Spartan-3A FPGA Family: Introduction and Ordering Information

DS529 (v2.1) December 18, 2018 **Product Specification**

Introduction

The Spartan®-3A family of Field-Programmable Gate Arrays (FPGAs) solves the design challenges in most high-volume, cost-sensitive, I/O-intensive electronic applications. The five-member family offers densities ranging from 50,000 to 1.4 million system gates, as shown in Table 1.

The Spartan-3A FPGAs are part of the Extended Spartan-3A family, which also include the non-volatile Spartan-3AN and the higher density Spartan-3A DSP FPGAs. The Spartan-3A family builds on the success of the earlier Spartan-3E and Spartan-3 FPGA families. New features improve system performance and reduce the cost of configuration. These Spartan-3A family enhancements, combined with proven 90 nm process technology, deliver more functionality and bandwidth per dollar than ever before, setting the new standard in the programmable logic industry.

Because of their exceptionally low cost, Spartan-3A FPGAs are ideally suited to a wide range of consumer electronics applications, including broadband access, home networking, display/projection, and digital television equipment.

The Spartan-3A family is a superior alternative to mask programmed ASICs. FPGAs avoid the high initial cost, lengthy development cycles, and the inherent inflexibility of conventional ASICs, and permit field design upgrades.

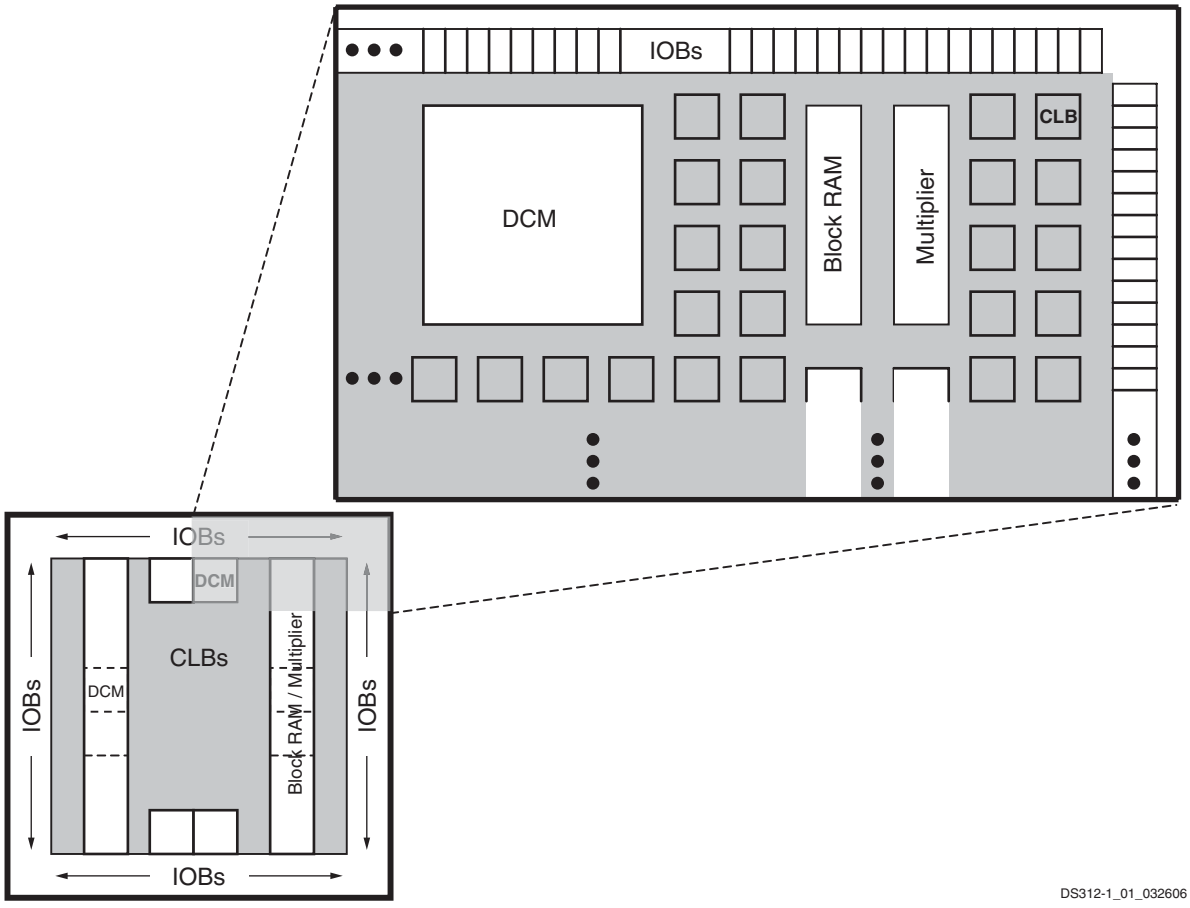
Architectural Overview

The Spartan-3A family architecture consists of five fundamental programmable functional elements:

- **Configurable Logic Blocks (CLBs)** contain flexible Look-Up Tables (LUTs) that implement logic plus storage elements used as flip-flops or latches. CLBs perform a wide variety of logical functions as well as store data.
- **Input/Output Blocks (IOBs)** control the flow of data between the I/O pins and the internal logic of the device. IOBs support bidirectional data flow plus 3-state operation. Supports a variety of signal standards, including several high-performance differential standards. Double Data-Rate (DDR) registers are included.
- **Block RAM** provides data storage in the form of 18-Kbit dual-port blocks.
- **Multiplier Blocks** accept two 18-bit binary numbers as inputs and calculate the product.
- **Digital Clock Manager (DCM) Blocks** provide self-calibrating, fully digital solutions for distributing, delaying, multiplying, dividing, and phase-shifting clock signals.

These elements are organized as shown in Figure 1. A dual ring of staggered IOBs surrounds a regular array of CLBs. Each device has two columns of block RAM except for the XC3S50A, which has one column. Each RAM column consists of several 18-Kbit RAM blocks. Each block RAM is associated with a dedicated multiplier. The DCMs are positioned in the center with two at the top and two at the bottom of the device. The XC3S50A has DCMs only at the top, while the XC3S700A and XC3S1400A add two DCMs in the middle of the two columns of block RAM and multipliers.

The Spartan-3A family features a rich network of routing that interconnect all five functional elements, transmitting signals among them. Each functional element has an associated switch matrix that permits multiple connections to the routing.



Notes:

1. The XC3S700A and XC3S1400A have two additional DCMs on both the left and right sides as indicated by the dashed lines. The XC3S50A has only two DCMs at the top and only one Block RAM/Multiplier column.

