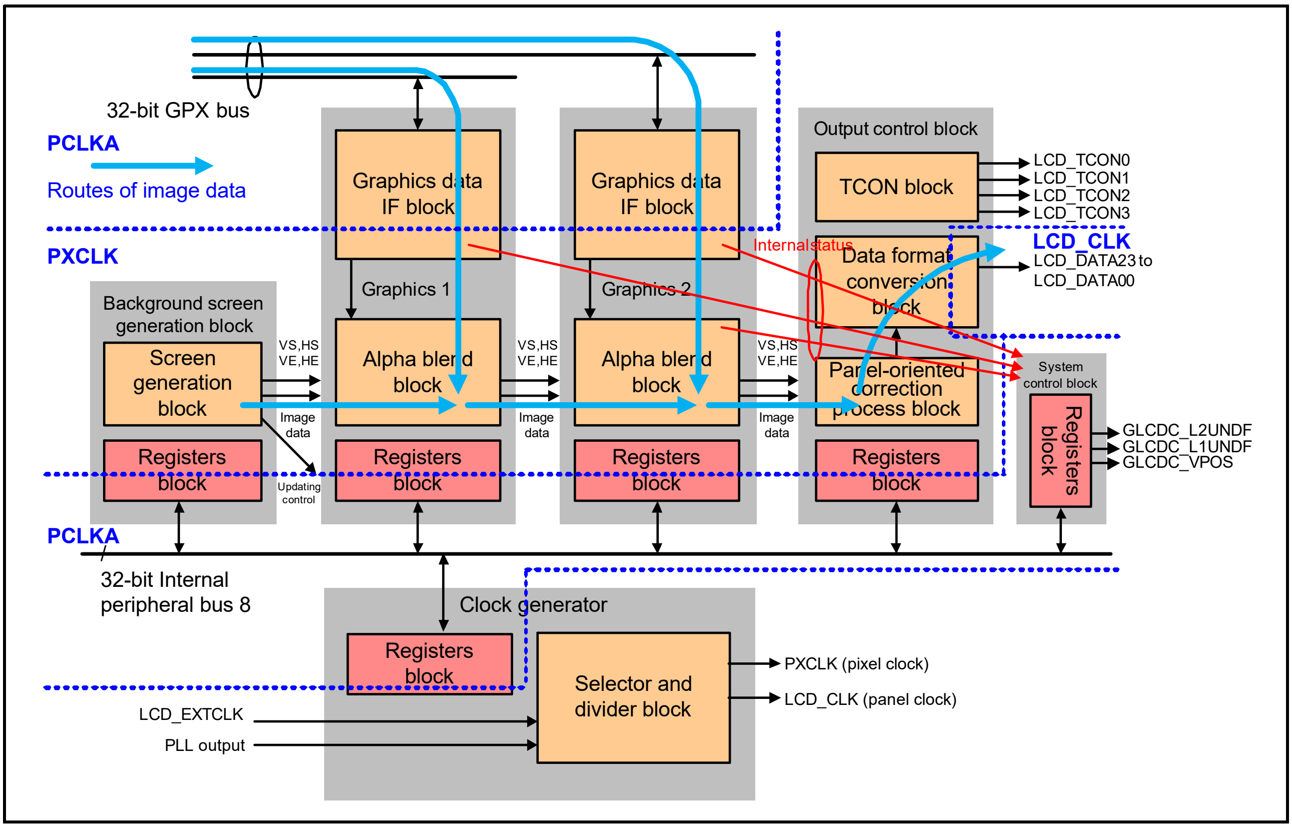

Figure 58.22 GLCDC configuration

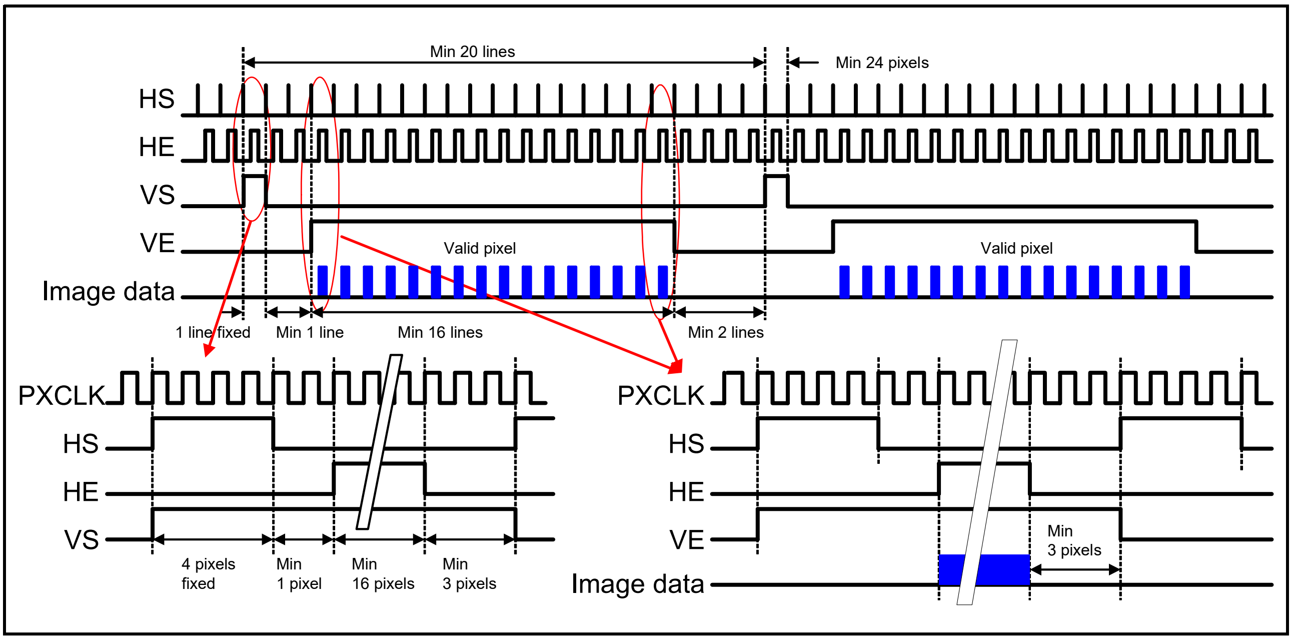

Figure 58.23 Image data carrier signals in the GLCDC

The graphics 1, graphics 2, and output control modules have no individual operation enable bits. By clearing the software reset state in the background screen generation module, these modules wait for vertical and horizontal synchronization signals VS, HS,VE, and HE, and image data (RGB888) to be input, detect assertion of the vertical synchronization signal VS, and start operation for each frame based on the values preset in the registers. For the system control module, clearing the software reset state in the background screen generation module allows it to monitor the status of graphics 1 and 2 in accordance with the register settings and assert interrupt request signals. These status flags are intended for observing the internal status and exert no influence on the internal operation. The operation between startup and stop of the GLCDC is outlined in this section.

(1) Startup

To start GLCDC operation:

1. Confirm that PCLKA is supplied to the GLCDC and that the reset is negated. When setting LCD_CLK to the same frequency as PXCLK or LCD_CLK to the quadruple speed clock, the setting must be consistent with the value in the register specified in the subsequent stage. The quadruple speed clock is required only when the output format is serial RGB888. Operation is not guaranteed if the quadruple speed clock is supplied to LCD_CLK in other output formats than serial RGB888.
2. Set 1 to the BG_EN.SWRST bit to release the entire GLCDC from a software reset.
3. Set parameters necessary for operation in each register. Although registers of any module can be set first, while the BG_EN.VEN bit (control of GLCDC internal register value reflection to internal operations), BG_EN.EN bit (background plane operation enable) of the background screen generation module, and the VEN bit in the register update control register of each module remain cleared to 0, confirm that PCLKA and PXCLK/LCD_CLK are supplied and the BG_MON.SWRST bit (entire module software reset state monitor) is set to 1.
4. When displaying the graphics data read by graphics 1 and 2 through the GPX bus, set 1 to the GRn_FLMRD.RENB bit (graphics data read enable).
5. Write the color palette data of graphics 1 and 2 (0 and 1 planes) to the CLUT memory through the register access bus (internal peripheral bus 8) as required. This is necessary for the LUT1, LUT4, LUT8, and ARGB1555 data formats. ARGB1555 uses addresses 80h and 00h on the two planes, LUT1 uses 01h and 00h, LUT4 uses the addresses from 0Fh to 00h, and LUT8 uses the addresses from FFh to 00h.
6. Set 1 to the BG_EN.VEN bit (control of background plane register value reflection to internal operations) and the BG_EN.EN bit (background plane operation enable) of the background screen generation module at the same time. This setting allows output of the vertical and horizontal synchronization signals VS, HS, VE, and HE, and the image data (RGB888) from the background screen generation module. When the pixel data is valid (both VE and HE are 1), output from the background screen generation module uses the value in the BG_BGC register. The data value is 00 0000h for pixels that are not valid.
7. Each module detects the assertion of the vertical synchronization signal (VS) output from its previous stage (background screen generation module for graphics 1, graphics 1 for graphics 2, and graphics 2 for the output control module) and starts operation in accordance with its register settings. All the modules control the operation in frame units. When the assertion of the vertical synchronization signal (VS) is detected, the current frame is taken as the frame head and the status is initialized. If necessary (when the VEN bits in the register update control registers are 1), the register values read through the register access bus are reflected to the internal operation.

(2) Changing parameters during operation

With the GLCDC, it is possible to update parameters of each module and reflect the updates to the internal operations during operation, without preventing graphics data to be read by the background screen generation module, graphics 1, or graphics 2. By setting 1 to the VEN bits of the modules, including the background screen generation module, almost all parameters are reflected to the internal operations at the start of the following frame (at the start of the control screen for the background screen generation module, and immediately after the VS assertion of the previous stage for the other modules). However, if the CLUT plane being used for internal operations (determined in the GRn_CLUTINT.SEL[1:0] bits) is modified, the updates are reflected to the internal operations immediately without waiting for the following VS assertion. To circumvent this immediate reflection of the CLUT plane modification to the internal operations, first write all the image data (ARGB8888) necessary for the CLUT plane that is not being used for internal operations, next modify the GRn_CLUTINT.SEL[1:0] bits, and finally set 1 to the VEN bit of the background screen generation module or the target module.

To modify parameters during operation:

1. Confirm that the VEN bit of each module is 0. Operation is not guaranteed if the target registers are modified when the VEN bit of the module to which the register values are to be reflected to the internal operations, or the VEN bit of the background screen generation module is 1.
2. Modify the value of the target registers.
3. If only a particular module is to be the target, set 1 to the VEN bit of the target module. If multiple modules or the

background screen generation module are to be the targets, set 1 to the VEN bit of the background screen generation module. In this case, all the modules are included as targets, not only the background screen generation module.

4. Confirm that the VEN bit to which 1 was set is 0. If the bit is cleared to 0, the target register contents are reflected to the internal operations. If the bit remains 1, however, the target register contents might not yet be reflected to the internal operations. The VEN bit of each module is cleared to 0 immediately after the target register values are internally reflected. However, the VEN bit of the background screen generation module is not cleared to 0 until the module output VE is negated (with all the modules, sufficient delay is secured in reference to the VS assertion of the background screen generation module so that the register values are reflected to the internal operations for the same frame). Figure 58.24 shows the operation of the signals output by the background screen generation module and the monitor bits.

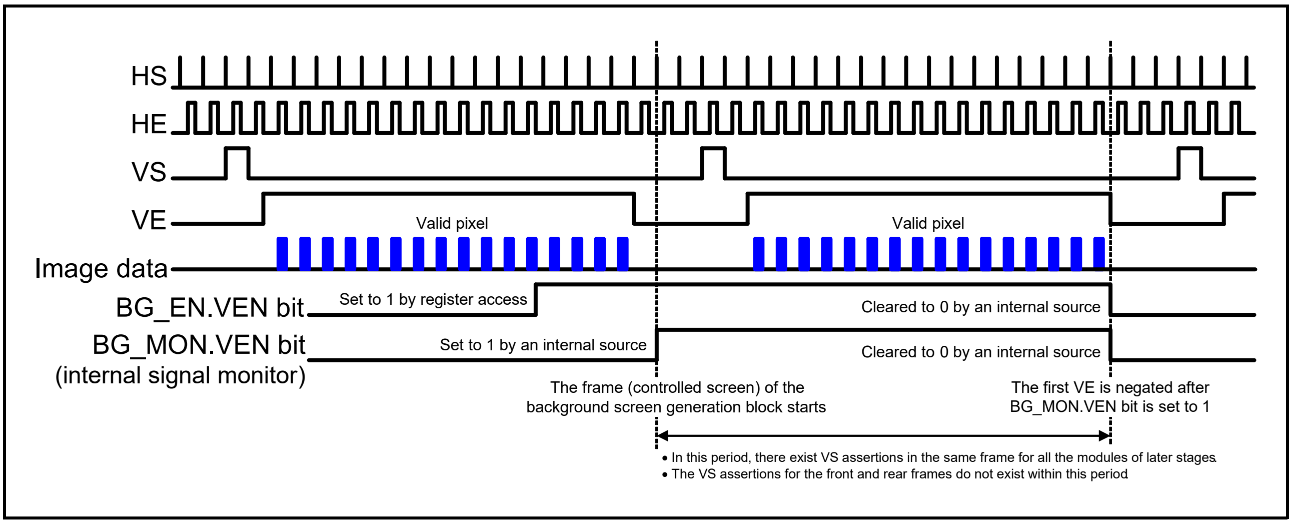

Figure 58.24 Control signals for register value reflection to internal operations

(3) Stopping and restarting in normal operation

To stop the GLCDC:

1. Confirm that the VEN bit of each module is cleared to 0.
2. Clear the BG_EN.EN bit (background plane operation enable) of the background screen generation module to 0.
3. Confirm that the BG_MON.EN bit (background plane operation monitor) of the background screen generation module has changed to 0. This bit is cleared to 0 only after operation has stopped. It is cleared at the frame end of the background screen generation module, not when the operations of all the modules are complete (not at the frame end of the output control module). If it is necessary to wait for all the modules to complete operations, a certain period (for example, a period equivalent to one line) is required.
4. Usually, a software reset can be safely applied (clearing of the BG_EN.SWRST bit) after confirming that the BG_MON.EN bit of the background screen generation module has changed to 0. (Even if the output signal returns to the initial value, no problems occur because the GLCDC has already entered the vertical blanking interval.)
5. When restarting the GLCDC by setting the relevant registers without applying a software reset, wait until sufficient time elapses after the BG_MON.EN bit becomes 0 (when the output control module output is the frame end) before starting the GLCDC. The GLCDC itself is not affected by this because the GLCDC starts operating after recognizing the assertion of the VS of the previous stage as the frame head. However, operation of some connected devices might be affected if a blanking interval or a period equivalent to one line is too short. For details, check the specifications of the connected device. When a software reset is applied, the register values are also initialized and almost all of the registers must be set again. Only the color palette data (CLUT memory content) is retained (only for a software reset after normal end).

Figure 58.25 shows the changes in signal lines and bits for the stop and restart in normal operation. Even if the background screen generation module is stopped by a clearing of the BG_EN.EN bit to 0, the GLCDC stops because of an abnormal operation sequence, not normal operation, if the GPX bus access is not complete at the frame end because of an underflow in graphics 1 or 2, inappropriate setting of graphics data access, or other undesirable conditions.

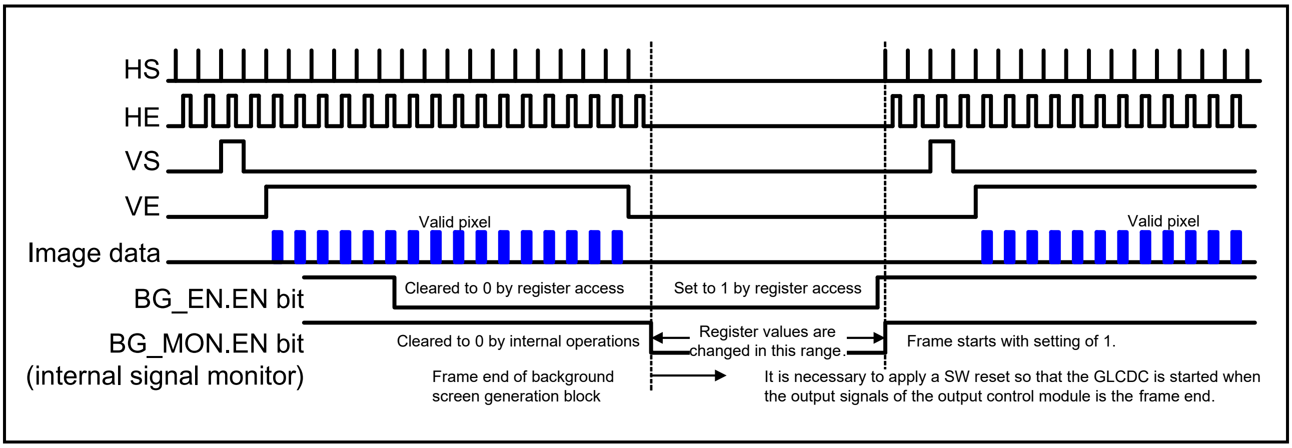

Figure 58.25 Stop and restart in normal operation

(4) Stopping and restarting in abnormal operation

Stop in abnormal operation occurs in the following cases:

- When during operation (BG_EN.EN or BG_MON.EN is set to 1), a software reset (BG_EN.SWRST bit is cleared to 0) or a reset is applied
- When unnecessary (unintended) access to the GPX bus occurs and a data cycle is not completed, even though the BG_EN.EN bit is cleared to 0 and so the BG_MON.EN bit is also cleared to 0.

In both cases, the GLCDC is internally initialized and the register access bus can be accessed normally (except for a hardware reset). However, the GPX bus might write unintended graphics data to the GLCDC. Therefore, it is advisable to apply a software reset (clear the BG_EN.SWRST bit to 0) and confirm that there is no unintended access to the GPX bus, even after confirming that both the BG_EN.EN and BG_MON.EN bits are cleared to 0. Next release the GLCDC from the software reset (set the BG_EN.SWRST bit to 1), set the relevant registers, and set the BG_EN.En and BG_EN.VEN bits in the background screen generation module to 1 to restart the GLCDC. For the procedure for checking the GPX bus state, see the *Arm® AHB Specification*. Use this procedure even after a reset when the GPX bus, a target device, or a target controller is not initialized. If these are initialized on a reset assertion for the GLCDC, a normal startup procedure can be used without checking the GPX bus state.

