

ex Automotive Family FPGAs

Specifications

- 3,000 to 12,000 Available System Gates
- Maximum 512 Flip-Flops (Using CC Macros)
- 0.22 μm CMOS Process Technology
- Up to 132 User-Programmable I/O Pins

Features

- 250 MHz Internal Performance, Low-Power Antifuse FPGA
- Advanced Small-Footprint Packages
- Pin-to-Pin Compatibility with eX Commercial- and Industrial-Grade Devices
- Hot-Swap Compliant I/Os
- Single-Chip Solution
- Nonvolatile

- Live on Power-Up
- No Power-Up/Down Sequence Required for Supply Voltages
- Configurable Weak Resistor Pull-Up or Pull-Down for Tristated Outputs during Power-Up
- Individual Output Slew-Rate Control
- 2.5 V and 3.3 V I/Os
- Software Design Support with Designer and Libero[®] Integrated Design Environment (IDE) Tools
- Up to 100% Resource Utilization with 100% Pin Locking
- Deterministic Timing
- Unique In-System Diagnostic and Verification Capability with Silicon Explorer II
- Boundary Scan Testing in Compliance with IEEE Standard 1149.1 (JTAG)
- FuseLock[™] Secure Programming Technology Designed to Prevent Reverse Engineering and Design Theft

CS	49, 128	49, 128	128, 180

Note: * The eX family is also offered in commercial and industrial temperature grades with -F, -P, and Std. speed grades. Refer to the eX Family FPGAs datasheet for more details.

Ordering Information

Note: Automotive grade parts (A grade) devices are tested at room temperature to specifications that have been guard banded based on characterization across the recommended operating conditions. A-grade parts are not tested at extended temperatures. If testing to ensure guaranteed operation at extended temperatures is required, please contact your local Microsemi SoC Products Group Sales office to discuss testing options available.

1 – ex Automotive Family FPGAs

General Description

Based on a 0.22 μm CMOS process technology, the eX family of FPGAs is a low-cost solution for low-power, high-performance designs. With the automotive temperature grade support (-40°C to 125°C), the eX devices can address many in-cabin telematics and automobile interconnect applications. The low-power attributes inherent in antifuse technology make the eX devices ideal for designers who are looking to integrate low-density, power-sensitive automotive applications into a programmable logic solution, enabling quick time-to-market.

eX Family Architecture

The eX family is implemented on a high-voltage twin-well CMOS process using 0.22 μm design rules. The eX family architecture uses a “sea-of-modules” structure where the entire floor of the device is covered with a grid of logic modules with virtually no chip area lost to interconnect elements or routing. Interconnection among these logic modules is achieved using Microsemi’s patented metal-to-metal programmable antifuse interconnect elements. The antifuse interconnect is made up of a combination of amorphous silicon and dielectric material with barrier metals and has an “on” state resistance of $25\ \Omega$ with a capacitance of 1.0 fF for low-signal impedance. The antifuses are normally open circuit and, when programmed, form a permanent low-impedance connection. The eX family provides two types of logic modules, the register cell (R-cell) and the combinatorial cell (C-cell).

The R-cell contains a flip-flop featuring asynchronous clear, asynchronous preset, and clock enable (using the S0 and S1 lines) control signals (Figure 1-1). The R-cell registers feature programmable clock polarity selectable on a register-by-register basis. This provides additional flexibility while allowing mapping of synthesized functions into the eX FPGA. The clock source for the R-cell can be chosen from either the hardwired clock or the routed clock.

The C-cell implements a range of combinatorial functions up to five inputs (Figure 1-2 on page 1-2). Inclusion of the DB input and its associated inverter function enables the implementation of more than 4,000 combinatorial functions in the eX architecture in a single module.

Two C-cells can be combined together to create a flip-flop to imitate an R-cell via the use of the CC macro. This is particularly useful when implementing nontiming-critical paths and when the design engineer is running out of R-cells. For more information about the CC macro, refer to the [Maximizing Logic Utilization in eX, SX and SX-A FPGA Devices Using CC Macros](#) application note.

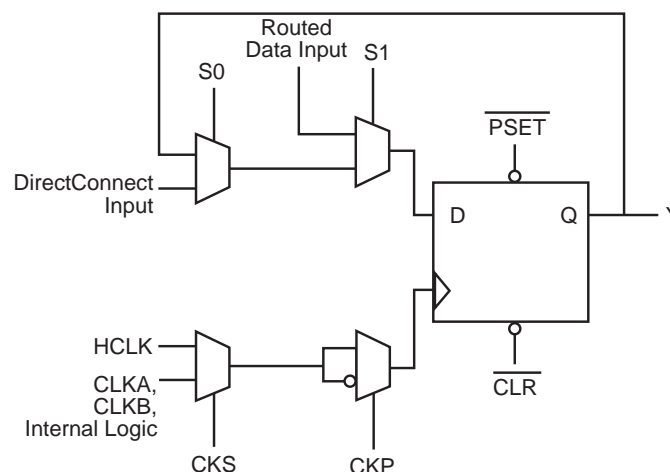

Figure 1-1 • R-Cell

Module Organization

C-cell and R-cell logic modules are arranged into horizontal banks called Clusters, each of which contains two C-cells and one R-cell in a C-R-C configuration.

Clusters are further organized into modules called SuperClusters for improved design efficiency and device performance, as shown in [Figure 1-3 on page 1-3](#). Each SuperCluster is a two-wide grouping of Clusters.