Figure 1: **Spartan-3A FPGA Architecture**

Configuration

Spartan-3A FPGAs are programmed by loading configuration data into robust, reprogrammable, static CMOS configuration latches (CCLs) that collectively control all functional elements and routing resources. The FPGA's configuration data is stored externally in a PROM or some other non-volatile medium, either on or off the board. After applying power, the configuration data is written to the FPGA using any of seven different modes:

- Master Serial from a Xilinx Platform Flash PROM
- Serial Peripheral Interface (SPI) from an industry-standard SPI serial Flash
- Byte Peripheral Interface (BPI) Up from an industry-standard x8 or x8/x16 parallel NOR Flash
- Slave Serial, typically downloaded from a processor
- Slave Parallel, typically downloaded from a processor
- Boundary Scan (JTAG), typically downloaded from a processor or system tester

Furthermore, Spartan-3A FPGAs support MultiBoot configuration, allowing two or more FPGA configuration bitstreams to be stored in a single SPI serial Flash or a BPI parallel NOR Flash. The FPGA application controls which configuration to load next and when to load it.

Additionally, each Spartan-3A FPGA contains a unique, factory-programmed Device DNA identifier useful for tracking purposes, anti-cloning designs, or IP protection.

I/O Capabilities

The Spartan-3A FPGA SelectIO interface supports many popular single-ended and differential standards. Table 2 shows the number of user I/Os as well as the number of differential I/O pairs available for each device/package combination. Package Marking

Figure 2 provides a top marking example for Spartan-3A FPGAs in the quad-flat packages. Figure 3 shows the top marking for Spartan-3A FPGAs in BGA packages. The markings for the BGA packages are nearly identical to those for the quad-flat packages, except that the marking is rotated with respect to the ball A1 indicator.

The "`5C`" and "`4I`" Speed Grade/Temperature Range part combinations may be dual marked as "`5C/4I`". Devices with a single mark are only guaranteed for the marked speed grade and temperature range.

DC Electrical Characteristics

In this section, specifications may be designated as Advance, Preliminary, or Production. These terms are defined as follows:

Advance: Initial estimates are based on simulation, early characterization, and/or extrapolation from the characteristics of other families. Values are subject to change. Use as estimates, not for production.

Preliminary: Based on characterization. Further changes are not expected.

Production: These specifications are approved once the silicon has been characterized over numerous production lots. Parameter values are considered stable with no future changes expected.

All parameter limits are representative of worst-case supply voltage and junction temperature conditions. **Unless otherwise noted, the published parameter values apply to all Spartan®-3A devices. AC and DC characteristics are specified using the same numbers for both commercial and industrial grades.**

Absolute Maximum Ratings

Stresses beyond those listed under Table 4: Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only; functional operation of the device at these or any other conditions beyond those listed under the Recommended Operating Conditions is not implied. Exposure to absolute maximum conditions for extended periods of time adversely affects device reliability.

1. This V_{CCO} range spans the lowest and highest operating voltages for all supported I/O standards. Table 11 lists the recommended V_{CCO} range specific to each of the single-ended I/O standards, and Table 13 lists that specific to the differential standards.
2. Define V_{CCAUX} selection using CONFIG VCCAUX constraint.
3. See XAPP459, “Eliminating I/O Coupling Effects when Interfacing Large-Swing Single-Ended Signals to User I/O Pins.”
4. For single-ended signals that are placed on a differential-capable I/O, V_{IN} of –0.2V to –0.5V is supported but can cause increased leakage between the two pins. See *Parasitic Leakage* in UG331, *Spartan-3 Generation FPGA User Guide*.
5. Measured between 10% and 90% V_{CCO}. Follow Signal Integrity recommendations.

		XC3S700A	6	28	34	mA
		XC3S1400A	10	50	58	mA

Notes:

1. The numbers in this table are based on the conditions set forth in Table 8.
2. Quiescent supply current is measured with all I/O drivers in a high-impedance state and with all pull-up/pull-down resistors at the I/O pads disabled. Typical values are characterized using typical devices at room temperature (T_J of 25°C at V_{CCINT} = 1.2V, V_{CCO} = 3.3V, and V_{CCAUX} = 2.5V). The maximum limits are tested for each device at the respective maximum specified junction temperature and at maximum voltage limits with V_{CCINT} = 1.26V, V_{CCO} = 3.6V, and V_{CCAUX} = 3.6V. The FPGA is programmed with a "blank" configuration data file (that is, a design with no functional elements instantiated). For conditions other than those described above (for example, a design including functional elements), measured quiescent current levels will be different than the values in the table.
3. For more accurate estimates for a specific design, use the Xilinx XPower tools. There are two recommended ways to estimate the total power consumption (quiescent plus dynamic) for a specific design: a) The Spartan-3A FPGA XPower Estimator provides quick, approximate, typical estimates, and does not require a netlist of the design. b) XPower Analyzer uses a netlist as input to provide maximum estimates as well as more accurate typical estimates.
4. The maximum numbers in this table indicate the minimum current each power rail requires in order for the FPGA to power-on successfully.
5. For information on the power-saving Suspend mode, see XAPP480: *Using Suspend Mode in Spartan-3 Generation FPGAs*. Suspend mode typically saves 40% total power consumption compared to quiescent current.

Notes:

1. Descriptions of the symbols used in this table are as follows:
   V_{CCO} – the supply voltage for output drivers
   V_{REF} – the reference voltage for setting the input switching threshold
   V_{IL} – the input voltage that indicates a Low logic level
   V_{IH} – the input voltage that indicates a High logic level
2. In general, the V_{CCO} rails supply only output drivers, not input circuits. The exceptions are for LVCMOS25 inputs when V_{CCAUX} = 3.3V range and for PCI I/O standards.
3. For device operation, the maximum signal voltage (V_{IH} max) can be as high as V_{IN} max. See Table 8.
4. There is approximately 100 mV of hysteresis on inputs using LVCMOS33 and LVCMOS25 I/O standards.
5. All Dedicated pins (PROG_B, DONE, SUSPEND, TCK, TDI, TDO, and TMS) draw power from the V_{CCAUX} rail and use the LVCMOS25 or LVCMOS33 standard depending on V_{CCAUX}. The dual-purpose configuration pins use the LVCMOS standard before the User mode. When using these pins as part of a standard 2.5V configuration interface, apply 2.5V to the V_{CCO} lines of Banks 0, 1, and 2 at power-on as well as throughout configuration.
6. For information on PCI IP solutions, see www.xilinx.com/pci. The PCI IOSTANDARD is not supported on input-only pins. The PCIX IOSTANDARD is available and has equivalent characteristics but no PCI-X IP is supported.