58.3.2 Screen Definition

The essential signals for GLCDC operations are generated by the background screen generation module, and the graphics 1 and 2 modules and output control module operate based on the sequentially transferred vertical and horizontal synchronization signals (VS and HS) and vertical and horizontal pixel enable signals (VE and HE). The reference point (frame start point) of the background screen cannot be determined by the output signals. The point shown in the figures is virtual and provided only for register settings. The reference points (frame start points) of the graphics 1 and 2 modules and output control module are the assertion of the vertical synchronization signal (VS), which is input (output) from the previous stage. Each module defines the valid pixel display area and special processing area for pixel data (rectangular areas for graphics 1 and 2) according to the position and width based on this reference point. Figure 58.26 shows the definition of the background screen, and Figure 58.27 shows the definition of the graphics 1 and 2 screen. The output control module performs correction for the entire valid pixel area (when both VE and HE are 1) output from the previous stage (graphics 2). (No registers are provided in the output control module for setting the correction area.) TCON in the output control module generates the control signals to be output based on the internal vertical and horizontal synchronization signals (VS and HS), and the change timing of the output signals can be freely modified within the valid setting range specifiable in the registers.

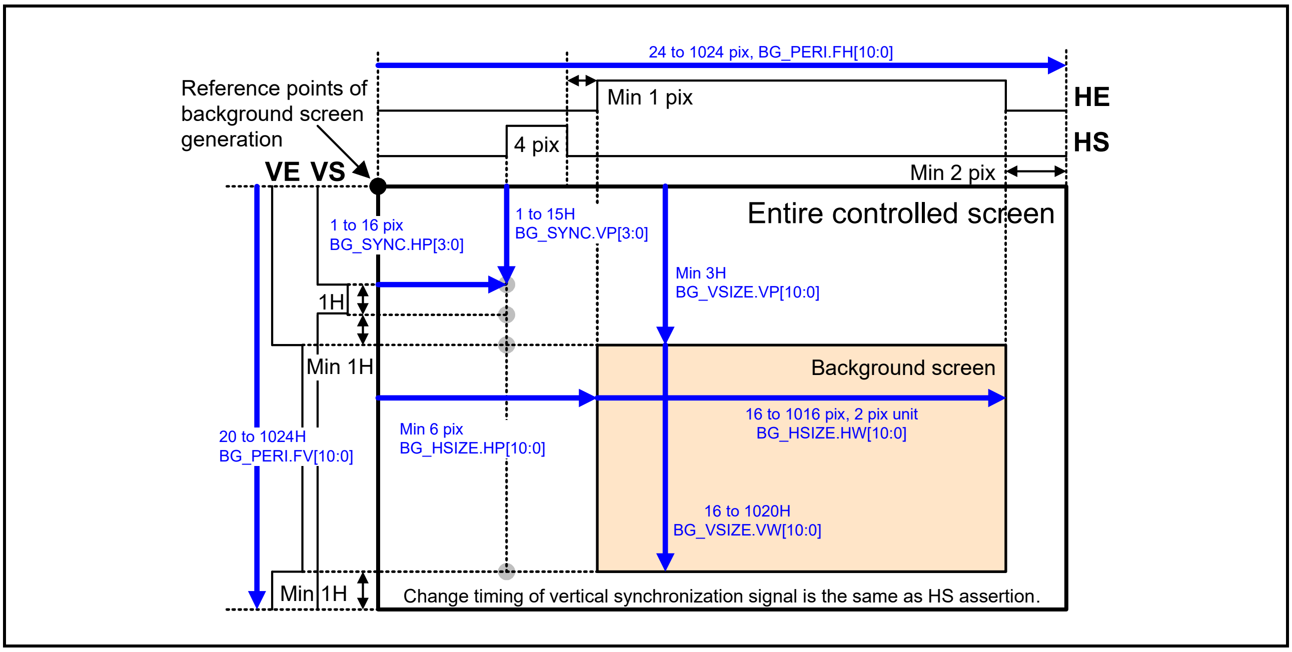

Figure 58.26 Internal definition of background screen

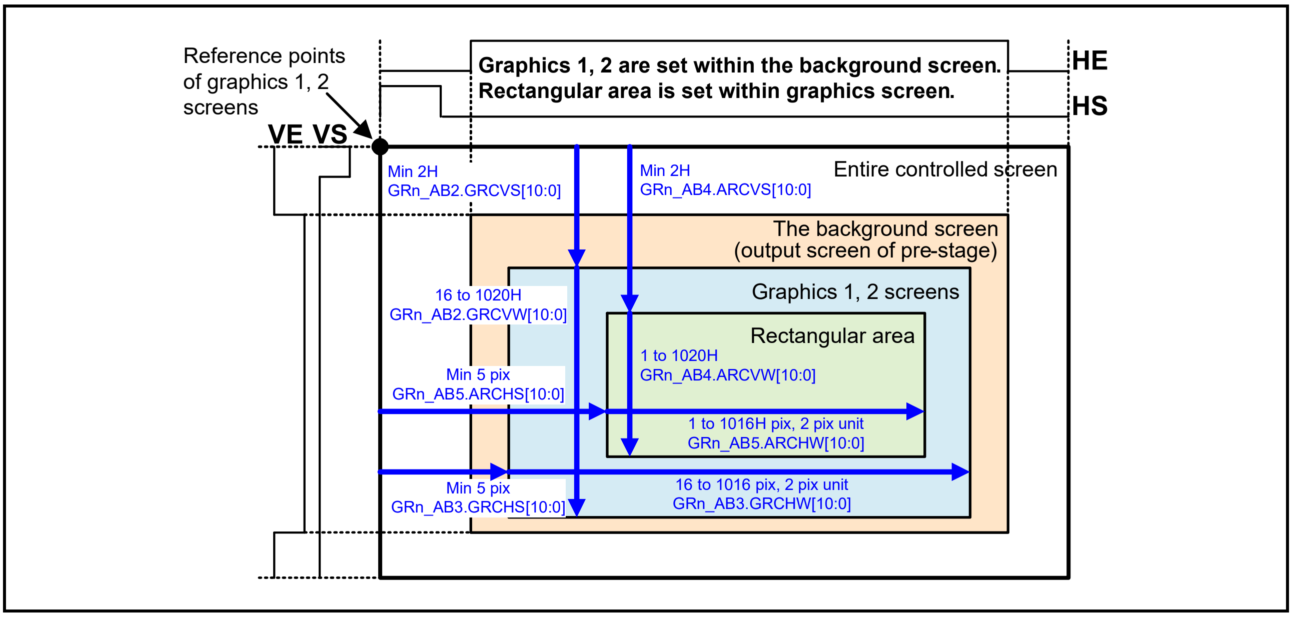

Figure 58.27 Internal definition of graphics 1 and 2 screens

58.3.3 Underflow and Interrupts

The GLCDC can detect the three types of status conditions described in this section. To detect each status condition, set the associated bit in the Status Detection Control Register (SYSCNT_DTCTEN) to 1.

58.3.3.1 Graphics 2 underflow detection

This function detects underflows in the graphics data interface block for graphics 2. The SYSCNT_STMON.L2UNDF flag sets to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 2 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

58.3.3.2 Graphics 1 underflow detection

This function detects underflows in the graphics data interface block for graphics 1. The SYSCNT_STMON.L1UNDF flag is set to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 1 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

58.3.3.3 Graphics 2 line detection

This function detects that the number of lines specified in the GR2_CLUTINT.LINE[10:0] bit was processed. The detection is performed on the HS (horizontal synchronization) signal assertion of the previous stage, not when valid pixels start to be processed. Each time the number of detected lines reach the value specified for graphics 2, the SYSCNT_STMON.VPOS flag sets to 1. As with underflow detection, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

58.3.3.4 Interrupts

The GLCDC provides three interrupt request output signals (GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS) that correspond to detection of the three status conditions. The GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS signals are associated with graphics 2 underflow detection, graphics 1 underflow detection, and graphics 2 line detection, respectively. Each of the interrupt request signals is asserted by setting the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) to 1. Detecting the status and enabling the associated interrupt request can be controlled separately. Even if detection is enabled, the interrupt request signal is not asserted unless the interrupt request output signal is enabled. In addition, if the Status Monitor Register (SYSCNT_STMON) clears while the interrupt request output signal is asserted (the associated bit in the Status Clear Register (SYSCNT_STCLR) is set to 1), or if the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) is cleared to 0, the interrupt request signal is negated. The interrupt request signal generation circuit is configured as shown in Figure 58.28. This circuit is glitch-free except for reset-induced glitches.

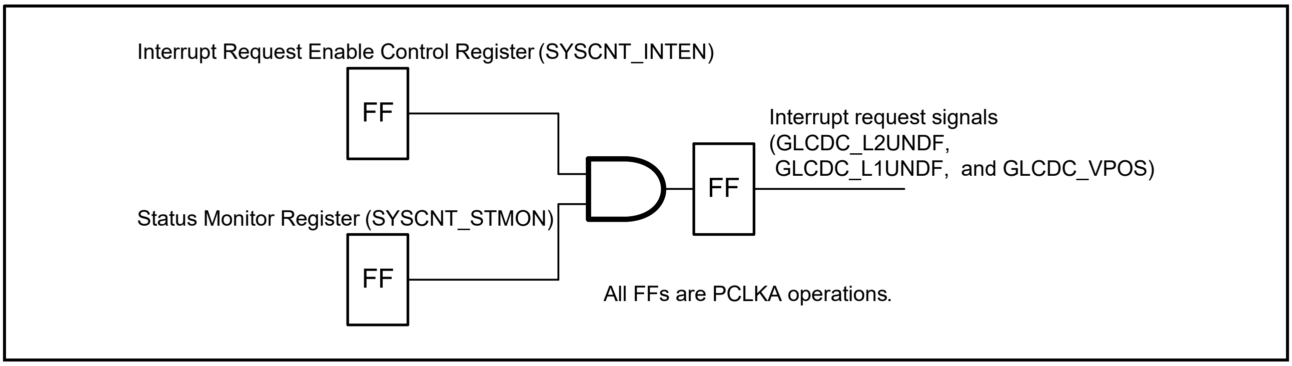

Figure 58.28 Interrupt request signal generation circuit

59. Internal Voltage Regulator

59.1 Overview

The MCU includes a linear regulator (LDO) that supplies voltage to the internal circuits and memory except for I/O, analog, USB, and battery backup power domain.

59.2 Operation

Table 59.1 lists the setting descriptions for the LDO mode pins, and Figure 59.1 shows the LDO mode settings. In LDO mode, the internal voltage is generated from VCC.

Table 59.1 Setting descriptions for the LDO mode pins

Parameter	Description
All VCC pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1-µF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL and VCL0 pins	Connect each pin to VSS through a 0.1-µF multilayer ceramic capacitor. Place the capacitor close to the pin.

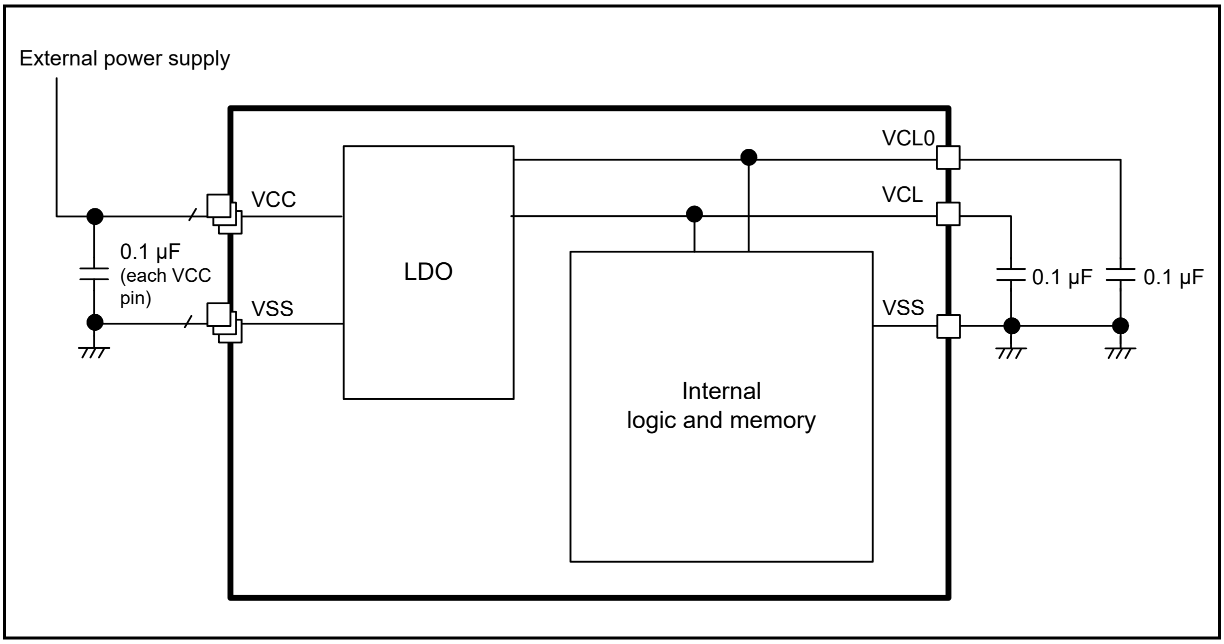

Figure 59.1 LDO mode settings

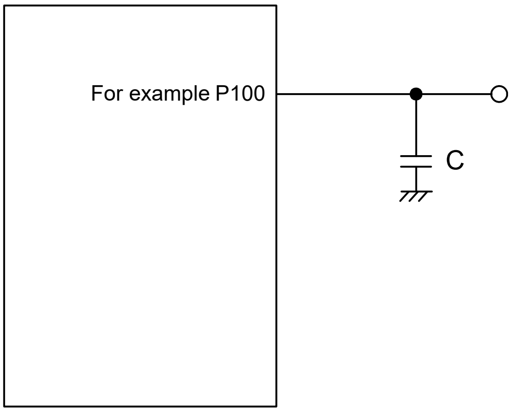
60. Electrical Characteristics

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

VCC = AVCC0 = VCC_USB = VBATT = 2.7 to 3.6 V, 2.7 ≤ VREFH0/VREFH ≤ AVCC0, VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V, VSS = AVSS0 = VREFL0/VREFL = VSS_USB = VSS1_USBHS = VSS2_USBHS = PVSS_USBHS = AVSS_USBHS = 0 V, Ta = Topr.

Figure 60.1 shows the timing conditions.



V_{OH} = VCC × 0.7, V_{OL} = VCC × 0.3
V_{IH} = VCC × 0.7, V_{IL} = VCC × 0.3
Load capacitance C = 30pF

Figure 60.1 Input or output timing measurement conditions

The measurement conditions of timing specification in each peripherals are recommended for the best peripheral operation, however make sure to adjust driving abilities of each pins to meet your conditions.

60.1 Absolute Maximum Ratings

Table 60.1 Absolute maximum ratings

Parameter	Symbol	Value	Unit
Power supply voltage	VCC, VCC_USB *2	-0.3 to +4.0	V
VBATT power supply voltage	VBATT	-0.3 to +4.0	V
Input voltage (except for 5V-tolerant ports*1)	V_{in}	-0.3 to VCC + 0.3	V
Input voltage (5V-tolerant ports*1)	V_{in}	-0.3 to + VCC + 4.0 (max 5.8)	V
Reference power supply voltage	VREFH/VREFH0	-0.3 to AVCC0 + 0.3	V
Analog power supply voltage	AVCC0 *2	-0.3 to +4.0	V
USBHS power supply voltage	VCC_USBHS	-0.3 to +4.0	V
USBHS analog power supply voltage	AVCC_USBHS	-0.3 to +4.0	V
Analog input voltage (except for P000 to P007)	V_{AN}	-0.3 to AVCC0 + 0.3	V
Analog input voltage (P000 to P007) when PGA differential input is disabled	V_{AN}	-0.3 to AVCC0 + 0.3	V
Analog input voltage (P000 to P002, P004 to P006) when PGA differential input is enabled	V_{AN}	-1.3 to AVCC0 + 0.3	V
Analog input voltage (P003, P007) when PGA differential input is enabled	V_{AN}	-0.8 to AVCC0 + 0.3	V
Operating temperature*3,*4,*5	T_{opr}	-40 to +85 -40 to +105	°C
Storage temperature	T_{stg}	-55 to +125	°C

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Note 1. Ports P205, P206, P400, P401, P407 to P415, P511, P512, P708 to P713, and PB01 are 5V-tolerant.

Note 2. Connect AVCC0 and VCC_USB to VCC.

Note 3. See section 60.2.1, T_j/T_a Definition.

Note 4. Contact a Renesas Electronics sales office for information on derating operation when T_a = +85°C to +105°C. Derating is the systematic reduction of load for improved reliability.

Note 5. The upper limit of operating temperature is 85°C or 105°C, depending on the product. For details, see section 1.3, Part Numbering.

Table 60.2 Recommended operating conditions

Parameter	Symbol	Value	Min	Typ	Max	Unit
Power supply voltages	VCC	When USB/SDRAM is not used	2.7	-	3.6	V
		When USB/SDRAM is used	3.0	-	3.6	V
	VSS		-	0	-	V
USB power supply voltages	VCC_USB, VCC_USBHS		-	VCC	-	V
	VSS_USB, AVSS_USBHS, PVSS_USBHS, VSS1_USBHS, VSS2_USBHS		-	0	-	V
VBATT power supply voltage	VBATT		1.8	-	3.6	V
Analog power supply voltages	AVCC0*1		-	VCC	-	V
	AVSS0		-	0	-	V

Note 1. Connect AVCC0 to VCC. When neither the A/D converter nor the D/A converter nor the comparator is in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.