Routing Resources

Clusters and SuperClusters can be connected through the use of two innovative local routing resources called FastConnect and DirectConnect, which enable extremely fast and predictable interconnection of modules within Clusters and SuperClusters ([Figure 1-4 on page 1-3](#)). This routing architecture also dramatically reduces the number of antifuses required to complete a circuit, ensuring the highest possible performance.

DirectConnect is a horizontal routing resource that provides connections from a C-cell to its neighboring R-cell in a given SuperCluster. DirectConnect uses a hardwired signal path requiring no programmable interconnection to achieve its fast signal propagation time of less than 0.1 ns.

FastConnect enables horizontal routing between any two logic modules within a given SuperCluster and vertical routing with the SuperCluster immediately below it. Only one programmable connection is used in a FastConnect path, delivering maximum pin-to-pin propagation of 0.6 ns.

In addition to DirectConnect and FastConnect, the architecture makes use of two globally oriented routing resources, known as segmented routing and high-drive routing. Microsemi's segmented routing structure provides a variety of track lengths for extremely fast routing between SuperClusters. The exact combination of track lengths and antifuses within each path is chosen by the fully automatic place-and-route software to minimize signal propagation delays.

Figure 1-2 • C-Cell

Figure 1-3 • Cluster Organization

Figure 1-4 • DirectConnect and FastConnect for SuperClusters

Clock Resources

eX's high-drive routing structure provides three clock networks. The first clock, called HCLK, is hardwired from the HCLK buffer to the clock select MUX in each R-cell. HCLK cannot be connected to combinational logic. This provides a dedicated propagation path for the clock signal for the automotive-grade eX devices. The hardwired clock is tuned to provide a clock skew of less than 0.1 ns worst case. If not used, the HCLK pin must be tied Low or High and must not be left floating. Figure 1-5 describes the clock circuit used for the constant load HCLK.

HCLK does not function until the fourth clock cycle each time the device is powered up to prevent false output levels due to any possible slow power-on-reset signal and fast start-up clock circuit. To activate HCLK from the first cycle, the TRST pin must be reserved in the Designer software and the pin must be tied to GND on the board. (See the "TRST, I/O Boundary Scan Reset Pin" on page 1-29).

The remaining two clocks (CLKA, CLKB) are global routed clock networks that can be sourced from external pins or from internal logic signals (via the CLKINT routed clock buffer) within the eX device. CLKA and CLKB may be connected to sequential cells or to combinational logic. If CLKA or CLKB is sourced from internal logic signals, the external clock pin cannot be used for any other input and must be tied Low or High and must not float. Figure 1-6 describes the CLKA and CLKB circuit used in eX devices.

Table 1-1 describes the possible connections of the routed clock networks, CLKA and CLKB.

Unused clock pins must not be left floating and must be tied to High or Low.

Other Architectural Features

Performance

The combination of the various architectural features enables automotive-grade eX devices to operate with internal clock frequencies at 250 MHz for fast execution of complex logic functions.

Automotive-grade eX devices are the optimal platforms upon which to integrate in-cabin telematics and automobile interconnect applications previously only contained in ASICs or gate arrays.

eX devices meet the performance goals of gate arrays, and, at the same time, present significant improvements in cost and time to market. Using timing-driven place-and-route tools, designers can achieve highly deterministic device performance.

User Security

The FuseLock advantage is designed to prevent unauthorized users from being able to read back the contents of a Microsemi antifuse FPGA. In addition to the inherent strengths of the architecture, there is a special Security Fuse inside the eX device that is intended to disable the probing circuitry and prohibit further programming of the device. This Fuse cannot be accessed or bypassed without destroying access to the rest of the device, making Microsemi antifuse FPGAs highly resistant to both invasive and more subtle noninvasive attacks.

Look for this symbol to ensure your valuable IP is protected with industry-standard security.

Figure 1-7 • FuseLock

For more information, refer to the [Implementation of Security in Actel Antifuse FPGAs](#) application note.

I/O Modules

Each I/O on an eX device can be configured as an input, an output, a tristate output, or a bidirectional pin. I/O cells in eX devices do not contain embedded latches or flip-flops and can be inferred directly from HDL code. The device can easily interface with any other device in the system, which in turn enables parallel design of system components and reduces overall design time.

All unused I/Os are configured as tristate outputs by Designer software, for maximum flexibility when designing new boards or migrating existing designs. However, it is still recommended to tie all unused I/O pins to GND on the board. Each I/O module has an available pull-up or pull-down resistor of approximately 50 k Ω that can configure the I/O in a known state during power-up. Just shortly before V_{CCA} reaches 2.5 V, the resistors are disabled and the I/Os will be controlled by user logic.

Table 1-2 describes the I/O features of eX devices. For more information on I/Os, refer to the [Microsemi eX, SX-A, and RT54SX-S I/Os](#) application note.

The automotive eX devices support I/O operation at 2.5 V and 3.3 V.

The detailed description of the I/O pins in eX automotive devices can be found in "Pin Descriptions" on page 1-28.