Notes:

1. The numbers in this table are based on the conditions set forth in Table 8 and Table 11.
2. Descriptions of the symbols used in this table are as follows:
   I_{OL} — the output current condition under which V_{OL} is tested
   I_{OH} — the output current condition under which V_{OH} is tested
   V_{OL} — the output voltage that indicates a Low logic level
   V_{OH} — the output voltage that indicates a High logic level
   V_{CCO} — the supply voltage for output drivers
   V_{TT} — the voltage applied to a resistor termination
3. For the LVCMOS and LVTTL standards: the same V_{OL} and V_{OH} limits apply for the Fast, Slow, and QUIETIO slew attributes.
4. These higher-drive output standards are supported only on FPGA banks 1 and 3. Inputs are unrestricted. See the chapter "Using I/O Resources" in UG331.

Notes:

1. The V_{CCO} rails supply only differential output drivers, not input circuits.
2. V_{ICM} must be less than V_{CCAUX}.
3. These true differential output standards are supported only on FPGA banks 0 and 2. Inputs are unrestricted. See the chapter "Using I/O Resources" in UG331.
4. See "External Termination Requirements for Differential I/O," page 20.
5. LVPECL is supported on inputs only, not outputs. LVPECL_33 requires V_{CCAUX}=3.3V ± 10%.
6. LVPECL_33 maximum V_{ICM} = the lower of 2.8V or $V_{CCAUX} - (V_{ID} / 2)$
7. Requires V_{CCAUX} = 3.3V ± 10% for inputs. $(V_{CCAUX} - 300\ mV) \le V_{ICM} \le (V_{CCAUX} - 37\ mV)$
8. These higher-drive output standards are supported only on FPGA banks 1 and 3. Inputs are unrestricted. See the chapter "Using I/O Resources" in UG331.
9. All standards except for LVPECL and TMDS can have V_{CCAUX} at either 2.5V or 3.3V. Define your V_{CCAUX} level using the CONFIG VCCAUX constraint.

Switching Characteristics

All Spartan-3A FPGAs ship in two speed grades: –4 and the higher performance –5. Switching characteristics in this document are designated as Advance, Preliminary, or Production, as shown in Table 16. Each category is defined as follows:

Advance: These specifications are based on simulations only and are typically available soon after establishing FPGA specifications. Although speed grades with this designation are considered relatively stable and conservative, some under-reporting might still occur.

Preliminary: These specifications are based on complete early silicon characterization. Devices and speed grades with this designation are intended to give a better indication of the expected performance of production silicon. The probability of under-reporting preliminary delays is greatly reduced compared to Advance data.

Production: These specifications are approved once enough production silicon of a particular device has been characterized to provide full correlation between speed files and devices over numerous production lots. There is no under-reporting of delays, and customers receive formal notification of any subsequent changes. Typically, the slowest speed grades transition to Production before faster speed grades.

Software Version Requirements

Production-quality systems must use FPGA designs compiled using a speed file designated as PRODUCTION status. FPGA designs using a less mature speed file designation should only be used during system prototyping or pre-production qualification. FPGA designs with speed files designated as Advance or Preliminary should not be used in a production-quality system.

Whenever a speed file designation changes, as a device matures toward Production status, rerun the latest Xilinx® ISE® software on the FPGA design to ensure that the FPGA design incorporates the latest timing information and software updates.

All parameter limits are representative of worst-case supply voltage and junction temperature conditions. **Unless otherwise noted, the published parameter values apply to all Spartan-3A devices. AC and DC characteristics are specified using the same numbers for both commercial and industrial grades.**

Timing parameters and their representative values are selected for inclusion below either because they are important as general design requirements or they indicate fundamental device performance characteristics. The Spartan-3A FPGA speed files (v1.41), part of the Xilinx Development Software, are the original source for many but not all of the values. The speed grade designations for these files are shown in Table 16. For more complete, more precise, and worst-case data, use the values reported by the Xilinx static timing analyzer (TRACE in the Xilinx development software) and back-annotated to the simulation netlist.

Notes:

1. The numbers in this table are tested using the methodology presented in Table 27 and are based on the operating conditions set forth in Table 8, Table 11, and Table 13.
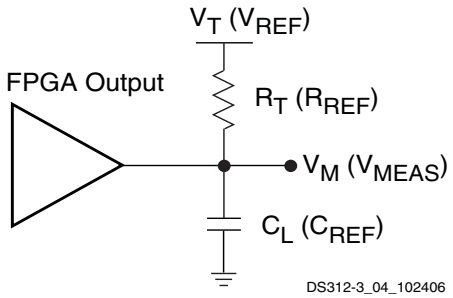
2. These adjustments are used to convert output- and three-state-path times originally specified for the LVCMOS25 standard with 12 mA drive and Fast slew rate to times that correspond to other signal standards. Do not adjust times that measure when outputs go into a high-impedance state.
3. Note that 16 mA drive is faster than 24 mA drive for the Slow slew rate.

Timing Measurement Methodology

When measuring timing parameters at the programmable I/Os, different signal standards call for different test conditions. Table 27 lists the conditions to use for each standard.

The method for measuring Input timing is as follows: A signal that swings between a Low logic level of V_L and a High logic level of V_H is applied to the Input under test. Some standards also require the application of a bias voltage to the V_{REF} pins of a given bank to properly set the input-switching threshold. The measurement point of the Input signal (V_M) is commonly located halfway between V_L and V_H.

The Output test setup is shown in Figure 9. A termination voltage V_T is applied to the termination resistor R_T, the other end of which is connected to the Output. For each standard, R_T and V_T generally take on the standard values recommended for minimizing signal reflections. If the standard does not ordinarily use terminations (for example, LVCMOS, LVTTL), then R_T is set to 1MΩ to indicate an open connection, and V_T is set to zero. The same measurement point (V_M) that was used at the Input is also used at the Output.



Notes:

1. The names shown in parentheses are used in the IBIS file.

Notes:

1. Descriptions of the relevant symbols are as follows:
   V_{REF} – The reference voltage for setting the input switching threshold
   V_{ICM} – The common mode input voltage
   V_M – Voltage of measurement point on signal transition
   V_L – Low-level test voltage at Input pin
   V_H – High-level test voltage at Input pin
   R_T – Effective termination resistance, which takes on a value of 1 MΩ when no parallel termination is required
   V_T – Termination voltage
2. The load capacitance (C_L) at the Output pin is 0 pF for all signal standards.
3. According to the PCI specification.

The capacitive load (C_L) is connected between the output and GND. *The Output timing for all standards, as published in the speed files and the data sheet, is always based on a C_L value of zero.* High-impedance probes (less than 1 pF) are used for all measurements. Any delay that the test fixture might contribute to test measurements is subtracted from those measurements to produce the final timing numbers as published in the speed files and data sheet.

