

Very high accuracy (25 μ V) high bandwidth (3 MHz) zero drift 5 V operational amplifiers

Features

- Very high accuracy and stability: offset voltage 25 μ V max. at 25 $^{\circ}$ C, 35 μ V over full temperature range (-40 $^{\circ}$ C to 125 $^{\circ}$ C)
- Rail-to-rail input and output
- Low supply voltage: 2.2 - 5.5 V
- Low power consumption: 1 mA max. at 5 V
- Gain bandwidth product: 3 MHz
- Automotive qualification
- Extended temperature range: -40 to 125 $^{\circ}$ C
- Micropackages: DFN8 2x2, SO8 and MiniSO8
- Benefits:
 - Higher accuracy without calibration
 - Accuracy virtually unaffected by temperature change

Applications

- High accuracy signal conditioning
- Automotive current measurement and sensor signal conditioning
- Medical instrumentation

Description

The **TSZ181**, **TSZ182** are single and dual operational amplifiers featuring very low offset voltages with virtually zero drift versus temperature changes.

The **TSZ181**, **TSZ182** offer rail-to-rail input and output, excellent speed/power consumption ratio, and 3 MHz gain bandwidth product, while consuming just 1 mA at 5 V. The device also features an ultra-low input bias current.

These features make the TSZ18x ideal for high-accuracy high-bandwidth sensor interfaces.

1 Package pin connections

Figure 1. Pin connections for each package (top view)

1. The exposed pad of the DFN8 2x2 can be connected to V_{CC-} or left floating.

2 Absolute maximum ratings and operating conditions

Table 1. Absolute maximum ratings (AMR)

Symbol	Parameter	Value	Unit	
V_{CC}	Supply voltage ⁽¹⁾	6	V	
V_{id}	Differential input voltage ⁽²⁾	$\pm V_{CC}$		
V_{in}	Input voltage ⁽³⁾	$(V_{CC-}) - 0.2$ to $(V_{CC+}) + 0.2$		
I_{in}	Input current ⁽⁴⁾	10	mA	
T_{stg}	Storage temperature	-65 to 150	°C	
T_j	Maximum junction temperature	150		
R_{thja}	Thermal resistance junction-to-ambient ^{(5) (6)}	DFN8 2x2	57	°C/W
		DFN6 1.2x1.3	232	
		SOT23-5	250	
		MiniSO8	190	
		SO8	125	
ESD	HBM: human body model ⁽⁷⁾	4	kV	
	CDM: charged device model ⁽⁸⁾	1.5		
	Latch-up immunity	200	mA	

1. All voltage values, except differential voltage, are with respect to network ground terminal.
2. The differential voltage is the non-inverting input terminal with respect to the inverting input terminal.
3. $V_{CC} - V_{in}$ must not exceed 6 V, V_{in} must not exceed 6 V.
4. Input current must be limited by a resistor in series with the inputs.
5. R_{th} are typical values.
6. Short-circuits can cause excessive heating and destructive dissipation.
7. Human body model: 100 pF discharged through a 1.5 kΩ resistor between two pins of the device, done for all couples of pin combinations with other pins floating.
8. Charged device model: all pins plus package are charged together to the specified voltage and then discharged directly to ground.

Table 2. Operating conditions

Symbol	Parameter	Value	Unit
V_{CC}	Supply voltage	2.2 to 5.5	V
V_{icm}	Common mode input voltage range	$(V_{CC-}) - 0.1$ to $(V_{CC+}) + 0.1$	
T_{oper}	Operating free-air temperature range	-40 to 125	°C

3 Electrical characteristics

Table 3. Electrical characteristics at $V_{CC+} = 2.2\text{ V}$ with $V_{CC-} = 0\text{ V}$, $V_{icm} = V_{CC}/2$, $T = 25\text{ }^\circ\text{C}$, and $R_L = 10\text{ k}\Omega$ connected to $V_{CC}/2$ (unless otherwise specified)

5 Application information

5.1 Operation theory

The TSZ18x is a high precision CMOS device. It can achieve a low offset drift and no 1/f noise thanks to its chopper architecture. Chopper-stabilized amps constantly correct low-frequency errors across the inputs of the amplifier.

Chopper-stabilized amplifiers can be explained with respect to:

- Time domain
- Frequency domain

5.1.1 Time domain

The basis of the chopper amplifier is realized in two steps. These steps are synchronized thanks to a clock running at 2.4 MHz.