Table 1-2 • I/O Features

Function	Description
Input Buffer Threshold Selection	<ul style="list-style-type: none"> • 3.3 V LVTTTL • 2.5 V LVCMOS2
Nominal Output Drive	<ul style="list-style-type: none"> • 3.3 V LVTTTL • 2.5 V LVCMO 2
Output Buffer	"Hot-Swap" Capability <ul style="list-style-type: none"> • I/O on an unpowered device does not sink current • Can be used for "cold sparing" • Selectable on an individual I/O basis Individually selectable low-slew option
Power-Up	Individually selectable pull-ups and pull-downs during power-up (default is to power-up in tristate) Enables deterministic power-up of device VCCA and VCCI can be powered in any order

Hot Swapping

eX I/Os are configured to be hot-swappable. During power-up/down (or partial up/down), all I/Os are tristated, provided VCCA ramps up within a diode drop of VCCI. VCCA and VCCI do not have to be stable during power-up/down, and they do not require a specific power-up or power-down sequence in order to avoid damage to the eX devices. In addition, all outputs can be programmed to have a weak resistor pull-up or pull-down for tristate output at power-up. After the eX device is plugged into an electrically active system, the device will not degrade the reliability of or cause damage to the host system. The device's output pins are driven to a high impedance state until normal chip operating conditions are reached. Please see the application note, [Microsemi SX-A and RT54SX-S Devices in Hot-Swap and Cold-Sparing Applications](#), which also applies to eX devices, for more information on hot swapping.

Power Requirements

Power consumption is extremely low for the automotive-grade eX devices due to the low capacitance of the antifuse interconnects. The antifuse architecture does not require active circuitry to hold a charge (as do SRAM or EPROM), making it the lowest-power FPGA architecture available today.

Figure 1-8 through Figure 1-11 on page 1-8 show some sample power characteristics of eX devices.

Notes:

1. Device filled with 16-bit counters.
2. V_{CCA} , $V_{CCI} = 2.7\text{ V}$, device tested at room temperature.

Figure 1-8 • eX Dynamic Power Consumption – High Frequency

Notes:

Figure 1-11 • System Power at 5%, 10%, and 15% Duty Cycle

Boundary Scan Testing (BST)

All eX devices are IEEE 1149.1 compliant. eX devices offer superior diagnostic and testing capabilities by providing Boundary Scan Testing (BST) and probing capabilities. These functions are controlled through the special test pins (TMS, TDI, TCK, TDO and TRST). The functionality of each pin is defined by two available modes, Dedicated and Flexible, and is described in [Table 1-3](#). In the dedicated test mode, TCK, TDI, and TDO are dedicated pins and cannot be used as regular I/Os. In flexible mode (default mode), TMS should be set High through a pull-up resistor of 10 k Ω . TMS can be pulled Low to initiate the test sequence.

Table 1-3 • Boundary Scan Pin Functionality

Dedicated Test Mode	Flexible Mode
TCK, TDI, TDO are dedicated BST pins	TCK, TDI, TDO are flexible and may be used as I/Os
No need for pull-up resistor for TMS and TDI	Use a pull-up resistor of 10 k Ω on TMS

Dedicated Test Mode

In Dedicated mode, all JTAG pins are reserved for BST; designers cannot use them as regular I/Os. An internal pull-up resistor is automatically enabled on both TMS and TDI pins, and the TMS pin will function as defined in the IEEE 1149.1 (JTAG) specification.

To select Dedicated mode, users need to reserve the JTAG pins in Designer software by checking the "Reserve JTAG" box in "Device Selection Wizard" ([Figure 1-12](#)). JTAG pins comply with LVTTTL/TTL I/O specification regardless of whether they are used as a user I/O or a JTAG I/O. Refer to the ["3.3 V LVTTTL Electrical Specifications"](#) on [page 1-16](#) for detailed specifications.

Figure 1-12 • Device Selection Wizard

Flexible Mode

In Flexible mode, TDI, TCK and TDO may be used as either user I/Os or as JTAG input pins. The internal resistors on the TMS and TDI pins are disabled in flexible JTAG mode, and an external 10 k Ω pull-resistor to V_{CC1} is required on the TMS pin.

To select the Flexible mode, users need to uncheck the "Reserve JTAG" box in "Device Selection Wizard" in the Designer software. The functionality of TDI, TCK, and TDO pins is controlled by the BST TAP controller. The TAP controller receives two control inputs; TMS and TCK. Upon power-up, the TAP controller enters the Test-Logic-Reset state. In this state, TDI, TCK, and TDO function as user I/Os. The TDI, TCK, and TDO pins are transformed from user I/Os into BST pins when the TMS pin is Low at the first rising edge of TCK. The TDI, TCK, and TDO pins return to user I/Os when TMS is held High for at least five TCK cycles.

Table 1-4 describes the different configuration requirements of BST pins and their functionality in different modes.

Table 1-4 • Boundary Scan Pin Configurations and Functions

Mode	Designer "Reserve JTAG" Selection	TAP Controller State
Dedicated (JTAG)	Checked	Any
Flexible (User I/O)	Unchecked	Test-Logic-Reset
Flexible (JTAG)	Unchecked	Any EXCEPT Test-Logic-Reset

TRST Pin

The TRST pin functions as a dedicated Boundary-Scan Reset pin when the "Reserve JTAG Test Reset" option is selected as shown in Figure 1-12. An internal pull-up resistor is permanently enabled on the TRST pin in this mode. It is recommended to connect this pin to GND in normal operation to keep the JTAG state controller in the Test-Logic-Reset state. When JTAG is being used, it can be left floating or be driven High.

When the "Reserve JTAG Test Reset" option is not selected, this pin will function as a regular I/O. If unused as an I/O in the design, it will be configured as a tristated output.

JTAG Instructions

Table 1-5 lists the supported instructions with the corresponding IR codes for eX devices.