Using IBIS Models to Simulate Load Conditions in Application

IBIS models permit the most accurate prediction of timing delays for a given application. The parameters found in the IBIS model (V_{REF}, R_{REF}, and V_{MEAS}) correspond directly with the parameters used in Table 27 (V_T, R_T, and V_M). Do not confuse V_{REF} (the termination voltage) from the IBIS model with V_{REF} (the input-switching threshold) from the table. A fourth parameter, C_{REF}, is always zero. The four parameters describe all relevant output test conditions. IBIS models are found in the Xilinx development software as well as at the following link:

www.xilinx.com/support/download/index.htm

Delays for a given application are simulated according to its specific load conditions as follows:

1. Simulate the desired signal standard with the output driver connected to the test setup shown in Figure 9. Use parameter values V_T, R_T, and V_M from Table 27. C_{REF} is zero.
2. Record the time to V_M.
3. Simulate the same signal standard with the output driver connected to the PCB trace with load. Use the appropriate IBIS model (including V_{REF}, R_{REF}, C_{REF}, and V_{MEAS} values) or capacitive value to represent the load.
4. Record the time to V_{MEAS}.
5. Compare the results of steps 2 and 4. Add (or subtract) the increase (or decrease) in delay to (or from) the appropriate Output standard adjustment (Table 26) to yield the worst-case delay of the PCB trace.

Simultaneously Switching Output Guidelines

This section provides guidelines for the recommended maximum allowable number of Simultaneous Switching Outputs (SSOs). These guidelines describe the maximum number of user I/O pins of a given output signal standard that should simultaneously switch in the same direction, while maintaining a safe level of switching noise. Meeting these guidelines for the stated test conditions ensures that the FPGA operates free from the adverse effects of ground and power bounce.

Ground or power bounce occurs when a large number of outputs simultaneously switch in the same direction. The output drive transistors all conduct current to a common voltage rail. Low-to-High transitions conduct to the V_{CCO} rail; High-to-Low transitions conduct to the GND rail. The resulting cumulative current transient induces a voltage difference across the inductance that exists between the die pad and the power supply or ground return. The inductance is associated with bonding wires, the package lead frame, and any other signal routing inside the package. Other variables contribute to SSO noise levels, including stray inductance on the PCB as well as capacitive loading at receivers. Any SSO-induced voltage consequently affects internal switching noise margins and ultimately signal quality.

Table 28 and Table 29 provide the essential SSO guidelines. For each device/package combination, Table 28 provides the number of equivalent V_{CCO}/GND pairs. The equivalent number of pairs is based on characterization and may not match the physical number of pairs. For each output signal standard and drive strength, Table 29 recommends the maximum number of SSOs, switching in the same direction, allowed per V_{CCO}/GND pair within an I/O bank. The guidelines in Table 29 are categorized by package style, slew rate, and output drive current. Furthermore, the number of SSOs is specified by I/O bank. Generally, the left and right I/O banks (Banks 1 and 3) support higher output drive current.

Multiply the appropriate numbers from Table 28 and Table 29 to calculate the maximum number of SSOs allowed within an I/O bank. Exceeding these SSO guidelines might result in increased power or ground bounce, degraded signal integrity, or increased system jitter.

SSO_{MAX}/IO Bank = Table 28 x Table 29

The recommended maximum SSO values assume that the FPGA is soldered on the printed circuit board and that the board uses sound design practices. The SSO values do not apply for FPGAs mounted in sockets, due to the lead inductance introduced by the socket.

The SSO values assume that the V_{CCAUX} is powered at 3.3V. Setting V_{CCAUX} to 2.5V provides better SSO characteristics.

The number of SSOs allowed for quad-flat packages (VQ/TQ) is lower than for ball grid array packages (FG) due to the larger lead inductance of the quad-flat packages. Ball grid array packages are recommended for applications with a large number of simultaneously switching outputs.

Notes:

1. Not all I/O standards are supported on all I/O banks. The left and right banks (I/O banks 1 and 3) support higher output drive current than the top and bottom banks (I/O banks 0 and 2). Similarly, true differential output standards, such as LVDS, RSDS, PPDS, miniLVDS, and TMDS, are only supported in top or bottom banks (I/O banks 0 and 2). Refer to UG331: *Spartan-3 Generation FPGA User Guide* for additional information.
2. The numbers in this table are recommendations that assume sound board lay out practice. Test limits are the V_{IL}/V_{IH} voltage limits for the respective I/O standard.
3. If more than one signal standard is assigned to the I/Os of a given bank, refer to XAPP689: *Managing Ground Bounce in Large FPGAs* for information on how to perform weighted average SSO calculations.

Digital Clock Manager (DCM) Timing

For specification purposes, the DCM consists of three key components: the Delay-Locked Loop (DLL), the Digital Frequency Synthesizer (DFS), and the Phase Shifter (PS).

Aspects of DLL operation play a role in all DCM applications. All such applications inevitably use the CLKIN and the CLKFB inputs connected to either the CLK0 or the CLK2X feedback, respectively. Thus, specifications in the DLL tables (Table 36 and Table 37) apply to any application that only employs the DLL component. When the DFS and/or the PS components are used together with the DLL, then the specifications listed in the DFS and PS tables (Table 38 through Table 41) supersede any corresponding ones in the DLL tables. DLL specifications that do not change with the addition of DFS or PS functions are presented in Table 36 and Table 37.

Period jitter and cycle-cycle jitter are two of many different ways of specifying clock jitter. Both specifications describe statistical variation from a mean value.

Period jitter is the worst-case deviation from the ideal clock period over a collection of millions of samples. In a histogram of period jitter, the mean value is the clock period.

Cycle-cycle jitter is the worst-case difference in clock period between adjacent clock cycles in the collection of clock periods sampled. In a histogram of cycle-cycle jitter, the mean value is zero.

Spread Spectrum

DCMs accept typical spread spectrum clocks as long as they meet the input requirements. The DLL will track the frequency changes created by the spread spectrum clock to drive the global clocks to the FPGA logic. See XAPP469, *Spread-Spectrum Clocking Reception for Displays* for details.

CLKFB_DELAY_VAR_EXT		Allowable variation of off-chip feedback delay from the DCM output to the CLKFB input		–	±1	–	±1	ns

Notes:

1. DLL specifications apply when any of the DLL outputs (CLK0, CLK90, CLK180, CLK270, CLK2X, CLK2X180, or CLKDV) are in use.
2. The DFS, when operating independently of the DLL, supports lower FCLKIN frequencies. See Table 38.
3. To support double the maximum effective FCLKIN limit, set the CLKIN_DIVIDE_BY_2 attribute to TRUE. This attribute divides the incoming clock frequency by two as it enters the DCM. The CLK2X output reproduces the clock frequency provided on the CLKIN input.
4. CLKIN input jitter beyond these limits might cause the DCM to lose lock.
5. The DCM specifications are guaranteed when both adjacent DCMs are locked.