Figure 46. Block diagram in the time domain (step 1)

Figure 47. Block diagram in the time domain (step 2)

Figure 46. Block diagram in the time domain (step 1) shows step 1, the first clock cycle, where V_{io} is amplified in the normal way.

Figure 47. Block diagram in the time domain (step 2) shows step 2, the second clock cycle, where Chop1 and Chop2 swap paths. At this time, the V_{io} is amplified in a reverse way as compared to step 1.

At the end of these two steps, the average V_{io} is close to zero.

The $A2(f)$ amplifier has a small impact on the V_{io} because the V_{io} is expressed as the input offset and is consequently divided by $A1(f)$.

In the time domain, the offset part of the output signal before filtering is shown in Figure 48. V_{io} cancellation principle.

Figure 48. V_{io} cancellation principle

The low pass filter averages the output value resulting in the cancellation of the V_{io} offset.

The $1/f$ noise can be considered as an offset in low frequency and it is canceled like the V_{io} , thanks to the chopper technique.

5.1.2 Frequency domain

The frequency domain gives a more accurate vision of chopper-stabilized amplifier architecture.

Figure 49. Block diagram in the frequency domain

The modulation technique transposes the signal to a higher frequency where there is no $1/f$ noise, and demodulate it back after amplification.

1. According to [Figure 49. Block diagram in the frequency domain](#), the input signal V_{in} is modulated once (Chop1) so all the input signal is transposed to the high frequency domain.
2. The amplifier adds its own error (V_{io} (output offset voltage) + the noise V_n ($1/f$ noise)) to this modulated signal.
3. This signal is then demodulated (Chop2), but since the noise and the offset are modulated only once, they are transposed to the high frequency, leaving the output signal of the amplifier without any offset and low frequency noise. Consequently, the input signal is amplified with a very low offset and $1/f$ noise.
4. To get rid of the high frequency part of the output signal (which is useless) a low pass filter is implemented. To further suppress the remaining ripple down to a desired level, another low pass filter may be added externally on the output of the TSZ18x.

5.2 Operating voltages

The TSZ18x device can operate from 2.2 to 5.5 V. The parameters are fully specified for 2.2 V, 3.3 V, and 5 V power supplies. However, the parameters are very stable in the full V_{CC} range and several characterization curves show the TSZ18x device characteristics at 2.2 V and 5.5 V. Additionally, the main specifications are guaranteed in extended temperature ranges from -40 to 125 °C.

5.3 Input pin voltage ranges

The TSZ18x device has internal ESD diode protection on the inputs. These diodes are connected between the input and each supply rail to protect the input MOSFETs from electrical discharge.

If the input pin voltage exceeds the power supply by 0.5 V, the ESD diodes become conductive and excessive current can flow through them. Without limitation this over current can damage the device. In this case, it is important to limit the current to 10 mA, by adding resistance on the input pin, as described in [Figure 50. Input current limitation](#).

Figure 50. Input current limitation

5.4 Rail-to-rail input/output

The TSZ18x has a rail-to-rail input, and the input common mode range is extended from $(V_{CC-}) - 0.1\text{ V}$ to $(V_{CC+}) + 0.1\text{ V}$.

The operational amplifier output levels can go close to the rails: to a maximum of 40 mV above and below the rail when connected to a 10 kΩ resistive load to $V_{CC}/2$.

5.5 Input offset voltage drift over temperature

The maximum input voltage drift variation over temperature is defined as the offset variation related to the offset value measured at 25 °C. The operational amplifier is one of the main circuits of the signal conditioning chain, and the amplifier input offset is a major contributor to the chain accuracy. The signal chain accuracy at 25 °C can be compensated during production at application level. The maximum input voltage drift over temperature enables the system designer to anticipate the effect of temperature variations.

The maximum input voltage drift over temperature is computed using [Equation 1](#).

Equation 1

$$\frac{\Delta V_{io}}{\Delta T} = \max \left| \frac{V_{io}(T) - V_{io}(25\text{ °C})}{T - 25\text{ °C}} \right|$$

Where $T = -40\text{ °C}$ and 125 °C .

The TSZ18x datasheet maximum value is guaranteed by measurements on a representative sample size ensuring a C_{pk} (process capability index) greater than 1.3.