60.2 DC Characteristics

60.2.1 T_j/T_a Definition

Table 60.3 DC characteristics

Conditions: Products with operating temperature (T_a) -40 to +105°C

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible junction temperature	T_j	-	125	°C	High-speed mode Low-speed mode Subosc-speed mode
			105*1		

Note: Make sure that $T_j = T_a + θja \times$ total power consumption (W), where total power consumption = $(VCC - V_{OH}) \times ΣI_{OH} + V_{OL} \times ΣI_{OL} + I_{CC}max \times VCC$.

Note 1. The upper limit of operating temperature is 85°C or 105°C, depending on the product. For details, see section 1.3, Part Numbering. If the part number shows the operation temperature to 85°C, then Tj max is 105°C, otherwise, 125°C.

60.2.2 I/O V_{IH}, V_{IL}

Table 60.4 I/O V_{IH}, V_{IL}

Parameter					Symbol	Min	Typ	Max	Unit
Input voltage (except for Schmitt trigger input pins)	Peripheral function pin	EXTAL(external clock input), WAIT, SPI (except RSPCK)			V_{IH}	VCC × 0.8	-	-	V
					V_{IL}	-	-	VCC × 0.2

					V_{IL}	-	-	VCC × 0.3	
		ETHERC			V_{IH}	2.3	-	-	
					V_{IL}	-	-	VCC × 0.2	
		IIC (SMBus)*1			V_{IH}	2.1	-	-	
					V_{IL}	-	-	0.8	
		IIC (SMBus)*2			V_{IH}	2.1	-	VCC + 3.6 (max 5.8)	
					V_{IL}	-	-	0.8	
Schmitt trigger input voltage		IIC (except for SMBus)*1			V_{IH}	VCC × 0.7	-	-	
					V_{IL}	-	-	VCC × 0.3	
					ΔV_T	VCC × 0.05	-	-	
		IIC (except for SMBus)*2			V_{IH}	VCC × 0.7	-	VCC + 3.6 (max 5.8)	
					V_{IL}	-	-	VCC × 0.3	
					ΔV_T	VCC × 0.05	-	-	
		5V-tolerant ports*3, *7			V_{IH}	VCC × 0.8	-	VCC + 3.6 (max 5.8)	
					V_{IL}	-	-	VCC × 0.2	
					ΔV_T	VCC × 0.05	-	-	
		RTCIC0, RTCIC1, RTCIC2	When using the Battery Backup Function	When VBATT power supply is selected	V_{IH}	V_{BATT} × 0.8	-	V_{BATT} + 0.3	
					V_{IL}	-	-	V_{BATT} × 0.2	
					ΔV_T	V_{BATT} × 0.05	-	-	
				When VCC power supply is selected	V_{IH}	VCC × 0.8	-	Higher voltage either VCC + 0.3 V or V_{BATT} + 0.3 V	
					V_{IL}	-	-	VCC × 0.2	
					ΔV_T	VCC × 0.05	-	-	
			When not using the Battery Backup Function		V_{IH}	VCC × 0.8	-	VCC + 0.3	
					V_{IL}	-	-	VCC × 0.2	
					ΔV_T	VCC × 0.05	-	-	
		Other input pins*4			V_{IH}	VCC × 0.8	-	-	
					V_{IL}	-	-	VCC × 0.2	
					ΔV_T	VCC × 0.05	-	-	
	Ports	5V-tolerant ports*5, *7			V_{IH}	VCC × 0.8	-	VCC + 3.6 (max 5.8)	
					V_{IL}	-	-	VCC × 0.2	
		Other input pins*6			V_{IH}	VCC × 0.8	-	-	
					V_{IL}	-	-	VCC × 0.2	

Note 1. SCL0_B (P204), SCL1_B, SDA1_B (total 3 pins).

Note 2. SCL0_A, SDA0_A, SCL0_B (P408), SDA0_B, SCL1_A, SDA1_A, SCL2, SDA2 (total 8 pins).

Note 3. RES and peripheral function pins associated with P205, P206, P400, P401, P407 to P415, P511, P512, P708 to P713, PB01 (total 23 pins).

Note 4. All input pins except for the peripheral function pins already described in the table.

Note 5. P205, P206, P400, P401, P407 to P415, P511, P512, P708 to P713, PB01 (total 22 pins).

Note 6. All input pins except for the ports already described in the table.

Note 7. When VCC is less than 2.7 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown might occur because the 5 V-tolerant ports are electrically controlled to not violate the breakdown voltage.

60.2.3 I/O I_{OH}, I_{OL}

Table 60.5 I/O I_{OH}, I_{OL}

Parameter			Symbol	Min	Typ	Max	Unit
Permissible output current (average value per pin)	Ports P008 to P010, P201	-	I_{OH}	-	--	-2.0	mA
			I_{OL}	-	-	2.0	mA
	Ports P014, P015	-	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
	Ports P205, P206, P407 to P415, P602, P708 to P713, PB01 (total 19 pins)	Low drive*1	I_{OH}	-	-	-2.0	mA
			I_{OL}	-	-	2.0	mA
		Middle drive*2	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
		High drive*3	I_{OH}	-	-	-20	mA
			I_{OL}	-	-	20	mA
	Other output pins*4	Low drive*1	I_{OH}	-	-	-2.0	mA
			I_{OL}	-	-	2.0	mA
		Middle drive*2	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
		High drive*3	I_{OH}	-	-	-16	mA
			I_{OL}	-	-	16	mA
Permissible output current (max value per pin)	Ports P008 to P010, P201	-	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
	Ports P014, P015	-	I_{OH}	-	-	-8.0	mA
			I_{OL}	-	-	8.0	mA
	Ports P205, P206, P407 to P415, P602, P708 to P713, PB01 (total 19 pins)	Low drive*1	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
		Middle drive*2	I_{OH}	-	-	-8.0	mA
			I_{OL}	-	-	8.0	mA
		High drive*3	I_{OH}	-	-	-40	mA
			I_{OL}	-	-	40	mA
	Other output pins*4	Low drive*1	I_{OH}	-	-	-4.0	mA
			I_{OL}	-	-	4.0	mA
		Middle drive*2	I_{OH}	-	-	-8.0	mA
			I_{OL}	-	-	8.0	mA
		High drive*3	I_{OH}	-	-	-32	mA
			I_{OL}	-	-	32	mA
Permissible output current (max value total pins)	Maximum of all output pins		$\Sigma I_{OH\ (max)}$	-	-	-80	mA
			$\Sigma I_{OL\ (max)}$	-	-	80	mA

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 µs.

Note 1. This is the value when low driving ability is selected in the port drive capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 2. This is the value when middle driving ability is selected in the port drive capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 3. This is the value when high driving ability is selected in the port drive capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

Note 4. Except for P000 to P007, P200, which are input ports.

60.2.4 I/O V_{OH}, V_{OL}, and Other Characteristics

Table 60.6 I/O V_{OH}, V_{OL}, and other characteristics

Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
Output voltage	IIC		V_{OL}	-	-	0.4	V	I_{OL} = 3.0 mA
			V_{OL}	-	-	0.6		I_{OL} = 6.0 mA
	IIC*1		V_{OL}	-	-	0.4		I_{OL} = 15.0 mA (ICFER.FMPE = 1)
			V_{OL}	-	0.4	-		I_{OL} = 20.0 mA (ICFER.FMPE = 1)
	ETHERC		V_{OH}	VCC - 0.5	-	-		I_{OH} = -1.0 mA
			V_{OL}	-	-	0.4		I_{OL} = 1.0 mA
	Ports P205, P206, P407 to P415, P602, P708 to P713, PB01 (total 19 pins)*2		V_{OH}	VCC - 1.0	-	-		I_{OH} = -20 mA VCC = 3.3 V
			V_{OL}	-	-	1.0		I_{OL} = 20 mA VCC = 3.3 V
	Other output pins		V_{OH}	VCC - 0.5	-	-		I_{OH} = -1.0 mA
			V_{OL}	-	-	0.5		I_{OL} = 1.0 mA
Input leakage current	RES		$\|I_{in}\|$	-	-	5.0	μA	V_{in} = 0 V V_{in} = 5.5 V
	Ports P000 to P002, P004 to P006, P200			-	-	1.0		V_{in} = 0 V V_{in} = VCC
	Ports P003, P007	Before initialization*3		-	-	45.0		V_{in} = 0 V V_{in} = VCC
		After initialization*4		-	-	1.0		V_{in} = 0 V V_{in} = VCC
Three-state leakage current (off state)	5V-tolerant ports		$\|I_{TSI}\|$	-	-	5.0	μA	V_{in} = 0 V V_{in} = 5.5 V
	Other ports (except for ports P000 to P007, P200)			-	-	1.0		V_{in} = 0 V V_{in} = VCC
Input pull-up MOS current	Ports P0 to PB (except for ports P000 to P007)		I_p	-300	-	-10	μA	VCC = 2.7 to 3.6 V V_{in} = 0 V
Input capacitance	USB_DP, USB_DM, and ports P003, P007, P014, P015, P400, P401, P511, P512		C_{in}	-	-	16	pF	Vbias = 0V Vamp = 20mV f = 1 MHz T_a = 25°C
	Other input pins			-	-	8		

Note 1. SCL0_A, SDA0_A (total 2 pins).
Note 2. This is the value when high driving ability is selected in the port drive capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 3. P0nPFS.ASEL (n = 3 or 7) = 1.
Note 4. P0nPFS.ASEL (n = 3 or 7) = 0.

60.2.5 Operating and Standby Current

Table 60.7 Operating and standby current (1 of 2)

Parameter				Symbol	Min	Typ	Max	Unit	Test conditions
Supply current*1	High-speed mode	Maximum*2		I_{CC}*3	-	-	137*2	mA	ICLK = 120 MHz PCLKA = 120 MHz*7 PCLKB = 60 MHz PCLKC = 60 MHz PCLKD = 120 MHz FCLK = 60 MHz BCLK = 120 MHz
		CoreMark®*5			-	21	-		
		Normal mode	All peripheral clocks enabled, while (1) code executing from flash*4		-	34	-		
			All peripheral clocks disabled, while (1) code executing from flash*5, *6		-	14	-		
		Sleep mode*5, *6			-	12	46		
		Increase during BGO operation	Data flash P/E		-	6	-		
			Code flash P/E		-	8	-		
	Low-speed mode*5				-	2.4	-		ICLK = 1 MHz
	Subosc-speed mode*5				-	2	-		ICLK = 32.768 kHz
	Software Standby mode				-	1.8	18		Ta ≤ 85°C
					-	1.8	28		Ta ≤ 105°C
	Deep Software Standby mode	Power supplied to Standby SRAM and USB resume detecting unit			-	30	79	μA	Ta ≤ 85°C
					-	30	113	μA	Ta ≤ 105°C
		Power not supplied to SRAM or USB resume detecting unit	Power-on reset circuit low-power function disabled		-	13	33	μA	Ta ≤ 85°C
					-	13	40		Ta ≤ 105°C
			Power-on reset circuit low-power function enabled		-	6.3	28		Ta ≤ 85°C
					-	6.3	34		Ta ≤ 105°C
		Increase when the RTC and AGT are operating	When the low-speed on-chip oscillator (LOCO) is in use		-	5	-		-
			When a crystal oscillator for low clock loads is in use		-	1.0	-		-
			When a crystal oscillator for standard clock loads is in use		-	1.5	-		-
	RTC operating while VCC is off (with the battery backup function, only the RTC and sub-clock oscillator operate)		When a crystal oscillator for low clock loads is in use		-	0.9	-		V_{BATT} = 1.8 V, VCC = 0 V
					-	1.3	-		V_{BATT} = 3.3 V, VCC = 0 V
			When a crystal oscillator for standard clock loads is in use		-	1.1	-		V_{BATT} = 1.8 V, VCC = 0 V
					-	1.8	-		V_{BATT} = 3.3 V, VCC = 0 V
Analog power supply current	During 12-bit A/D conversion			AI_{CC}	-	0.8	1.1	mA	-
	During 12-bit A/D conversion with S/H amp				-	2.3	3.3	mA	-
	PGA (1ch)				-	1	3	mA	-
	ACMPHS (1unit)				-	100	150	μA	-
	Temperature sensor				-	0.1	0.2	mA	-
	During D/A conversion (per unit)		Without AMP output		-	0.1	0.2	mA	-
			With AMP output		-	0.6	1.1	mA	-
	Waiting for A/D, D/A conversion (all units)				-	0.9	1.6	mA	-
	ADC12, DAC12 in standby modes (all units)*8				-	2	8	μA	-
Reference power supply current (VREFH0)	During 12-bit A/D conversion (unit 0)			AI_{REFH0}	-	70	120	μA	-
	Waiting for 12-bit A/D conversion (unit 0)				-	0.07	0.5	μA	-
	ADC12 in standby modes (unit 0)				-	0.07	0.5	μA	-
Reference power supply current (VREFH)	During 12-bit A/D conversion (unit 1)			AI_{REFH}	-	70	120	μA	-
	During D/A conversion (per unit)		Without AMP output		-	0.1	0.4	mA	-
			With AMP ouput		-	0.1	0.4	mA	-
	Waiting for 12-bit A/D (unit 1), D/A (all units) conversion				-	0.07	0.8	μA	-
	ADC12 unit 1 in standby modes				-	0.07	0.8	μA	-

Table 60.7 Operating and standby current (2 of 2)

Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
USB operating current	Low speed	USB	$I_{CCUSBLS}$	-	3.5	6.5	mA	VCC_USB
		USBHS		-	10.5	13.5	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 0)
		USBHS		-	2.8	3.6	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 1)
	Full speed	USB	$I_{CCUSBFS}$	-	4.0	10.0	mA	VCC_USB
		USBHS		-	14	22	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 0)
		USBHS		-	6.5	13.0	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 1)
	High speed	USBHS	$I_{CCUSBHS}$	-	50	65	mA	VCC_USBHS = AVCC_USBHS
	Standby mode (direct power down)	USBHS	$I_{CCUSBSBY}$	-	0.5	4.5	μA	VCC_USBHS = AVCC_USBHS

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOS transistors in the off state.

Note 2. Measured with clocks supplied to the peripheral functions. This does not include the BGO operation.

Note 3. ICC depends on f (ICLK) as follows. (ICLK:PCLKA:PCLKB:PCLKC:PCLKD:BCK:EBCLK = 2:2:1:1:2:1:1)
ICC Max. = 0.84 × f + 37 (max. operation in High-speed mode)
ICC Typ. = 0.09 × f + 3.7 (normal operation in High-speed mode)
ICC Typ. = 0.6 × f + 1.8 (Low-speed mode 1)
ICC Max. = 0.08 × f + 37 (Sleep mode).

Note 4. This does not include the BGO operation.

Note 5. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 6. FCLK, BCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (3.75 MHz).

Note 7. When using ETHERC, GLCDC, DRW, and JPEG, PCLKA frequency is such that PCLKA = ICLK.

Note 8. When the MCU is in Software Standby mode or the MSTPCRD.MSTPD16 (ADC120 Module Stop bit) and MSTPCRD.MSTPD15 (ADC121 Module Stop bit) are in the module-stop state. See section 47.6.8, Available Functions and Register Settings of AN000 to AN002, AN007, AN100 to AN102, and AN107.

60.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 60.8 Rise and fall gradient characteristics

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
VCC rising gradient	Voltage monitor 0 reset disabled at startup	SrVCC	0.0084	-	20	ms/V	-
	Voltage monitor 0 reset enabled at startup		0.0084	-	-		-
	SCI/USB boot mode*1		0.0084	-	20		-
VCC falling gradient*2		SfVCC	0.0084	-	-	ms/V	-

Note 1. At boot mode, the reset from voltage monitor 0 is disabled regardless of the value of OFS1.LVDAS bit.
Note 2. This applies when VBATT is used.

Table 60.9 Rise and fall gradient and ripple frequency characteristics

The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (2.7 V). When the VCC change exceeds VCC ±10%, the allowable voltage change rising and falling gradient dt/dVCC must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_{r\ (VCC)}$	-	-	10	kHz	Figure 60.6 $V_{r\ (VCC)} \leq VCC \times 0.2$
		-	-	1	MHz	Figure 60.6 $V_{r\ (VCC)} \leq VCC \times 0.08$
		-	-	10	MHz	Figure 60.6 $V_{r\ (VCC)} \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	dt/dVCC	1.0	-	-	ms/V	When VCC change exceeds VCC ±10%

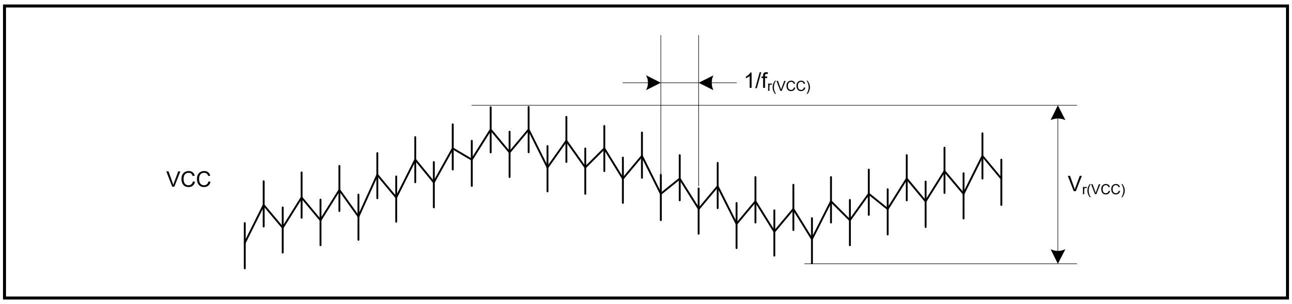

Figure 60.6 Ripple waveform

60.3 AC Characteristics

60.3.1 Frequency

Table 60.10 Operation frequency value in high-speed mode

Parameter			Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK*2)		f	-	-	120	MHz
	Peripheral module clock (PCLKA)*2			-	-	120	
	Peripheral module clock (PCLKB)*2			-	-	60	
	Peripheral module clock (PCLKC)*2			-*3	-	60	
	Peripheral module clock (PCLKD)*2			-	-	120	
	Flash interface clock (FCLK)*2			-*1	-	60	
	External bus clock (BCLK)*2			-	-	120	
	EBCLK pin output			-	-	60	
	SDCLK pin output	VCC ≥ 3.0 V		-	-	120	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.
Note 2. See section 9, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

Table 60.11 Operation frequency value in low-speed mode

Parameter		Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK)*2	f	-	-	1	MHz
	Peripheral module clock (PCLKA)*2		-	-	1	
	Peripheral module clock (PCLKB)*2		-	-	1	
	Peripheral module clock (PCLKC)*2,*3		-*3	-	1	
	Peripheral module clock (PCLKD)*2		-	-	1	
	Flash interface clock (FCLK)*1, *2		-	-	1	
	External bus clock (BCLK)		-	-	1	
	EBCLK pin output		-	-	1	

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.
Note 2. See section 9, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be set to at least 1 MHz.