Table 1-5 • JTAG Instruction Code

Instructions (IR4: IR0)	Binary Code
EXTEST	00000
SAMPLE / PRELOAD	00001
INTEST	00010
USERCODE	00011
IDCODE	00100
HIGHZ	01110
CLAMP	01111
Diagnostic	10000
BYPASS	11111
Reserved	All others

Table 1-6 lists the codes returned after executing the IDCODE instruction for eX devices. Note that bit 0 is always "1." Bits 11-1 are always "02F," which is Microsemi's manufacturer code.

Table 1-6 • IDCODE for eX Devices

Device	Revision	Bits 31-28	Bits 27-12
eX64	0	8	40B2, 42B2
eX128	0	9	40B0, 42B0
eX256	0	9	40B5, 42B5
eX64	1	A	40B2, 42B2
eX128	1	B	40B0, 42B0
eX256	1	B	40B5, 42B5

Programming

Device programming is supported through Silicon Sculptor series of programmers. In particular, Silicon Sculptor II is a compact, robust, single-site and multi-site device programmer for the PC.

With standalone software, Silicon Sculptor II allows concurrent programming of multiple units from the same PC, ensuring the fastest programming times possible. Each fuse is subsequently verified by Silicon Sculptor II to insure correct programming. In addition, integrity tests ensure that no extra fuses are programmed. Silicon Sculptor II also provides extensive hardware self-testing capability.

The procedure for programming an eX device using Silicon Sculptor II is as follows:

1. Load the *.AFM file
2. Select the device to be programmed
3. Begin programming

When the design is ready to go to production, Microsemi offers device volume-programming services either through distribution partners or via in-house programming from the factory.

For more details on programming eX Automotive devices, please refer to the [Programming Antifuse Devices](#) and the [Silicon Sculptor II User's Guides](#).

Probing Capabilities

Automotive-grade eX devices provide internal probing capability that is accessed with the JTAG pins. The Silicon Explorer II Diagnostic hardware is used to control the TDI, TCK, TMS, and TDO pins to select the desired nets for debugging. The user assigns the selected internal nets in the Silicon Explorer II software to the PRA/PRB output pins for observation. Probing functionality is activated when the BST pins are in JTAG mode and the TRST pin is driven High or left floating. If the TRST pin is held Low, the TAP controller will remain in the Test-Logic-Reset state, so no probing can be performed. The Silicon Explorer II automatically places the device into JTAG mode, but the user must drive the TRST pin High or allow the internal pull-up resistor to pull TRST High.

When you select the "Reserve Probe" box, as shown in [Figure 1-12 on page 1-9](#), the Designer software reserves the PRA and PRB pins as dedicated outputs for probing. This "reserve" option is merely a guideline. If the Designer software requires that the PRA and PRB pins be user I/Os to achieve successful layout, the tool will use these pins for user I/Os. If you assign user I/Os to the PRA and PRB pins and select the "Reserve Probe" option, Designer Layout will override the option and place user I/Os on those pins.

To allow for probing capabilities, the security fuse must not be programmed. Programming the security fuse will disable the probe circuitry. [Table 1-7 on page 1-12](#) summarizes the possible device configurations for probing once the device leaves the "Test-Logic-Reset" JTAG state.

Silicon Explorer II Probe

Silicon Explorer II is an integrated hardware and software solution that, in conjunction with Designer software tools, allows users to examine any of the internal nets of the device while it is operating in a prototype or a production system. The user can probe into an eX device via the PRA and PRB pins without changing the placement and routing of the design and without using any additional resources. Silicon Explorer II's noninvasive method does not alter timing or loading effects, thus shortening the debug cycle.

Silicon Explorer II does not require relayout or additional MUXes to bring signals out to an external pin, which is necessary when using programmable logic devices from other suppliers.

Silicon Explorer II samples data at 100 MHz (asynchronous) or 66 MHz (synchronous). Silicon Explorer II attaches to a PC's standard COM port, turning the PC into a fully functional 18-channel logic analyzer. Silicon Explorer II allows designers to complete the design verification process at their desks and reduces verification time from several hours per cycle to a few seconds.

The Silicon Explorer II tool uses the boundary scan ports (TDI, TCK, TMS and TDO) to select the desired nets for verification. The selected internal nets are assigned to the PRA/PRB pins for observation. [Figure 1-13](#) illustrates the interconnection between Silicon Explorer II and the automotive-grade eX device to perform in-circuit verification.

Design Considerations

The TDI, TCK, TDO, PRA, and PRB pins should not be used as input or bidirectional ports. Since these pins are active during probing, critical signals input through these pins are not available while probing. In addition, the Security Fuse should not be programmed because doing so disables the probe circuitry. It is recommended to use a 70Ω series termination resistor on every probe connector (TDI, TCK, TMS, TDO, PRA, PRB). The 70 Ω series termination is used to prevent data transmission corruption during probing and reading back the checksum.

Table 1-7 • Device Configuration Options for Probe Capability (TRST pin reserved)

JTAG Mode	TRST ¹	Security Fuse Programmed	PRA, PRB ²	TDI, TCK, TDO ²
Dedicated	Low	No	User I/O ³	Probing Unavailable
Flexible	Low	No	User I/O ³	User I/O ³
Dedicated	High	No	Probe Circuit Outputs	Probe Circuit Inputs
Flexible	High	No	Probe Circuit Outputs	Probe Circuit Inputs
–	–	Yes	Probe Circuit Secured	Probe Circuit Secured

Notes:

1. If TRST pin is not reserved, the device behaves according to TRST = High in the table.
2. Avoid using the TDI, TCK, TDO, PRA, and PRB pins as input or bidirectional ports. Since these pins are active during probing, input signals will not pass through these pins and may cause contention.
3. If no user signal is assigned to these pins, they will behave as unused I/Os in this mode. Unused pins are automatically tristated by Designer software.