Notes:

1. The numbers in this table are based on the operating conditions set forth in Table 8 and Table 36.
2. Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
3. For optimal jitter tolerance and faster lock time, use the CLKIN_PERIOD attribute.
4. Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, the data sheet specifies a maximum jitter of "±[1% of CLKIN period + 150]". Assume the CLKIN frequency is 100 MHz. The equivalent CLKIN period is 10 ns and 1% of 10 ns is 0.1 ns or 100 ps. According to the data sheet, the maximum jitter is ±[100 ps + 150 ps] = ±250ps.
5. The typical delay step size is 23 ps.

Notes:

1. DFS specifications apply when either of the DFS outputs (CLKFX or CLKFX180) are used.
2. If both DFS and DLL outputs are used on the same DCM, follow the more restrictive CLKIN_FREQ_DLL specifications in Table 36.
3. CLKIN input jitter beyond these limits may cause the DCM to lose lock.
4. To support double the maximum effective FCLKIN limit, set the CLKIN_DIVIDE_BY_2 attribute to TRUE. This attribute divides the incoming clock frequency by two as it enters the DCM.

Lock Time								
LOCK_FX[2, 3]	The time from deassertion at the DCM's Reset input to the rising transition at its LOCKED output. The DFS asserts LOCKED when the CLKFX and CLKFX180 signals are valid. If using both the DLL and the DFS, use the longer locking time.	5 MHz ≤ F_{CLKIN} ≤ 15 MHz	All	–	5	–	5	ms
		F_{CLKIN} > 15 MHz		–	450	–	450	µs

Notes:

1. The numbers in this table are based on the operating conditions set forth in Table 8 and Table 38.
2. DFS performance requires the additional logic automatically added by ISE 9.1i and later software revisions.
3. For optimal jitter tolerance and faster lock time, use the CLKIN_PERIOD attribute.
4. Maximum output jitter is characterized within a reasonable noise environment (150 ps input period jitter, 40 SSOs and 25% CLB switching) on an XC3S1400A FPGA. Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply and PCB design. The actual maximum output jitter depends on the system application.
5. The CLKFX and CLKFX180 outputs always have an approximate 50% duty cycle.
6. Some duty-cycle and alignment specifications include a percentage of the CLKFX output period. For example, the data sheet specifies a maximum CLKFX jitter of "±[1% of CLKFX period + 200]". Assume the CLKFX output frequency is 100 MHz. The equivalent CLKFX period is 10 ns and 1% of 10 ns is 0.1 ns or 100 ps. According to the data sheet, the maximum jitter is ±[100 ps + 200 ps] = ±300 ps.

1. The V_{CCINT}, V_{CCAUX}, and V_{CCO} supplies can be applied in any order.
2. The Low-going pulse on PROG_B is optional after power-on but necessary for reconfiguration without a power cycle.
3. The rising edge of INIT_B samples the voltage levels applied to the mode pins (M0 - M2).

2. Power-on reset and the clearing of configuration memory occurs during this period.
3. This specification applies only to the Master Serial, SPI, and BPI modes.
4. For details on configuration, see UG332 *Spartan-3 Generation Configuration User Guide*.

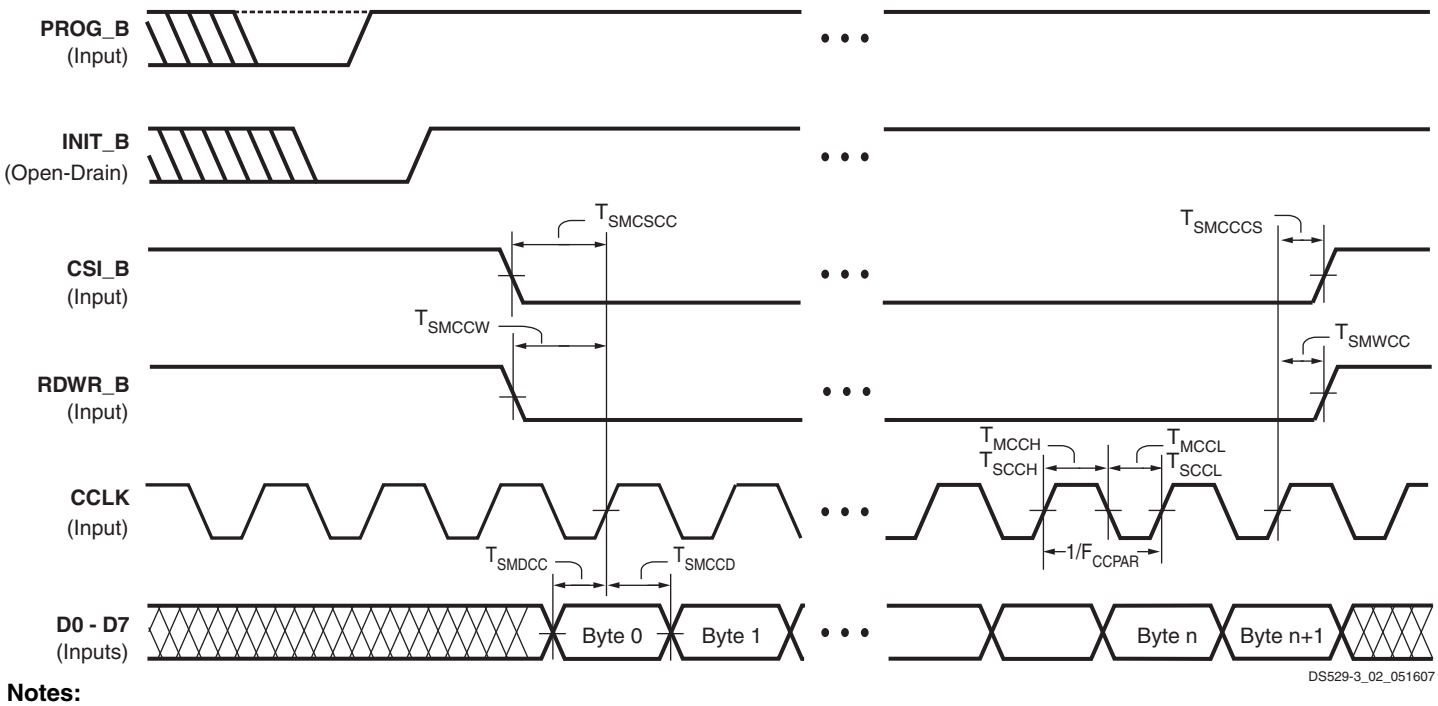
2. For serial configuration with a daisy-chain of multiple FPGAs, the maximum limit is 25 MHz.