5.6 Capacitive load

Driving large capacitive loads can cause stability problems. Increasing the load capacitance produces gain peaking in the frequency response, with overshoot and ringing in the step response. It is usually considered that with a gain peaking higher than 2.3 dB an op amp might become unstable.

Generally, the unity gain configuration is the worst case for stability and the ability to drive large capacitive loads.

[Figure 51. Stability criteria with a serial resistor at \$V_{CC} = 5\text{ V}\$](#) , [Figure 52. Stability criteria with a serial resistor at \$V_{CC} = 3.3\text{ V}\$](#) , and [Figure 53. Stability criteria with a serial resistor at \$V_{CC} = 2.2\text{ V}\$](#) show the serial resistors that must be added to the output, to make a system stable. [Figure 54. Test configuration for Riso](#) shows the test configuration using an isolation resistor, Riso.

Figure 51. Stability criteria with a serial resistor at $V_{CC} = 5\text{ V}$

Figure 52. Stability criteria with a serial resistor at $V_{CC} = 3.3\text{ V}$

Figure 53. Stability criteria with a serial resistor at $V_{CC} = 2.2\text{ V}$

Figure 54. Test configuration for Riso

Note that the resistance R_{iso} is in series with R_{load} and thus acts as a voltage divider, and reduces the output swing a little. Thanks to the natural good stability of TSZ18x, the R_{iso} needed to keep the system stable when the capacitive load exceeds 200pF is lower than 50 Ω ($V_{CC} = 5\text{ V}$), and so the error introduced is generally negligible. The R_{iso} also modifies the open loop gain of the circuit, and tends to improve the phase margin as described in Table 6. [Riso impact on stability.](#)

Table 6. Riso impact on stability

	Capacitive load									
		100 pF	1 nF	10 nF	100 nF	1 μ F				
Riso (Ω)	0	100	47	100	22	47	8	13	10	6
Measured overshoot (%)	20.9	15	23	9	16	8	21	10	12	8
Estimated phase margin ($^\circ$)	47	53	46	59	52	61	47	58	56	61

5.7 PCB layout recommendations

Particular attention must be paid to the layout of the PCB tracks connected to the amplifier, load and power supply. It is good practice to use short and wide PCB traces to minimize voltage drops and parasitic inductance. To minimize parasitic impedance over the entire surface, a multi-via technique that connects the bottom and top layer ground planes together in many locations is often used.

The copper traces that connect the output pins to the load and supply pins should be as wide as possible to minimize trace resistance.

A ground plane generally helps to reduce EMI, which is why it is generally recommended to use a multilayer PCB and use the ground plane as a shield to protect the internal track. In this case, pay attention to separate the digital from the analog ground and avoid any ground loop.

Place external components as close as possible to the op amp and keep the gain resistances, R_f and R_g , close to the inverting pin to minimize parasitic capacitances.

5.8 Optimized application recommendation

The TSZ18x is based on a chopper architecture. As the device includes internal switching circuitry, it is strongly recommended to place a 0.1 μ F capacitor as close as possible to the supply pins.

A good decoupling has several advantages for an application. First, it helps to reduce electromagnetic interference. Due to the modulation of the chopper, the decoupling capacitance also helps to reject the small ripple that may appear on the output.

The TSZ18x has been optimized for use with 10 k Ω in the feedback loop. With this, or a higher value resistance, this device offers the best performance.

5.9 EMI rejection ration (EMIRR)

The electromagnetic interference (EMI) rejection ratio, or EMIRR, describes the EMI immunity of operational amplifiers. An adverse effect that is common to many op amps is a change in the offset voltage as a result of RF signal rectification.

The TSZ18x has been specially designed to minimize susceptibility to EMIRR and show an extremely good sensitivity. [Figure 55. EMIRR on IN+ pin](#) shows the EMIRR IN+, [Figure 56. EMIRR on IN- pin](#) shows the EMIRR IN- of the TSZ18x measured from 10 MHz up to 2.4 GHz.