Table 60.12 Operation frequency value in Subosc-speed mode

Parameter		Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK)*2	f	27.8	-	37.7	kHz
	Peripheral module clock (PCLKA)*2		-	-	37.7	
	Peripheral module clock (PCLKB)*2		-	-	37.7	
	Peripheral module clock (PCLKC)*2,*3		-	-	37.7	
	Peripheral module clock (PCLKD)*2		-	-	37.7	
	Flash interface clock (FCLK)*1, *2		27.8	-	37.7	
	External bus clock (BCLK)*2		-	-	37.7	
	EBCLK pin output		-	-	37.7	

Note 1. Programming or erasing the flash memory is disable in Subosc-speed mode.
Note 2. See section 9, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. The ADC12 cannot be used.

60.3.2 Clock Timing

Table 60.13 Clock timing except for sub-clock oscillator (1 of 2)

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time	t_{Bcyc}	16.6	-	-	ns	Figure 60.7
EBCLK pin output high pulse width	t_{CH}	3.3	-	-	ns	
EBCLK pin output low pulse width	t_{CL}	3.3	-	-	ns	
EBCLK pin output rise time	t_{Cr}	-	-	5.0	ns	
EBCLK pin output fall time	t_{Cf}	-	-	5.0	ns	
SDCLK pin output cycle time	t_{SDcyc}	8.33	-	-	ns	
SDCLK pin output high pulse width	t_{CH}	1.0	-	-	ns	
SDCLK pin output low pulse width	t_{CL}	1.0	-	-	ns	
SDCLK pin output rise time	t_{Cr}	-	-	3.0	ns	
SDCLK pin output fall time	t_{Cf}	-	-	3.0	ns	

Table 60.13 Clock timing except for sub-clock oscillator (2 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EXTAL external clock input cycle time		t_{EXcyc}	41.66	-	-	ns	Figure 60.8
EXTAL external clock input high pulse width		t_{EXH}	15.83	-	-	ns	
EXTAL external clock input low pulse width		t_{EXL}	15.83	-	-	ns	
EXTAL external clock rise time		t_{EXr}	-	-	5.0	ns	
EXTAL external clock fall time		t_{EXf}	-	-	5.0	ns	
Main clock oscillator frequency		f_{MAIN}	8	-	24	MHz	-
Main clock oscillation stabilization wait time (crystal) *1		$t_{MAINOSCWT}$	-	-	-*1	ms	Figure 60.9
LOCO clock oscillation frequency		f_{LOCO}	27.8528	32.768	37.6832	kHz	-
LOCO clock oscillation stabilization wait time		t_{LOCOWT}	-	-	60.4	μs	Figure 60.10
ILOCO clock oscillation frequency		f_{ILOCO}	12.75	15	17.25	kHz	-
MOCO clock oscillation frequency		F_{MOCO}	6.8	8	9.2	MHz	-
MOCO clock oscillation stabilization wait time		t_{MOCOWT}	-	-	15.0	μs	-
HOCO clock oscillator oscillation frequency	Without FLL	f_{HOCO16}	15.78	16	16.22	MHz	-20 ≤ Ta ≤ 105°C
		f_{HOCO18}	17.75	18	18.25		
		f_{HOCO20}	19.72	20	20.28		
		f_{HOCO16}	15.71	16	16.29		-40 ≤ Ta ≤ -20°C
		f_{HOCO18}	17.68	18	18.32		
		f_{HOCO20}	19.64	20	20.36		
	With FLL	f_{HOCO16}	15.955	16	16.045		-40 ≤ Ta ≤ 105°C Sub-clock frequency accuracy is ±50 ppm.
		f_{HOCO18}	17.949	18	18.051		
		f_{HOCO20}	19.944	20	20.056		
HOCO clock oscillation stabilization wait time*2		t_{HOCOWT}	-	-	64.7	μs	-
FLL stabilization wait time		t_{FLLWT}	-	-	1.8	ms	-
PLL clock frequency		f_{PLL}	120	-	240	MHz	-
PLL clock oscillation stabilization wait time		t_{PLLWT}	-	-	174.9	μs	Figure 60.11

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (fHOCO) reaches the range for guaranteed operation.

Table 60.14 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	-	32.768	-	kHz	-
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	-	-	*1	s	Figure 60.12

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. Two times the value shown is recommended.

Note: Only operate the PLL is operated after main clock oscillation has stabilized.

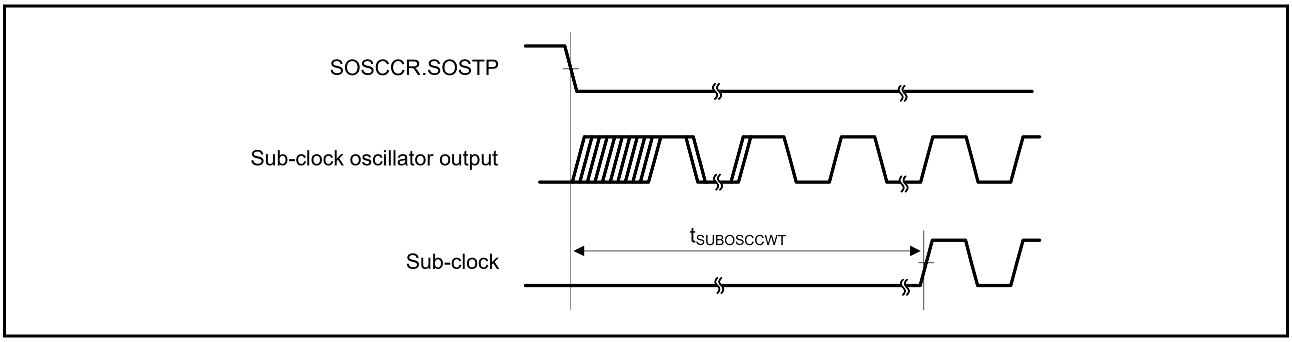

Figure 60.12 Sub-clock oscillation start timing

60.3.3 Reset Timing

Table 60.15 Reset timing

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
RES pulse width	Power-on	t_{RESWP}	1	-	-	ms	Figure 60.13
	Deep Software Standby mode	t_{RESWD}	0.6	-	-	ms	Figure 60.14
	Software Standby mode, Subosc-speed mode	t_{RESWS}	0.3	-	-	ms	
	All other	t_{RESW}	200	-	-	μs	
Wait time after RES cancellation		t_{RESWT}	-	29	33	μs	Figure 60.13
Wait time after internal reset cancellation (IWDT reset, WDT reset, software reset, SRAM parity error reset, SRAM ECC error reset, bus master MPU error reset, bus slave MPU error reset, stack pointer error reset)		t_{RESW2}	-	320	408	μs	-

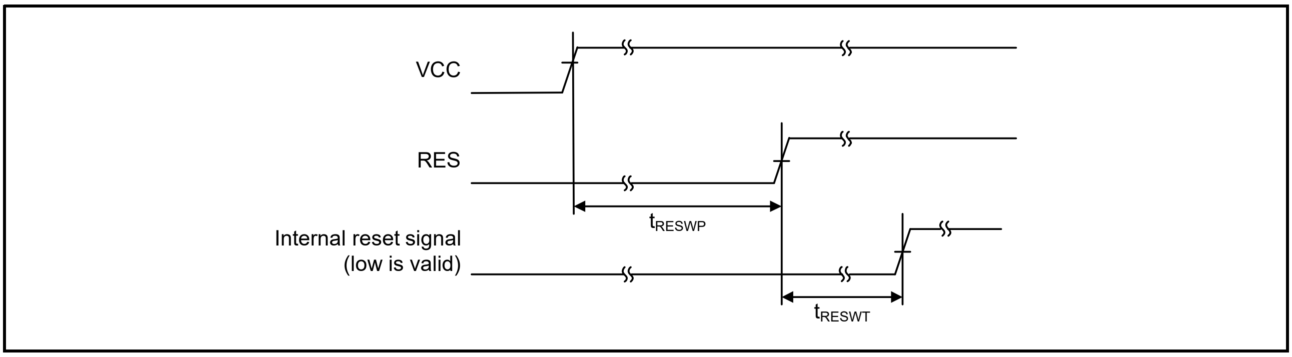

Figure 60.13 Power-on reset timing

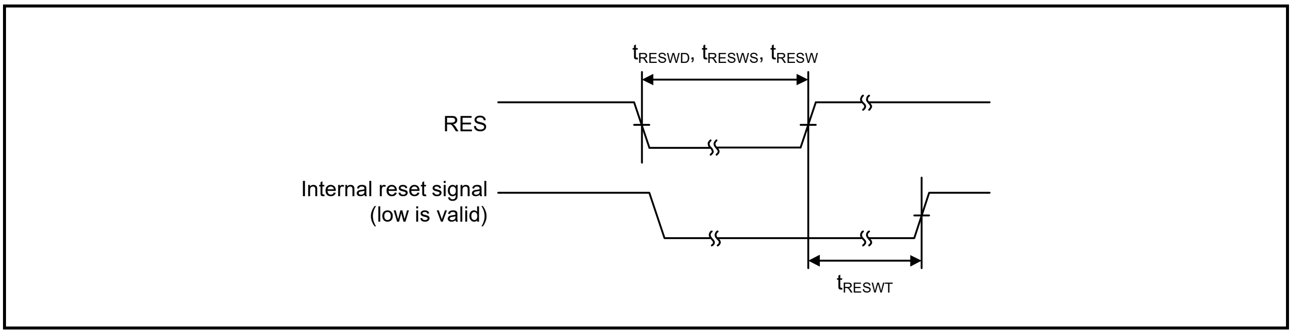

Figure 60.14 Reset input timing

60.3.4 Wakeup Timing

Table 60.16 Timing of recovery from low power modes

Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
Recovery time from Software Standby mode*1	Crystal resonator connected to main clock oscillator	System clock source is main clock oscillator*2	t_{SBYMC}	-	2.4*9	2.8*9	ms	Figure 60.15 The division ratio of all oscillators is 1.
		System clock source is PLL with main clock oscillator*3	t_{SBYPC}	-	2.7*9	3.2*9	ms	
	External clock input to main clock oscillator	System clock source is main clock oscillator*4	t_{SBYEX}	-	230*9	280*9	µs	
		System clock source is PLL with main clock oscillator*5	t_{SBYPE}	-	570*9	700*9	µs	
	System clock source is sub-clock oscillator*8		t_{SBYSC}	-	1.2*9	1.3*9	ms	
	System clock source is LOCO*8		t_{SBYLO}	-	1.2*9	1.4*9	ms	
	System clock source is HOCO clock oscillator*6		t_{SBYHO}	-	240*9, *10	310 *9, *10	µs	
	System clock source is MOCO clock oscillator*7		t_{SBYMO}	-	220*9	300*9	µs	
Recovery time from Deep Software Standby mode			t_{DSBY}	-	0.65	1.0	ms	Figure 60.16
Wait time after cancellation of Deep Software Standby mode			t_{DSBYWT}	34	-	35	t_{cyc}	
Recovery time from Software Standby mode to Snooze mode	High-speed mode when system clock source is HOCO (20 MHz)		t_{SNZ}	-	35*9, *10	71 *9, *10	µs	Figure 60.17
	High-speed mode when system clock source is MOCO (8 MHz)		t_{SNZ}	-	11*9	14*9	µs	

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:
Total recovery time = recovery time for an oscillator as the system clock source + the longest oscillation stabilization time of any oscillators requiring longer stabilization times than the system clock source + 2 LOCO cycles (when LOCO is operating) + 3 SOSC cycles (when Subosc is oscillating and MSTPC0 = 0 (CAC module stop)).

Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 05h). For other settings (MOSCWTCR is set to Xh), the recovery time can be determined with the following equation:
t_{SBYMC} (MOSCWTCR = Xh) = t_{SBYMC} (MOSCWTCR = 05h) + ($t_{MAINOSCWT}$ (MOSCWTCR = Xh) - $t_{MAINOSCWT}$ (MOSCWTCR = 05h))

Note 3. When the frequency of PLL is 240 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 05h). For other settings (MOSCWTCR is set to Xh), the recovery time can be determined with the following equation:
t_{SBYMC} (MOSCWTCR = Xh) = t_{SBYMC} (MOSCWTCR = 05h) + ($t_{MAINOSCWT}$ (MOSCWTCR = Xh) - $t_{MAINOSCWT}$ (MOSCWTCR = 05h))

Note 4. When the frequency of the external clock is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 00h). For other settings (MOSCWTCR is set to Xh), the recovery time can be determined with the following equation:
t_{SBYMC} (MOSCWTCR = Xh) = t_{SBYMC} (MOSCWTCR = 00h) + ($t_{MAINOSCWT}$ (MOSCWTCR = Xh) - $t_{MAINOSCWT}$ (MOSCWTCR = 00h))

Note 5. When the frequency of PLL is 240 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 00h). For other settings (MOSCWTCR is set to Xh), the recovery time can be determined with the following equation:
t_{SBYMC} (MOSCWTCR = Xh) = t_{SBYMC} (MOSCWTCR = 00h) + ($t_{MAINOSCWT}$ (MOSCWTCR = Xh) - $t_{MAINOSCWT}$ (MOSCWTCR = 00h))

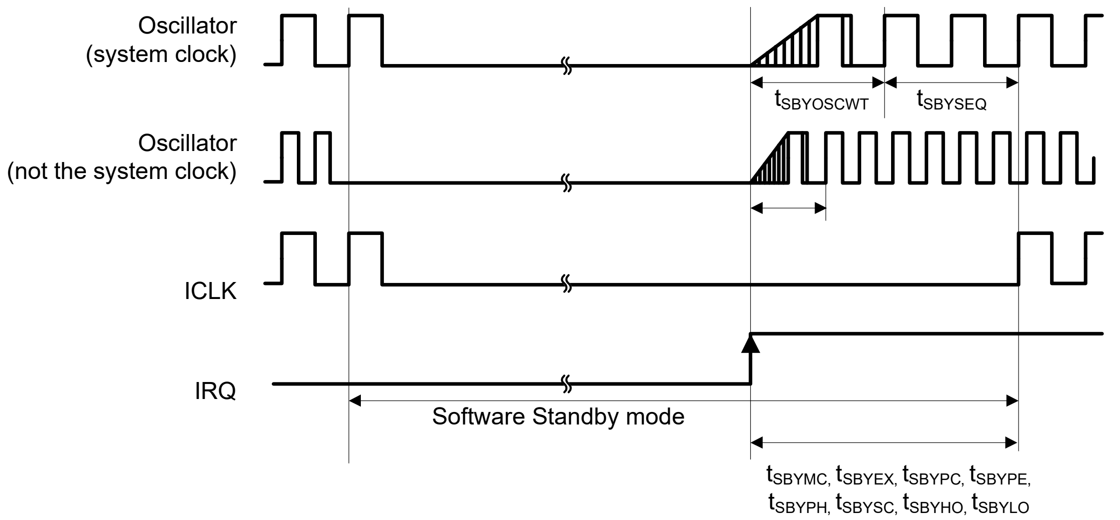
Note 6. The HOCO frequency is 20 MHz.

Note 7. The MOCO frequency is 8 MHz.

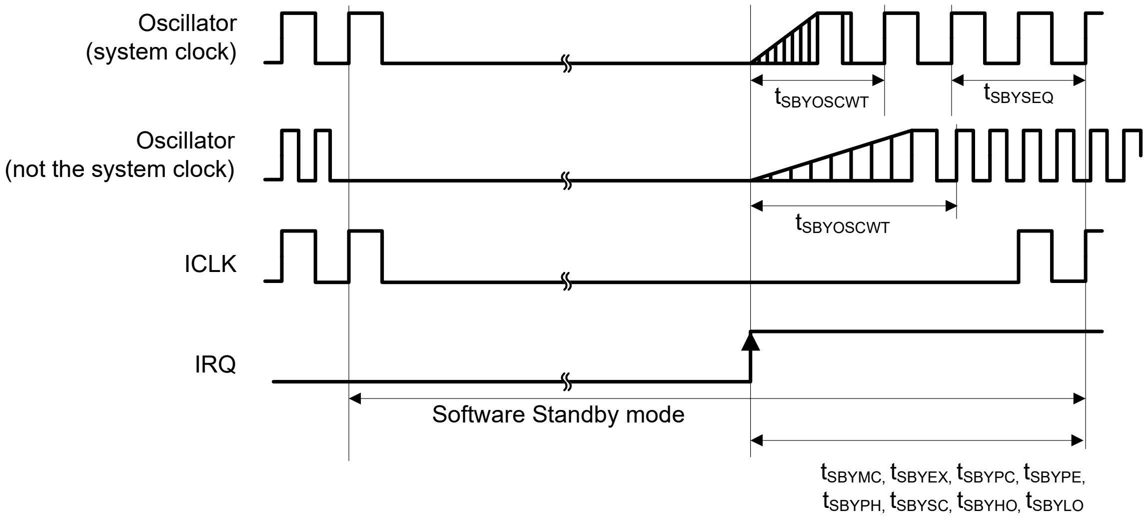
Note 8. In Subosc-speed mode, the sub-clock oscillator or LOCO continues oscillating in Software Standby mode.

Note 9. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time:
STCONR.STCON[1:0] = 00b:16 µs (typical), 34 µs (maximum)
STCONR.STCON[1:0] = 11b:16 µs (typical), 104 µs (maximum).

Note 10. When the SNZCR.RXDREQEN bit is set to 0, 16 µs (typical) or 18 µs (maximum) is added as the HOCO wait time.