Slave Parallel Mode Timing



Notes:

1. It is possible to abort configuration by pulling CSI_B Low in a given CCLK cycle, then switching RDWR_B Low or High in any subsequent cycle for which CSI_B remains Low. The RDWR_B pin asynchronously controls the driver impedance of the D0 - D7 bus. When RDWR_B switches High, be careful to avoid contention on the D0 - D7 bus.
2. To pause configuration, pause CCLK instead of de-asserting CSI_B. See UG332 Chapter 7 section “Non-Continuous SelectMAP Data Loading” for more details.

Introduction

This section describes how the various pins on a Spartan®-3A FPGA connect within the supported component packages, and provides device-specific thermal characteristics. For general information on the pin functions and the package characteristics, see the Packaging section of UG331: *Spartan-3 Generation FPGA User Guide*.

- **UG331: Spartan-3 Generation FPGA User Guide**
  www.xilinx.com/support/documentation/user_guides/ug331.pdf

Spartan-3A FPGAs are available in both standard and Pb-free, RoHS versions of each package, with the Pb-free version adding a "G" to the middle of the package code. Except for the thermal characteristics, all information for the standard package applies equally to the Pb-free package.

Pin Types

Most pins on a Spartan-3A FPGA are general-purpose, user-defined I/O pins. There are, however, up to 12 different functional types of pins on Spartan-3A FPGA packages, as outlined in Table 57. In the package footprint drawings that follow, the individual pins are color-coded according to pin type as in the table.

Table 57: **Types of Pins on Spartan-3A FPGAs**

Type / Color Code	Description	Pin Name(s) in Type
I/O	Unrestricted, general-purpose user-I/O pin. Most pins can be paired together to form differential I/Os.	IO_# IO_Lxxy_#
INPUT	Unrestricted, general-purpose input-only pin. This pin does not have an output structure, differential termination resistor, or PCI clamp diode.	IP_# IP_Lxxy_#
DUAL	Dual-purpose pin used in some configuration modes during the configuration process and then usually available as a user I/O after configuration. If the pin is not used during configuration, this pin behaves as an I/O-type pin. See UG332: *Spartan-3 Generation Configuration User Guide* for additional information on these signals.	M[2:0] PUDC_B CCLK MOSI/CSI_B D[7:1] D0/DIN DOUT CSO_B RDWR_B INIT_B A[25:0] VS[2:0] LDC[2:0] HDC
VREF	Dual-purpose pin that is either a user-I/O pin or Input-only pin, or, along with all other VREF pins in the same bank, provides a reference voltage input for certain I/O standards. If used for a reference voltage within a bank, all VREF pins within the bank must be connected.	IP/VREF_# IP_Lxxy_#/VREF_# IO/VREF_# IO_Lxxy_#/VREF_#
CLK	Either a user-I/O pin or an input to a specific clock buffer driver. Most packages have 16 global clock inputs that optionally clock the entire device. The exceptions are the TQ144 and the XC3S50A in the FT256 package). The RHCLK inputs optionally clock the right half of the device. The LHCLK inputs optionally clock the left half of the device. See the Using Global Clock Resources chapter in UG331: *Spartan-3 Generation FPGA User Guide* for additional information on these signals.	IO_Lxxy_#/GCLK[15:0], IO_Lxxy_#/LHCLK[7:0], IO_Lxxy_#/RHCLK[7:0]
CONFIG	Dedicated configuration pin, two per device. Not available as a user-I/O pin. Every package has two dedicated configuration pins. These pins are powered by VCCAUX. See the UG332: *Spartan-3 Generation Configuration User Guide* for additional information on the DONE and PROG_B signals.	DONE, PROG_B

Table 57: **Types of Pins on Spartan-3A FPGAs *(Continued)***

Type / Color Code	Description	Pin Name(s) in Type
PWR MGMT	Control and status pins for the power-saving Suspend mode. SUSPEND is a dedicated pin and is powered by V_{CCAUX}. AWAKE is a dual-purpose pin. Unless Suspend mode is enabled in the application, AWAKE is available as a user-I/O pin.	SUSPEND, AWAKE
JTAG	Dedicated JTAG pin - 4 per device. Not available as a user-I/O pin. Every package has four dedicated JTAG pins. These pins are powered by VCCAUX.	TDI, TMS, TCK, TDO
GND	Dedicated ground pin. The number of GND pins depends on the package used. All must be connected.	GND
VCCAUX	Dedicated auxiliary power supply pin. The number of VCCAUX pins depends on the package used. All must be connected. V_{CCAUX} can be either 2.5V or 3.3V. Set on board and using CONFIG VCCAUX constraint.	VCCAUX
VCCINT	Dedicated internal core logic power supply pin. The number of VCCINT pins depends on the package used. All must be connected to +1.2V.	VCCINT
VCCO	Along with all the other VCCO pins in the same bank, this pin supplies power to the output buffers within the I/O bank and sets the input threshold voltage for some I/O standards. All must be connected.	VCCO_#
N.C.	This package pin is not connected in this specific device/package combination but may be connected in larger devices in the same package.	N.C.

Notes:

1. # = I/O bank number, an integer between 0 and 3.

Package Pins by Type

Each package has three separate voltage supply inputs—VCCINT, VCCAUX, and VCCO—and a common ground return, GND. The numbers of pins dedicated to these functions vary by package, as shown in Table 58.

Table 58: **Power and Ground Supply Pins by Package**

Package	VCCINT	VCCAUX	VCCO	GND
VQ100	4	3	6	13
TQ144	4	4	8	13
FT256 (50A/200A/400A)	6	4	16	28
FT256 (700A/1400A)	15	10	13	50
FG320	6	8	16	32
FG400	9	8	22	43
FG484	15	10	24	53
FG676	23	14	36	77

A majority of package pins are user-defined I/O or input pins. However, the numbers and characteristics of these I/O depend on the device type and the package in which it is available, as shown in Table 59. The table shows the maximum number of single-ended I/O pins available, assuming that all I/O-, INPUT-, DUAL-, VREF-, and CLK-type pins are used as general-purpose I/O. AWAKE is counted here as a dual-purpose I/O pin. Likewise, the table shows the maximum number of differential pin-pairs available on the package. Finally, the table shows how the total maximum user-I/Os are distributed by pin type, including the number of unconnected—N.C.—pins on the device.