Figure 55. EMIRR on IN+ pin

Figure 56. EMIRR on IN- pin

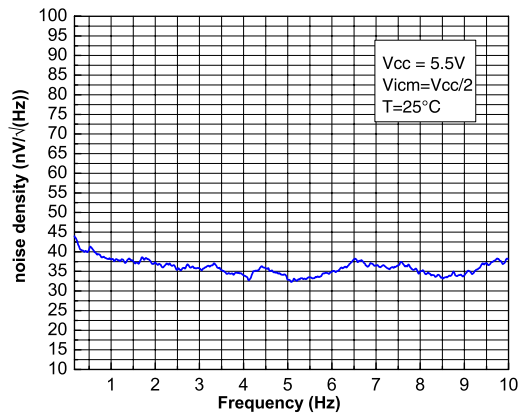

5.10 1/f noise

1/f noise, also known as pink noise or flicker noise, is caused by defects, at the atomic level, in semiconductor devices. The noise is a non-periodic signal and it cannot be calibrated. So for an application requiring precision, it is extremely important to take this noise into account.

1/f noise is a major noise contributor at low frequencies and causes a significant output voltage offset when amplified by the noise gain of the circuit. But, the TSZ18x, thanks to its chopper architecture, rejects 1/f noise and thus makes this device an excellent choice for DC high precision applications.

As shown in [Figure 28. Noise 0.1 - 10 Hz vs. time](#), 0.1 Hz to 10 Hz amplifier voltage noise is only 400 nVpp for a $V_{CC} = 5$ V. [Figure 29. Noise vs. frequency](#) and [Figure 30. Noise vs. frequency and temperature](#) show the voltage noise density of the amplifier with no 1/f noise on a large bandwidth. [Figure 57. Noise vs frequency between 0.1 and 10 Hz exhibiting no 1/f noise](#) below depicts noise vs frequency between 0.1 and 10 Hz exhibiting no 1/f noise.

Figure 57. Noise vs frequency between 0.1 and 10 Hz exhibiting no 1/f noise

5.11 Overload recovery

Overload recovery is defined as the time required for the op amp output to recover from a saturated state to a linear state.

The saturation state occurs when the output voltage gets very close to either rail in the application. It can happen due to an excessive input voltage or when the gain setting is too high.

When the output of the TSZ18x enters in saturation state it needs 10 μ s to get back to a linear state as shown in [Figure 58. Negative overvoltage recovery \$V_{CC} = 5\$ V](#) and [Figure 59. Positive overvoltage recovery \$V_{CC} = 5\$ V](#).

[Figure 36. Negative overvoltage recovery \$V_{CC} = 2.2\$ V](#) and [Figure 37. Positive overvoltage recovery \$V_{CC} = 2.2\$ V](#) show the overvoltage recovery for a $V_{CC} = 2.2$ V.

Figure 58. Negative overvoltage recovery $V_{CC} = 5$ V

Figure 59. Positive overvoltage recovery $V_{CC} = 5$ V

5.12 Phase reversal protection

Some op amps can show a phase reversal when the common-mode voltage exceeds the V_{CC} range.

Phase reversal is a specific behavior of an op amp where its output reacts as if the inputs were inverted when at least one input is out of the specified common-mode voltage.

The TSZ18x has been carefully designed to prevent any output phase reversal. The TSZ18x is a rail-to-rail input op amp, therefore, the common-mode range can extend up to the rails. If the input signal goes above the rail it does not cause any inversion of the output signal as shown in [Figure 60. No phase reversal](#).

If, in the application, the operating common-mode voltage is exceeded please read [Section 5.3 Input pin voltage ranges](#).

Figure 60. No phase reversal

5.13 Open loop gain close to the rail

One of the key parameters of current measurement in low-side applications is precision. Moreover, it is generally interesting to be able to make a measurement when there is no current through the shunt resistance. But, when the output voltage gets close to the rail some internal transistors saturate resulting in a loss of open loop gain. Therefore, the output voltage can be as high as several mV while it is expected to be close to 0 V.

The TSZ18x has been designed to keep a high gain even when the op amp output is very close to the rail, to ensure good accuracy at low current.

Figure 61. Gain vs. output voltage, $V_{CC} = 5\text{ V}$, $R_I = 10\text{ k}\Omega$ to GND shows the open loop gain of the TSZ18x vs. output voltage. A single power supply of 5 V and a common-mode voltage of 0 V is used, with a 10 k Ω resistor connected to GND.

Figure 61. Gain vs. output voltage, $V_{CC} = 5\text{ V}$, $R_I = 10\text{ k}\Omega$ to GND

5.14 Application examples

5.14.1 Measuring gas concentration using the NDIR principle (thermopile)

A thermopile is a serial interconnected array of thermocouples. Based on the Seebeck principle, a thermocouple is able to deliver an output voltage which depends on the temperature difference between a reference junction and an active junction.