Figure 1-13 • Silicon Explorer II Probe Setup

Development Tool Support

The automotive-grade eX family of FPGAs is fully supported by both the Libero[®] Integrated Design Environment (IDE) and Designer FPGA Development software. Libero IDE is a design management environment, seamlessly integrating design tools while guiding the user through the design flow, managing all design and log files, and passing necessary design data among tools. Libero IDE allows users to integrate both schematic and HDL synthesis into a single flow and verify the entire design in a single environment. Libero IDE includes Synplify[®] for Actel from Synplicity[®], ViewDraw[®] for Actel from Mentor Graphics[®], ModelSim[®] HDL Simulator from Mentor Graphics, WaveFormer Lite[™] from SynaptiCAD[®], and Designer software from Microsemi. Refer to the [Libero IDE flow](#) (located on the Microsemi SoC Products Group website) diagram for more information.

Designer software is a place-and-route tool and provides a comprehensive suite of backend support tools for FPGA development. The Designer software includes timing-driven place-and-route, and a world-class integrated static timing analyzer and constraints editor. With the Designer software, a user can select and lock package pins while only minimally impacting the results of place-and-route. Additionally, the back-annotation flow is compatible with all the major simulators and the simulation results can be cross-probed with Silicon Explorer II, Microsemi's integrated verification and logic analysis tool. Another tool included in the Designer software is the SmartGen core builder, which easily creates popular and commonly used logic functions for implementation into your schematic or HDL design. Designer software is compatible with the most popular FPGA design entry and verification systems from companies such as Mentor Graphics, Synplicity, Synopsys[®], and Cadence Design Systems. The Designer software is available for both the Windows and UNIX operating systems.

Operating Conditions

Table 1-8 • Absolute Maximum Ratings*

Symbol	Parameter	Limits	Units
VCCI	DC Supply Voltage for I/Os	-0.3 to +4.0	V
VCCA	DC Supply Voltage for Array	-0.3 to +3.0	V
VI	Input Voltage	-0.5 to $V_{CCI} + 0.5$	V
VO	Output Voltage	-0.5 to V_{CCI}	V
T _{STG}	Storage Temperature	-65 to +150	°C
T _j	Maximum Junction Temperature	-65 to +150	°C

Note: *Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. Exposure to temperatures between absolute maximum and recommended operating conditions for extended periods may affect device reliability. Devices should not be operated outside the Recommended Operating Conditions.

Table 1-9 • Recommended Operating Conditions

Parameter	Automotive	Units
Temperature Range (T _j)	-40 to +125	°C
2.5 V Power Supply Range (VCCA, VCCI)	2.3 to 2.7	V
3.3 V Power Supply Range (VCCI)	3.0 to 3.6	V

Note: Automotive grade parts (A grade) devices are tested at room temperature to specifications that have been guard banded based on characterization across the recommended operating conditions. A-grade parts are not tested at extended temperatures. If testing to ensure guaranteed operation at extended temperatures is required, contact your local Microsemi SoC Products Group Sales office to discuss testing options available.

CIN	Input Capacitance			10	pF
ICC3	Standby Current			25	mA
IV Curve	Can be derived from the IBIS model at www.microsemi.com/soc/download/ibis/default.aspx .				

Notes:

1. t_R is the transition time from 0.7 V to 1.7 V.
2. t_F is the transition time from 1.7 V to 0.7 V.
3. ICC = ICC1 + ICCA

3.3 V LVTTTL Electrical Specifications

Symbol	Parameter		Automotive		Units
			Min.	Max.	
VOH	VCCI = MIN, VI = VIH or VIL	(IOH = -3.5 mA)	2.4		V
VOL	VCCI = MIN, VI = VIH or VIL	(IOL = 3.5 mA)		0.4	V
VIL	Input Low Voltage, VOUT ≤ VOL(max)			0.8	V
VIH	Input High Voltage, VOUT ≥ VOH(min)		2.0		V
IIL / IIH	Input Leakage Current, VIN = VCCI or GND		-20	20	μA
IOZ	Tristate Output Leakage Current, VOUT = Tristate		-20	20	μA
t _R , t _{F1,2}	Input Transition Time t _R , t _F			10	ns
CIN	Input Capacitance			10	pF
ICC3	Standby Current			35	mA
IV Curve	Can be derived from the IBIS model at www.microsemi.com/soc/download/ibis/default.aspx .				

Notes:

1. t_R is the transition time from 0.8 V to 2.0 V.
2. t_F is the transition time from 2.0 V to 0.8 V.
3. ICC = ICC1 + ICCA
4. JTAG pins comply with LVTTTL/TTL I/O specification regardless of whether they are used as a user I/O or a JTAG I/O.

5 V Tolerance of 3.3 V LVTTTL I/Os Using a Tristate Buffer

Input: 3.3 V LVTTTL I/Os are 5-V-input tolerant only if the non-PCI mode is used (no clamp diode).