Not all I/O standards are supported on all I/O banks. The left and right banks (I/O banks 1 and 3) support higher output drive current than the top and bottom banks (I/O banks 0 and 2). Similarly, true differential output standards, such as LVDS, RSDS, PPDS, miniLVDS, and TMDS, are only supported in the top or bottom banks (I/O banks 0 and 2). Inputs are unrestricted. For more details, see the chapter "*Using I/O Resources*" in UG331.

1. Some VREFs are on INPUT pins. See pinout tables for details.

Electronic versions of the package pinout tables and footprints are available for download from the Xilinx website. Using a spreadsheet program, the data can be sorted and reformatted according to any specific needs. Similarly, the ASCII-text file is easily parsed by most scripting programs.

1. See the package material declaration data sheet for package mass.

Each package style is available in an environmentally friendly lead-free (Pb-free) option. The Pb-free packages include an extra 'G' in the package style name. For example, the standard "CS484" package becomes "CSG484" when ordered as the Pb-free option. The mechanical dimensions of the standard and Pb-free packages are similar. Package drawings and package material declaration data sheets (MDDS) are available on www.xilinx.com.

For additional package information, see UG112: *Device Package User Guide*.

Mechanical Drawings

Material Declaration Data Sheets (MDDS) are also available on the www.xilinx.com for each package.

Package Thermal Characteristics

The power dissipated by an FPGA application has implications on package selection and system design. The power consumed by a Spartan-3A FPGA is reported using either the XPower Power Estimator or the XPower Analyzer calculator integrated in the Xilinx® ISE® development software. Table 61 provides the thermal characteristics for the various Spartan-3A FPGA package offerings. This information is also available using the Thermal Query tool on xilinx.com (www.xilinx.com/cgi-bin/thermal/thermal.pl).

The junction-to-case thermal resistance (θ_{JC}) indicates the difference between the temperature measured on the package body (case) and the die junction temperature per watt of power consumption. The junction-to-board (θ_{JB}) value similarly reports the difference between the board and junction temperature. The junction-to-ambient (θ_{JA}) value reports the temperature difference between the ambient environment and the junction temperature. The θ_{JA} value is reported at different air velocities, measured in linear feet per minute (LFM). The “Still Air (0 LFM)” column shows the θ_{JA} value in a system without a fan. The thermal resistance drops with increasing air flow.

VQ100: 100-lead Very Thin Quad Flat Package

The XC3S50A and XC3S200 are available in the 100-lead very thin quad flat package, VQ100.

Table 62 lists all the package pins. They are sorted by bank number and then by pin name. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The VQ100 does not support Suspend mode (SUSPEND and AWAKE are not connected), the address output pins for the Byte-wide Peripheral Interface (BPI) configuration mode, or daisy chain configuration (DOUT is not connected).

Table 62 also indicates that some differential I/O pairs have different assignments between the XC3S50A and the XC3S200A, highlighted in light blue. See "Footprint Migration Differences," page 72 for additional information.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at

Footprint Migration Differences

The XC3S50A and XC3S200 have common VQ100 pinouts except for some differences in alignment of differential I/O pairs.

Differential I/O Alignment Differences

Some differential I/O pairs in the VQ100 on the XC3S50A FPGA are aligned differently than the corresponding pairs on the XC3S200A FPGAs, as shown in Table 64. All the mismatched pairs are in I/O Bank 2. These differences are indicated with the black diamond character (◆) in the footprint diagrams Figure 17 and Figure 18.

TQ144: 144-lead Thin Quad Flat Package

The XC3S50A is available in the 144-lead thin quad flat package, TQ144.

Table 65 lists all the package pins. They are sorted by bank number and then by pin name. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The XC3S50A does not support the address output pins for the Byte-wide Peripheral Interface (BPI) configuration mode.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at

FT256: 256-ball Fine-pitch, Thin Ball Grid Array

The 256-ball fine-pitch, thin ball grid array package, FT256, supports all five Spartan-3A FPGAs. The XC3S200A and XC3S400A have identical footprints, and the XC3S700A and XC3S1400A have identical footprints. The XC3S50A is compatible with the XC3S200A/XC3S400A but has 51 unconnected balls. The XC3S200A/XC3S400A is similar to the XC3S700A/XC3S1400A, but the XC3S700A/XC3S1400A adds more power and ground pins and therefore is not compatible.

Table 67 lists all the package pins for the XC3S50A, XC3S200A, and XC3S400A. They are sorted by bank number and then by pin name of the largest device. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The highlighted rows indicate pinout differences between the XC3S50A, the XC3S200A, and the XC3S400A FPGAs. The XC3S50A has 51 unconnected balls, indicated as N.C. (No Connection) in Table 67 and Figure 20 and with the black diamond character (◆) in Table 67. Figure 21 provides the common footprint for the XC3S200A and XC3S400A.

Table 67 also indicates that some differential I/O pairs have different assignments between the XC3S50A and the XC3S200A/XC3S400A, highlighted in light blue. See "Footprint Migration Differences," page 99 for additional information.

All other balls have nearly identical functionality on all three devices. Table 72 summarizes the XC3S50A FPGA footprint migration differences for the FT256 package.

The XC3S50A does not support the address output pins for the Byte-wide Peripheral Interface (BPI) configuration mode.

Table 68 lists all the package pins for the XC3S700A and XC3S1400A. They are sorted by bank number and then by pin name. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier. Figure 22 provides the common footprint for the XC3S200A and XC3S400A.

User I/Os by Bank

Table 69, Table 70, and Table 71 indicate how the available user-I/O pins are distributed between the four I/O banks on the FT256 package. The AWAKE pin is counted as a dual-purpose I/O.

The XC3S50A FPGA in the FT256 package has 51 unconnected balls, labeled with an “N.C.” type. These pins are also indicated in Figure 20.

Footprint Migration Differences

Unconnected Balls on XC3S50A

Table 72 summarizes any footprint and functionality differences between the XC3S50A and the XC3S200A or XC3S400A FPGAs that might affect easy migration between these devices in the FT256 package. The XC3S200A and XC3S400A have identical pinouts. The XC3S50A pinout is compatible, but there are 52 balls that are different. Generally, designs easily migrate upward from the XC3S50A to either the XC3S200A or XC3S400A. If using differential I/O, see Table 73. If using the BPI configuration mode (parallel Flash), see Table 74.

XC3S50A Differential I/O Alignment Differences

Also, some differential I/O pairs on the XC3S50A FPGA are aligned differently than the corresponding pairs on the XC3S200A or XC3S400A FPGAs, as shown in Table 73. All the mismatched pairs are in I/O Bank 2. The shading highlights the N side of each pair.

Differences Between XC3S200A/XC3S400A and XC3S700A/XC3S1400A

The XC3S700A and XC3S1400A FPGAs have several additional power and ground pins as compared to the XC3S200A and XC3S400A. Table 75 summarizes all the differences. All dedicated and dual-purpose configuration pins are in the same location.