When stabilization of the system clock oscillator is slower



When stabilization of an oscillator other than the system clock is slower

Figure 60.15 Software Standby mode cancellation timing

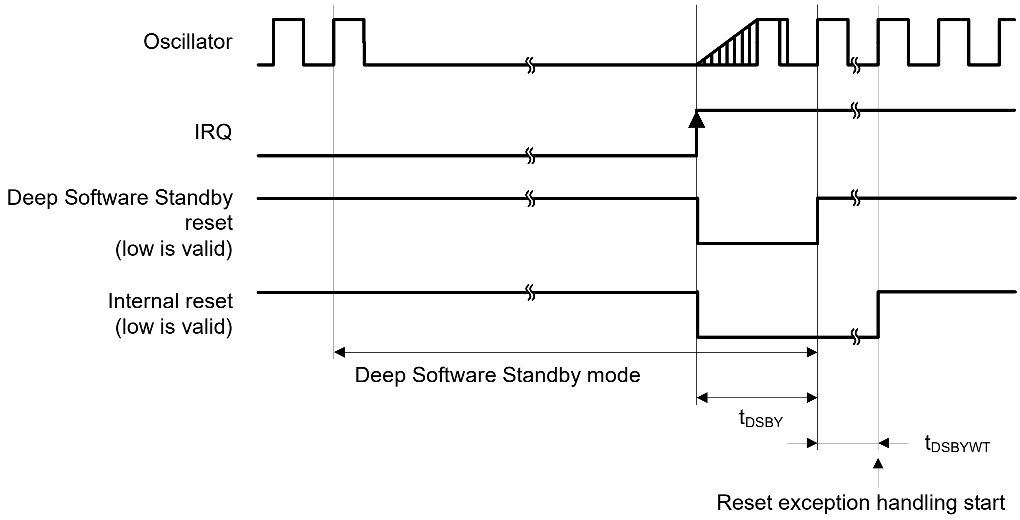


Figure 60.16 Deep Software Standby mode cancellation timing

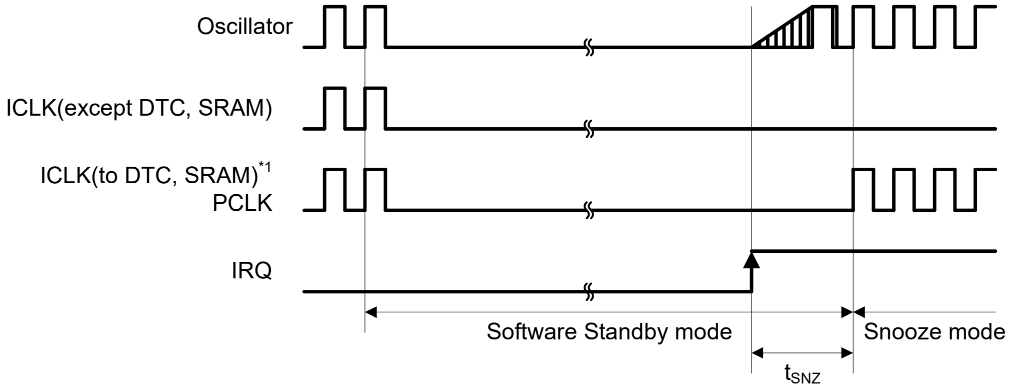

Note 1. When SNZCR.SNZDTCEN is set to 1, ICLK is supplied to DTC and SRAM.

Figure 60.17 Recovery timing from Software Standby mode to Snooze mode

60.3.5 NMI and IRQ Noise Filter

Table 60.17 NMI and IRQ noise filter

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions	
NMI pulse width	t_{NMIW}	200	-	-	ns	NMI digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$[*1]	-	-			$t_{Pcyc} \times 2 > 200$ ns
		200	-	-		NMI digital filter enabled	$t_{NMICK} \times 3 \leq 200$ ns
		$t_{NMICK} \times 3.5$[*2]	-	-			$t_{NMICK} \times 3 > 200$ ns
IRQ pulse width	t_{IRQW}	200	-	-	ns	IRQ digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$[*1]	-	-			$t_{Pcyc} \times 2 > 200$ ns
		200	-	-		IRQ digital filter enabled	$t_{IRQCK} \times 3 \leq 200$ ns
		$t_{IRQCK} \times 3.5$[*3]	-	-			$t_{IRQCK} \times 3 > 200$ ns

Note: 200 ns minimum in Software Standby mode.
Note: If the clock source is switched, add 4 clock cycles of the switched source.

Note 1. t_{Pcyc} indicates the PCLKB cycle.
Note 2. t_{NMICK} indicates the cycle of the NMI digital filter sampling clock.
Note 3. t_{IRQCK} indicates the cycle of the IRQi digital filter sampling clock.

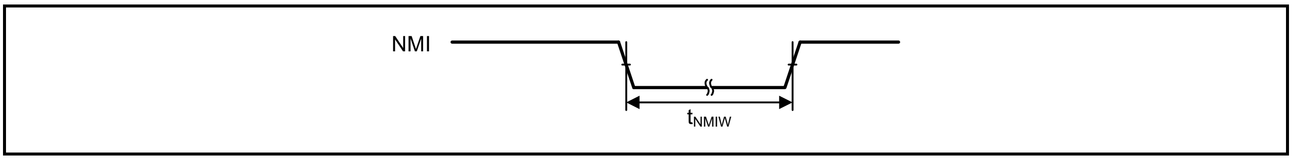

Figure 60.18 NMI interrupt input timing

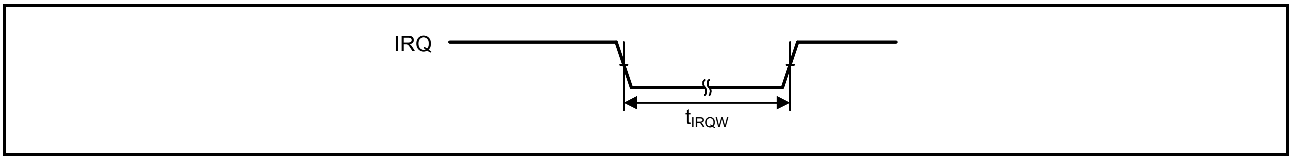

Figure 60.19 IRQ interrupt input timing

60.3.6 Bus Timing

Table 60.18 Bus timing (1 of 2)

Condition 1: When using the CS area controller (CSC).
BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz
VCC = AVCC0 = VCC_USB = VBATT = 2.7 to 3.6 V, VREFH/VREFH0 = 2.7 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF
EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).
BCLK = SDCLK = 8 to 120 MHz
VCC = AVCC0 = VCC_USB = VBATT = 3.0 to 3.6 V, VREFH/VREFH0 = 3.0 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.
BCLK = SDCLK = 8 to 60 MHz
VCC = AVCC0 = VCC_USB = VBATT = 3.0 to 3.6 V, VREFH/VREFH0 = 3.0 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
High drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter	Symbol	Min	Max	Unit	Test conditions
Address delay	t_{AD}	-	12.5	ns	Figure 60.20 to Figure 60.25
Byte control delay	t_{BCD}	-	12.5	ns	
CS delay	t_{CSD}	-	12.5	ns	
ALE delay time	t_{ALED}	-	12.5	ns	
RD delay	t_{RSD}	-	12.5	ns	
Read data setup time	t_{RDS}	12.5	-	ns	
Read data hold time	t_{RDH}	0	-	ns	
WR/WRn delay	t_{WRD}	-	12.5	ns	
Write data delay	t_{WDD}	-	12.5	ns	
Write data hold time	t_{WDH}	0	-	ns	
WAIT setup time	t_{WTS}	12.5	-	ns	Figure 60.26
WAIT hold time	t_{WTH}	0	-	ns	

Table 60.18 Bus timing (2 of 2)

Condition 1: When using the CS area controller (CSC).
BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz
VCC = AVCC0 = VCC_USB = VBATT = 2.7 to 3.6 V, VREFH/VREFH0 = 2.7 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF
EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).
BCLK = SDCLK = 8 to 120 MHz
VCC = AVCC0 = VCC_USB = VBATT = 3.0 to 3.6 V, VREFH/VREFH0 = 3.0 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.
BCLK = SDCLK = 8 to 60 MHz
VCC = AVCC0 = VCC_USB = VBATT = 3.0 to 3.6 V, VREFH/VREFH0 = 3.0 V to AVCC0,
VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
High drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter	Symbol	Min	Max	Unit	Test conditions
Address delay 2 (SDRAM)	t_{AD2}	0.8	6.8	ns	Figure 60.27 to Figure 60.33
CS delay 2 (SDRAM)	t_{CSD2}	0.8	6.8	ns

60.3.7 I/O Ports, POEG, GPT32, AGT, KINT, and ADC12 Trigger Timing

Table 60.19 I/O ports, POEG, GPT32, AGT, KINT, and ADC12 trigger timing (1 of 2)

GPT32 Conditions:
High drive output is selected in the port drive capability bit in the PmnPFS register.

AGT Conditions:
Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
I/O ports	Input data pulse width	t_{PRW}	1.5	-	t_{Pcyc}	Figure 60.34
POEG	POEG input trigger pulse width	t_{POEW}	3	-	t_{Pcyc}	Figure 60.35

Table 60.19 I/O ports, POEG, GPT32, AGT, KINT, and ADC12 trigger timing (2 of 2)

GPT32 Conditions:
High drive output is selected in the port drive capability bit in the PmnPFS register.

AGT Conditions:
Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
GPT32	Input capture pulse width	Single edge	t_{GTICW}	1.5	-	t_{PDcyc}	Figure 60.36
		Dual edge		2.5	-		
	GTIOCxY output skew (x = 0 to 7, Y= A or B)	Middle drive buffer	t_{GTISK}*1	-	4	ns	Figure 60.37
		High drive buffer		-	4		
	GTIOCxY output skew (x = 8 to 13, Y = A or B)	Middle drive buffer		-	4		
		High drive buffer		-	4		
	GTIOCxY output skew (x = 0 to 13, Y = A or B)	Middle drive buffer		-	6		
		High drive buffer		-	6		
	OPS output skew GTOUUP, GTOULO, GTOVUP, GTOVLO, GTOWUP, GTOWLO		t_{GTOSK}	-	5	ns	Figure 60.38
GPT(PWM Delay Generation Circuit)	GTIOCxY_Z output skew (x = 0 to 3, Y = A or B, Z = A)		t_{HRSK}*2	-	2.0	ns	Figure 60.39
AGT	AGTIO, AGTEE input cycle		t_{ACYC}*3	100	-	ns	Figure 60.40
	AGTIO, AGTEE input high width, low width		t_{ACKWH}, t_{ACKWL}	40	-	ns	
	AGTIO, AGTO, AGTOA, AGTOB output cycle		t_{ACYC2}	62.5	-	ns	
ADC12	ADC12 trigger input pulse width		t_{TRGW}	1.5	-	t_{Pcyc}	Figure 60.41
KINT	KRn (n = 00 to 07) pulse width		t_{KR}	250	-	ns	Figure 60.42

Note: t_{Pcyc}: PCLKB cycle, t_{PDcyc}: PCLKD cycle.

Note 1. This skew applies when the same driver I/O is used. If the I/O of the middle and high drivers is mixed, operation is not guaranteed.

Note 2. The load is 30 pF.

Note 3. Constraints on input cycle:
When not switching the source clock: $t_{Pcyc} \times 2 < t_{ACYC}$ should be satisfied.
When switching the source clock: $t_{Pcyc} \times 6 < t_{ACYC}$ should be satisfied.

60.3.8 PWM Delay Generation Circuit Timing

Table 60.20 PWM Delay Generation Circuit timing

Parameter	Min	Typ	Max	Unit	Test conditions
Operation frequency	80	-	120	MHz	-
Resolution	-	260	-	ps	PCLKD = 120 MHz
DNL*1	-	±2.0	-	LSB	-

Note 1. This value normalizes the differences between lines in 1-LSB resolution.

60.3.9 CAC Timing

Table 60.21 CAC timing

Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
CAC	CACREF input pulse width	$t_{PBcyc} \le tcac^{*2}$	t_{CACREF}	$4.5 \times t_{cac} + 3 \times t_{PBcyc}$	-	-	ns	-
		$t_{PBcyc} > tcac^{*2}$		$5 \times t_{cac} + 6.5 \times t_{PBcyc}$	-	-	ns	

Note 1. t_{PBcyc}: PCLKB cycle.

Note 2. t_{cac}: CAC count clock source cycle.

60.3.10 SCI Timing

Table 60.22 SCI timing (1)

Conditions: High drive output is selected in the port drive capability bit in the PmnPFS register for the following pins: SCK0 to SCK9. For other pins, middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit*1	Test conditions
SCI	Input clock cycle	Asynchronous	t_{Scyc}	4	-	t_{Pcyc}	Figure 60.43
		Clock synchronous		6	-		
	Input clock pulse width		t_{SCKW}	0.4	0.6	t_{Scyc}	
	Input clock rise time		t_{SCKr}	-	5	ns	
	Input clock fall time		t_{SCKf}	-	5	ns	
	Output clock cycle	Asynchronous	t_{Scyc}	6	-	t_{Pcyc}	
		Clock synchronous		4	-		
	Output clock pulse width		t_{SCKW}	0.4	0.6	t_{Scyc}	
	Output clock rise time		t_{SCKr}	-	5	ns	
	Output clock fall time		t_{SCKf}	-	5	ns	
	Transmit data delay	Clock synchronous	t_{TXD}	-	25	ns	Figure 60.44
	Receive data setup time	Clock synchronous	t_{RXS}	15	-	ns	
	Receive data hold time	Clock synchronous	t_{RXH}	5	-	ns	

Note 1. t_{Pcyc}: PCLKA cycle.

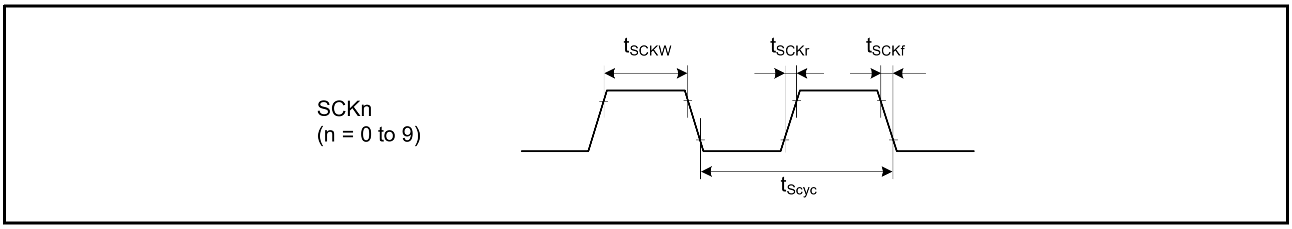

Figure 60.43 SCK clock input/output timing

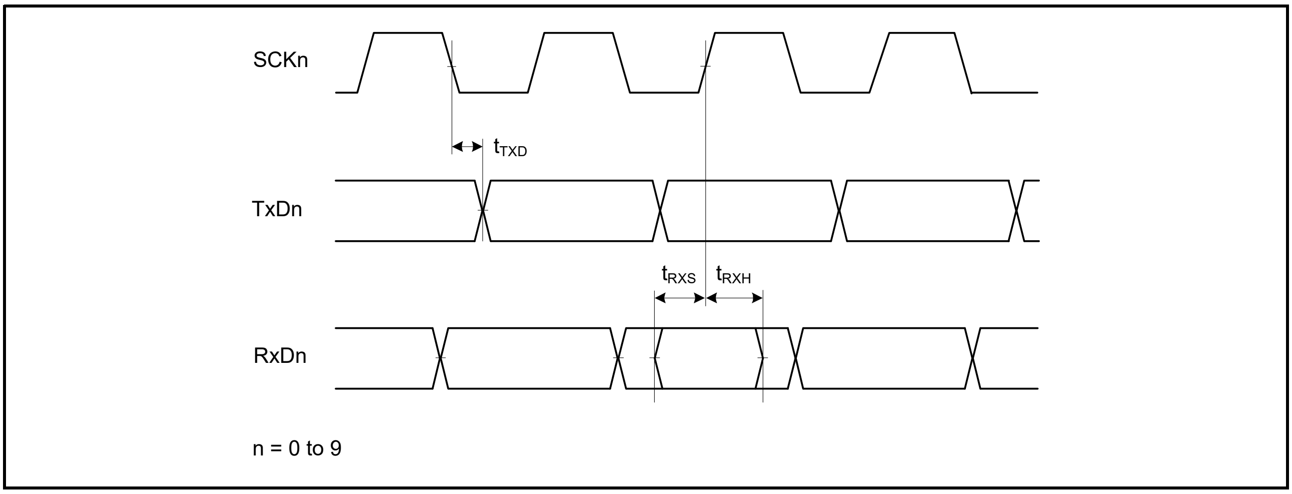

Figure 60.44 SCI input/output timing in clock synchronous mode

Table 60.23 SCI timing (2)

Conditions: High drive output is selected in the port drive capability bit in the PmnPFS register for the following pins: SCK0 to SCK9.
For other pins, middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Simple SPI	SCK clock cycle output (master)	t_{SPcyc}	4 (PCLKA ≤ 60 MHz) 8 (PCLKA > 60 MHz)	65536	t_{Pcyc}	Figure 60.45
	SCK clock cycle input (slave)	-	6 (PCLKA ≤ 60 MHz) 12 (PCLKA > 60 MHz)	65536		
	SCK clock high pulse width	t_{SPCKWH}	0.4	0.6	t_{SPcyc}	
	SCK clock low pulse width	t_{SPCKWL}	0.4	0.6	t_{SPcyc}	
	SCK clock rise and fall time	t_{SPCKr}, t_{SPCKf}	-	20	ns	
	Data input setup time	t_{SU}	33.3	-	ns	Figure 60.46 to Figure 60.49
	Data input hold time	t_H	33.3	-	ns

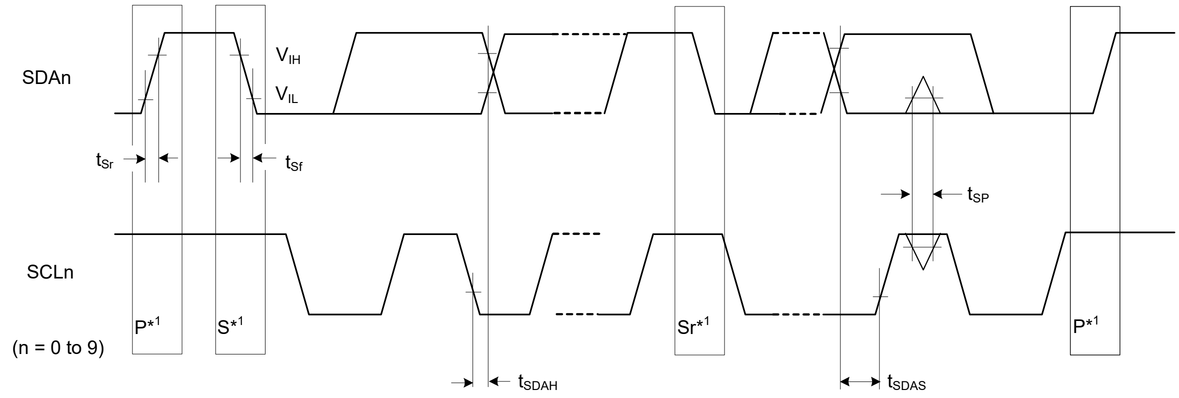
Table 60.24 SCI timing (3) (1 of 2)
Conditions: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Simple IIC (Standard mode)	SDA input rise time	t_{Sr}	-	1000	ns	Figure 60.50
	SDA input fall time	t_{Sf}	-	300	ns	
	SDA input spike pulse removal time	t_{SP}	0	4 × t_{IICcyc}	ns	
	Data input setup time	t_{SDAS}	250	-	ns	
	Data input hold time	t_{SDAH}	0	-	ns	
	SCL, SDA capacitive load	C_b*1	-	400	pF	

Table 60.24 SCI timing (3) (2 of 2)
Conditions: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
Simple IIC (Fast mode)	SDA input rise time	t_{Sr}	-	300	ns	Figure 60.50
	SDA input fall time	t_{Sf}	-	300	ns	
	SDA input spike pulse removal time	t_{SP}	0	4 × t_{IICcyc}	ns	
	Data input setup time	t_{SDAS}	100	-	ns	
	Data input hold time	t_{SDAH}	0	-	ns	
	SCL, SDA capacitive load	C_{b}*[1]	-	400	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle.
Note 1. Cb indicates the total capacity of the bus line.