Output: To configure an eX device to drive 5 V with $V_{CCI} = 3.3$ V, users can utilize an Open Drain configuration of the I/O cell with an array inverter cell and an external pull-up resistor to 5 V. The recommended configuration is illustrated in Figure 1-14. The I/O configuration must be set to LVTTTL to disable the PCI clamp diode. For the recommended resistor value in a specific application, please contact Microsemi SoC Products Group Technical Support. For more details, refer to the Design Tips section of the *Microsemi eX, SX-A and RT54SX-S I/Os* application note.

Figure 1-14 • Open-Drain Configuration for eX

Power Dissipation

Power consumption for eX devices can be divided into two components: static and dynamic.

Static Power Component

The power due to standby current is typically a small component of the overall power. Typical standby current for eX devices is listed in Table 1-10 on page 1-15. For example, the typical static power for eX128 at 3.3 V V_{CCI} is:

$$I_{CC} * V_{CCA} = 795 \mu\text{A} * 2.5 \text{ V} = 1.99 \text{ mW}$$

EQ 1

Dynamic Power Component

Power dissipation in CMOS devices is usually dominated by the dynamic power dissipation. This component is frequency-dependent and a function of the logic and the external I/O. Dynamic power dissipation results from charging internal chip capacitance. An additional component of the dynamic power dissipation is the totem pole current in the CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent dynamic power dissipation.

$$\text{Dynamic power dissipation} = C_{EQ} * V_{CCA}^2 * F$$

EQ 2

where:

C_{EQ} = Equivalent capacitance

F = switching frequency

Equivalent capacitance is calculated by measuring ICCA at a specified frequency and voltage for each circuit component of interest. Measurements have been made over a range of frequencies at a fixed value of VCCA. Equivalent capacitance is frequency-independent, so the results can be used over a wide range of operating conditions. Equivalent capacitance values are shown below.

CEQ Values for eX Devices

Combinatorial modules (Ceqcm)	1.70 pF
Sequential modules (Ceqsm)	1.70 pF
Input buffers (Ceqi)	1.30 pF
Output buffers (Ceqo)	7.40 pF
Routed array clocks (Ceqcr)	1.05 pF

The variable and fixed capacitance of other device components must also be taken into account when estimating the dynamic power dissipation.

Table 1-11 shows the capacitance of the clock components of eX devices.

Table 1-11 • Capacitance of Clock Components of eX Devices

	eX64	eX128	eX256
Dedicated array clock – variable (Ceqhv)	0.85 pF	0.85 pF	0.85 pF
Dedicated array clock – fixed (Ceqhf)	18.00 pF	20.00 pF	25.00 pF
Routed array clock A (r1)	23.00 pF	28.00 pF	35.00 pF
Routed array clock B (r2)	23.00 pF	28.00 pF	35.00 pF

The estimation of the dynamic power dissipation is a piece-wise linear summation of the power dissipation of each component.

Dynamic power dissipation

$$= VCCA^2 * [(m_c * C_{eqcm} * f_{m_c})_{\text{Comb Modules}} + (m_s * C_{eqsm} * f_{m_s})_{\text{Seq Modules}} + (n * C_{eqi} * f_n)_{\text{Input Buffers}} + (0.5 * (q1 * C_{eqcr} * fq1) + (r1 * fq1))_{\text{RCLKA}} + (0.5 * (q2 * C_{eqcr} * fq2) + (r2 * fq2))_{\text{RCLKB}} + (0.5 * (s1 * C_{eqhv} * fs1) + (C_{eqhf} * fs1))_{\text{HCLK}}] + VCCI^2 * [(p * (C_{eqo} + C_L) * fp)_{\text{Output Buffers}}]$$

where:

- m_c = Number of combinatorial cells switching at frequency f_m , typically 20% of C-cells
- m_s = Number of sequential cells switching at frequency f_m , typically 20% of R-cells
- n = Number of input buffers switching at frequency f_n , typically number of inputs / 4
- p = Number of output buffers switching at frequency f_p , typically number of outputs / 4
- $q1$ = Number of R-cells driven by routed array clock A
- $q2$ = Number of R-cells driven by routed array clock B
- $r1$ = Fixed capacitance due to routed array clock A
- $r2$ = Fixed capacitance due to routed array clock B
- $s1$ = Number of R-cells driven by dedicated array clock
- C_{eqcm} = Equivalent capacitance of combinatorial modules
- C_{eqsm} = Equivalent capacitance of sequential modules
- C_{eqi} = Equivalent capacitance of input buffers
- C_{eqcr} = Equivalent capacitance of routed array clocks
- C_{eqhv} = Variable capacitance of dedicated array clock
- C_{eqhf} = Fixed capacitance of dedicated array clock
- C_{eqo} = Equivalent capacitance of output buffers
- C_L = Average output loading capacitance, typically 10pF
- f_{m_c} = Average C-cell switching frequency, typically F/10
- f_{m_s} = Average R-cell switching frequency, typically F/10
- f_n = Average input buffer switching frequency, typically F/5
- f_p = Average output buffer switching frequency, typically F/5
- $fq1$ = Frequency of routed clock A
- $fq2$ = Frequency of routed clock B
- $fs1$ = Frequency of dedicated array clock

The eX, SX-A and RTSX-S Power Calculator can be used to estimate the total power dissipation (static and dynamic) of eX devices and can be found at www.microsemi.com/soc/techdocs/calculators.aspx.