An NDIR sensor (non dispersive infrared) is generally composed of an infrared (IR) source, an optical cavity, a dual channel detector, and an internal thermistor. Both channels are made with a thermopile. One channel is considered as a reference and the other is considered as the active channel.

Certain gases absorb IR radiation at a specific wavelength. Each channel has a specific wavelength filter. The active channel has a filter centered on gas absorption while the reference channel has a filter on another wavelength which is still in the IR range.

When a gas enters the optical cavity, the radiation hitting the active channel decreases, whereas it remains the same on the reference channel.

The difference between the reference and active channel gives the concentration of gas present in the optical cavity.

As the thermopile delivers extremely low voltages (hundreds of μV to several mV) the output signal must be amplified with a high gain and a very low offset in order to minimize DC errors.

Moreover, the drift of V_{io} depending on temperature must be as low as possible not to impact the measurement once the calibration has been made.

An NDIR sensor generally works at low frequency and the noise of the amplifiers must be as low as possible (0.1-10 Hz $e_{n-pp} = 0.4 \mu\text{Vpp}$).

Thanks to its chopper architecture, the TSZ18x combines all these specifications, particularly in having a $\Delta V_{io}/\Delta t$ of $0.1 \mu\text{V}/^\circ\text{C}$, no $1/f$ noise in low frequency, and a white noise of $37 \text{ nV}/\sqrt{\text{Hz}}$.

Figure 62. Principle schematic shows an NDIR gas sensing schematic where the active and reference channels are pre-amplified before treatment by an ADC thanks to the TSZ18x.

A V_{ref} voltage (in hundreds of mV) can be used to ensure the amplifiers are not saturated when the signal is close to the low rail. A gain of 1000 is used to allow amplification of the signal coming from the NDIR sensor (3 mV).

Figure 62. Principle schematic

5.14.2 Precision instrumentation amplifier

The instrumentation amplifier uses three op amps. The circuit, shown in Figure 63. Precision instrumentation amplifier schematic, exhibits high input impedance, so that the source impedance of the connected sensor has no impact on the amplification.

Figure 63. Precision instrumentation amplifier schematic

The gain is set by tuning the R_g resistor. To have the best performance, it is suggested to have $R_1 = R_2 = R_3 = R_4$. The output is given by [Equation 2](#).

Equation 2

$$V_{out} = (V_2 - V_1) \left[\frac{2R_f}{R_g} + 1 \right]$$

The matching of R_1 , R_2 and R_3 , R_4 is important to ensure a good common mode rejection ratio (CMR).

5.14.3 Low-side current sensing

Power management mechanisms are found in most electronic systems. Current sensing is useful for protecting applications. The low-side current sensing method consists of placing a sense resistor between the load and the circuit ground. The resulting voltage drop is amplified using the TSZ181 (see [Figure 64. Low-side current sensing schematic](#)).

Figure 64. Low-side current sensing schematic

V_{out} can be expressed as follows:

Equation 3

$$V_{out} = R_{shunt} \times I \left(1 - \frac{R_{g2}}{R_{g2} + R_{f2}} \right) \left(1 + \frac{R_{f1}}{R_{g1}} \right) + I_p \left(\frac{R_{g2} \times R_{f2}}{R_{g2} + R_{f2}} \right) \times \left(1 + \frac{R_{f1}}{R_{g1}} \right) - I_n \times R_{f1} - V_{io} \left(1 + \frac{R_{f1}}{R_{g1}} \right)$$

Assuming that $R_{f2} = R_{f1} = R_f$ and $R_{g2} = R_{g1} = R_g$, Equation 3 can be simplified as follows:

Equation 4

$$V_{out} = R_{shunt} \times I \left(\frac{R_f}{R_g} \right) - V_{io} \left(1 + \frac{R_f}{R_g} \right) + R_f \times I_{io}$$

The main advantage of using the chopper of the TSZ18x for a low-side current sensing, is that the errors due to V_{i0} and I_{i0} are extremely low and may be neglected.

Therefore, for the same accuracy, the shunt resistor can be chosen with a lower value, resulting in lower power dissipation, lower drop in the ground path, and lower cost.

Particular attention must be paid to the matching and precision of R_{g1} , R_{g2} , R_{f1} , and R_{f2} , to maximize the accuracy of the measurement.

6 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions and product status are available at: www.st.com. ECOPACK® is an ST trademark.