Note 1. S, P, and Sr indicate the following:
S: Start condition
P: Stop condition
Sr: Restart condition

Test conditions:
V_{IH} = VCC × 0.7, V_{IL} = VCC × 0.3
V_{OL} = 0.6 V, I_{OL} = 6 mA

Figure 60.50 SCI simple IIC mode timing

60.3.11 SPI Timing

Table 60.25 SPI timing

Conditions:
For RSPCKA and RSPCKB pins, high drive output is selected with the port drive capability bit in the PmnPFS register.
For other pins, middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit*1	Test conditions*2
SPI	RSPCK clock cycle	Master	t_{SPcyc}	2 (PCLKA ≤ 60 MHz) 4 (PCLKA > 60 MHz)	4096	t_{Pcyc}	Figure 60.51 C = 30 pF
		Slave		4	4096		
	RSPCK clock high pulse width	Master	t_{SPCKWH}	$(t_{SPcyc} - t_{SPCKr} - t_{SPCKf}) / 2 - 3$	-	ns	
		Slave		$2 \times t_{Pcyc}$	-		
	RSPCK clock low pulse width	Master	t_{SPCKWL}	$(t_{SPcyc} - t_{SPCKr} - t_{SPCKf}) / 2 - 3$	-	ns	
		Slave		$2 \times t_{Pcyc}$	-		
	RSPCK clock rise and fall time	Master	t_{SPCKr}, t_{SPCKf}	-	5	ns	
		Slave		-	1	μs	
	Data input setup time	Master	t_{SU}	4	-	ns	Figure 60.52 to Figure 60.57 C = 30 pF
		Slave		5	-		
	Data input hold time	Master (PCLKA division ratio set to 1/2)	t_{HF}	0	-	ns	
		Master (PCLKA division ratio set to a value other than 1/2)	t_{H}	t_{Pcyc}	-		
		Slave	t_{H}	20	-		
	SSL setup time	Master	t_{LEAD}	N × t_{SPcyc} - 10*3	N × t_{SPcyc} + 100*3	ns	
		Slave		6 x t_{Pcyc}	-	ns	
	SSL hold time	Master	t_{LAG}	N × t_{SPcyc} - 10 *4	N × t_{SPcyc} + 100*4	ns	
		Slave		6 x t_{Pcyc}	-	ns	
	Data output delay	Master	t_{OD}	-	6.3	ns	
		Slave		-	20		
	Data output hold time	Master	t_{OH}	0	-	ns	
		Slave		0	-		
	Successive transmission delay	Master	t_{TD}	$t_{SPcyc} + 2 \times t_{Pcyc}$	$8 \times t_{SPcyc} + 2 \times t_{Pcyc}$	ns	
		Slave		$6 \times t_{Pcyc}$			
	MOSI and MISO rise and fall time	Output	t_{Dr}, t_{Df}	-	5	ns	
		Input		-	1	μs	
	SSL rise and fall time	Output	t_{SSLr}, t_{SSLf}	-	5	ns	
		Input		-	1	μs	
	Slave access time		t_{SA}	-	2 x t_{Pcyc} + 28	ns	Figure 60.56 and Figure 60.57 C = 30pF
	Slave output release time		t_{REL}	-	2 x t_{Pcyc} + 28		

Note 1. t_{Pcyc}: PCLKA cycle.

Note 2. Must use pins that have a letter ("_A", "_B") to indicate group membership appended to their name as groups. For the SPI interface, the AC portion of the electrical characteristics is measured for each group.
Note 3. N is set to an integer from 1 to 8 by the SPCKD register.
Note 4. N is set to an integer from 1 to 8 by the SSLND register.

60.3.13 IIC Timing

Table 60.27 IIC timing (1) (1 of 2)

(1) Conditions: Middle drive output is selected in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_A, SCL1_A, SDA1_B, SCL1_B.

(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL2, SDA2.

(3) Use pins that have a letter appended to their names, for instance “_A” or “_B”, to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	Min*1	Max	Unit	Test conditions*3
IIC (Standard mode, SMBus) ICFER.FMPE = 0	SCL input cycle time	t_{SCL}	6 (12) × t_{IICcyc} + 1300	-	ns	Figure 60.60
	SCL input high pulse width	t_{SCLH}	3 (6) × t_{IICcyc} + 300	-	ns	
	SCL input low pulse width	t_{SCLL}	3 (6) × t_{IICcyc} + 300	-	ns	
	SCL, SDA input rise time	t_{Sr}	-	1000	ns	
	SCL, SDA input fall time	t_{Sf}	-	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	3 (6) × t_{IICcyc} + 300	-	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	-	ns	
	START condition input hold time when wakeup function is disabled	t_{STAH}	t_{IICcyc} + 300	-	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	-	ns	
	Repeated START condition input setup time	t_{STAS}	1000	-	ns	
	STOP condition input setup time	t_{STOS}	1000	-	ns	
	Data input setup time	t_{SDAS}	t_{IICcyc} + 50	-	ns	
	Data input hold time	t_{SDAH}	0	-	ns	
	SCL, SDA capacitive load	C_b	-	400	pF	

Table 60.27 IIC timing (1) (2 of 2)

(1) Conditions: Middle drive output is selected in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_A, SCL1_A, SDA1_B, SCL1_B.
(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL2, SDA2.
(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	Min*1	Max	Unit	Test conditions*3
IIC (Fast mode)	SCL input cycle time	t_{SCL}	6 (12) × t_{IICcyc} + 600	-	ns	Figure 60.60
	SCL input high pulse width	t_{SCLH}	3 (6) × t_{IICcyc} + 300	-	ns	
	SCL input low pulse width	t_{SCLL}	3 (6) × t_{IICcyc} + 300	-	ns	
	SCL, SDA input rise time	t_{Sr}	20 × (external pullup voltage/5.5V)*2	300	ns	
	SCL, SDA input fall time	t_{Sf}	20 × (external pullup voltage/5.5V)*2	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	3 (6) × t_{IICcyc} + 300	-	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	-	ns	
	START condition input hold time when wakeup function is disabled	t_{STAH}	t_{IICcyc} + 300	-	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	-	ns	
	Repeated START condition input setup time	t_{STAS}	300	-	ns	
	STOP condition input setup time	t_{STOS}	300	-	ns	
	Data input setup time	t_{SDAS}	t_{IICcyc} + 50	-	ns	
	Data input hold time	t_{SDAH}	0	-	ns	
	SCL, SDA capacitive load	C_b	-	400	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.

Note 1. Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 2. Only supported for SCL0_A, SDA0_A, SCL2, and SDA2.

Note 3. Must use pins that have a letter ("_A", "_B") to indicate group membership appended to their name as groups. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Table 60.28 IIC timing (2)

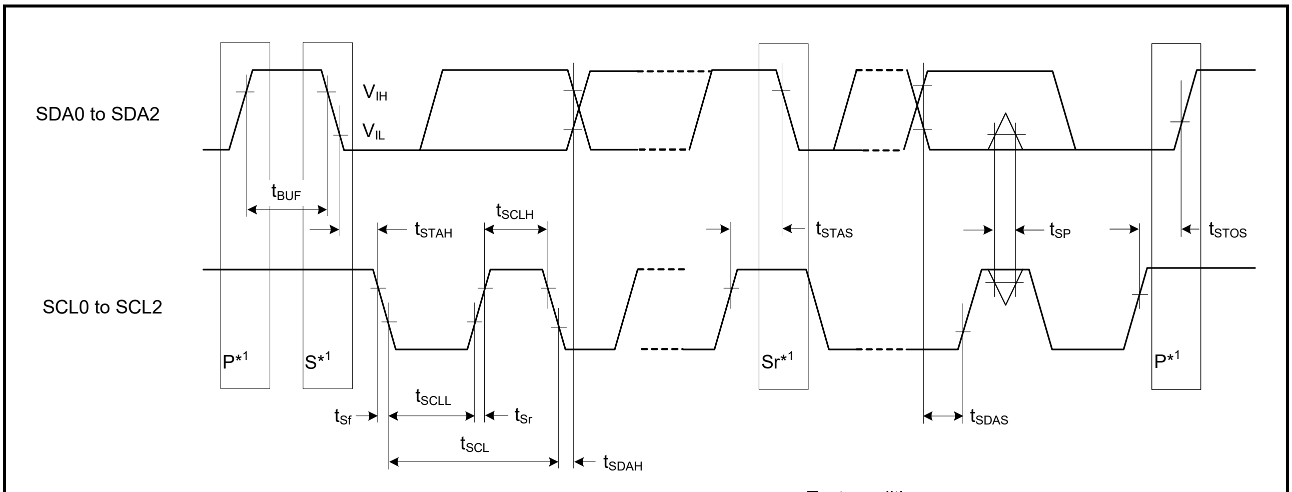
Setting of the SCL0_A, SDA0_A pins is not required with the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min*1,*2	Max	Unit	Test conditions
IIC (Fast-mode+) ICFER.FMPE = 1	SCL input cycle time	t_{SCL}	$6\ (12) \times t_{IICcyc} + 240$	-	ns	Figure 60.60
	SCL input high pulse width	t_{SCLH}	$3\ (6) \times t_{IICcyc} + 120$	-	ns	
	SCL input low pulse width	t_{SCLL}	$3\ (6) \times t_{IICcyc} + 120$	-	ns	
	SCL, SDA input rise time	t_{Sr}	-	120	ns	
	SCL, SDA input fall time	t_{Sf}	-	120	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	$1\ (4) \times t_{IICcyc}$	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	$3\ (6) \times t_{IICcyc} + 120$	-	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	$3\ (6) \times t_{IICcyc} + 4 \times t_{Pcyc} + 120$	-	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	$t_{IICcyc} + 120$	-	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	$1\ (5) \times t_{IICcyc} + t_{Pcyc} + 120$	-	ns	
	Restart condition input setup time	t_{STAS}	120	-	ns	
	Stop condition input setup time	t_{STOS}	120	-	ns	
	Data input setup time	t_{SDAS}	$t_{IICcyc} + 30$	-	ns	
	Data input hold time	t_{SDAH}	0	-	ns	
	SCL, SDA capacitive load	C_b	-	550	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.

Note 1. Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 2. Cb indicates the total capacity of the bus line.



Note 1. S, P, and Sr indicate the following:
S: Start condition
P: Stop condition
Sr: Restart condition

Test conditions:
$V_{IH} = VCC \times 0.7$, $V_{IL} = VCC \times 0.3$
$V_{OL} = 0.6$ V, $I_{OL} = 6$ mA (ICFER.FMPE = 0)
$V_{OL} = 0.4$ V, $I_{OL} = 15$ mA (ICFER.FMPE = 1)

Figure 60.60 I²C bus interface input/output timing

60.3.14 SSIE Timing

Table 60.29 SSIE timing

(1) High drive output is selected with the port drive capability bit in the PmnPFS register.

(2) Use pins that have a letter appended to their names, for instance "_A" or "_B" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	Target specification		Unit	Comments
				Min.	Max.		
SSIBCK	Cycle	Master	t_O	80	-	ns	Figure 60.61
		Slave	t_I	80	-	ns	
	High level/ low level	Master	t_{HC}/t_{LC}	0.35	-	t_O	
		Slave		0.35	-	t_I	
	Rising time/falling time	Master	t_{RC}/t_{FC}	-	0.15	t_O / t_I	
		Slave		-	0.15	t_O / t_I	
SSILRCK/SSIFS, SSITXD0, SSIRXD0, SSIDATA1	Input set up time	Master	t_{SR}	12	-	ns	Figure 60.63, Figure 60.64
		Slave		12	-	ns	
	Input hold time	Master	t_{HR}	8	-	ns	
		Slave		15	-	ns	
	Output delay time	Master	t_{DTR}	-10	5	ns	
		Slave		0	20	ns	Figure 60.63, Figure 60.64
	Output delay time from SSILRCK/SSIFS change	Slave	t_{DTRW}	-	20	ns	Figure 60.65*1
GTIOC1A, AUDIO_CLK	Cycle		t_{EXcyc}	20	-	ns	Figure 60.62
	High level/ low level		$t_{EXL}/$ t_{EXH}	0.4	0.6	t_{EXcyc}	

Note 1. For slave-mode transmission, SSIE has a path, through which the signal input from the SSILRCK/SSIFS pin is used to generate transmit data, and the transmit data is logically output to the SSITXD0 or SSIDATA1 pin.

60.3.15 SD/MMC Host Interface Timing

Table 60.30 SD/MMC Host Interface signal timing
Conditions: High drive output is selected in the port drive capability bit in the PmnPFS register.
Clock duty ratio is 50%.

Parameter	Symbol	Min	Max	Unit	Test conditions*1
SDCLK clock cycle	T_{SDCYC}	20	-	ns	Figure 60.66
SDCLK clock high pulse width	T_{SDWH}	6.5	-	ns	
SDCLK clock low pulse width	T_{SDWL}	6.5	-	ns	
SDCLK clock rise time	T_{SDLH}	-	3	ns	
SDCLK clock fall time	T_{SDHL}	-	3	ns	
SDCMD/SDDAT output data delay	T_{SDODLY}	-6	5	ns	
SDCMD/SDDAT input data setup	T_{SDIS}	4	-	ns	
SDCMD/SDDAT input data hold	T_{SDIH}	2	-	ns	

Note 1. Must use pins that have a letter ("_A", "_B") to indicate group membership appended to their name as groups. For

the SD/MMC Host interface, the AC portion of the electrical characteristics is measured for each group.