Junction Temperature

The temperature variable in the Designer software refers to the junction temperature, not the ambient temperature. This is an important distinction because the heat generated from dynamic power consumption is usually hotter than the ambient temperature. EQ , shown below, can be used to calculate junction temperature. Please refer to Table 1-9 on page 1-15 for the recommended operating conditions.

$$\text{Junction Temperature} = \Delta T + T_a(1)$$

EQ 3

Where:

T_a = Ambient Temperature

ΔT = Temperature gradient between junction (silicon) and ambient = $\theta_{ja} * P$

P = Power

θ_{ja} = Junction to ambient of package. θ_{ja} numbers are located in the "Package Thermal Characteristics" on page 1-19.

Package Thermal Characteristics

The device junction-to-case thermal characteristic is θ_{jc} , and the junction-to-ambient air characteristic is θ_{ja} . The thermal characteristics for θ_{ja} are shown with two different air flow rates. θ_{jc} is provided for reference. The maximum junction temperature is 150°C.

The maximum power dissipation allowed for eX devices is a function of θ_{ja} . A sample calculation of the absolute maximum power dissipation allowed for a TQFP 100-pin package at automotive temperature and still air is as follows:

$$\text{Maximum Power Allowed} = \frac{\text{Max. junction temp. (}^\circ\text{C)} - \text{Max. ambient temp. (}^\circ\text{C)}}{\theta_{ja}(\text{}^\circ\text{C/W)}} = \frac{150^\circ\text{C} - 125^\circ\text{C}}{33.5^\circ\text{C/W}} = 0.746 \text{ W}$$

Table 1-12 • Package Thermal Characteristics

Package Type	Pin Count	θ_{jc}	θ_{ja}			Units
			Still Air	θ_{ja} 1.0 m/s	θ_{ja} 2.5 m/s	
Thin Quad Flat Pack	64	12.0	42.4	36.3	34.0	°C/W

Cell Timing Characteristics

Figure 1-17 • Flip-Flops

Timing Characteristics

Timing characteristics for eX devices fall into three categories: family-dependent, device-dependent, and design-dependent. The input and output buffer characteristics are common to all eX family members. Internal routing delays are device-dependent. Design dependency means actual delays are not determined until after placement and routing of the user's design are complete. Delay values may then be determined by using the Timer tool in the Designer software or performing simulation with post-layout delays.

Table 1-17 on page 1-25 lists sample timing characteristics for automotive eX devices.

Critical Nets and Typical Nets

Propagation delays are expressed only for typical nets, which are used for initial design performance evaluation. Critical net delays can then be applied to the most timing critical paths. Critical nets are determined by net property assignment prior to placement and routing. Up to six percent of the nets in a design may be designated as critical.

Long Tracks

Some nets in the design use long tracks. Long tracks are special routing resources that span multiple rows, columns, or modules. Long tracks employ three to five antifuse connections. This increases capacitance and resistance, resulting in longer net delays for macros connected to long tracks. Typically, no more than six percent of nets in a fully utilized device require long tracks. Long tracks contribute approximately 4 ns to 8.4 ns delay. This additional delay is represented statistically in higher fanout routing delays.

Timing Derating

eX devices are manufactured with a CMOS process. Therefore, device performance varies according to temperature, voltage, and process changes. Minimum timing parameters reflect maximum operating voltage, minimum operating temperature, and best-case processing. Maximum timing parameters reflect minimum operating voltage, maximum operating temperature, and worst-case processing.

Temperature and Voltage Derating Factors

Table 1-16 • Temperature and Voltage Derating Factors
 (Normalized to Worst-Case Commercial, $T_J = 125^\circ\text{C}$, $V_{CCA} = 2.3\text{ V}$)

VCCA	Junction Temperature (T_J)						
	-55	-40	0	25	70	85	125
2.3	0.70	0.70	0.77	0.78	0.88	0.91	1.00
2.5	0.65	0.66	0.72	0.73	0.83	0.85	0.93
2.7	0.61	0.62	0.67	0.69	0.78	0.80	0.88

eX Family Timing Characteristics

Table 1-17 • eX Family Timing Characteristics
(Worst-Case Automotive Conditions, VCCA = 2.3 V, T_J = 125°C)

Parameter	Description	'Std.' Speed		Units
		Min.	Max.	
C-Cell Propagation Delays¹				
t _{PD}	Internal Array Module		1.1	ns

4. Delays based on 35 pF loading.

Pin Descriptions

CLKA/B **Routed Clock A and B**

These pins are clock inputs for clock distribution networks. Input levels are compatible with LVTTTL and LVCMOS specifications. The clock input is buffered prior to clocking the R-cells. If not used, this pin must be set Low or High on the board. It must not be left floating.

GND **Ground**

Low supply voltage.

HCLK **Dedicated (Hardwired) Array Clock**

This pin is the clock input for sequential modules. Input levels are compatible with LVTTTL and LVCMOS specifications. This input is directly wired to each R-cell and offers clock speeds independent of the number of R-cells being driven. If not used, this pin must be set Low or High on the board. It must not be left floating.

I/O **Input/Output**

The I/O pin functions as an input, output, tristate, or bidirectional buffer. Input and output levels are compatible with LVTTTL and LVCMOS specifications. Unused I/O pins are automatically tristated by the Designer software. It is recommended to tie unused I/Os to Low on the board. This also applies to dual-purpose pins when configured as I/Os.

NC **No Connection**

This pin is not connected to circuitry within the device. These pins can be driven to any voltage or can be left floating with no effect on the operation of the device.