FG320: 320-ball Fine-pitch Ball Grid Array

The 320-ball fine-pitch ball grid array package, FG320, supports two Spartan-3A FPGAs, the XC3S200A and the XC3S400A, as shown in Table 76 and Figure 23.

The FG320 package is an 18 x 18 array of solder balls minus the four center balls.

Table 76 lists all the package pins. They are sorted by bank number and then by pin name of the largest device. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The shaded rows indicate pinout differences between the XC3S200A and the XC3S400A FPGAs. The XC3S200A has three unconnected balls, indicated as N.C. (No Connection) in Table 76 and with the black diamond character (◆) in Table 76 and Figure 23.

All other balls have nearly identical functionality on all three devices. Table 79 summarizes the Spartan-3A FPGA footprint migration differences for the FG320 package.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at

www.xilinx.com/support/documentation/data_sheets/s3a_pin.zip.

User I/Os by Bank

Table 77 and Table 78 indicate how the available user-I/O pins are distributed between the four I/O banks on the FG320 package. The AWAKE pin is counted as a dual-purpose I/O.

Footprint Migration Differences

Table 79 summarizes any footprint and functionality differences between the XC3S200A and the XC3S400A FPGAs that might affect easy migration between devices available in the FG320 package. There are three such balls. All other pins not listed in Table 79 unconditionally migrate between Spartan-3A devices available in the FG320 package.

The arrows indicate the direction for easy migration.

Table 79: **FG320 Footprint Migration Differences**

Pin	Bank	XC3S200A	Migration	XC3S400A
E13	0	N.C.	→	INPUT
N7	2	N.C.	→	INPUT
P14	2	N.C.	→	INPUT/VREF
DIFFERENCES			**3**	

Legend:

→ This pin can unconditionally migrate from the device on the left to the device on the right. Migration in the other direction is possible depending on how the pin is configured for the device on the right.

FG400: 400-ball Fine-pitch Ball Grid Array

The 400-ball fine-pitch ball grid array, FG400, supports two different Spartan-3A FPGAs, the XC3S400A and the XC3S700A. Both devices share a common footprint for this package as shown in Table 80 and Figure 24.

Table 80 lists all the FG400 package pins. They are sorted by bank number and then by pin name. Pairs of pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at

www.xilinx.com/support/documentation/data_sheets/s3a_pin.zip.

User I/Os by Bank

Table 81 indicates how the 311 available user-I/O pins are distributed between the four I/O banks on the FG400 package. The AWAKE pin is counted as a dual-purpose I/O.

Footprint Migration Differences

The XC3S400A and XC3S700A FPGAs have identical footprints in the FG400 package. Designs can migrate between the XC3S400A and XC3S700A FPGAs without further consideration.

FG484: 484-ball Fine-pitch Ball Grid Array

The 484-ball fine-pitch ball grid array, FG484, supports both the XC3S700A and the XC3S1400A FPGAs. There are three pinout differences, as described in Table 85.

Table 82 lists all the FG484 package pins. They are sorted by bank number and then by pin name. Pairs of pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The shaded rows indicate pinout differences between the XC3S700A and the XC3S1400A FPGAs. The XC3S700A has three unconnected balls, indicated as N.C. (No Connection) in Table 82 and with the black diamond character (◆) in Table 82 and Figure 25.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at

www.xilinx.com/support/documentation/data_sheets/s3a_pin.zip.

User I/Os by Bank

Table 83 and Table 84 indicate how the user-I/O pins are distributed between the four I/O banks on the FG484 package. The AWAKE pin is counted as a dual-purpose I/O.

Footprint Migration Differences

Table 85 summarizes any footprint and functionality differences between the XC3S700A and the XC3S1400A FPGAs that might affect easy migration between devices available in the FG484 package. There are three such balls. All other pins not listed in Table 85 unconditionally migrate between Spartan-3A devices available in the FG484 package.

The arrows indicate the direction for easy migration.

Legend:

→ This pin can unconditionally migrate from the device on the left to the device on the right. Migration in the other direction is possible depending on how the pin is configured for the device on the right.

FG676: 676-ball Fine-pitch Ball Grid Array

The 676-ball fine-pitch ball grid array, FG676, supports the XC3S1400A FPGA.

Table 86 lists all the FG676 package pins. They are sorted by bank number and then by pin name. Pairs of pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The XC3S1400A has 17 unconnected balls, indicated as N.C. (No Connection) in Table 86 and with the black diamond character (◆) in Table 86 and Figure 27.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx website at:

User I/Os by Bank

Table 87 indicates how the 502 available user-I/O pins are distributed between the four I/O banks on the FG676 package. The AWAKE pin is counted as a dual-purpose I/O.

Footprint Migration Differences

The XC3S1400A FPGA is the only Spartan-3A device offered in the FG676 package. However, Table 88 summarizes footprint and functionality differences between the XC3S1400A and the XC3SD1800A in the Spartan-3A DSP family. There are 17 unconnected balls in the XC3S1400A that become 16 input-only pins and one I/O pin in the XC3SD1800A. All other pins not listed in Table 88 unconditionally migrate between the Spartan-3A devices and the Spartan-3A DSP devices available in the FG676 package. The arrows indicate the direction for easy migration. For more details on the Spartan-3A DSP family and pinouts, and additional differences in the FG676 pinout for the XC3SD3400A device, see DS610.

Legend:

→ This pin can unconditionally migrate from the device on the left to the device on the right. Migration in the other direction is possible depending on how the pin is configured for the device on the right.

02/02/07	1.1	Promoted to Preliminary status. Added DOUT pin to DUAL-type pins in Table 57. Corrected counts for DUAL pins and differential pairs in Table 59. Corrected minor typographical error on pin names for pin numbers P24 and P25 in Table 65. Highlighted the differences in differential I/O pairs between the XC3S50A and XC3S200A in the FT256 package, shown in Table 67 and added Table 73 and Table 74 to summarize the differences.
03/16/07	1.2	Corrected minor typographical error in Figure 19.
04/23/07	1.3	Added reference to compatible Spartan-3A DSP family.
05/08/07	1.4	Added note regarding banking rules.
07/10/07	1.5	Updated Thermal Characteristics in Table 61.
04/15/08	1.6	Added VQ100 for XC3S50A and XC3S200A and added FT256 for XC3S700A and XCS1400A to Table 58, Table 59, and Table 61. Updated Thermal Characteristics with latest data in Table 61. Corrected bank for T8 and type for U16 in Table 85. Removed VREF name on 6 unconnected N.C. pins for XC3S1400A FG676 in Table 86 and Figure 27.