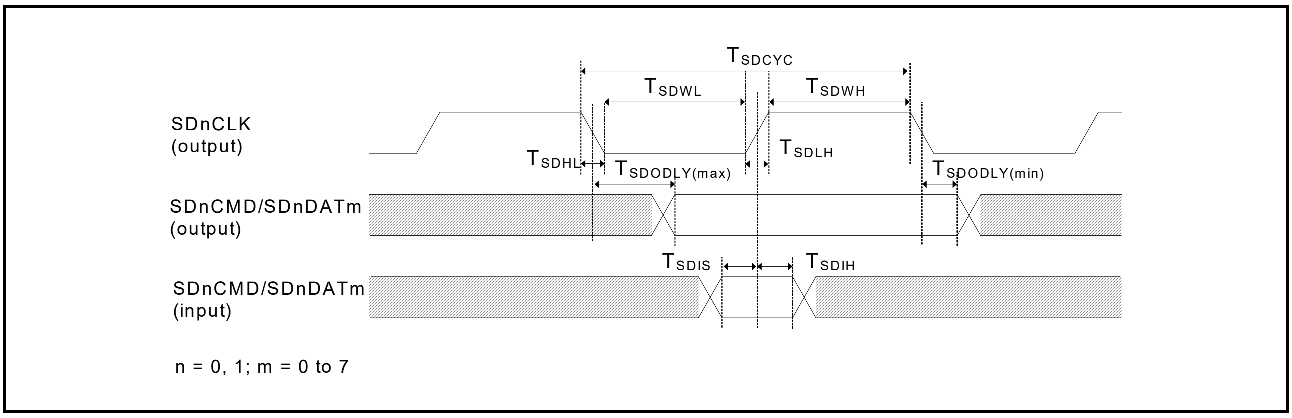

Figure 60.66 SD/MMC Host Interface signal timing

60.3.16 ETHERC Timing

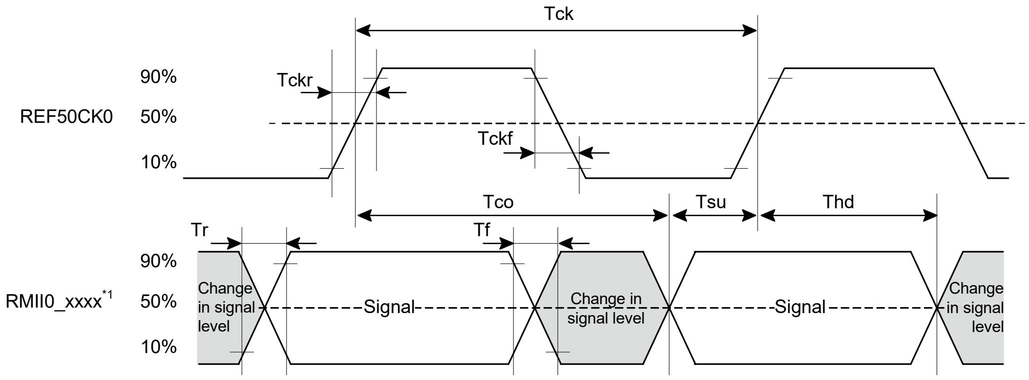
Table 60.31 ETHERC timing

Conditions: ETHERC (RMII): Middle drive output is selected in the port drive capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.
For other pins, high drive output is selected in the port drive capability bit in the PmnPFS register.
ETHERC (MII): Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions*3
ETHERC (RMII)	REF50CK cycle time	T_{ck}	20	-	ns	Figure 60.67 to Figure 60.70
	REF50CK frequency, typical 50 MHz	-	-	50 + 100 ppm	MHz	
	REF50CK duty	-	35	65	%	
	REF50CK rise/fall time	$T_{ckr/ckf}$	0.5	3.5	ns	
	RMII0_xxxx*1 output delay	T_{co}	2.5	12.0	ns	
	RMII0_xxxx*2 setup time	T_{su}	3	-	ns	
	RMII0_xxxx*2 hold time	T_{hd}	1	-	ns	
	RMII0_xxxx*1, *2 rise/fall time	T_r/T_f	0.5	4	ns	
	ET0_WOL output delay	t_{WOLd}	1	23.5	ns	Figure 60.71
ETHERC (MII)	ET0_TX_CLK cycle time	t_{Tcyc}	40	-	ns	-
	ET0_TX_EN output delay	t_{TENd}	1	20	ns	Figure 60.72
	ET0_ETXD0 to ET0_ETXD3 output delay	t_{MTDd}	1	20	ns	
	ET0_CRS setup time	t_{CRSs}	10	-	ns	
	ET0_CRS hold time	t_{CRSh}	10	-	ns	
	ET0_COL setup time	t_{COLs}	10	-	ns	Figure 60.73
	ET0_COL hold time	t_{COLh}	10	-	ns	
	ET0_RX_CLK cycle time	t_{TRcyc}	40	-	ns	-
	ET0_RX_DV setup time	t_{RDVs}	10	-	ns	Figure 60.74
	ET0_RX_DV hold time	t_{RDVh}	10	-	ns	
	ET0_ERXD0 to ET0_ERXD3 setup time	t_{MRDs}	10	-	ns	
	ET0_ERXD0 to ET0_ERXD3 hold time	t_{MRDh}	10	-	ns	
	ET0_RX_ER setup time	t_{RERs}	10	-	ns	Figure 60.75
	ET0_RX_ER hold time	t_{RESh}	10	-	ns	
	ET0_WOL output delay	t_{WOLd}	1	23.5	ns	Figure 60.76

Note 1. RMII0_TXD_EN, RMII0_TXD1, RMII0_TXD0.
Note 2. RMII0_CRS_DV, RMII0_RXD1, RMII0_RXD0, RMII0_RX_ER.

Note 3. The following pins, must use pins that have a letter ("_A", "_B") to indicate group membership appended to their name as groups. For the ETHERC (RMII) Host interface, the AC portion of the electrical characteristics is measured for each group. REF50CK0_A, REF50CK0_B, RMII0_xxxx_A, RMII0_xxxx_B



Note 1. RMII0_TXD_EN, RMII0_TXD1, RMII0_TXD0, RMII0_CRS_DV, RMII0_RXD1, RMII0_RXD0, RMII0_RX_ER

Table 60.42 A/D conversion characteristics for simultaneous using of channel-dedicated sample-and-hold circuits in unit0 and unit1

Conditions: PCLKC = 30/60 MHz

Parameter		Min	Typ	Max	Test conditions
Channel-dedicated sample-and-hold circuits in use with continious sampling function enabled (AN000 to AN002)	Offset error	-	±1.5	±5.0	• PCLKC = 60 MHz • Sampling in 15 states
	Full-scale error	-	±2.5	±5.0	
	Absolute accuracy	-	±4.0	±8.0	
Channel-dedicated sample-and-hold circuits in use with continious sampling function enabled (AN100 to AN102)	Offset error	-	±1.5	±5.0	
	Full-scale error	-	±2.5	±5.0	
	Absolute accuracy	-	±4.0	±8.0	
Channel-dedicated sample-and-hold circuits in use with continious sampling function enabled (AN000 to AN002)	Offset error	-	±1.5	±3.5	• PCLKC = 30 MHz • Sampling in 7 states
	Full-scale error	-	±1.5	±3.5	
	Absolute accuracy	-	±3.0	±5.5	
Channel-dedicated sample-and-hold circuits in use with continious sampling function enabled (AN100 to AN102)	Offset error	-	±1.5	±3.5	
	Full-scale error	-	±1.5	±3.5	
	Absolute accuracy	-	±3.0	±5.5	

Note: When simultaneously using channel-dedicated sample-and-hold circuits in unit0 and unit1, setting the ADSHMSR.SHMD bit to 1 is recommended.

Table 60.43 A/D internal reference voltage characteristics

Parameter	Min	Typ	Max	Unit	Test conditions
A/D internal reference voltage	1.13	1.18	1.23	V	-
Sampling time	4.15	-	-	μs	-

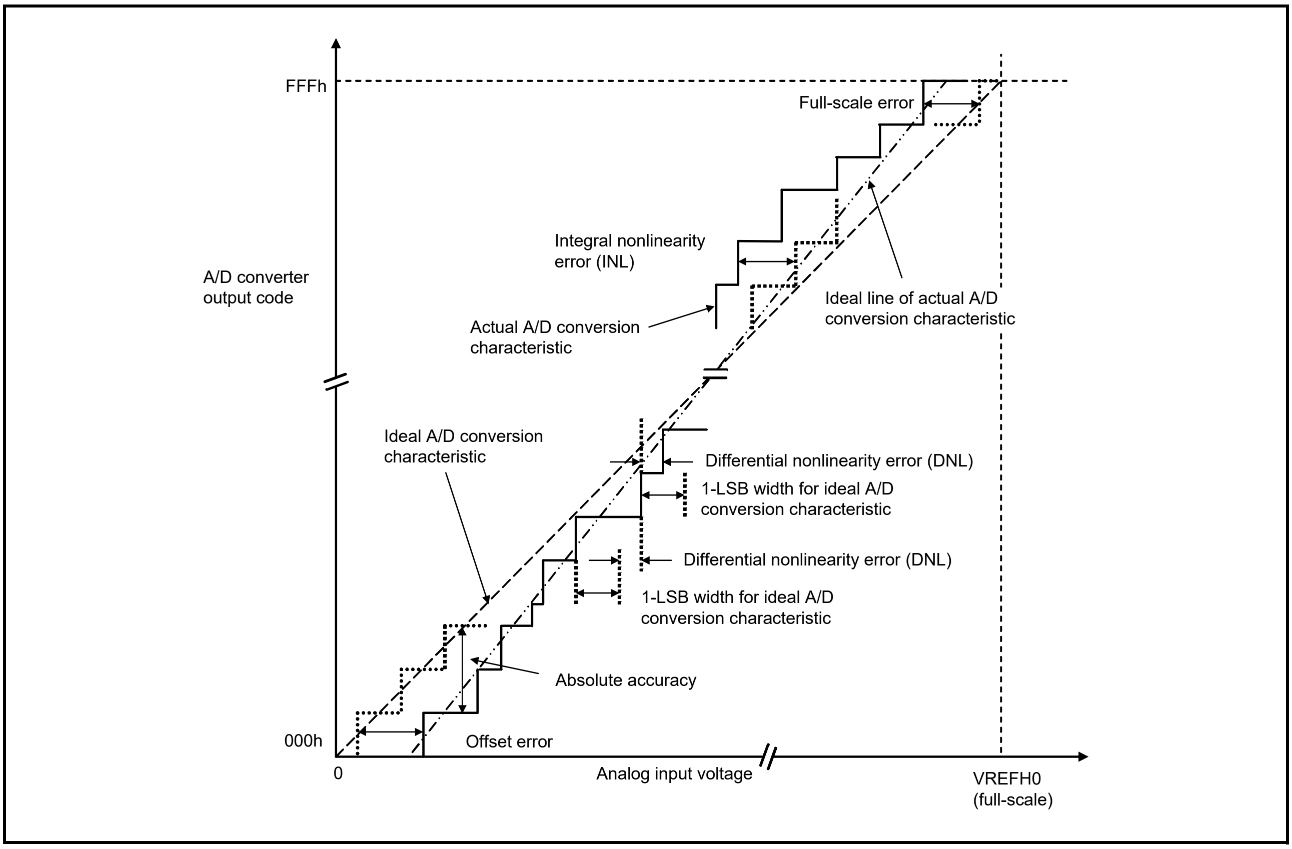

Figure 60.95 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 003h to 00Dh, though an output code of 008h can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

60.6 DAC12 Characteristics

Table 60.44 D/A conversion characteristics

Parameter	Min	Typ	Max	Unit	Test conditions
Resolution	-	-	12	Bits	-

	32-KB	t_{P32K}	-	234	848	-	106	384	ms	
Erasure time N_{PEC} ≤ 100 times	8-KB	t_{E8K}	-	78	216	-	43	120	ms	
	32-KB	t_{E32K}	-	283	864	-	157	480	ms	
Erasure time N_{PEC} > 100 times	8-KB	t_{E8K}	-	94	260	-	52	144	ms	
	32-KB	t_{E32K}	-	341	1040	-	189	576	ms	
Reprogramming/erasure cycle*Note:		N_{PEC}	10000*1	-	-	10000*1	-	-	Times	
Suspend delay during programming		t_{SPD}	-	-	264	-	-	120	μs	
First suspend delay during erasure in suspend priority mode		t_{SESD1}	-	-	216	-	-	120	μs	
Second suspend delay during erasure in suspend priority mode		t_{SESD2}	-	-	1.7	-	-	1.7	ms	
Suspend delay during erasure in erasure priority mode		t_{SEED}	-	-	1.7	-	-	1.7	ms	
Forced stop command		t_{FD}	-	-	32	-	-	20	μs	
Data hold time*2		t_{DRP}	10*2, *3	-	-	10*2, *3	-	-	Years	
			30*2, *3	-	-	30*2, *3	-	-		Ta = +85°C

Note: The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. (Overwriting is prohibited.)

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 3. This result is obtained from reliability testing.

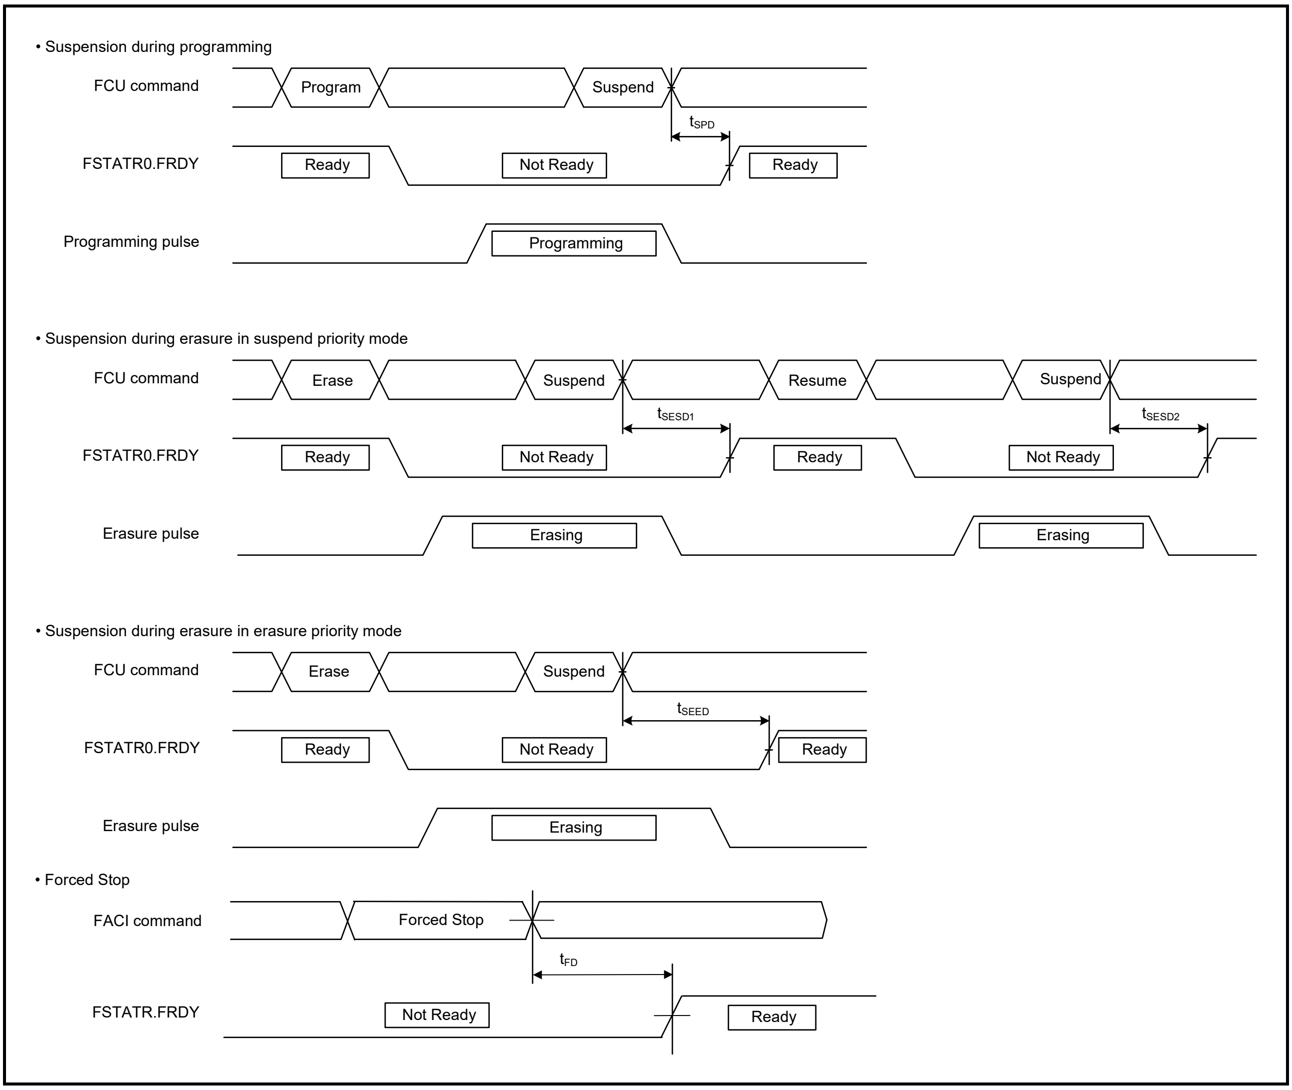

Figure 60.102 Suspension and forced stop timing for flash memory programming and erasure

Data hold time*3		t_{DRP}	10*3,*4	-	-	10*3,*4	-	-	Year	
			30*3,*4	-	-	30*3,*4	-	-		Ta = +85°C

Note 1. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 125,000), erasing can be performed n times for each block. For example, when 4-byte programming is performed 16 times for different addresses in 64-byte blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. (Overwriting is prohibited.)

Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 3. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 4. This result is obtained from reliability testing.

60.15 Boundary Scan

Table 60.55 Boundary scan characteristics

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
TCK clock cycle time	t_{TCKcyc}	100	-	-	ns	Figure 60.103

L: Low-level
Hi-Z: High-impedance
Keep-O: Output pins retain their previous values. Input pins go to high-impedance.
Keep: Pin states are retained during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.
Note 4. Input is enabled while the pin is used as an input pin.
Note 5. For host operation, set the USBHS.SYSCFG.DRPD bit to 1 to enable the USBHS_DP and USBHS_DM pull-down resistors. For device operation, set the USBHS.SYSCFG.DPRPU bit to 1 to enable the DP pull-up resistor.

Appendix 2.Package Dimensions

For information on the latest version of the package dimensions or mountings, go to "Packages" on the Renesas Electronics Corporation website.

Appendix 3. I/O Registers

This appendix describes I/O register addresses, access cycles, and reset values by function.

3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual.

Table 3.1 shows the name, description, and the base address of each peripheral.

Table 3.1 Peripheral base address (1 of 3)

Name	Description	Base address
MMPU	Bus Master MPU	0x40000000
SMPU	Bus Slave MPU	0x40000C00
SPMON	CPU Stack Pointer Monitor	0x40000D00
MMF	Memory Mirror Function	0x40001000
SRAM	SRAM Control	0x40002000
BUS	Bus Control	0x40003000
DMAC0	Direct Memory Access Controller 0	0x40005000
DMAC1	Direct Memory Access Controller 1	0x40005040
DMAC2	Direct Memory Access Controller 2	0x40005080
DMAC3	Direct Memory Access Controller 3	0x400050C0
DMAC4	Direct Memory Access Controller 4	0x40005100
DMAC5	Direct Memory Access Controller 5	0x40005140
DMAC6	Direct Memory Access Controller 6	0x40005180
DMAC7	Direct Memory Access Controller 7	0x400051C0
DMA	DMAC Module Activation	0x40005200
DTC	Data Transfer Controller	0x40005400
ICU	Interrupt Controller	0x40006000
DBG	Debug Function	0x4001B000
FCACHE	Flash Cache	0x4001C000
SYSTEM	System Control	0x4001E000
PORT0	Port 0 Control Registers	0x40040000
PORT1	Port 1 Control Registers	0x40040020
PORT2	Port 2 Control Registers	0x40040040
PORT3	Port 3 Control Registers	0x40040060
PORT4	Port 4 Control Registers	0x40040080

Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

The following information applies to Table 3.2 and Table 3.3:

- Registers are grouped by associated module
- The number of access cycles indicates the number of cycles based on the specified reference clock
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table 3.2 Access cycles (1 of 2)

	Address		Number of access cycles					
			ICLK = PCLK		ICLK > PCLK^{*1}		Cycle Unit	
Peripherals	**From**	**To**	**Read**	**Write**	**Read**	**Write**		**Related function**

JPEG	400E 6000h	400E 603Fh	13	5	-		PCLKA	JPEG Codec
JPEG	400E 6040h	400E 6FFFh	5	4	-		PCLKA	JPEG Codec
QSPI	6400 0000h	6400 000Fh	3	13 to *6	2 to 3	12 to *6	PCLKA	Quad Serial Peripheral Interface
QSPI	6400 0010h	6400 0013h	24 to *6	5 to *6	23 to *6	4 to *6	PCLKA	Quad Serial Peripheral Interface
QSPI	6400 0014h	6400 0037h	3	13 to *6	2 to 3	12 to *6	PCLKA	Quad Serial Peripheral Interface
QSPI	6400 0804h	6400 0807h	2	2	1 to 2	1 to 2	PCLKA	Quad Serial Peripheral Interface

Note 1. If the number of PCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.