PRA/PRB, I/O **Probe A/B**

The Probe pin is used to output data from any user-defined design node within the device. This diagnostic pin can be used independently or in conjunction with the other probe pin to allow real-time diagnostic output of any signal path within the device. The Probe pin can be employed as a user-defined I/O when verification has been completed. The pin's probe capabilities can be permanently disabled to protect programmed design confidentiality.

TCK, I/O **Test Clock**

Test clock input for diagnostic probe and device programming. In flexible mode, TCK becomes active when the TMS pin is set Low (refer to [Table 1-3 on page 1-9](#)). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state.

TDI, I/O **Test Data Input**

Serial input for boundary scan testing and diagnostic probe. In flexible mode, TDI is active when the TMS pin is set Low (refer to [Table 1-3 on page 1-9](#)). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state.

TDO, I/O **Test Data Output**

Serial output for boundary scan testing. In flexible mode, TDO is active when the TMS pin is set Low (refer to [Table 1-3 on page 1-9](#)). This pin functions as an I/O when the boundary scan state machine reaches the "logic reset" state. When Silicon Explorer is being used, TDO will act as an output when the "checksum" command is run. It will return to a user I/O when "checksum" is complete.

TMS **Test Mode Select**

The TMS pin controls the use of the IEEE 1149.1 boundary scan pins (TCK, TDI, TDO, TRST). In flexible mode, when the TMS pin is set Low, the TCK, TDI, and TDO pins are boundary scan pins (refer to [Table 1-3 on page 1-9](#)). Once the boundary scan pins are in test mode, they will remain in that mode until the internal boundary scan state machine reaches the "logic reset" state. At this point, the boundary scan pins will be released and will function as regular I/O pins. The "logic reset" state is reached five TCK cycles after the TMS pin is set High. In dedicated test mode, TMS functions as specified in the IEEE 1149.1 specifications.

TRST, I/O Boundary Scan Reset Pin

Once it is configured as the JTAG Reset pin, the TRST pin functions as an active-low input to asynchronously initialize or reset the boundary scan circuit. The TRST pin is equipped with an internal pull-up resistor. This pin functions as an I/O when the “Reserve JTAG Reset Pin” is not selected in the Designer software.

VCCI Supply Voltage

Supply voltage for I/Os.

VCCA Supply Voltage

Supply voltage for Array.

3 – Datasheet Information

List of Changes

The following table lists critical changes that were made in the current version of the document.

Revision	Changes	Page
Revision 5 (October 2012)	The datasheet was updated for Microsemi, including hyperlinks to the Microsemi SoC Products Group website. The versioning system has been changed. Datasheets are assigned a revision number that increments each time the datasheet is revised.	All
	The "Features" section and "User Security" section were updated to clarify that although no existing security measures can give an absolute guarantee, Microsemi FPGAs implement industry standard security (SAR 34676).	i, 1-5
	Package names used in the product profile tables and "Package Pin Assignments" section were revised to match standards given in <i>Package Mechanical Drawings</i> (SAR 34778).	i, 2-1
v3.2 (June 2006)	The "Ordering Information" section was updated to include RoHS information. The TQFP measurement was also updated.	ii
	The "Dedicated Test Mode" section was updated.	1-9
	Note 4 was added to the "3.3 V LVTTTL Electrical Specifications" table.	1-16
v3.1 (April 2006)	A note was added to the "Ordering Information" section.	ii
	The Junction temperature was added to Table 1-8 • Absolute Maximum Ratings*.	1-15
	The note was changed in Table 1-9 • Recommended Operating Conditions.	1-15
	The IOH and IOL values were updated in the "3.3 V LVTTTL Electrical Specifications" table.	1-16
	The "5 V Tolerance of 3.3 V LVTTTL I/Os Using a Tristate Buffer" section is new.	1-17
	A reference to Table 1-9 • Recommended Operating Conditions was added to the "Junction Temperature".	1-15
v3.0 (June 2004)	The "Speed Grade and Temperature Grade Matrix" table is new.	ii
	Table 1-2 • I/O Features was updated.	1-6
	Table 1-9 • Recommended Operating Conditions was updated.	1-15
	The "CEQ Values for eX Devices" section is new.	1-18
	The "Package Thermal Characteristics" section was updated.	1-19
	Table 1-14 • Input Buffer Delays was updated.	1-22
	Figure 1-15 • eX Timing Model was updated.	1-20
	The "Pin Descriptions" section was updated.	1-28

Datasheet Categories

Categories

In order to provide the latest information to designers, some datasheet parameters are published before data has been fully characterized from silicon devices. The data provided is designated as either "Product Brief," "Advance," "Preliminary," or "Production." The definitions of these categories are as follows:

Product Brief

The product brief is a summarized version of a datasheet (advance or production) and contains general product information. This document gives an overview of specific device and family information.

Advance

This version contains initial estimated information based on simulation, other products, devices, or speed grades. This information can be used as estimates, but not for production. This label only applies to the DC and Switching Characteristics chapter of the datasheet and will only be used when the data has not been fully characterized.

Preliminary

The datasheet contains information based on simulation and/or initial characterization. The information is believed to be correct, but changes are possible.

Production

This version contains information that is considered to be final.

Export Administration Regulations (EAR)

The product described in this datasheet is subject to the Export Administration Regulations (EAR). They could require an approved export license prior to export from the United States. An export includes release of product or disclosure of technology to a foreign national inside or outside the United States.