Note 2. BWAIT is the number of waits (not cycles) described in the USBHS.BUSWAIT register.

Note 3. The wait cycle refers to the EPTPC chapter (30.6.2 Wait Cycles for Register Access).

Note 4. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in Table 3.2. When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in Table 3.2.

Note 5. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in Table 3.2. When accessing an 8-bit or 16-bit register (SPDR_HA), the access cycles are as shown in Table 3.2.

Note 6. The access cycles depend on the QSPI bus cycles.

3.3 Register Descriptions

This section provides information associated with registers described in this manual.

Table 3.3 shows a list of registers including address offsets, address sizes, access rights, and reset values.

Table 3.3 Register description (1 of 44)

Peripheral	Dim	Dim incr.	Dim index	Register name	Description	Address offset	Size	Access	Reset value	Reset mask

QSPI	-	-	-	SFMCMD	Communication Mode Control Register	0x014	32	read/ write	0x00000000	0xFFFFFFFF
QSPI	-	-	-	SFMCST	Communication Status Register	0x018	32	read/ write	0x00000000	0xFFFFFFFF
QSPI	-	-	-	SFMSIC	Instruction Code Register	0x020	32	read/ write	0x00000000	0xFFFFFFFF
QSPI	-	-	-	SFMSAC	Address Mode Control Register	0x024	32	read/ write	0x00000002	0xFFFFFFFF
QSPI	-	-	-	SFMSDC	Dummy Cycle Control Register	0x028	32	read/ write	0x0000FF00	0xFFFFFFFF
QSPI	-	-	-	SFMSPC	SPI Protocol Control Register	0x030	32	read/ write	0x00000010	0xFFFFFFFF
QSPI	-	-	-	SFMPMD	Port Control Register	0x034	32	read/ write	0x00000000	0xFFFFFFFF
QSPI	-	-	-	SFMCNT1	External QSPI Address Register 1	0x804	32	read/ write	0x00000000	0xFFFFFFFF

Peripheral name = Name of peripheral
Dim = Number of elements in an array of registers
Dim inc = Address increment between two simultaneous registers of a register array in the address map

Dim index = Sub string that replaces the %s placeholder within the register name
Register name = Name of register
Description = Register description
Address offset = Address of the register relative to the base address defined by the peripheral of the register
Size = Bit width of the register
Access = Register access rights:
Read-only: Read access is permitted. Write operations have undefined results.
Write-only: Write access is permitted. Read operations have undefined results.
Read/write: Both read and write accesses are permitted. Writes affect the state of the register and reads return a value related to the register.
Reset value = Default reset value of a register
Reset mask = Identifies which register bits have a defined reset value

Revision History	S5D9 Microcontroller Group User’s Manual

Rev.	Date	Chapter	Summary
1.00	Nov 3, 2016	-	First release
1.10	Mar 23, 2018	-	Second release
		Features	Updated description for 64-KB data flash memory from 100,000 erase/write cycles to 125,000 erase/write cycles
		section 1, Overview	Updated Table 1.1 and Table 1.2
			Updated Figure 1.2, Part numbering scheme
			Updated Table 1.16, Pin functions
		section 2, CPU	Updated section 2.1.1 and section 2.5.1
			Updated description for the EDBGRQ bit and added a note in section 2.6.5.3, MCU Control Register (MCUCTRL)
			Added a note in section 2.9, SysTick System Timer
			Added section (4), When OSIS[127:126] = 2’b11 in 2.11.3.4
		section 4, Address Space	Updated Figure 4.1 and Figure 4.2
		section 5, Memory Mirror Function (MMF)	Added a new paragraph after Figure 5.2
			Modified description in section 5.3.2, Setting Example
		section 7, Option-Setting Memory	Updated Table 7.1, Specifications for ID code protection
		section 8, Low Voltage Detection (LVD)	Updated Figure 8.4
		section 9, Clock Generation Circuit	Updated Table 9.2
			Updated Figure 9.1
			Updated description of section 9.2.13, FLL Control Register 1 (FLLCR1)
			Updated section 9.5.2
		section 11, Low Power Modes	Updated Table 11.2
			Updated names of bit [7] and bit [8] in section 11.2.4
			Updated symbol name of bit [2] in section 11.2.15 and section 11.2.19
			Updated Table 11.10
		section 12, Battery Backup Function	Updated Figure 12.1
		section 14, Interrupt Controller Unit (ICU)	Updated description for the IRQCRi register in section 14.2.1
		section 15, Buses	Updated the values after reset in section 15.3.21 and section 15.3.22
		section 16, Memory Protection Unit (MPU)	Updated Figure 16.4
			Updated section 16.4.1.2, and section 16.6.1.1 through section 16.6.1.10
		section 18, Data Transfer Controller (DTC)	Updated Figure 18.2
			Updated section 18.6.3
		section 19, Event Link Controller (ELC)	Added a new section 19.4.4, ELC Delay Time
		section 20, I/O Ports	Updated section 20.2.1 through section 20.2.5
			Updated Table 20.3, Table 20.10, Table 20.14, and Table 20.15

Rev.	Date	Chapter	Summary
1.10	Mar 23, 2018	section 21, Key Interrupt Function (KINT)	Updated Figure 21.1 and added a new paragraph after the figure
			Updated the note in section 21.2.2
		section 22, Port Output Enable for GPT (POEG)	Updated description in section 22.3.2
		section 23, General PWM Timer (GPT)	Updated Table 23.2
			Updated Figure 23.1
			Updated section 23.2.15
			Updated description of the DTEF flag in section 23.2.16
			Updated section 23.2.18 and section 23.2.32
			Updated Figure 23.81 through Figure 23.85
			Updated Table 23.20 and Table 23.21
		section 25, Asynchronous General-Purpose Timer (AGT)	Updated Figure 25.1
		section 26, Realtime Clock (RTC)	Updated section 26.2.22, section 26.2.26, and section 26.2.27
			Updated Figure 26.7
		section 27, Watchdog Timer (WDT)	Updated Figure 27.3
			Updated section 27.5.1
		section 28, Independent Watchdog Timer (IWDT)	Updated Figure 28.1
		section 29, Ethernet MAC Controller (ETHERC)	Updated the value after reset for bits [15:0] in section 29.2.10
			Updated section 29.2.15 through section 29.2.26
		section 30, Ethernet PTP Controller (EPTPC)	Updated description for the SYTH[3:0] bits in section 30.2.8
			Updated register symbol name in section 30.2.66
		section 32, USB 2.0 Full-Speed Module (USBFS)	Updated section 32.2.4, section 32.2.5, section 32.2.8, section 32.2.13, section 32.2.14, and section 32.2.31
			Updated Table 32.16
			Updated Figure 32.12
			Updated 32.3.4.7
		section 33, USB 2.0 High-Speed Module (USBHS)	Updated description for MBW[1:0] bits in section 33.2.8 and section 33.2.9
			Updated the value after reset for bit [3] and bit [2] in section 33.2.16
		section 34, Serial Communications Interface (SCI)	Updated section 34.2.10
			Updated description of bit [3] and bit [6] in section 34.2.11
			Added a note to the description of the RDRF and TDRE flags in section 34.2.13 through section 34.2.15
			Updated Table 34.13, Table 34.15, Table 34.17, and Table 34.18
			Updated section 34.3.5
			Updated Figure 34.5, Figure 34.6, and Figure 34.30
			Updated section 34.5.2
			Updated Figure 34.38, Figure 34.45, and Figure 34.50. Added Figure 34.51
			Updated Figure 34.52, Figure 34.53, and Figure 34.57
			Updated Table 34.25, added Note 1 to Table 34.26 and Table 34.27
			Updated Figure 34.74 and Figure 34.75

Rev.	Date	Chapter	Summary
1.10	Mar 23, 2018	section 36, I^{2}C Bus Interface (IIC)	Updated section 36.2.1
			Updated Table 36.3
			Updated Figure 36.26, Figure 36.31, Figure 36.36, and Figure 36.45
			Updated section 36.12, Bus Hanging
			Updated Table 36.10
		section 37, Controller Area Network (CAN) Module	Updated the note in section 37.2.6
		section 38, Serial Peripheral Interface (SPI)	Updated Figure 38.29, Figure 38.30, and Figure 38.37 through Figure 38.39
			Updated Table 38.13 and Table 38.15
		section 39, Quad Serial Peripheral Interface (QSPI)	Updated Figure 39.2 and Figure 39.12
		section 41, Serial Sound Interface Enhanced (SSIE)	Updated Figure 41.26
		section 43, SD/MMC Host Interface (SDHI)	Updated Table 43.1
			Updated Figure 43.6
		section 45, Boundary Scan	Updated the value after reset for bits [20], [18], and [17] in section 45.2.2
			Updated the constraints for the boundary scan function in section 45.4, Usage Notes
		section 47, 12-Bit A/D Converter (ADC12)	Updated Note 1 and Note 2 in section 47.2.1
			Updated description of ADST bit in section 47.2.3
			Updated Figure 47.3
			Updated section 47.2.17
			Updated description for the CMPSTB flag in section 47.2.31
			Updated step 2 and step 5 in section 47.3.2.9
			Updated Figure 47.15, Figure 47.20
			Updated section 47.3.4.3
			Updated Figure 47.26 through Figure 47.30, and Figure 47.32
			Updated Table 47.10 and Table 47.13
			Updated section 47.3.9
			Updated formula for calculating the error in absolute accuracy of the ADC12 in section 47.6.7
			Updated section 47.6.8 and section 47.6.12
		section 48, 12-Bit D/A Converter (DAC12)	Updated Figure 48.4
		section 49, Temperature Sensor (TSN)	Updated Table 49.1
			Added section 49.2.2, Temperature Sensor Calibration Data Register(TSCDR)
			Updated section 49.3.1, Preparation for Using the Temperature Sensor
			Updated Figure 49.2
		section 50, High-Speed Analog Comparator (ACMPHS)	Updated Note 1. Note 3., Note 4. and Note 6. in Table 50.2
			Updated description of bit [6] and bit [5] in section 50.2.1
			Updated the name of the register in Step 9 of Table 50.3
		section 51, Capacitive Touch Sensing Unit (CTSU)	Updated Figure 51.14 and Figure 51.16
		section 53, SRAM	Added Note 2. to Table 53.3
			Added section 53.4.3, Store Buffer of SRAM
1.10	Mar 23, 2018	section 55, Flash Memory	Updated Table 55.5
		section 56, 2D Drawing Engine (DRW)	Updated section 56.2.2, section 56.2.6, and section 56.2.10 through section 56.2.13
		section 58, Graphics LCD Controller (GLCDC)	Updated section 58.2.56
		section 60, Electrical Characteristics	Updated Table 60.1, Table 60.6, Table 60.7, Table 60.24
			Updated Figure 60.51 through Figure 60.57, Figure 60.63, Figure 60.64, and Figure 60.66 through Figure 60.76
			Updated Table 60.31, Table 60.40, Table 60.41, Table 60.53, and Table 60.54
		section 3, I/O Registers	Updated Table 3.1 and Table 3.2

Rev.	Date	Chapter	Summary
1.20	Aug 10, 2018	-	Third release
		Features	Updated Features
		section 1, Overview	Updated Table 1.3 and Table 1.13, Security
		section 2, CPU	Updated section 2.1.2, Debug
			Updated Table 2.1
		section 4, Address Space	Updated Figure 4.1 and Figure 4.2
		section 7, Option-Setting Memory	Added a Note: in Changing the option-setting memory by self-programming
		section 15, Buses	Updated Table 15.1 and Table 15.2
		section 16, Memory Protection Unit (MPU)	Updated Table 16.7
		section 20, I/O Ports	Updated description for the PDR and PODR bits in section 20.2.1, Port Control Register 1 (PCNTR1/PODR/PDR)
			Updated description for the PIDR bit in section 20.2.2, Port Control Register 2 (PCNTR2/EIDR/PIDR)
			Updated Figure 20.2 and Figure 20.4
		section 22, Port Output Enable for GPT (POEG)	Updated Figure 22.4
		section 27, Watchdog Timer (WDT)	Updated Figure 27.4
		section 30, Ethernet PTP Controller (EPTPC)	Updated section 30.3.1, Transmission and Reception of Non-PTP Messages
		section 33, USB 2.0 High-Speed Module (USBHS)	Updated Table 33.17
		section 43, SD/MMC Host Interface (SDHI)	Updated value after reset in section 43.2.17
		section 46, Secure Cryptographic Engine (SCE7)	Updated section 46, Secure Cryptographic Engine (SCE7)
		section 47, 12-Bit A/D Converter (ADC12)	Updated Table 47.10, Table 47.14
		section 49, Temperature Sensor (TSN)	Updated Figure 49.1
		section 60, Electrical Characteristics	Updated Table 60.14
			Updated Figure 60.12
1.30	Aug 30, 2019	-	Fourth release
		section 2, CPU	Updated Table 2.3, JTAG/SWD pins
			Updated section 2.6.5.2, MCU Status Register (MCUSTAT)
		section 6, Resets	Updated Table 6.3, Module-related registers initialized by each reset source
		section 8, Low Voltage Detection (LVD)	Updated description for the DET flag in section 8.2.2, Voltage Monitor 1 Circuit Status Register (LVD1SR) and section 8.2.4, Voltage Monitor 2 Circuit Status Register (LVD2SR)
		section 9, Clock Generation Circuit	Updated section 9.2.3, System Clock Source Control Register (SCKSCR)
			Updated section 9.7.1, System Clock (ICLK), added Figure 9.13 and Figure 9.14
			Updated section 9.7.3, Flash Interface Clock (FCLK)
		section 14, Interrupt Controller Unit (ICU)	Updated Table 14.4, Event table
		section 15, Buses	Updated Table 15.14, Conditions for register modification
		section 17, DMA Controller (DMAC)	Updated Figure 17.1, DMAC block diagram
		section 18, Data Transfer Controller (DTC)	Updated section 18.6.3
		section 20, I/O Ports	Updated section 20.2.1, section 20.2.3, and section 20.2.4
			Updated Table 20.12
		section 22, Port Output Enable for GPT (POEG)	Updated Table 22.1 and changed “GTETRGA to GTETRGD” to “GTETRGn” throughout the chapter

Rev.	Date	Chapter	Summary
1.30	Aug 30, 2019	section 23, General PWM Timer (GPT)	Updated section 23.2.8, section 23.2.9
			Updated description for the OmDTYR bit in section 23.2.13
			Updated section 23.2.18
			Changed GTADTRm to GTADTRn in section 23.2.24
			Changed GTADTBRm to GTADTBRn in section 23.2.25
			Changed GTADTDBRm to GTADTDBRn in section 23.2.26
			Updated section 23.2.28
			Changed GTDBm to GTDBn, and changed GTDVm to GTDVn in section 23.2.29
			Updated b31 to b1 in section 23.2.31
			Updated section 23.3.4, Automatic Dead Time Setting Function
			Updated Figure 23.93
			Updated section 23.10.4
		section 25, Asynchronous General-Purpose Timer (AGT)	Updated the note for the AGTIO Pin Select bit name in section 25.2.10, AGT Pin Select Register (AGTIOSEL)
			Added section 25.4.11, When Switching Source Clock
		section 26, Realtime Clock (RTC)	Added section 26.6.8, When Switching Source Clock
		section 29, Ethernet MAC Controller (ETHERC)	Updated the R/W permission for bits in section 29.2.10, Manual PAUSE Frame Register (MPR)
			Updated Figure 29.13 and Figure 29.14
			Added section 29.5.3, Processing when Erroneous Frame Is Detected and section 29.5.4, Collision Occurrence in Half-Duplex Mode
		section 30, Ethernet PTP Controller (EPTPC)	Updated description for the INFABT flag in section 30.2.30, SYNFP Status Register (SYSR)
		section 33, USB 2.0 High-Speed Module (USBHS)	Updated description for bits[15:12] in section 33.2.31, DCP Maximum Packet Size Register (DCPMAXP)
			Updated Figure 33.2
		section 34, Serial Communications Interface (SCI)	Updated Table 34.13
		section 39, Quad Serial Peripheral Interface (QSPI)	Updated Figure 39.3
		section 47, 12-Bit A/D Converter (ADC12)	Updated Step 6 of section 47.3.2.8, A/D conversion in double-trigger mode
			Added Table 47.12, PGA output voltage
		section 48, 12-Bit D/A Converter (DAC12)	Updated the address of section 48.2.6, D/A Amplifier Stabilization Wait Control Register (DAASWCR)
		section 51, Capacitive Touch Sensing Unit (CTSU)	Updated description for b0 and b4 in section 51.2.1, CTSU Control Register 0 (CTSUCR0)
		section 57, JPEG Codec (JPEG)	Added section 57.6, Usage Notes
		section 58, Graphics LCD Controller (GLCDC)	Updated Table 58.2
			Updated Figure 58.22
		section 60, Electrical Characteristics	Updated description for voltage detection level in Table 60.47
			Added a Note to Table 60.17, NMI and IRQ noise filter
			Updated the Note in Table 60.19
		section 1, Port States in Each Processing Mode	Updated Note 5. in Table 1.1, Port states in each processing state
